CURVATURE OBSERVABLES, DYNAMICS, AND CONDITIONAL CONFINEMENT IN THREE-DIMENSIONAL LATTICE YANG–MILLS THEORY

Abstract. Reflection-positive symmetric-tensor correlations with bounded slab insertions, a power bound in the integrable norm, a scale-independent off-diagonal bound and conservation are Euclidean covariant. We prove this implication and apply it to the curvature bilinears of three-dimensional $SU(2)$ lattice Yang–Mills theory. We also give quantitative construction estimates and the two-term short-distance calculation, and study local nets, dynamics and Wilson loops. Confinement assumes a box inequality uniform along a fixed physical scale and label. The quantitative short-distance law at arbitrary order is an additional hypothesis; its continuum and state-transfer consequences retain that hypothesis. Weighted critical backgrounds are constructed near real regular references, with uniform local response and Hessian estimates. The moved-background and centering results retain a complex scalar gauge-transfer hypothesis. Overlapping-source rates, some centre-flux limits, flowed observables and complete gauge-group transfers retain the additional hypotheses stated for them.

1. Introduction

Let $V = \mathrm{Sym}_3(\mathbb{R})$ and $V_{\mathbb{C}} = \mathrm{Sym}_3(\mathbb{C})$. An isometry $r : x \mapsto Rx + v$ acts on tensor tests by

$$(rH)(x) = RH(r^{-1}x)R^{\mathrm{T}}.$$

For an open set O, let $\mathfrak{S}_V(O)$ consist of finite tuples of continuous compactly supported V-valued functions in O with pairwise disjoint supports. Tuples are concatenated by juxtaposition and the empty tuple is denoted by $\varnothing$. Complex combinations and complex tensor values are interpreted by multilinearity. A tuple has type $(d; R)$ if its supports are at mutual distance at least d and each lies in a ball of radius R. Write $|H|_\infty = \sup_x \max_{i,j} |H_{ij}(x)|$. For a compactly supported vector field η put

$$H_\eta = (\nabla\cdot\eta)\mathbf{1} - \nabla\eta - (\nabla\eta)^{\mathrm{T}}.$$

The vanishing of its insertions expresses conservation of $S_{ij} = \frac{1}{2}\delta_{ij}\,\mathrm{tr}\,T - T_{ij}$. Here T denotes the gauge-invariant curvature bilinear, defined below by lattice observables; separate gauge-dependent fields B_i are not assumed to have been constructed. The scalar observable $\frac{1}{2}\,\mathrm{tr}\,T$ is the action density considered in the companion manuscript [1].

Write $\theta(x_1, x_2, x_3) = (x_1, x_2, -x_3)$ and $\langle [F], [G]\rangle = \sigma(\theta\bar{F}\cdot G)$ for the reflection-positive form on half-space tuples. We use the tensor action $\rho(R)E = RER^{\mathrm{T}}$. Reflection of a test function includes this action on its values. For $o_{ij} = e_i e_j^{\mathrm{T}} + e_j e_i^{\mathrm{T}}$, $i \neq j$, the following abstract theorem gives the principal covariance argument.

Theorem A. Let σ be a real, symmetric multilinear functional on the tuples just defined, with $\sigma(\varnothing) = 1$ and $\sigma((H)) = 0$. Suppose that:

(i) For every n, d, R there is $C_n(d; R) < \infty$ such that $|\sigma(H_1, \dots, H_n)| \le C_n(d; R)\prod_a |H_a|_\infty$ on tuples of type $(d; R)$.

(ii) The functional is invariant under translations and signed permutations, and is reflection positive in every plane $x_i = c$ and $x_i \pm x_j = c$.

(iii) In the Hilbert space of reflection positivity at $x_3 = 0$, with vacuum $\Omega = [\varnothing]$, time translations are e^{-tH}, spatial translations are $e^{iv\cdot P}$, and $H \ge |P_1|, |P_2|$.

(iv) If h is supported in $0 < x_3 < l$, the insertion

$$\mathsf{B}_l(h)[F] = [(h)\cdot\tau_{le_3}F]$$

extends to a bounded operator, with norm at most $\mathsf{C}(\mathcal{K}, l)|h|_\infty$ for $\mathrm{supp}\,h \subset \mathcal{K} \Subset \{0 < x_3 < l\}$. For some $p < \infty$ and $C < \infty$ it also satisfies

$$\|\mathsf{B}_{2d}(\tau_{de_3}h)\| \le C\min\{1, d - d'\}^{-p}\|h\|_{L^1}$$

when $0 \le d' < d$ and $\mathrm{supp}\,h \subset \{|x_3| \le d'\}$.

(v) There is $C_{\mathrm{od}} < \infty$ such that

$$\sigma(\theta(ho_{ij}), ho_{ij}) \le C_{\mathrm{od}} |h|_\infty^2$$

for real h supported in $B(x_0, d)$, $0 < d < 1$, with $3d/2 \le x_{0,3} \le 2d$.

(vi) For every $\eta \in C_c^2(\{x_3 > 0\}; \mathbb{R}^3)$, $[(H_\eta)] = 0$ in that Hilbert space.

Then $\sigma(rX) = \sigma(X)$ for every Euclidean isometry r. Moreover,

$$\sigma((H_\eta) \cdot X) = 0$$

for every $\eta \in C_c^2(\mathbb{R}^3; \mathbb{R}^3)$ and every tuple X whose supports are disjoint from $\operatorname{supp} \eta$. ■□

We now specify the lattice observable. Fix the admitted construction constants of [1], with odd $L \ge 13$, running-coupling increment bound $B_\sharp$ and the short-distance ceiling γ_W^{sd}. Put

$$\bar{B} = \frac{L B_\sharp}{L-1}, \qquad I(g) = (g^{-2} + \bar{B},\, L(g^{-2} + B_\sharp) - \bar{B}], \qquad a_K = L^{-K}.$$

The admitted torus sides form $\mathfrak{L}(g) = \{2L^m : m \ge m_{\mathfrak{L}}(g)\}$, with the construction threshold $m_{\mathfrak{L}}(g)$. On the lattice of spacing a_K, every bond carries an $SU(2)$ matrix and the Wilson weight is $\exp(-\beta_K \sum_p a_p)$, with Haar probability measure on each bond and $a_p = 1 - \frac{1}{2} \operatorname{tr} \partial U(p)$. For $b = \langle x, x + a_K e_\mu \rangle$, let $\lambda_b < \lambda_b'$ be the other two directions. Write $W_x(\mu, \pm\alpha)$ for the corresponding based plaquette holonomies, and set

$$w(G) = \frac{G - G^{-1}}{2i}, \qquad u_{b,\alpha} = -\tfrac{1}{2}[w(W_x(\mu,\alpha)) - w(W_x(\mu,-\alpha))], \qquad q_b = \tfrac{1}{2} \operatorname{tr}(u_{b,\lambda_b} u_{b,\lambda_b'}).$$

The gauge-invariant form is

$$O_K^T(H) = a_K^{-1} \left[\sum_p H_{\lambda(p)\lambda(p)}(x(p)) a_p - \sum_b H_{\lambda_b \lambda_b'}(x_b) q_b \right], \tag{1}$$

where $x(p)$ and x_b are the midpoints and $\lambda(p)$ is the plaquette normal. This represents $\frac{1}{2} \int \operatorname{tr}(HT)$; $O_K^T(f\mathbf{1})$ is the action-density observable.

Corollary 1.1 (Curvature bilinears in the $SU(2)$ model)**.** Let $0 < g \le \gamma_W^{\mathrm{sd}}$, $b \in I(g)$ and $\ell \in \mathfrak{L}(g)$, and put $\beta_K = L^K b$.

(i) For $n \ge 2$, on T_ℓ the joint cumulants of $O_K^T(H_1), \dots, O_K^T(H_n)$ converge as $K \to \infty$ for every tuple of Lipschitz tensor weights with pairwise disjoint supports.

(ii) For any sequence ν_K of Gibbs states at (a_K, β_K) invariant under a subgroup of finite index of the lattice translations, there is a subsequence along which

$$\nu_K \left(\prod_{a=1}^{n} [O_K^T(H_a) - \nu_K(O_K^T(H_a))] \right)$$

converges for every tuple of continuous compactly supported tensor weights on $\mathbb{R}^3$ with pairwise disjoint supports. Every such limit σ is invariant under all Euclidean isometries, is reflection positive in every plane, and satisfies

$$\sigma((H_\eta) \cdot X) = 0$$

for $\eta \in C_c^2(\mathbb{R}^3; \mathbb{R}^3)$ and every tuple X with supports disjoint from $\operatorname{supp} \eta$.

(iii) The functional σ is a probability mixture of its canonical components. After recentering, each component reconstructs tempered local Poincaré-covariant tensor fields in $1 + 2$ dimensions, with spectrum in the closed forward cone and a cyclic vacuum unique in that component.

■□

Proof. Theorem G(E3)(ii) gives (i). Theorem C(b) gives the subsequence in (ii), and Theorem R(b),(c) gives conservation and covariance. The positivity and reconstruction statements follow from Theorems D and F, with the component decomposition of the latter. □

Theorem T gives the analytic form of this result and its variants. Its proof has two steps. Conservation and the scale-independent off-diagonal estimate eliminate the extreme two-point angular harmonics. Positivity, applied to polygon configurations, and halving then eliminate the higher-point harmonics. The argument requires the analytic continuation of the coefficient kernels; we give that continuation as part of the proof.

For curvature bilinears the hypotheses come from estimates for bond sources and from the lattice stress identity. The latter has a remainder, and its conditional mean must be estimated through the renormalisation steps before conservation passes to the limit. We keep these estimates separate from the abstract covariance theorem.

The later sections concern short-distance coefficients, compact gauge groups, local nets, lattice dynamics, Wilson loops and infrared estimates. Their limiting objects and hypotheses are stated separately. In particular, confinement assumes a box inequality at a fixed physical side and every sufficiently large cutoff along one label. No verification of these additional hypotheses is inferred from the short-distance construction. The weighted critical-background assertion in Theorem AI(a) is proved in the regular-reference setting of Definition 8.5; its moved-background and centering clauses retain the scalar gauge-transfer hypothesis of Definition 8.22. The arbitrary-order quantitative torus law is the additional hypothesis in Definition 8.2; Theorem AD(f), the free-law conclusion in (g)(i), and (g)(ii) retain it. The comparison estimate in (g)(i) and the separately stated narrower results in (h) do not use that additional input.

The general-group construction assumes the estimates in Definition 11.7. Proposition 11.36 proves the quotient extensions with their stated separation conditions and local bounds.

We use the scalar construction in the companion manuscript [1], citing its results and pages at each application. The supplementary arguments are given here. Additional estimates required by the later extensions are stated as hypotheses where they enter.

2. Curvature bilinears: estimates and continuum limits

We assemble the six curvature bilinears into a symmetric-matrix-valued field. The principal estimate bounds one centred insertion in a chessboard cell by every power greater than 11/2 of the inverse cell size. It holds uniformly in the cutoff, the admissible datum, the torus side and the periodic Gibbs state.

This estimate gives subsequential limits and bounded insertion operators. The sharper comparison between consecutive cutoffs gives full convergence on a fixed torus. Conservation and the abstract covariance theorem then yield the tensor fields in real time. We state the quantitative results first; the source estimates, comparison arguments, component decomposition and contact extensions follow.

2.1. Notation and hypotheses.

Theorem YMM1:D gives the inductive description of the effective densities; Theorem YMM1:AJ supplies its sourced form, and Theorem YMM1:AD gives the pressure bounds. The covariance of the tensor limits under O(3) is Proposition 2.19; we state it with its conditions and give the outline of its proof, from the exact stress identity of the lattice, the smallness of its remainder after the renormalisation steps, and a theorem for data. The bound of the conditional mean of the cubic remainder of the stress identity is Proposition 2.21 (b); we state it and give the five inputs on which it rests, with proofs and precise references for the construction estimates used.

Lattices. We work in dimension 3. $L \geq 13$ is an odd integer, $a_i = L^{-i}$, $\mathbb{L}_K = a_K\mathbb{Z}^3$, T_ℓ is the torus of side ℓ, and $\Lambda_{K,\ell}$ is the lattice of spacing a_K on T_ℓ; the gauge field assigns $U(\mathfrak{b}) \in \mathrm{SU}(2)$ to the bonds $\mathfrak{b}$, and $a_p = 1 - \frac{1}{2}\operatorname{tr}\partial U(p)$ for a plaquette p with boundary loop $\partial U(p)$. $\langle\cdot\rangle_{K,\ell,\beta}$ is the

Wilson mean on $\Lambda_{K,\ell}$ at the bare inverse coupling β, $\langle\cdot;\dots;\cdot\rangle_{K,\ell,\beta}$ the joint cumulant, and $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ the set of the periodic Gibbs states on $\mathbb{L}_K$ at β. An observable is centred by subtracting its mean.

Constants. Fix one choice of the real and source construction constants and auxiliary data as in Section YMM1:82, at the source radius required by Theorems YMM1:AJ and YMM1:AD, with the numerical source reserve (211). Write ς^{S} for that choice, ς for its unchanged restriction to the real construction, and π^+ for this restriction. The real construction keeps the same numerical constants; the additional source floors are imposed in their stated order before the coupling ceiling is chosen. The geometric source choice also retains (194). The hypotheses are uniform for $x \geq \gamma^{-2}$. In particular, we retain $\gamma^{-2} \geq 2B_\sharp$ and $\log \gamma^{-2} > 2\mathfrak{p}_0$.

The constants that occur below are: L; $\mathfrak{p}_0 \in \mathbb{N}$; A_0, M, $B_\sharp$, $\bar{B} = B_\sharp L/(L-1)$ and $\gamma \in (0, \frac{1}{2}]$; c', $C_{W,0}$ and $c_W = C_{W,0}A_0^2$; the ceilings $\gamma_W^{\mathrm{sd}} \leq \gamma_W^{\mathrm{ref}} \leq \gamma$, where $(\gamma_W^{\mathrm{ref}})^{-2} = \mathsf{x}_W$ is the number of equation YMM1:(2326); the function $p_0(g') = A_0(\log g'^{-2})^{\mathfrak{p}_0}$; the function $\mathsf{B}(\cdot)$ of the definition of a small side, with $\mathsf{B}(x) \geq \frac{9}{2}\log x + 2$; the function $R(\cdot)$ of the condition (Sd.1), which grows like the power $(\log x)^r$ of the logarithm, r a constant; the constant $C_{\mathrm{s}} \geq 2$ of the definition of the admissible sides; the function $\theta(\cdot)$ of the definitions preceding (228), a constant times $\mathsf{t}^{-1/2}(\log \mathsf{t})^{\mathfrak{p}_0}$, and the function T of the definitions preceding (228); the enlargement fraction $\beta_{\mathrm{s}} \in (0, \frac{1}{5}]$ and the decay rate $\kappa > 0$ and the fixed radius $\alpha_0 \in (0, 1]$ of Definition B.7, where $M = L^{m'}$ is the cube size, and the number $\mathsf{c}^\flat$ of (196); the decay rate enters only through the numbers $T_r(u)$ and the sizes $\|\cdot\|_{j,\kappa}$ of the families of the progression, and elsewhere the letter κ is free.

The numbers $T_r(u)$ used in condition (N.θ) are defined below. A *number* is a quantity formed from the constants and from what is displayed as its argument; it does not depend on the cutoff, the bare coupling, the side, the position or the state, unless this is said.

Couplings and data. A reference coupling is a real number $g > 0$. We use the first-passage definitions and Proposition YMM1:74.1, its room estimate YMM1:(1533), and Lemma G.3: $X_g = L(g^{-2} + B_\sharp)$; $x_j(\beta)$ is the sequence of running couplings, written as inverse squares, with $x_0(\beta) = \beta$; $g_j = x_j^{-1/2}$ and $y_j = \log x_j$. A pair (K, β) is a *first-passage datum at* g if $\beta > X_g$ and $K = K(\beta, g)$; then

$$g^{-2} < x_K(\beta) \leq X_g < x_{K-1}(\beta) < \cdots < x_0(\beta) = \beta.$$

Its *label* is $b = a_K\beta$; by YMM1:(1531), $g^{-2} < b \leq L(g^{-2} + \bar{B})$. By YMM1:(1532) and Lemma G.3, $\log g^{-2} < y_K \leq \log g^{-2} + \log \frac{3L}{2}$ and $K - k \leq y_k/\log L$. $\mathfrak{L}(g)$ is the set of the admissible sides $\ell = 2L^m$, $m \geq m_{\mathfrak{L}}(g)$, of Proposition YMM1:74.1; the least of them is the *least side* at g. For $1 \leq i \leq K-1$ the *stopped coupling* $g_{(i)}$ is given by $g_{(i)}^{-2} = L^{-1}x_{K-i}(\beta) - B_\sharp$; by Corollary YMM1:74.3 and Lemma G.3, $g_{(i)} < g$, the pair $(K-i, \beta)$ is a first-passage datum at $g_{(i)}$ with label $L^i b$, $L^i\ell \in \mathfrak{L}(g_{(i)})$ for $\ell \in \mathfrak{L}(g)$, and

$$C_{g_{(i)}} \leq C_g + \tfrac{9}{2}\, i \log L + \tfrac{1}{8}, \qquad C_g = C_{\mathrm{st}} + \tfrac{9}{2}\log X_g, \tag{2}$$

Here $C_g = C_{\mathrm{st}} + \frac{9}{2}\log X_g$. With the vacuum constants $C_\flat, C_{\mathfrak{E}}$ of equation YMM1:(1408), put $E_+ = C_{\mathrm{maj}} + 2$ and

$$C_{\mathrm{st}} = \max\{C_\flat, C_{\mathfrak{E}}, E_+, C_{\mathfrak{E}} + E_+, c_{\mathrm{low}}, c_{\mathrm{low}} + C_{\mathfrak{E}}\}.$$

The constants c_{low} and C_{maj} are those of Proposition YMM1:70.2. In particular $C_{\mathrm{st}} \geq c_{\mathrm{low}}$, so the lower bound of Proposition YMM1:74.4 applies with C_g at first passage. The *pressure* of the torus T_ℓ at (K, β) is $p_\ell = \ell^{-3}\log Z_{K,\ell,\beta}$. We put

$$G_g = C_{\mathrm{S}} + C_g + 2C_{\mathrm{tt}}C'_{\mathrm{tt}}E_0,$$

where, by Theorems YMM1:AJ and YMM1:AD at the source 0, $-C_g \leq p_\ell - E_{K,\ell,\beta}\,\ell^{-3} \leq C_{\mathrm{S}}$ for every first-passage datum (K, β) at g and every side $\ell \in \mathfrak{L}(g)$, $E_{K,\ell,\beta}$ the normalising energy of Theorems YMM1:AJ and YMM1:AD at the source 0, and $2C_{\mathrm{tt}}C'_{\mathrm{tt}}E_0$ bounds the difference of the numbers $E_{K,\ell,\beta}\,\ell^{-3}$ at two such sides; C_{S}, C_{tt}, C'_{tt}, E_0 depend on no coupling, cutoff, side or source.

Boards and the chessboard seminorm. A board (i,o) of $\mathbb{L}_K$ is given by an integer $i \le K-1$ and an offset $o \in a_K\mathbb{Z}^3$; it is the partition of $\mathbb{R}^3$ into the cubes $\square_{\mathbf{k}} = o + a_i\mathbf{k} + [-\frac{a_i}{2}, \frac{a_i}{2}]^3$, $\mathbf{k} \in \mathbb{Z}^3$, its *cells*, whose faces lie on the *wall planes* $\{x_\mu = o_\mu + a_i(t+\frac12)\}$, $\mu \in \{1,2,3\}$, $t \in \mathbb{Z}$. As $a_i/a_K = L^{K-i}$ is odd, $o_\mu + a_i(t+\frac12) \in a_K(\mathbb{Z}+\frac12)$: the wall planes are mid-planes of the lattice, no site lies on them, and the reflections in them are isometries of $\mathbb{L}_K$. The mirror map from $\square_{\mathbf{k}}$ to $\square_{\mathbf{k}'}$, $x \mapsto o + a_i\mathbf{k}' + \mathrm{diag}(\sigma_1,\sigma_2,\sigma_3)(x - o - a_i\mathbf{k})$ with $\sigma_\mu = (-1)^{\mathbf{k}'_\mu - \mathbf{k}_\mu}$, is the composition of the $|\mathbf{k}'-\mathbf{k}|_1$ reflections in the wall planes between the two cells, and the pair of cells is *even* or *odd* with this number.

The mirror copy in $\square_{\mathbf{k}'}$ of a bounded complex function F of the bonds inside $\square_{\mathbf{k}}$ is the image of F under the mirror map if the pair is even, and the complex conjugate of this image if the pair is odd; for a real F it is the image in every cell. For a side ℓ with ℓ/a_i an even integer, the mean on T_ℓ of the product of the mirror copies of F over the $(\ell/a_i)^3$ cells of a period box is ≥ 0, and the *chessboard seminorm* $\|F\|_\ell = \|F\|^{(i,o)}_{\mathrm{ch},\ell}$ is its $(\ell/a_i)^3$-th root (Proposition YMM1:86.3); the seminorm of a constant is its modulus. We use the chessboard estimate, seminorm properties and volume comparison of Propositions YMM1:86.3 and YMM1:86.4, and Corollary YMM1:86.6: $\|\cdot\|_\ell$ is a seminorm, $|\langle F\rangle_{K,\ell,\beta}| \le \|F\|_\ell$, the mean on T_ℓ of a product of functions of different cells modulo the side is at most the product of their seminorms, and for two sides $\ell \ge \ell' \ge 2a_i$

$$\|F\|_\ell \le e^{a_i^3(p_{\ell'} - p_\ell)}\, \|F\|_{\ell'};$$

and the domination of the periodic Gibbs states, Proposition YMM1:91.9 (b): for $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, a board, finitely many different cells and functions Φ_k of the bonds inside them,

$$\Big|\nu\Big(\prod_k \Phi_k\Big)\Big| \le \liminf_{\ell\to\infty} \prod_k \|\Phi_k\|_\ell,$$

the lower limit along the sides of $\mathfrak{L}(g)$.

The space of labels. $V = \mathrm{Sym}_3(\mathbb{R})$, $V_{\mathbb{C}} = \mathrm{Sym}_3(\mathbb{C})$, $V_0 = \mathbb{R}\mathbf{1}$; $\mathrm{O}(3)$ acts by $\rho(\mathsf{R})A = \mathsf{R}A\mathsf{R}^{\mathrm{T}}$. We use the two norms $|A|_\infty = \max_{\lambda\lambda'}|A_{\lambda\lambda'}|$ and $|A| = (\mathrm{tr}\,\bar{A}A)^{1/2}$, which is invariant; $|A|_\infty \le |A|$. In sup norms $|H|_\infty = \sup_x |H(x)|_\infty$ the norm of V is $|\cdot|_\infty$; in $\|h\|_{L^1} = \int |h(x)|\,dx$ it is the invariant norm unless the contrary is said. W_3 is the group of the 48 signed permutation matrices, and $\theta = \mathrm{diag}(1,1,-1)$. For $1 \le i,j \le 3$ the *label matrices of the stress tensor* are

$$\mathsf{m}_{ij} = \delta_{ij}\mathbf{1} - e_ie_j^{\mathrm{T}} - e_je_i^{\mathrm{T}}; \qquad \rho(\mathsf{R})\mathsf{m}_{ij} = \sum_{i',j'} \mathsf{R}_{i'i}\mathsf{R}_{j'j}\,\mathsf{m}_{i'j'} \quad (\mathsf{R} \in \mathrm{O}(3)), \qquad \theta\mathsf{m}_{ij}\theta = \vartheta_i\vartheta_j\mathsf{m}_{ij},$$

$$|\mathsf{m}_{ij}| \le \sqrt{3},$$

with $\vartheta_1 = \vartheta_2 = 1$, $\vartheta_3 = -1$; for a symmetric matrix T, $\frac12\,\mathrm{tr}(\mathsf{m}_{ij}T) = \frac12\delta_{ij}\,\mathrm{tr}\,T - T_{ij}$.

Definition 2.1 (Lattice forms)**.** We use the tensor form (1) and write $\mathcal{T}_K(H) = O_K^T(H)$. For arbitrary plaquette weights w and bond weights w, put

$$\mathcal{O}(w) = a_K^{-1}\sum_p w(p)a_p, \qquad Y[\mathsf{w}] = -a_K^{-1}\sum_{\mathfrak{b}} \mathsf{w}(\mathfrak{b})q_{\mathfrak{b}}.$$

Thus $\mathcal{T}_K(H) = \mathcal{O}(w_H) + Y[\mathsf{w}_H]$, with $w_H(p) = H_{\lambda(p)\lambda(p)}(x(p))$ and $\mathsf{w}_H(\mathfrak{b}) = H_{\lambda_{\mathfrak{b}}\lambda'_{\mathfrak{b}}}(x_{\mathfrak{b}})$. The midpoint and plaquette-normal conventions, $q_{\mathfrak{b}}$ and $u_\alpha = u_{\mathfrak{b},\alpha}$ are those of the introduction. The scalar form $\mathcal{T}_K(f\mathbf{1}) = \mathcal{O}(f)$ is the action-density observable. ■

Sources. Theorem YMM1:D describes on a small torus the effective densities that the renormalisation steps produce from the lattice measure. With sources on the plaquettes in the exponent, $\sum_a \lambda_a\mathcal{O}(w_a)$ with complex parameters λ_a, the steps are carried by the weighted progression of Definition B.7, in which the source w_a enters at the height j through a family of the size $\mathsf{m}_{j,a} = 12M^3\alpha_0^2L^{K-j}|w_a|_\infty$ of (196). A source under a majorant is what this progression carries in the place of a plaquette weight. A *majorant* is a pair (s, S) of a number $\mathsf{s} \ge 0$ and a finite set S of

plaquettes; its weight is the plaquette weight $\tilde w = \mathsf{s}\mathbf{1}_S$, and its numbers are $\mathsf{m}_j = 12M^3\alpha_0^2 L^{K-j}\mathsf{s}$, $0 \le j \le k$, the sizes (196) at $\tilde w$, k being the last height of the progression.

A *source under the majorant* (s, S) is a triple $(F, \mathbb{V}, (H^{(j)})_{1\le j\le k})$ such that: (So0) F is a continuous gauge-invariant function of the bare configurations with $|F(U)| \le L^K \sum_p \tilde w(p)\, a_p(U)$; (So1) $\mathbb{V}$ is a family in the fourth place at the height 0 (Section S.1) of size at most $\mathsf{c}^\flat\mathsf{m}_0$, whose members vanish on the domains whose plaquettes miss S, and which sums to F at the configurations of the height 0, as the family of the action density of a plaquette weight w sums to $\mathcal{O}(w)$ under the height-zero global sum condition (355); (So2) for $1 \le j \le k$, $H^{(j)}$ is a family without base point of level j at the fixed radii (Definition YMM1:49.5) with $\|H^{(j)}\|_{j,\kappa} \le \frac12 \mathsf{m}_j$, whose members $H^{(j)}(X,\cdot)$ vanish unless the plaquettes of X meet S, and $\sum_{X\in\mathcal{D}_j}[H^{(j)}(X,U) - H^{(j)}(X,\mathbf{1})] = F(U)$ at every bare configuration U at which the action of the bare arrays of the height j is defined.

The function F is the *first member* of the source, and, the triple being understood, F itself is also called a source under (s, S); the source is *real* if F is real. A *source system* is a finite tuple of sources $(F_a, \mathbb{V}_a, (H_a^{(j)}))$ under majorants (s_a, S_a), entered with independent complex parameters λ_a in the places of the plaquette sources of Definition B.7, the exponent being $\sum_a \lambda_a F_a$ and all the numbers of the progression being formed at the weights $\mathsf{s}_a\mathbf{1}_{S_a}$; its first members are the F_a. The bounds of Propositions 2.9 and 2.10 read of a source the properties (So0)–(So2) alone.

The *working level* of a datum, the *history* without large-field regions and the weights w_t of the first creation of a large field at the step t are those among the construction results; so are the *small sides*, the sides that are small over the running couplings of a datum, among whose conditions is (Sd.4), $\mathsf{B}(x_K)\ell^3 \le \frac12 c' p_0(g_K)^2$; the least side at g is small for $g \le \gamma_W^{\mathrm{sd}}$. The *depth* $s(d)$ of a distance $0 < d < 1$ is the least s with $L^s d \ge C_W(s) = c_W Y_s^{2\mathfrak{p}_0}$, $Y_s = (s+1)\log L + \log(g^{-2} + \bar B)$, formed at the reference coupling of the datum, with the room constant $C_{W,0} = \max\{1, 4L^2M/A_0^2\}$ in $c_W = C_{W,0}A_0^2$, so that $C_W(s) \ge 4L^2 M Y_s^{2\mathfrak{p}_0}$; we write $\bar x_s = e^{Y_s}$.

For $u > 0$ and an integer $r \ge 1$ we put

$$T_r(u) = \sum_{n'\ge 1} (n'+1) L^{-(n'-1)} \Big[\big(\tfrac43\big)^{1/2} L^{n'/2} (1+n')^{\mathfrak{p}_0} \Big]^r e^{-4\beta_{\mathsf{s}}\kappa [L^{n'-1}u - 2]_+}, \qquad [v]_+ = \max\{v, 0\}; \quad (3)$$

the series converges, the quotient of two consecutive terms tending to 0; $T_r(u)$ does not increase in u and does not decrease in r, the bracket being ≥ 1; and $T_2 = \frac43 L\,\mathsf{T}$ with the function T of the definitions preceding (228). The condition (N.θ) at (n, g, s) is $2T_n(3)\theta(L^{s-2}g^{-2}) \le 1$; as $T_r(3)$ does not decrease in r, (N.θ) at (n, g, s) gives (N.θ) at (m, g, s) for $2 \le m \le n$.

Definition 2.2 (Tuples, tensor limits, the reconstructed space)**.** (1) For an open $O \subset \mathbb{R}^3$, $\mathfrak{S}_V(O)$ is the set of the tuples $X = (H_1, \dots, H_n)$, $n \ge 0$, of continuous V-valued functions with compact, pairwise disjoint supports in O; $\mathfrak{S}^1_V(O)$ is the same with C^1_c entries; $\varnothing$ is the empty tuple. $\mathbb{C}\mathfrak{S}_V(O)$ is the space of the formal complex combinations of tuples, $F \cdot F'$ the concatenation (formed at disjoint supports), $\bar F$ the conjugate combination, and (h) the tuple with the one entry h; an entry $h = h' + ih''$ with values in $V_{\mathbb{C}}$ stands for $(h') + i(h'')$. An isometry $\mathsf{r}x = \mathsf{R}x + v$ acts by $(\mathsf{r}H)(x) = \mathsf{R}H(\mathsf{r}^{-1}x)\mathsf{R}^{\mathrm{T}}$, entry by entry; τ_v is the translation and θ acts as the reflection in $\{x_3 = 0\}$, on points and on labels. $\mathbb{E}_+ = \{x_3 > 0\}$.

(2) A *tensor limit at* g is a functional on $\mathfrak{S}_V(\mathbb{R}^3)$ of the form

$$\sigma(X) = \lim_{j\to\infty} \rho_j\Big(\prod_a [\mathcal{T}_{K_j}(H_a) - \rho_j(\mathcal{T}_{K_j}(H_a))]\Big),$$

the limit existing at every tuple, where (K_j, β_j) are first-passage data at g with $K_j \to \infty$, $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$, and the labels converge, $a_{K_j}\beta_j \to b_*$; b_* is the label of σ. Its restriction to $\mathfrak{S}^1_V(\mathbb{R}^3)$ is written σ^1.

(3) Given that $\sigma(\theta\bar F \cdot F) \ge 0$ on $\mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$, $\mathcal{H}(\sigma)$ is the completion of $\mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$ modulo the null vectors of $\langle [F'], [F]\rangle = \sigma(\theta\bar F' \cdot F)$; $\Omega = [\varnothing]$; $e^{-tH}[F] = [\tau_{te_3}F]$ and $\mathcal{U}(v)[F] = [\tau_{(v,0)}F]$

define $H \geq 0$ and a unitary representation $\mathcal{U}$ of $\mathbb{R}^2$, and $\mathcal{P}$ is the joint spectral measure on $[0,\infty)\times\mathbb{R}^2$ with $e^{-tH}\mathcal{U}(v) = \int e^{-tE+iv\cdot q}d\mathcal{P}(E,q)$; the momenta are $P_k = \int q_k\, d\mathcal{P}$, $k=1,2$, so that $\mathcal{U}(v) = e^{iv\cdot P}$. The *square cone* is $\{E \geq \max(|q_1|,|q_2|)\}$, the *circular cone* $\{E \geq |q|\}$. $\mathcal{H}_0 \subset \mathcal{H}(\sigma)$ is the closed span of the classes of the tuples with entries in V_0. $\mathcal{H}^{\mathrm{ord}}(\sigma)$ is the closed span of Ω and of the classes of the $X \in \mathfrak{S}_V(\mathbb{E}_+)$ whose entries lie in pairwise disjoint slabs $\{t < x_3 < t'\}$.

(4) For $l > 0$ and h carried by $\{0 < x_3 < l\}$, the *slab operator* $\mathsf{B}_l(h)$ is the bounded operator, if there is one, with $\mathsf{B}_l(h)[F] = [(h)\cdot\tau_{le_3}F]$ for all $F \in \mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$.

(5) Let σ be a functional on $\mathfrak{S}_V(\mathbb{R}^3)$ that is invariant under the permutations of the entries, $q \geq 1$ and $X^1,\dots,X^q \in \mathfrak{S}_V(\mathbb{R}^3)$. For $1 \leq p \leq q$ let $\mathsf{A}^{(p)}$ be the set of the $\underline{v} = (v_{p+1},\dots,v_q) \in (\mathbb{R}^3)^{q-p}$ at which the unions of the supports of the entries of $X^1, \tau_{v_{p+1}}X^{p+1},\dots,\tau_{v_q}X^q$ are pairwise disjoint, so that the concatenation $X'_p(\underline{v}) = X^1\cdot\tau_{v_{p+1}}X^{p+1}\cdots\tau_{v_q}X^q$ is formed, and put $G^{(1)}(\underline{v}) = \sigma(X'_1(\underline{v}))$ on $\mathsf{A}^{(1)}$. Then σ *has iterated plateaux* at $(X^1,\dots,X^q)$ if, successively for $p = 2,\dots,q$, at every $\underline{v} \in \mathsf{A}^{(p)}$ the limit

$$G^{(p)}(\underline{v}) = \lim_{|v_p|\to\infty} G^{(p-1)}(v_p,\underline{v}), \qquad v_p \in \mathbb{R}^3,$$

exists; $\mathsf{A}^{(q)}$ is a point, and the number $G^{(q)}$ is the *iterated plateau* of σ at $(X^1,\dots,X^q)$. At $q=1$ the iterated plateau is $\sigma(X^1)$; at $q=2$ it is the two-fold plateau $\lim_{|v|\to\infty}\sigma(X^1\cdot\tau_v X^2)$. ■

Definition 2.3 (Data with labels; real time; the frame)**.** (1) A *symmetric functional on labelled tuples* is a map σ on $\mathfrak{S}^1_V(\mathbb{R}^3)$ with $\sigma(\varnothing) = 1$, invariant under the permutations of the entries and n-linear on $\prod_a C^1_c(O_a;V)$ for open sets O_a with pairwise disjoint closures; it is continued linearly to $\mathbb{C}\mathfrak{S}^1_V$. It is *reconstruction data with labels* with the numbers $C_V, p_V \geq 0$, $c_0 \in (0,\frac12]$, if: $(\mathrm{Rec1})_V$ $\sigma(\mathsf{r}X) = \sigma(X)$ for every isometry r; $(\mathrm{Rec2})_V$ $\sigma(\theta\bar F\cdot F) \geq 0$ on $\mathbb{C}\mathfrak{S}^1_V(\mathbb{E}_+)$, the space $\mathcal{H}(\sigma)$ is separable, and H, $\mathcal{U}$, $\mathcal{P}$ are formed as in Definition 2.2 (3); $(\mathrm{Rec3})_V$ $\mathcal{P}(\{E<|q|\}) = 0$; $(\mathrm{Rec4})_V$ for $\eta \in (0,1]$, $F, F' \in \mathbb{C}\mathfrak{S}^1_V(\{x_3 > \eta\})$ and $h \in C^1_c(\{|x_3| < c_0\eta\};V)$,

$$|\sigma(\theta\bar F\cdot(h)\cdot F')| \leq C_V\eta^{-p_V}\|h\|_{L^1}\,\|[\tau_{-\eta e_3}F]\|\,\|[\tau_{-\eta e_3}F']\|.$$

(Rec5) is the condition $\ker H = \mathbb{C}\Omega$; it is not part of the data.

(2) A point of $\mathbb{R}^{1+2}$ is $x = (t,\vec x)$; $U(x) = e^{itH}\mathcal{U}(\vec x)$; $\mathcal{D}_\infty = \bigcap_j \operatorname{dom} H^j$; $\mathcal{S}_V = \mathcal{S}(\mathbb{R}^{1+2};V_{\mathbb{C}})$ and $f^* = \rho(\theta)\bar f$. $\iota(t,\vec x) = (\vec x, -it)$; $\mathcal{L}$ is the restricted Lorentz group of $\mathbb{R}^{1+2}$, and $\hat\Lambda = \iota\Lambda\iota^{-1} \in \mathrm{SO}(3,\mathbb{C})$. For $\mathfrak{z} \in \mathbb{C}^3$, $d_\square(\mathfrak{z}) = \operatorname{Re}\mathfrak{z}_3 - |\operatorname{Im}\mathfrak{z}_1| - |\operatorname{Im}\mathfrak{z}_2|$ and $d_\circ(\mathfrak{z}) = \operatorname{Re}\mathfrak{z}_3 - |(\operatorname{Im}\mathfrak{z}_1, \operatorname{Im}\mathfrak{z}_2)|$.

(3) The *frame* (M1)–(M5) concerns a tensor carrying one label on a space with a scalar field $\phi(f)$, $f \in \mathcal{S}(\mathbb{R}^{1+2})$, a unique vacuum and a representation U of $\mathbb{R}^{1+2}\rtimes\mathcal{L}$; with $\vartheta_1 = \vartheta_2 = 1$, $\vartheta_3 = -1$: (M1) sesquilinear forms $\mathfrak{q}_{ij} = \mathfrak{q}_{ji}$ on $\mathcal{D}_\infty\times\mathcal{D}_\infty$ with $|\mathfrak{q}_{ij}(\psi',\psi)| \leq c_T\|(1+H)^l\psi'\|\,\|(1+H)^l\psi\|$, $\overline{\mathfrak{q}_{ij}(\psi',\psi)} = \vartheta_i\vartheta_j\mathfrak{q}_{ij}(\psi,\psi')$, $\mathfrak{q}_{ij}(\Omega,\Omega) = 0$, and the operators $T^E_{ij}(F)$ they define, with the real-time components $T_{00} = -T^E_{33}$, $T_{0j} = -iT^E_{3j}$, $T_{jk} = T^E_{jk}$; (M2) continuous kernels $\mathsf{s}_{ij}(x;y_1,\dots,y_m)$ of one tensor entry among m scalar entries, covariant under $\mathrm{O}(3)$ and the translations, $\mathsf{s}_{ij}(\mathsf{R}x+b;\mathsf{R}y+b) = \mathsf{R}_{ii'}\mathsf{R}_{jj'}\mathsf{s}_{i'j'}(x;y)$, related to the forms by the product formula of two point operators at different heights, $\mathsf{s}^{F',G}_{ij}(x,y) = \mathfrak{q}_{ij}(\psi'_x,\psi_x)$ as written out in the proof of Lemma 2.22 (c); (M3) $T^E_{ij}(F_1)\phi(f)\psi = \phi(f)T^E_{ij}(F_1)\psi$ on the span $\mathcal{D}_0$ of Ω and the vectors $\phi(f_1)\cdots\phi(f_n)\Omega$, for spacelike separated supports; (M4) (a) $T_{0\nu}(\partial_0 F)\psi = \sum_{k=1,2}T_{k\nu}(\partial_k F)\psi$ on $\mathcal{D}_0$; (M5) $U(\Lambda)T[a,b](F)\Omega = T[\Lambda a,\Lambda b](F\circ\Lambda^{-1})\Omega$, $T[a,b] = a^\mu b^\nu T_{\mu\nu}$.

■

Definition 2.4 (The setting of the cumulants on a torus)**.** Let $n \ge 2$, $0 < g \le \gamma_W^{\mathrm{ref}}$, (K,β) a first-passage datum at g with label b, and ℓ a side. For bounded $H_a : T_\ell \to V_{\mathbb{C}}$, Σ_a is the set of the points $x(p)$, $x_{\mathfrak{b}}$ at which the component of H_a that enters $\mathcal{T}_K(H_a)$ is not 0. The tuple has the property *(Geo) at d* if each Σ_a lies in a ball of radius $0.87\,d$ and any two of the Σ_a are at distance $\ge 1.26\,d$. We put $\bar{x}_0 = L(g^{-2}+\bar{B})$ and $\mathsf{c}(\ell) = 2\ell^3 e^{\mathsf{B}(\bar{x}_0)\ell^3}/(c' A_0^2)$.

For the extensions over the diagonals, on T_ℓ with the sup distance: for $\lambda > 0$ and an integer $m \ge 0$, $\|F\|_{(\lambda),m} = \max_{|\gamma|\le m} \lambda^{|\gamma|} \sup |\partial^\gamma F|$; a function F on T_ℓ^n is *λ-supported* if its support lies in a product $\prod_a \bar{B}_\infty(z_a,\lambda)$ of closed sup balls, the points $z_a \in T_\ell$ coinciding or not. For a real number κ, the parameter of the power counting, $\mathfrak{E}_n(\kappa)$ is the class of the distributions T on T_ℓ^n, acting on the $V_{\mathbb{C}}^{\otimes n}$-valued test functions, for which there are C, q, m and $h_1 > 0$ with

$$|T(F)| \le C\lambda^\kappa (1+\log\tfrac{h_1}{\lambda})^q \|F\|_{(\lambda),m} \qquad \text{for all } 0<\lambda\le h_1 \text{ and all smooth } \lambda\text{-supported } F :$$

the power counting κ, up to logarithms, also where points meet. For a partition π of $\{1,\dots,n\}$ into k blocks, $B(a)$ the block of a and $a_B = \min B$, the *coordinates at π* are $y_B = x_{a_B} \in T_\ell$ and $\xi_a = x_a - x_{a_B}$ for $a \ne a_{B(a)}$, taken where these differences are below $\ell/4$; $\Delta_\pi = \{\xi = 0\}$, and $\iota_\pi(y)_a = y_{B(a)}$. For a distribution T' on T_ℓ^k and a multi-index α of ξ, $(\partial_\xi^\alpha \delta_\pi \otimes T')(F) = (-1)^{|\alpha|}\, T'((\partial_\xi^\alpha F)\circ \iota_\pi)$. ■

2.2. **Principal results.**

Theorem B (The estimate at a cutoff)**.** Let $0 < \delta \le \frac14$.

(a) Let $0 < g \le \gamma_W^{\mathrm{sd}}$. Put

$$c_E = \log(L^2 c_W/\delta) + 2\mathfrak{p}_0 \log(4\mathfrak{p}_0) + \log(X_g + \bar{B}), \qquad \mathsf{Y}_i = 2[c_E + \log(1/a_i)], \qquad q_E = (4+\mathfrak{p}_0)(2\mathfrak{p}_0 - 1) + 10\mathfrak{p}_0,$$

$$C_E = 510 \cdot 2^{2\mathfrak{p}_0+1}\, \delta^{-4} e^{G_g + 1/8}\, (1 + c' A_0^2/9)^{4+\mathfrak{p}_0} \max\{C^I, C_2\}\, L^5 c_W^4\, (X_g + \bar{B}),$$

where C^I, C_2 are numbers formed from the constants alone, which enter through Proposition 2.9. There are numbers $i_E = i_E(g,\delta) \ge 1$ and $s_E(i) = s_E(i; g, \delta)$ such that the following holds for every $i \ge i_E$, every first-passage datum (K,β) at g with $K \ge K_E(i) := i + s_E(i)$, every board (i,o) of $\mathbb{L}_K$, every cell $\square$ of it, every $\ell \in \mathfrak{L}(g)$ and every bounded $H : \mathbb{R}^3 \to V_{\mathbb{C}}$ that vanishes at the points whose sup distance from the complement of $\square$ is $< \delta a_i$: if c is the mean of $\mathcal{T}_K(H)$ on a torus T_{ℓ_1} with $\ell_1 \in \mathfrak{L}(g)$, or in a state $\nu \in \mathcal{G}_{K,\beta}^{\mathrm{per}}$, then

$$\|\mathcal{T}_K(H) - c\|_{\mathrm{ch},\ell}^{(i,o)} \le 2C_E\, \mathsf{Y}_i^{q_E}\, a_i^{-11/2}\, b^{-1} |H|_\infty. \tag{4}$$

The dependence on δ is by powers: i_E may be taken with $L^{i_E} \le c_i \delta^{-1}$, and $C_E \mathsf{Y}_i^{q_E} a_i^{-11/2} \le c_3 \delta^{-5} a_i^{-13/2}$ for all $i \ge 1$, where c_i, c_3 are numbers formed from the constants and g.

(b) Let $0 < g \le \gamma_W^{\mathrm{sd}}$. Put $c'_E = \log(2L(g^{-2}+\bar{B}))$, $\mathsf{Y}'_i = 2[c'_E + \log(1/a_i)]$, $q'_E = 15r + 4$,

$$c_N = \max\{1,\, 8L^6 M^3 C_{\mathrm{s}}^3\, 2^{-3r}\}, \qquad c_u = 4 + \tfrac{2}{A_{\mathfrak{b}}}\big(2c_N[c_2 + \log(8c_N) + 3r] + 3\log L + \log 3\big),$$

with the numbers $A_{\mathfrak{b}}$, c_2, C_1 and the threshold function u'_* of Proposition 2.9 (b); let s_i be the least integer $s \ge 1$ with $\delta L^s \ge M\, u'_*(\lceil c_N \mathsf{Y}_i'^{3r} \rceil)$, and

$$C'_E = 480\, e^{G_g + 1/8} c_N C_1 (LM c_u/\delta)^4 L(g^{-2} + \bar{B}).$$

Then the bound

$$\|\mathcal{T}_K(H) - c\|_{\mathrm{ch},\ell}^{(i,o)} \le 2C'_E\, \mathsf{Y}_i'^{q'_E}\, a_i^{-11/2}\, b^{-1} |H|_\infty$$

holds for every integer $i \ge 1$ and every first-passage datum with $K \ge i + s_i + 2$, with the other quantifiers of (a).

(c) Let $0 < g \le \gamma$. There are numbers $i_A(g,\delta)$ and, for $i \ge 0$, $K_0(i)$ and N_i, formed from the constants, g, δ and i, such that: (i) for $i \ge i_A(g,\delta)$, every first-passage datum at g with $K \ge K_E(i)$ (formed at g by the formulas of (a)), every board, cell and side $\ell \in \mathfrak{L}(g)$, every bounded Borel $H : \mathbb{R}^3 \to V_{\mathbb{C}}$ vanishing at sup distance $< \delta a_i$ from the complement of the cell, and both centrings of (a),

$$\|\mathcal{T}_K(H) - c\|^{(i,o)}_{\mathrm{ch},\ell} \le 2e^{1/8} C_E\, \mathsf{Y}_i^{q_E} L^{11i/2}\, b^{-1} |H|_\infty, \qquad b^{-1} < g^2,$$

with C_E, Y_i formed at g by the formulas of (a); (ii) for every integer $i \ge 0$, every first-passage datum at g with $K \ge K_0(i)$, every board (i,o), cell $\square$ and side $\ell \in \mathfrak{L}(g)$, every real bounded h that vanishes off $\square$ and at the points within sup distance $a_i/32$ of its boundary, and both centrings,

$$\|\mathcal{T}_K(h) - c\|^{(i,o)}_{\mathrm{ch},\ell} \le \mathsf{N}_i\, b^{-1} |h|_\infty \le C_T L^{i p_T} |h|_\infty \qquad \text{for every } p_T > \tfrac{11}{2}, \quad C_T = g^2 \sup_{i \ge 0} \mathsf{N}_i L^{-i p_T} < \infty;$$

(iii) *(uniform bounds)* for $n \ge 1$, $d > 0$, $R > 0$ let $\delta_n = 1/(8n)$, i^A the least $i \ge i_A(g,\delta_n)$ with $2a_i \le d$, K^A the least $K \ge K_E(i^A)$ (formed at g and δ_n by the formulas of (a)) with $L^{K - i^A} \ge 8n$, and

$$C_n^A(d;R) = \Big[\big(16nR/a_{i^A} + 3\big)^3\, 2e^{1/8} C_E(\delta_n)\, \mathsf{Y}_{i^A}^{q_E}\, a_{i^A}^{-11/2} \Big]^n,$$

C_E and Y_i formed at g; then for every first-passage datum (K,β) at g with $K \ge K^A$, any two states $\nu, \nu' \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ and all bounded $H_1, \dots, H_n : \mathbb{R}^3 \to V_{\mathbb{C}}$ whose supports lie in balls of radius R and are pairwise at distance $\ge d$,

$$\Big| \nu\Big(\prod_a [\mathcal{T}_K(H_a) - \nu'(\mathcal{T}_K(H_a))] \Big) \Big| \le C_n^A(d;R)\, b^{-n} \prod_a |H_a|_\infty.$$

All bounds are uniform in the cutoff, the first-passage datum, the board, the cell, the side (hence in the number of the cells) and the state. ■□

Theorem C (The tensor limits without the rotations)**.** Let $0 < g \le \gamma_W^{\mathrm{sd}}$, and let the numbers of Theorem B (a) be taken at the value of δ that is displayed.

(a) *(Uniform bounds.)* For $n \ge 1$, $d > 0$, $R > 0$ put $\delta_n = 1/(8n)$; let i^G be the least $i \ge i_E(g,\delta_n)$ with $2a_i \le d$, K^G the least $K \ge K_E(i^G)$ (at δ_n) with $L^{K - i^G} \ge 8n$, and

$$C_n^G(d;R) = \Big[\big(16nR/a_{i^G} + 3\big)^3\, 2C_E(\delta_n)\, \mathsf{Y}_{i^G}^{q_E}\, a_{i^G}^{-11/2} \Big]^n.$$

For every first-passage datum (K,β) at g with $K \ge K^G$, every $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ and all bounded $H_1, \dots, H_n : \mathbb{R}^3 \to V_{\mathbb{C}}$ whose supports lie in balls of radius R and are pairwise at distance $\ge d$,

$$\Big| \nu\Big(\prod_a [\mathcal{T}_K(H_a) - \nu(\mathcal{T}_K(H_a))] \Big) \Big| \le C_n^G(d;R)\, b^{-n} \prod_a |H_a|_\infty,$$

and the same holds with the centring by the mean on any torus T_ℓ, $\ell \in \mathfrak{L}(g)$. If $d \le 2a_{i_E(g,\delta_n)}$, then $C_n^G(d;R) \le \big[(32nLR/d + 3)^3\, 2C_E(\delta_n)\, (2[c_E(\delta_n) + \log(2L/d)])^{q_E} (2L/d)^{11/2}\big]^n$.

(b) *(Limits; the reconstructed space.)* Every sequence of first-passage data (K_j, β_j) at g with $K_j \to \infty$, with states $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$, has a subsequence along which the tensor limit exists at every tuple. Every tensor limit σ at g has a label $b_* \in [g^{-2}, L(g^{-2} + \bar{B})]$; it is real, symmetric and multilinear, $\sigma(\varnothing) = 1$, $\sigma((H)) = 0$, $|\sigma(X)| \le C_n^G(d;R)\, g^{2n} \prod_a |H_a|_\infty$ for the tuples of (a), and σ is continuous under the motion of its entries; it is invariant under $\mathbb{R}^3 \rtimes W_3$ and $\sigma(\theta \bar{F} \cdot F) \ge 0$ on $\mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$. Hence $\mathcal{H}(\sigma)$, Ω, H, $\mathcal{U}$, $\mathcal{P}$ are formed; $\mathcal{P}$ is carried by the square cone; $\mathcal{H}_0$ reduces H, $\mathcal{U}$, $\mathcal{P}$.

With $i_1 = i_E(g, \frac{1}{16})$ and $\mathsf{c}_E(i) = 2C_E \mathsf{Y}_i^{q_E} a_i^{-11/2}$ at $\delta = \frac{1}{16}$: for $i \geq i_1$, $z \in \mathbb{R}^3$ with $z_3 = a_i/2$ and $h \in C_c(\mathbb{R}^3; V_{\mathbb{C}})$ carried by $\{|x - z|_\infty \leq \frac{3}{8} a_i\}$, the slab operator $\mathsf{B}_{a_i}(h)$ exists and $\|\mathsf{B}_{a_i}(h)\| \leq \mathsf{c}_E(i)\, b_*^{-1} |h|_\infty$; and wherever slab operators exist, $e^{-tH} \mathsf{B}_l(h) e^{-t'H} = \mathsf{B}_{l+t+t'}(\tau_{te_3} h)$ and $\mathcal{U}(v) \mathsf{B}_l(h) \mathcal{U}(v)^{-1} = \mathsf{B}_l(\tau_{(v,0)} h)$.

(c) *(The point bound.)* For every $p > \frac{17}{2}$ there is a number C_p formed from the constants, g and p such that for $0 \leq d' < d$, $\vartheta = d - d'$ and $h \in C_c(\mathbb{R}^3; V_{\mathbb{C}})$ carried by $\{|x_3| \leq d'\}$,

$$\|\mathsf{B}_{2d}(\tau_{de_3} h)\| \leq C_p \min\{1, \vartheta\}^{-p}\, b_*^{-1} \|h\|_{L^1},$$

either norm of V being used in $\|h\|_{L^1}$. Consequently σ^1 satisfies (Rec4)$_V$ with $c_0 = \frac{1}{2}$, every $p_V > \frac{17}{2}$ and $C_V = 2^{p_V} C_{p_V} b_*^{-1} \leq 2^{p_V} C_{p_V} g^2$: one triple $(2^{p_V} C_{p_V} g^2, p_V, \frac{1}{2})$ serves all the tensor limits at g. In the sup norm of a cell every power $> \frac{11}{2}$ is admissible.

(d) *(Real time.)* Let $p = p_V$, C_V be as in (c) and l the least integer $> p$. (i) $\mathcal{T}(\mathfrak{z}) = \int e^{-\mathfrak{z}_3 E + i(\mathfrak{z}_1 q_1 + \mathfrak{z}_2 q_2)} d\mathcal{P}$ are contractions on $\{d_\square \geq 0\}$, form a semigroup, and are holomorphic in norm on $\{d_\square > 0\}$. (ii) There are bounded point operators $\mathsf{b}(w|e|w')$, $d_\square(w), d_\square(w') > 0$, $e \in V_{\mathbb{C}}$, holomorphic in norm and linear in e, with $\|\mathsf{b}(w|e|w')\| \leq \sqrt{2} C_V s^{-p} |e|$ for $0 < s \leq \min\{1, d_\square(w), d_\square(w')\}$, $\mathcal{T}(a) \mathsf{b}(w|e|w') \mathcal{T}(a') = \mathsf{b}(w + a|e|w' + a')$, and $\mathsf{B}_{2\eta}(\tau_{\eta e_3} h) = \int \mathsf{b}(y + \eta e_3 | h(y) | - y + \eta e_3)\, dy$. (iii) The functions

$$\mathbf{W}_n(\mathfrak{z}; e) = \langle \Omega, \mathsf{b}(w|e_1|\tfrac{1}{2}\mathfrak{z}_1)\, \mathsf{b}(\tfrac{1}{2}\mathfrak{z}_1|e_2|\tfrac{1}{2}\mathfrak{z}_2) \cdots \mathsf{b}(\tfrac{1}{2}\mathfrak{z}_{n-1}|e_n|w)\Omega \rangle,$$

which do not depend on w, are holomorphic on $\{d_\square > 0\}^{n-1}$, n-linear in e, and $|\mathbf{W}_n(\mathfrak{z}; e)| \leq (C_V \eta^{-p})^n \prod_k |e_k|$ for $e \in V^n$, $d_\square(\mathfrak{z}_k) \geq 2\eta$, $0 < \eta \leq 1$; $\sigma(X) = \int \mathbf{W}_n(x_2 - x_1, \ldots, x_n - x_{n-1}; h_1(x_1), \ldots, h_n(x_n))\, dx$ for tuples ordered in the third coordinate, and correspondingly for tuples ordered in another coordinate direction; so $|\sigma(X)| \leq \prod_k C_V \eta^{-p} \|h_k\|_{L^1}$ for gaps $\geq 2\eta$, with no factorial. (iv) For $f \in \mathcal{S}_V$ there is exactly one operator $T(f) : \mathcal{D}_\infty \to \mathcal{D}_\infty$ with $\langle \psi, T(f)\psi' \rangle = \int q_0(U(x)^{-1}\psi, U(x)^{-1}\psi'; f(x))\, dx$, where $q_0(\psi, \psi'; e) = \langle (1 + H)^l \psi, \mathsf{A}_l(e)(1 + H)^l \psi' \rangle$ with $\mathsf{A}_l(e)$ bounded; $\langle \psi, T(f)\psi' \rangle = \langle T(f^*)\psi, \psi' \rangle$, $U(a) T(f) U(a)^{-1} = T(f(\cdot - a))$, $[H, T(f)] = iT(\partial_t f)$, $\|(1 + H)^j T(f) \psi\| \leq c_j(f) \|(1 + H)^{2l+j} \psi\|$, and T is covariant under the eight signed permutations that fix e_3; $T(f)$ is determined by σ alone. (v) $\langle \Omega, T(f_1) \cdots T(f_n) \Omega \rangle$ are tempered and are the boundary values of the $\mathbf{W}_n$. (vi) For every $E \in V$ the form $q_0(\cdot, \cdot; E)$ on $\mathcal{D}_\infty \cap \mathcal{H}_0$ is bounded by $\|\mathsf{A}_l\|\, |E|\, \|(1 + H)^l \psi'\|\, \|(1 + H)^l \psi\|$, vanishes at (Ω, Ω) and has $\overline{q_0(\psi', \psi; E)} = q_0(\psi, \psi'; \rho(\theta) E)$; so the forms $\mathfrak{q}_{ij} = q_0(\cdot, \cdot; \mathsf{m}_{ij})$ at the label matrices of the stress tensor satisfy (M1) with $c_T = \sqrt{3}\, \|\mathsf{A}_l\|$, and the operator formula of (M2) holds at different heights for the kernels $\mathsf{s}_{ij}(x; y) = \mathsf{s}_{1+m}(x, y; \mathsf{m}_{ij}, \mathbf{1}, \ldots, \mathbf{1})$, s_{1+m} the kernels of (g).

(e) *(The circular cone.)* $\mathcal{P}(\{E < |q|\}) = 0$. The operators $\mathcal{T}(\mathfrak{z})$ are contractions on the closure of $\{d_\circ > 0\}$ and holomorphic inside, and $\mathbf{W}_n$ continues holomorphically to $\{d_\circ > 0\}^{n-1}$, n-linear in e; for $\varepsilon > 0$ and the $\mathfrak{z}$ with $d_\circ(\mathfrak{z}_k - 2\varepsilon e_3) > 0$ for all k it is bounded by $\prod_k C_{\mathrm{pt}}(\varepsilon) |e_k|_\infty$, where

$$C_{\mathrm{pt}}(\varepsilon) = 3\sqrt{2}\, C_V \min\{1, \varepsilon\}^{-p},$$

C_V and p as in (d). Indeed, at $w = \varepsilon e_3$ the relation $\mathcal{T}(a) \mathsf{b}(w|e|w') \mathcal{T}(a') = \mathsf{b}(w + a|e|w' + a')$ of (d) (ii) and the semigroup law give $\mathbf{W}_n(\mathfrak{z}; e) = \langle \Omega, \mathsf{b}_1 \mathcal{T}(\mathfrak{z}_1 - 2\varepsilon e_3) \mathsf{b}_2 \cdots \mathcal{T}(\mathfrak{z}_{n-1} - 2\varepsilon e_3) \mathsf{b}_n \Omega \rangle$, $\mathsf{b}_k = \mathsf{b}(\varepsilon e_3 | e_k | \varepsilon e_3)$; the right member continues holomorphically to the $\mathfrak{z}$ with $d_\circ(\mathfrak{z}_k - 2\varepsilon e_3) > 0$, where the factors $\mathcal{T}(\cdot)$ are contractions, and $\|\mathsf{b}_k\| \leq \sqrt{2} C_V \min\{1, \varepsilon\}^{-p} |e_k| \leq 3\sqrt{2} C_V \min\{1, \varepsilon\}^{-p} |e_k|_\infty$ by (d) (ii) at $s = \min\{1, \varepsilon\}$ and $|e| \leq 3|e|_\infty$.

In each of the nine pictures u of the coordinate and diagonal mirrors, with the joint spectral measure $\mathcal{P}_u$ formed as in Definition 2.2 (3) with u in the place of e_3, $\mathcal{P}_u(\{E < |q|\}) = 0$, and the operators $\mathcal{T}_u(\mathfrak{z})$ formed with $\mathcal{P}_u$ as $\mathcal{T}(\mathfrak{z})$ with $\mathcal{P}$ are contractions on the closure of $\{d_\circ > 0\}$ and holomorphic inside; the continuation of $\mathbf{W}_n$, with its bound, holds in the pictures of e_1, e_2, e_3, the invariance under W_3 carrying the picture of e_3 to the two others.

There are two strongly continuous unitary groups V_1, V_2 on $\mathcal{H}(\sigma)$ with $V_k(s)\Omega = \Omega$ and $V_k(s)\mathcal{P}(B)V_k(s)^{-1} = \mathcal{P}(\Lambda^{(k)}_{-\pi s/2}B)$ for every Borel set B, $\Lambda^{(k)}_{\varsigma}$ the boost of rapidity ς in the plane of (E, q_k), which multiplies $E + q_k$ by e^{ς} and $E - q_k$ by $e^{-\varsigma}$ and fixes the other momentum; the two boosts generate the restricted Lorentz group $\mathrm{SO}_0(1,2)$ of the form $E^2 - |q|^2$, so the null sets and the support of $\mathcal{P}$ are invariant under it.

This clause holds also for the tensor limits of Theorem D (e) at every $0 < g \le \gamma_W^{\mathrm{ref}}$.

(f) *(Ordered classes.)* $\mathcal{H}^{\mathrm{ord}}(\sigma) = \mathcal{H}(\sigma)$; Ω and the vectors $\mathsf{B}_{l_1}(h_1)\cdots\mathsf{B}_{l_n}(h_n)\Omega$ are total, and the span $\mathcal{D}_0$ of Ω and of the $T(f_1)\cdots T(f_n)\Omega$ is dense in $\mathcal{H}(\sigma)$. Two tensor limits that agree on ordered tuples are equal; so σ is determined by its functions $\mathbf{W}_n$.

(g) *(Kernels.)* Let $\mathsf{K}_n = (10n)^{\lceil pn\rceil n(n-1)/2}$. For every admissible tuple $M = (h_1, \dots, h_n)$ of continuous compactly supported $V_{\mathbb{C}}$-valued entries with pairwise disjoint supports in a slab $\{0 < x_3 < l\}$, entries side by side allowed, there is a bounded operator $\mathsf{B}_l(M)$ with $[M \cdot \tau_{le_3}F] = \mathsf{B}_l(M)[F]$ and

$$\|\mathsf{B}_l(M)\| \le \mathsf{K}_n\big(\sqrt{2}C_V(3/d(M))^p\big)^n \prod_a \|h_a\|_{L^1},$$

$d(M)$ the least of 1, of the distance of the supports from the two faces, and of the sup distances between two supports. For every $X \in \mathfrak{S}_V(\mathbb{R}^3)$, $\sigma(X) = \int \mathsf{s}_n(x; h_1(x_1), \dots, h_n(x_n))\,dx$ with a kernel s_n continuous at all non-coinciding points, n-linear in e, real-analytic in the coordinates of one direction at fixed values of the others, and

$$|\mathsf{s}_n(x;e)| \le \mathsf{K}_n\Big(\sqrt{2}C_V\big(3/\min\{1, \min_{a\neq b}|x_a - x_b|_\infty\}\big)^p\Big)^n \prod_a |e_a|;$$

hence $|\sigma(X)| \le \mathsf{K}_n(\sqrt{2}C_V(3/\min\{1, d/\sqrt{3}\})^p \frac{4\pi}{3}R^3)^n \prod_a \sup|h_a|$ for tuples in balls of radius R at distances $\ge d$, whatever their position. σ does not charge the configurations with two equal heights. The scalar part $\sigma_0(f_1, \dots, f_n) = \sigma(f_1\mathbf{1}, \dots, f_n\mathbf{1})$, at C^1_c entries, is the limit of the centred products of the action densities along the data (K_j, β_j, ρ_j) of σ, since $\mathcal{T}_K(f\mathbf{1}) = \mathcal{O}(f)$; these data form a convergent Gibbs sequence at g (Definition 15.4(2)), so σ_0 is scalar data (Rec) with the numbers $16\,C^g_{\mathrm{pt}}, 4, \frac{1}{2}$ (Theorem YMM1:AP, Section YMM1:107). With it, the kernel of one tensor entry among m scalar entries is real-analytic at all non-coinciding points, for every m (Proposition 2.18 (c)).

(h) *(Growth.)* There is a number c_4 formed from the constants and g such that for $n \ge 1$, $0 < d \le 1$, $i = \max\{i_E(g, \frac{1}{8n}),$ the least i with $a_i \le d/4\}$, every first-passage datum with $K \ge K_E(i)$ (at $\delta = \frac{1}{8n}$), $K \ge i + 1$, $8na_K \le a_i$, any two states $\mathfrak{s}, \mathfrak{s}' \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, and real H_a vanishing off closed sets in balls of radius 1 at Euclidean distances $\ge d$,

$$\Big|\mathfrak{s}\Big(\prod_a(\mathcal{T}_K(H_a) - \mathfrak{s}'(\mathcal{T}_K(H_a)))\Big)\Big| \le (c_4 n^{35/2} d^{-19/2} b^{-1})^n \prod_a |H_a|_\infty;$$

so $|\sigma(X)| \le (c_4 g^2 e^{35/2})^n (n!)^{35/2} d^{-(19/2)n} \prod_a |H_a|_\infty$ for every tensor limit and every component of Theorem F. With the upper Riemann sums $\|H\|_\natural = \sum_\square |\square| \sup_\square |H|_\infty$ of $|H|_\infty$ over the boxes $\square = \frac{a_i}{4n}(\mathbf{k} + [0,1)^3)$, $\mathbf{k} \in \mathbb{Z}^3$, of the mesh $a_i/(4n) \le d/(16n)$, i the index of the first display, in the place of the sup norms, $|\sigma(X)| \le (Cn^{16}d^{-9})^n \prod_a \|H_a\|_\natural$ for entries of any size at pairwise sup distances $\ge 2d$, ordered or not, C formed from the constants and g. For every n there is exactly one linear functional S_n on the $V_{\mathbb{C}}^{\otimes n}$-valued Schwartz functions on $\mathbb{R}^{3n}$ that vanish with all their derivatives on the diagonals, bounded for one Schwartz norm, with $\mathsf{S}_n(H_1 \otimes \cdots \otimes H_n) = \sigma(H_1, \dots, H_n)$ at smooth tuples; it satisfies

$$|\mathsf{S}_n(\varphi)| \le (C^V_E)^n (n!)^{51/2} |\varphi|_{18n},$$

the growth hypothesis in Proposition YMM1:93.5 with a label, with C^V_E formed from the constants and g, the same for all tensor limits at g and all their components; the pairs

$(17n, \frac{49}{2})$ and $(15n, \frac{43}{2})$ of the index of the norm and the power of the factorial serve as well, with other numbers; on compact subsets of the non-coinciding configurations it is a distribution of order at most $4n+1$.

The proofs of (a)–(h) use no covariance of σ under rotations outside W_3 at tuples with nonscalar entries; neither Theorem D (a) nor Proposition 2.19 is used. The last two sentences of (g) use only the previously established Euclidean invariance of the scalar limit, through its scalar reconstruction data (Rec); see Theorem YMM1:AP. ■□

Theorem D (Covariance, reconstruction, locality)**.** Let $0 < g \le \gamma_W^{\mathrm{sd}}$ and let σ be a tensor limit at g with label b_*.

(a) $\sigma(\mathsf{R}X) = \sigma(X)$ for every $\mathsf{R} \in \mathrm{O}(3)$ and every $X \in \mathfrak{S}_V(\mathbb{R}^3)$.

(b) $\sigma(\theta_{n,c}\bar{F} \cdot F) \ge 0$ for every unit vector n, every $c \in \mathbb{R}$ and every $F \in \mathbb{C}\mathfrak{S}_V(\{n \cdot x > c\})$, where $(\theta_{n,c}H)(x) = \Theta_n H(x - 2(n \cdot x - c)n)\Theta_n$ and $\Theta_n = 1 - 2nn^{\mathrm{T}}$.

(c) σ^1 is reconstruction data with labels at $V = \mathrm{Sym}_3(\mathbb{R})$ with the invariant norm, with $c_0 = \frac{1}{2}$, every $p_V > \frac{17}{2}$ and $C_V = 2^{p_V} C_{p_V} b_*^{-1} \le 2^{p_V} C_{p_V} g^2$; its invariance holds at all tuples of continuous entries. The map $[F]_{\sigma^1} \mapsto [F]_\sigma$ extends to a unitary map of $\mathcal{H}(\sigma^1)$ onto $\mathcal{H}(\sigma)$ that carries Ω, H, $\mathcal{U}$, $\mathcal{P}$ to Ω, H, $\mathcal{U}$, $\mathcal{P}$.

(d) (i) For every n there is exactly one continuous function $\mathsf{s}_n(x; e)$ on the non-coinciding configurations, n-linear in $e \in V^n$, with $\sigma(H_1, \dots, H_n) = \int \mathsf{s}_n(x; H_1(x_1), \dots, H_n(x_n))\, dx$ for all $X \in \mathfrak{S}_V(\mathbb{R}^3)$; it is real-analytic, symmetric when points and labels are permuted together, $\mathsf{s}_n(\mathsf{r}x_1, \dots, \mathsf{r}x_n; \rho(\mathsf{R})e_1, \dots, \rho(\mathsf{R})e_n) = \mathsf{s}_n(x; e)$ for every isometry $\mathsf{r}x = \mathsf{R}x + v$, and $|\mathsf{s}_n(x; e)| \le \big(C_V(2n^2/\min\{1, \mathsf{d}(x)\})^{p_V}\big)^n \prod_a |e_a|$ at every point, $\mathsf{d}(x) = \min_{a \ne b} |x_a - x_b|$; so $|\sigma(X)| \le (C_V(2n^2/d)^{p_V})^n \prod_a \|H_a\|_{L^1}$ at pairwise distances $\ge d$, $0 < d \le 1$, and $|\mathsf{S}_n(\varphi)| \le (8\pi^2 3^{\lceil p_V \rceil + 2}(2e^2)^{p_V} C_V)^n (n!)^{2p_V} |\varphi|_{(\lceil p_V \rceil + 4)n}$. (ii) There is a strongly continuous unitary representation U of $\mathbb{R}^{1+2} \rtimes \mathcal{L}$ on $\mathcal{H}(\sigma)$ with $U(x, 1) = e^{itH}\mathcal{U}(\vec{x})$, $U(a, \Lambda)\Omega = \Omega$, $U(a, \Lambda)\mathcal{D}_0 = \mathcal{D}_0$, the joint spectrum in the closed forward cone, and

$$U(a, \Lambda)T(f)U(a, \Lambda)^{-1} = T\big(\hat{\Lambda} f(\Lambda^{-1}(\cdot - a))\hat{\Lambda}^{\mathrm{T}}\big) \quad \text{on } \mathcal{D}_0,$$

with the transpose, not the adjoint. (iii) $T(f)T(f')\psi = T(f')T(f)\psi$ for $\psi \in \mathcal{D}_0$ whenever $f, f' \in \mathcal{S}_V$ have spacelike separated supports: all six components are local with respect to all six.

(e) Let $0 < g \le \gamma$. Every sequence of first-passage data at g with $K_j \to \infty$ and periodic Gibbs states has a subsequence along which the tensor limit exists. Every such limit σ satisfies (a), (b) and the conclusion of Theorem E (c), and σ^1 is reconstruction data with labels with $c_0 = \frac{1}{2}$, every $p_V > \frac{17}{2}$ and

$$C_V = 3^{p_V} L^{4z} \max_{k=1,2} 2^{p_V} C_{p_V}[g'_k]\, g'^2_k,$$

where z is the least integer ≥ 1 with $L^z g^{-2} \ge 2(\gamma_W^{\mathrm{sd}})^{-2}$, $g'^{-2}_1 = L^z g^{-2}/2$, $g'^{-2}_2 = L^{z+1} g^{-2}/4$, and $C_p[g']$ is the number C_p of Theorem C (c) at the coupling g': a number formed from the constants, g and p_V, one triple for all the tensor limits at g; so (c) and (d) hold for it.

■□

Theorem E (Conservation)**.** For $\eta \in C_c^2(\mathbb{R}^3; \mathbb{R}^3)$ put $H^{\mathrm{cons}}[\eta] = (\nabla \cdot \eta)\mathbf{1} - \nabla\eta - (\nabla\eta)^{\mathrm{T}}$ and $\|\eta\|_{C^2} = \sup|\eta| + \sup|\nabla\eta| + \sup|\nabla^2\eta|$; with the label matrices $\mathsf{m}_{ij} = \delta_{ij}\mathbf{1} - e_i e_j^{\mathrm{T}} - e_j e_i^{\mathrm{T}}$ of the stress tensor one has $\sum_i (\partial_i \zeta)\mathsf{m}_{ij} = H^{\mathrm{cons}}[\zeta e_j]$, and $\frac{1}{2}\operatorname{tr}(\mathsf{m}_{ij}T) = \frac{1}{2}\delta_{ij}\operatorname{tr} T - T_{ij}$ is the stress tensor. Let $0 < g \le \gamma$.

(a) *(At a cutoff, in every periodic Gibbs state.)* Let $n \ge 2$, $1 \le n_1 \le n$, $R > 0$, $0 < c < \frac{1}{28}$, $\phi = (\frac{1}{28} - c)/(4n - 1)$ and $u = \lceil \phi K \rceil$. There are numbers C, p (from the constants, g, n, R, c) and K_0 (from the constants, g, n, c) such that for all first-passage data (K, β) at g

with $K \geq K_0$, all $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, every $d > 0$ with $dL^u \geq K^2$, all $\eta_1, \dots, \eta_{n_1} \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and all $H_{n_1+1}, \dots, H_n \in C_c(\mathbb{R}^3; V)$ whose n supports lie in a ball of radius R and are pairwise at sup distance $\geq d$, with $X_a = \mathcal{T}_K(H^{\mathrm{cons}}[\eta_a])$ for $a \leq n_1$ and $X_a = \mathcal{T}_K(H_a)$ for $a > n_1$,

$$\Big|\nu\Big(\prod_{a=1}^{n}\big[X_a - \nu(X_a)\big]\Big)\Big| \leq C\,K^p L^{-cn_1K} \prod_{a\leq n_1}\|\eta_a\|_{C^2} \prod_{a>n_1}|H_a|_\infty,$$

and the same bound holds for the joint cumulant of $X_1, \dots, X_n$ under ν. At $c = \frac{1}{56}$, $n_1 = 1$ the rate is $K^p L^{-K/56}$.

(b) *(A second form; tori.)* Write $A^\nu[F] = F - \nu(F)$. For $q \geq 2$, $d > 0$, $R > 0$ there are C, p, K_0, formed from the constants, g, q, d, R, such that for all first-passage data (K, β) at g with $K \geq K_0$, all $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, every $\eta \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and all bounded $H_2, \dots, H_q : \mathbb{R}^3 \to V$ whose supports, together with $\operatorname{supp}\eta$, lie in a cube of side $2R$ at pairwise sup distances $\geq d$,

$$\Big|\nu\Big(A^\nu\big[\mathcal{T}_K(H^{\mathrm{cons}}[\eta])\big]\prod_{a=2}^{q} A^\nu\big[\mathcal{T}_K(H_a)\big]\Big)\Big| \leq C\,K^p L^{-K/36}\,\|\eta\|_{C^2}\prod_{a=2}^{q}|H_a|_\infty,$$

also for the joint cumulant. For the same first-passage data, on every torus T_ℓ, $\ell \in \mathfrak{L}(g)$, the corresponding bound holds for C^2 vector fields η on T_ℓ and bounded $H_2, \dots, H_q$ whose supports, together with $\operatorname{supp}\eta$, are pairwise at sup distance $\geq d$ on T_ℓ:

$$|\langle \mathcal{T}_K(H^{\mathrm{cons}}[\eta]); \mathcal{T}_K(H_2); \dots; \mathcal{T}_K(H_q)\rangle_{K,\ell,\beta}| \leq CK^pL^{-K/36}\|\eta\|_{C^2}\prod_{a=2}^{q}|H_a|_\infty,$$

with C, p, K_0 depending besides on ℓ.

(c) *(In the limit.)* For every tensor limit σ at g (in the sense of Theorem D (e) if $g > \gamma^{\mathrm{sd}}_W$), every $n \geq 2$, every $\eta \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and all continuous $H_2, \dots, H_n$ with compact, pairwise disjoint supports off $\operatorname{supp}\eta$,

$$\sigma(H^{\mathrm{cons}}[\eta], H_2, \dots, H_n) = 0, \qquad \text{equivalently} \qquad \sum_i \sigma\big((\partial_i\zeta)\mathsf{m}_{ij}, H_2, \dots, H_n\big) = 0 \quad (\zeta \in C^2_c). \tag{5}$$

On every torus T_ℓ, $\ell \in \mathfrak{L}(g)$, the limits of the cumulants of Theorem G (E3) vanish at $(H^{\mathrm{cons}}[\eta], H_2, \dots, H_q)$ for Lipschitz H_a.

(d) *(Kernels and operators.)* Let σ' be scalar reconstruction data with the frame (M1), (M2) and a unique vacuum. Then the identity (5) for the kernels s_{ij} of (M2) among scalar entries, $\sum_i \int \partial_i\zeta(x)\mathsf{s}_{ij}(x;y)\,dx = 0$, and (M4) (a) are equivalent.

■□

Theorem F (Components and Wightman tensor fields)**.** Let σ be the tensor limit of a sequence (K_j, β_j, ν_j) of first-passage data and periodic Gibbs states at g, and $A^\nu_K(X) = \prod_a[\mathcal{T}_K(H_a) - \nu(\mathcal{T}_K(H_a))]$.

(a) *(Decomposition; $0 < g \leq \gamma^{\mathrm{ref}}_W$.)* There are a compact metrisable space X, a Borel probability measure λ on X with support X, and real symmetric functionals σ_ξ, $\xi \in \mathsf{X}$, on labelled tuples, with $\xi \mapsto \sigma_\xi(X)$ continuous and $\xi \mapsto \sigma_\xi$ injective, such that σ has iterated plateaux in the sense of Definition 2.2 (5) at every $(X^1, \dots, X^q)$, $q \geq 1$, $X^i \in \mathfrak{S}_V(\mathbb{R}^3)$, and its iterated plateau there is $\int \prod_i \sigma_\xi(X^i)\,d\lambda(\xi)$.

(b) *(Each component; $0 < g \leq \gamma^{\mathrm{ref}}_W$.)* For every $\xi \in \mathsf{X}$: (i) there are translation-invariant events E_j with $\nu_j(E_j) > 0$ such that $\rho_j = \nu_j(\cdot\,|\,E_j) \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$ and $\sigma_\xi(X) = \lim_j \rho_j(A^{\nu_j}_{K_j}(X))$ along the full sequence, indeed $\|E_{\rho_j}[A^{\nu_j}_{K_j}(X)\,|\,\mathcal{I}] - \sigma_\xi(X)\|_{L^\infty(\rho_j)} \to 0$, $\mathcal{I}$ the invariant σ-field; (ii) $\sigma_\xi((H)) = \frac{c_{\pi(\xi)}}{3}\int \operatorname{tr} H$ with a real number $c_{\pi(\xi)}$, and the recentred functional $\sigma^c_\xi(X) = \sum_{J\subset\{1..n\}}\prod_{a\notin J}(-\sigma_\xi((H_a)))\,\sigma_\xi(X_J)$ is the tensor limit of (K_j, β_j, ρ_j); so it has

all the properties of a tensor limit, and $[F] \mapsto [\mathsf{S}_\xi F]$, $\mathsf{S}_\xi X = \sum_J \prod_{a \notin J} \sigma_\xi((H_a))X_J$, is a unitary map of $\mathcal{H}(\sigma_\xi)$ onto $\mathcal{H}(\sigma^c_\xi)$ that carries Ω_ξ to Ω and intertwines H and $\mathcal{P}$; (iii) $\ker H_\xi = \mathbb{C}\Omega_\xi$; (iv) there is exactly one map π of X onto the space X_0 of the canonical decomposition $(\mathsf{X}_0, \lambda_0, (\sigma_{0,\zeta}))$ of the scalar part $\sigma|_{V_0}$ with $\sigma_\xi(f_1\mathbf{1}, \dots, f_n\mathbf{1}) = \sigma_{0,\pi(\xi)}(f_1, \dots, f_n)$; it is continuous and onto, and $\pi_*\lambda = \lambda_0$.

(c) *(Wightman fields; $0 < g \le \gamma^{\mathrm{sd}}_W$.)* For every ξ, the restriction of σ^c_ξ to C^1_c entries is reconstruction data with labels with $c_0 = \frac{1}{2}$, every $p_V > \frac{17}{2}$ and the numbers of Theorem D (c), and it has (Rec5). Its reconstruction is a Wightman tensor field of six components in $1+2$ dimensions: the fields $T(f)$, $f \in \mathcal{S}_V$, on $\mathcal{D}_0$ are tempered; $\langle \psi, T(f)\psi' \rangle = \langle T(f^*)\psi, \psi' \rangle$, so that T_{33} and T_{jk}, $j,k \le 2$, are Hermitian and T_{3j} is Hermitian after the factor i; $U(a,\Lambda)T(f)U(a,\Lambda)^{-1} = T(\hat\Lambda f(\Lambda^{-1}(\cdot - a))\hat\Lambda^{\mathrm{T}})$; the joint spectrum lies in the closed forward cone; Ω_ξ is the only invariant vector and is cyclic; all components are local with respect to all. The growth condition of Theorem C (h) holds with the same numbers for all components. The given limit σ is the integral over λ of its components in the sense of (a).

(d) *(The frame over a component; $0 < g \le \gamma^{\mathrm{sd}}_W$.)* On the scalar subspace of $\mathcal{H}(\sigma^c_\xi)$ the frame (M1)–(M5) holds for the tensor formed at the label matrices m_{ij} of the stress tensor, with the forms $q_0(\cdot,\cdot;\mathsf{m}_{ij})$, the kernels $\mathsf{s}_{ij}(x;y) = \mathsf{s}_{1+m}(x,y;\mathsf{m}_{ij},\mathbf{1},\dots,\mathbf{1})$, the scalar field $\phi(f) = T(f\mathbf{1})$ and the restriction to the scalar subspace of the representation U of Theorem D (d) (ii) for σ^c_ξ. The scalar subspace reduces $U(a,\Lambda)$: $\phi(f)$ keeps it; $U(a,\Lambda)\phi(f)U(a,\Lambda)^{-1} = \phi(f(\Lambda^{-1}(\cdot - a)))$ on $\mathcal{D}_0$, since $\hat\Lambda\mathbf{1}\hat\Lambda^{\mathrm{T}} = \mathbf{1}$; $U(a,\Lambda)\Omega = \Omega$; and Ω with the vectors $\phi(f_1)\cdots\phi(f_n)\Omega$ spans a dense subspace of it, by Proposition 2.16 (a) (v) for the restriction of σ^c_ξ to the tuples with entries in V_0, whose space is the scalar subspace and whose fields are the restrictions of the $T(f\mathbf{1})$. In particular the real-time stress tensor is conserved, (M4) (a).

(e) *(The frame on $\mathcal{H}_0$; $0 < g \le \gamma^{\mathrm{sd}}_W$.)* For σ itself, (M1) holds, the kernels $\mathsf{s}_{ij}(x;y)$ of one tensor entry among scalar entries are covariant as in (M2) and continuous at all non-coinciding points, $[T^E_{ij}(F), \phi(f)] = 0$ between scalar vectors at spacelike separation as in (M3), and $\langle \Omega, \phi(f_1)\cdots\phi(f_n)T[t](F)\Omega\rangle$ is invariant under $(f,t,F) \mapsto (f\circ\Lambda^{-1}, \Lambda t, F\circ\Lambda^{-1})$ as in (M5). ■□

Proposition 2.5 (Covariance at one label suffices)**.** Let $0 < g \le \gamma^{\mathrm{sd}}_W$ and let σ be a tensor limit at g. If $\sigma(\mathsf{R}X) = \sigma(X)$ for all $\mathsf{R} \in \mathrm{O}(3)$ at the tuples with exactly one entry outside V_0, then the kernels of (M2) are covariant at all non-coinciding points and (M3), (M5) hold on $\mathcal{H}_0$. ■

By Theorem D (a) every tensor limit at g satisfies the condition of Proposition 2.5, and its conclusion is contained in Theorem F (e). Its proof uses rotational covariance only for tuples with exactly one entry outside V_0. It follows the proofs of Propositions YMM1:108.3, YMM1:110.2 and YMM1:110.1, with one labelled insertion.

Theorem G (Cumulants on a torus; laws at short distance)**.** Assume the setting of Definition 2.4; let $k'_n(g,s)$ and $C_n(g)$, $C(g)$ be the numbers of Proposition 2.10.

(E1) Let ℓ be small over the running couplings of (K,β), $0 < d < 1$ with $s(d) \le K$, and (N.θ) at $(n, g, s(d))$. For all $H_a : T_\ell \to V_{\mathbb{C}}$ with (Geo) at d,

$$|\langle \mathcal{T}_K(H_1); \dots; \mathcal{T}_K(H_n)\rangle_{K,\ell,\beta}| \le 60^n k'_n(g,s(d))\, b^{-n} \prod_a |H_a|_\infty \le 60^n C_n(g)\big[2\log\tfrac{1}{d} + C(g)\big]^{8np_0} b^{-n} \prod_a |H_a|_\infty.$$

No upper bound on the distances and no smoothness is required. On sides with (Sd.1), in particular on every $\ell \in \mathfrak{L}(g)$, the bound holds with the factor $\max\{1, \mathsf{c}(\ell)\}^n$.

(E2) Let $s_{\mathrm{th}}(n)$ be the least integer ≥ 3 from which on (N.θ) holds at $(n,g,\cdot)$, $d'' = \min\{\frac{3}{4}d, L^{-s_{\mathrm{th}}(n)}\}$, $s'' = s(d'')$, cut T_ℓ into boxes $\square$ of sides $\le 0.99\, d''$, and let the sets Σ_a

be pairwise at distance $\geq d$. (i) If ℓ is small and $K \geq s''$: $|\langle \mathcal{T}_K(H_1); \dots; \mathcal{T}_K(H_n)\rangle| \leq 60^n k_n'(g,s'')\, b^{-n} \prod_a \sum_\square \sup_\square |H_a| \leq 60^n k_n'(g,s'')(2\ell/d'')^{3n} b^{-n} \prod_a |H_a|_\infty$. (ii) If $K < s''$, on any side and with or without the separation: the same cumulant is at most $f_n[18\bar{x}_0(C_W(s'')+1)^4/d'']^n b^{-n} \prod_a \sum_\square \sup_\square |H_a|$, $f_n = \sum_\pi (|\pi|-1)!$ over the partitions π of $\{1..n\}$. (iii) On small sides, at every cutoff, it is at most $k_n b^{-n} \prod_a |H_a|_\infty$ with $k_n \leq C(n,g,\ell)\, d^{-3n}[2\log\frac{1}{d} + C']^{8n\mathfrak{p}_0}$.

(E3) (i) *(Scaling.)* Let $g_\star \leq \gamma_W^{\mathrm{ref}}$, $\beta > X_{g_\star}$, $K_\star = K(\beta, g_\star)$, $z = K - K_\star$, and let $L^z\ell$ be small over the running couplings of $(K_\star, \beta)$. Then $\delta_\star b \leq L^{-z} < g_\star^2 b$ with $\delta_\star = [L(g_\star^{-2} + \bar{B})]^{-1}$, and for $0 < d < L^{-z}$ with $s(L^z d) \leq K_\star$, (N.θ) and (Geo) at d: $|\langle \mathcal{T}_K(H_1); \dots; \mathcal{T}_K(H_n)\rangle_{K,\ell,\beta}| \leq 60^n C_n(g_\star)[2\log\frac{b}{d} + C(g_\star)]^{8n\mathfrak{p}_0} b^{-n} \prod_a |H_a|_\infty$; at $g_\star = \gamma_W^{\mathrm{sd}}$ the numbers depend on n alone. (ii) *(The limit of the cutoff on one torus.)* Let $0 < g \leq \gamma_W^{\mathrm{ref}}$, $b \in (g^{-2} + \bar{B}, X_g - \bar{B}]$, $\ell \in \mathfrak{L}(g)$, and let H_a be bounded Borel functions vanishing off closed sets at positive distances, entering through their means over the lattice cubes.

The cumulants κ_K at $(K, \ell, L^K b)$ converge along the full sequence $K \to \infty$; the limit is n-linear, symmetric, and translation invariant at uniformly continuous entries; at Lipschitz entries it equals the limit with point values. The rates are those of Proposition 2.12: with the least sup distance d of the sets there are numbers C, p, formed from the constants, n and b, and a cutoff K_1, formed besides from g, ℓ and d, such that for $K \geq K_1$

$$|\kappa_{K+1} - \kappa_K| \leq C\ell^{3(n+1)} K^p L^{-\theta_n K} \prod_a |H_a|_\infty, \qquad \theta_n = \frac{1}{1260\, n(8n+3)},$$

for the entries through their means over the lattice cubes, and the same with $|H_a|_\infty + \mathrm{Lip}_\infty H_a$ in the place of $|H_a|_\infty$ for Lipschitz entries read at the points; for one bond form among action densities, with real Lipschitz weights, none of them 0, read at the points and supports with no common point, whose spread (the definition preceding Lemma YMM1:114.6) is at least $\mathsf{d}_0 > 0$, the rate is $K^p L^{-K/120}$ from a cutoff on, with C, p and the cutoff formed from the constants, n, ℓ, b and d_0. If the sets lie in balls of radius $0.86\, d$ at distances $\geq 1.27\, d$ and (N.θ) holds at $(n, g, s(d))$, the limit is at most $60^n \max\{1, \mathsf{c}(\ell)\}^n k_n'(g, s(d)) b^{-n} \prod_a |H_a|_\infty$.

(E4) *(Finer forms.)* (i) Let $g \leq \gamma_W^{\mathrm{sd}}$, $0 < d < 1$, $K \geq s(d)$, and let $2\mathsf{l}$ be the least side at g. For two insertions of any components with real weights whose supports lie in balls of radius $d - 3a_K$ whose centres are at sup distance $\geq 3d + a_K$ (on a torus, modulo its side), in every periodic Gibbs state and on every torus of $\mathfrak{L}(g)$:

$$|\langle \mathcal{T}_K(H_1); \mathcal{T}_K(H_2)\rangle| \leq 180^2 C^\diamond(g)\, b^{-2} |H_1|_\infty |H_2|_\infty, \qquad C^\diamond(g) = \max\{2\, \mathsf{c}_\diamond(g)^2,\ C_2^T(\tfrac{1}{2}; 1)\},$$

with no power of d and no logarithm, and with the factor 4 for complex weights. Here C_2^T is the number of (E5) (i), and $\mathsf{c}_\diamond(g) = e^{G_g|^3} \mathsf{c}_\diamond'(g)$, where $\mathsf{c}_\diamond'(g)$, formed from the constants and g, is the larger of a bound of the eighth root of the mean of the eight mirror copies of a centred form of one direction near a point on the least torus $T_{2\mathsf{l}}$ and of the crude bound of such a form at the cutoffs below a threshold formed from g; the factor $e^{G_g|^3}$ is that of the transfer from the least torus to every side and every state (Lemma 2.7). So $C^\diamond(g)$ is a number of the constants and g.

On one torus, from a first depth $s_1(g,\ell)$ on, the same bound holds for two cubes of side $\frac{3}{2}h$ at sup distance $\geq \frac{5}{2}h$, with a number depending on ℓ in the place of $180^2 C^\diamond(g)$. (ii) At $n = 3$, on one torus, for supports in three cubes of a common side $\delta \leq \delta_\star(g,\ell)$ at pairwise sup distances $\geq 2\delta$ and $s(\delta/4) \leq K$, the cumulant is at most $64^3\, \Theta(\delta/4) \prod_a \sup |H_a|$ with $\Theta(\delta/4) \leq C(g,\ell)[2\log\frac{4}{\delta} + C(g)]^{16\mathfrak{p}_0} b^{-3}$: the power $16\mathfrak{p}_0$ of the logarithm in the place of $24\mathfrak{p}_0$. (iii) Let $p \geq 2$, $\ell = 2L^m \in \mathfrak{L}(g)$, $0 < d < 1$, and let $w_1, \dots, w_p$ be real weights of the plaquettes whose supports have their barycentres in sup balls of radius d, the balls being pairwise at sup distance $\geq d$ (complex weights cost the factor 2^p).

Let $y_K \geq \mathsf{Y}^\natural$, where $\mathsf{Y}^\natural$ is the threshold of Definition L.1, under which Proposition L.6 bounds the large-field regions uniformly in the volume with its constant $c_2^\natural$: a ceiling on the running coupling at the unit scale, formed from the constants. Let T be the largest level with $\hat{d} := dL^{K-T} \geq M(2+\frac{p}{2}y_T)+1$, so that two supports are at least $M(2+\frac{p}{2}y_T)$ apart in the units of the level T; let $T \geq 2$, which holds from a cutoff on that is formed from d, b and p; and let $d \leq b\,e^{-y^\sharp}$, where $y^\sharp \geq 1$, formed from the constants, p and ℓ/b, is the least number such that for all $y \geq y^\sharp$: $e^y \geq x_{\mathrm{J}}$, the threshold of the definitions preceding (228); $\theta(e^y)$ is at most a number formed from the constants and p; $2\mathfrak{p}_0 c_2^\natural A_0^2 y^{2\mathfrak{p}_0-1} \geq 4+(3+p)p$; $4\cdot 24^3(\frac{5}{4})^3(\ell/b)^3\exp\bigl((3+p^2)y - c_2^\natural A_0^2 y^{2\mathfrak{p}_0}\bigr) \leq 1$; and $c_{\mathrm{A}}\alpha_0 e^{y/2} \geq 2MB_3A_0y^{\mathfrak{p}_0}(\frac{y}{2}+1)$, with the number c_{A} of equation YMM1:(2262) and the constant B_3.

These conditions give $d_*(T) \geq \frac{1}{2}y_T$ for the distance

$$d_*(T) = \min\{c_{\mathrm{A}}\alpha_0/(2MB_3\varepsilon(x_T)),\,(L^{m+K-T}-4)/(2M)\} - 1$$

of equation YMM1:(2262) at the level T, $\varepsilon(t) = A_0 t^{-1/2}(\log t)^{\mathfrak{p}_0}$. Then

$$|\langle \mathcal{O}(w_1);\dots;\mathcal{O}(w_p)\rangle_{K,\ell,\beta}| \leq \mathsf{C}^{(p)} \prod_{a=1}^{p} \frac{y_T^{2\mathfrak{p}_0}\hat{d}^3|w_a|_\infty}{b} \leq \mathsf{C}'^{(p)} \prod_{a=1}^{p} \frac{y_T^{2\mathfrak{p}_0+3}|w_a|_\infty}{b}, \qquad y_T \leq \log\tfrac{b}{d} + \log\bigl(\tfrac{4}{3}L(M(2+\tfrac{p}{2}y_T)+1)\bigr),$$

with numbers $\mathsf{C}^{(p)}$, $\mathsf{C}'^{(p)}$ formed from the constants and p: no power of d, and for each entry the power $2\mathfrak{p}_0+3$ of the logarithm of b/d in the place of the power $8\mathfrak{p}_0$ of (E1).

(E5) *(Bounds independent of the side and of the state; $0 < g \leq \gamma_W^{\mathrm{sd}}$.)* (i) For $n \geq 2$, $d, R > 0$ there is a number $C_n^T(d;R)$, formed from the constants, g, n, d, R, such that in every periodic Gibbs state and on every torus of $\mathfrak{L}(g)$, for supports in balls of radius R pairwise at distance $\geq d$, at every cutoff: $|\langle \mathcal{T}_K(H_1);\dots;\mathcal{T}_K(H_n)\rangle| \leq 60^n C_n^T(d;R) b^{-n}\prod_a |H_a|_\infty$. With the numbers of Theorem C (a), each formed at its own order: for $K \geq \max_{2\leq m\leq n} K^G(m)$, $K^G(m)$ the cutoff of that clause at the order m, the cumulant in a periodic Gibbs state is at most $\sum_\pi (|\pi|-1)!\prod_{B\in\pi} C^G_{\#B}(d;R)\,b^{-n}\prod_a |H_a|_\infty$, the sum over the partitions π of $\{1,\dots,n\}$ without singletons; on a torus of $\mathfrak{L}(g)$ the same holds, by the chessboard estimate in the place of the domination, with the distances taken on the torus. (ii) Limits through arbitrary periodic Gibbs states, and along growing tori, exist along subsequences and obey these bounds; they are tensors over the scalar limit, invariant under $\mathbb{R}^3 \rtimes W_3$ and reflection positive; on every torus of $\mathfrak{L}(g)$ the full sequence of cutoffs converges, with bounds independent of the side. (iii) *(Folding.)* Let $n \geq 2$, $\ell' = 2\mathsf{l}$ the least side at g, $0 < d < 1$ with $1.74\,d \leq \mathsf{l}/(4n)$ and (N.θ) at $(8n, g, s(d))$.

For $r \geq 2$ let $\mathfrak{m}_r(g,s) = \sum_{\pi'}\prod_{I\in\pi'} k'_{\#I}(g,s)$, the sum over the partitions π' of a set of r members into blocks of at least two members, and

$$k_n^{\mathrm{fold}}(g,s) = \max_{\mathcal{C}} \sum_{\pi} (|\pi|-1)! \prod_{B\in\pi} \prod_{C\in\mathcal{C},\ B\cap C\neq\varnothing} e^{\mathsf{l}^3 G_g}\,\mathfrak{m}_{8\#(B\cap C)}(g,s)^{1/8},$$

the sum over the partitions π of $\{1,\dots,n\}$, the maximum over the partitions $\mathcal{C}$ of $\{1,\dots,n\}$. Then for every first-passage datum (K,β) at g with $s(d) \leq K$, in every periodic Gibbs state and on every torus of $\mathfrak{L}(g)$, and for all H_a with (Geo) at d,

$$|\langle \mathcal{T}_K(H_1);\dots;\mathcal{T}_K(H_n)\rangle| \leq 60^n k_n^{\mathrm{fold}}(g,s(d))\,b^{-n}\prod_a |H_a|_\infty, \qquad k_n^{\mathrm{fold}}(g,s(d)) \leq C'_n(g)\bigl[2\log\tfrac{1}{d} + C(g)\bigr]^{8n\mathfrak{p}_0},$$

$C'_n(g)$ a number formed from the constants, n and g: a power of the logarithm alone, free of the side and of the state. The cumulants of every tensor limit at g, formed from σ by the

recursion over the partitions, are at most $60^n k_n^{\mathrm{fold}}(g, s(d))\, b_*^{-n} \prod_a |H_a|_\infty$ at the tuples with (Geo) at d.

(E6) *(The free two-point law; $0 < g \le \gamma_W^{\mathrm{sd}}$.)* Put $K_3(u)_{\lambda\lambda'} = (3\hat u_\lambda \hat u_{\lambda'} - \delta_{\lambda\lambda'})/(4\pi|u|^3)$ and

$$\mathsf{W}(H_1, H_2) = \tfrac{3}{2} \iint \mathrm{tr}\big[H_1(x) K_3(x-y) H_2(y) K_3(x-y)\big]\, dx\, dy.$$

There are $d_0(g) > 0$ and a function $e_g(d)$, formed from the constants and g, with $e_g(d) \to 0$ as $d \to 0$ and $\sup_d (\log \frac{1}{d})^{\mathfrak{p}_0/4} e_g(d) < \infty$, such that for every tensor limit σ at g, all $0 < d_- < d < d_0(g)$, all x_0, y_0 with $3d \le |x_0 - y_0| \le 4d$ and all $H_1, H_2 \in C_c^1$ with supports in the balls of radius d_- about x_0, y_0, for all 21 pairs of components,

$$|\sigma(H_1, H_2) - b_*^{-2} \mathsf{W}(H_1, H_2)| \le e_g(d)\, b_*^{-2} |H_1|_\infty |H_2|_\infty;$$

the label b_* is determined by σ. The same holds on every torus of $\mathfrak{L}(g)$ at every label of the interval $(g^{-2} + \bar B, X_g - \bar B]$, for Lipschitz weights, and at a finite cutoff in every periodic Gibbs state with an explicit remainder. Consequently, for $0 < d < d_0(g)$, $x_0 = \frac{3}{2} d\, e_3$, every $\varphi \in C_c^1(\mathbb{R}^3)$ with $0 \le \varphi \le 1$, $\varphi = 1$ on $B(x_0, d/128)$ and $\varphi = 0$ off $B(x_0, d/64)$, and every $E \in V$,

$$\sigma(\theta(\varphi E), \varphi E) \ge (w_0 - e_g(d))\, b_*^{-2}\, \mathrm{tr}\, E^2, \qquad w_0 = \tfrac{1}{12} 388^{-6}:$$

the two supports lie in the balls of radius $d/64$ about the points $\pm x_0$, whose distance is $3d$; $\mathsf{W}(\theta(\varphi E), \varphi E) \ge w_0\, \mathrm{tr}\, E^2$, which reads $\varphi \ge 0$ and $\varphi = 1$ on $B(x_0, d/128)$; and the remainder is at most $e_g(d) b_*^{-2} |E|_\infty^2 \le e_g(d) b_*^{-2}\, \mathrm{tr}\, E^2$, which reads $\varphi \le 1$. At the d with $e_g(d) < w_0$, which exist since $e_g(d) \to 0$, $\|[(\varphi E)]\| > 0$ for $E \ne 0$, and no real combination of the six fields vanishes.

(E7) *(Extension over the diagonals; one torus.)* Let $0 < g \le \gamma_W^{\mathrm{ref}}$, $b \in (g^{-2} + \bar B, X_g - \bar B]$ and $\ell \in \mathfrak{L}(g)$, as in (E3) (ii); let S_n be the cumulant functional of n entries of the limit (E3) (ii), continued complex linearly to $V_{\mathbb{C}}$-valued entries; let $h_0 \in \ell 2^{-\mathbb{N}}$ with $h_0 \le \min\{\ell/(64n), \frac{1}{2} L^{-s_{\mathrm{th}}(n)}\}$, $s_{\mathrm{th}}(n)$ as in (E2), and $l(\lambda) = 1 + \log(h_0/\lambda)$; the norms, the λ-supported functions, the classes $\mathfrak{E}_n(\kappa)$ and the coordinates at a partition are those of Definition 2.4. Then S_n extends to a distribution $\tilde S_n$ on the whole configuration space T_ℓ^n, of order at most $3n - 2$, with

$$|\tilde S_n(F)| \le C b^{-n} l(\lambda)^{8n\mathfrak{p}_0 + 1} \|F\|_{(\lambda), 3n-2} \qquad \text{for all } 0 < \lambda \le h_0 \text{ and all } \lambda\text{-supported } F,$$

C formed from the constants, n, g and ℓ; so $\tilde S_n \in \mathfrak{E}_n(0)$, the class of the power counting of S_n. The subtracted lattice cumulants, the sums of Lemma 2.25 over the Whitney cubes Q with $s(1.52\, h(Q)) \le K$, $h(Q)$ the side of Q, obey this bound with one number for all the cutoffs K, at all λ with $8h_K \le \lambda \le h_0$, h_K the least side of these cubes, and converge to $\tilde S_n$. A distribution on T_ℓ^n lies in $\mathfrak{E}_n(0)$ and is carried by the diagonals if and only if it is a sum

$$\sum_{|\pi| \le n-1} \sum_{|\alpha| \le 3|\pi|} \partial_\xi^\alpha \delta_\pi \otimes T_{\pi,\alpha}, \qquad T_{\pi,\alpha} \in \mathfrak{E}_{|\pi|}(|\alpha|) \text{ on } T_\ell^{|\pi|},$$

over the partitions π of the points into at most $n - 1$ clusters and the multi-indices α of the coordinates ξ at π. So two extensions of S_n in $\mathfrak{E}_n(0)$ differ by such a sum, and an extension plus any such sum is again an extension of S_n in $\mathfrak{E}_n(0)$; a term with $|\alpha| > 3|\pi|$ and a coefficient in $\mathfrak{E}_{|\pi|}(|\alpha|)$ vanishes. For translation-invariant, real, symmetric two-point contact terms in $\mathfrak{E}_2(0)$, the invariant space has dimension six under O(3) on $\mathbb{R}^3$, and twelve under the cubic group on $\mathbb{R}^3$ or T_ℓ.

■□

2.3. **Construction estimates.**

Remark 2.6 (The input). (1) The real and sourced finite constructions, Theorems YMM1:D and YMM1:AJ, with the small-field and first-large-field estimates recalled below: on a torus that is small over the running couplings of a first-passage datum, the inductive description of the effective densities with sources under majorants, the step map and its domain, the term of the history without large-field regions, the weights w_t of the first creation of a large field at the step t, which on a small side obey $\mathsf{w}_t \le 2M^{-3}\ell^3 L^{3(K-t)} e^{-\frac{1}{2}c' p_0(g_t)^2}$, the working level of a distance d, at which $a_K \le d/C_W(s(d))$ for $s(d) \le K$, the depth being formed with the room constant $C_{W,0} = \max\{1, 4L^2M/A_0^2\}$, so that $C_W(s) \ge 4L^2 M Y_s^{2\mathfrak{p}_0}$, and the floor of B; on every side with (Sd.1) the same with $\mathsf{w}_t \le 2M^{-3}\ell^3 e^{\mathsf{B}(x_K)\ell^3} L^{3(K-t)} e^{-c' p_0(g_t)^2}$.

(2) Theorems YMM1:AJ and YMM1:AD, at the source 0 alone: the bounds $-C_g \le p_\ell - E_{K,\ell,\beta}\,\ell^{-3} \le C_{\mathrm{S}}$ with the normalising energy $E_{K,\ell,\beta}$, and the comparison of the normalising energies of two sides.

(3) The flow and the label, Proposition YMM1:74.1, its room estimate YMM1:(1533), and Lemma G.3 with the flow bound YMM1:(1530), $|x_j - L^{-(j-i)}x_i| \le \bar{B}\,(1 - L^{-(j-i)})$ for $0 \le i \le j \le K$, and with YMM1:(1531), YMM1:(1532) and Lemma G.3, G.2; the stopped sequence, Corollary YMM1:74.3 and Lemma G.3; the first-passage windows $\mathcal{W}_K(g)$ and the interval $I(g) = (g^{-2} + \bar{B}, X_g - \bar{B}]$ of Corollary YMM1:74.2, with $L^K \cdot I(g) \subset \mathcal{W}_K(g)$; and the estimate (291): for $0 \le t \le k \le K$,

$$p_0(g_t)^2 - p_0(g_k)^2 \ge 2\mathfrak{p}_0 A_0^2\, y_k^{2\mathfrak{p}_0 - 1}(k-t)\log\tfrac{L}{2}.$$

(4) The exact dilation of the lattice model (Propositions YMM1:119.1, K.1); the chessboard estimate and the seminorm as the mean of the mirror copies over a period box (Corollary B.1, equation (189)); the domination of the periodic Gibbs states (Proposition YMM1:91.9); their invariance under the lattice isometries, their reflection positivity at the nine families of lattice mirrors, the five-point inequality and the clustering at the rate $ra/|x|_\infty$ on one lattice (Propositions YMM1:103.4 and YMM1:99.7, and Lemma F.5, Proposition YMM1:99.7); the multiple reflections (Proposition YMM1:104.2); for the action density, the comparison of two consecutive cutoffs on one torus, the convergence of the laws of the block fields and the convergence along the full sequence of cutoffs (Theorem YMM1:AR, Corollaries B.30, YMM1:117.1, Corollary YMM1:118.4), with the comparison of the background actions at two consecutive cutoffs and the loss of memory of the flows (Proposition YMM1:113.9, Propositions YMM1:114.2, YMM1:114.3); the conditional expectations given the invariant σ-field (Proposition YMM1:100.1) and the clustering uniformly in the cutoff (Proposition YMM1:100.1); for the scalar limits, the canonical decomposition and its uniqueness (Theorem YMM1:AL, Proposition YMM1:101.1); the limit of a convergent Gibbs sequence at g (Definition 15.4(2)), which is invariant under all the isometries of $\mathbb{R}^3$ and is scalar data (Rec) with the numbers $16\,C_{\mathrm{pt}}^g, 4, \frac{1}{2}$ (Theorem YMM1:AP, Section YMM1:107), the scalar part of a tensor limit on C_c^1 entries being such a limit; for scalar data (Rec), the kernels, the one holomorphic function on the union of the tubes, the Lorentz covariance, the locality and the reconstruction of the Wightman field (Propositions YMM1:108.3, YMM1:110.1, YMM1:110.2, Theorem YMM1:AO); two mirrors at the angle $\frac{\pi}{4}$ (Proposition YMM1:94.4); the kernel theorem on the non-coinciding configurations (Proposition YMM1:93.1); the extension of multilinear forms on separated test functions (Proposition YMM1:93.3) and the growth hypothesis in Proposition YMM1:93.5; the threshold x_{J} of the couplings (the definitions preceding (228)).

(5) For the stress identity, in the setting (Th) of Section B.13 with the top level $t = K - \lceil \phi K \rceil$ (Lemma YMM1:118.1) and the small-field chain of Proposition YMM1:115.2: the chain with one insertion and with several insertions of disjoint carriers; the conditional means

at the level t, and the cut of the configurations at a level by the field cuts (the definitions preceding Lemma YMM1:113.10, Lemma YMM1:113.10); the bound of the cumulants of insertions whose carriers are at sup distance $d_\times = \min\{d, 2\delta\} - 8a_K$, d the separation and δ the margin of Proposition 2.21 (c), so that $d_\times L^{K-i} \geq \frac{1}{2}K^2$ at the levels $i \leq t$ once $dL^{K-t} \geq K^2$ and $2\delta L^{\phi K} \geq K^2$, through the polymers that hold boxes of two insertions ((320) and (321)), with a second member for the configurations with large fields; and the bound of the conditional mean of the cubic remainder, with its five inputs: the linearisation of a step (Proposition E.7), the size of an insertion at the background of a level, the parity of the births in the fluctuation field, the Hölder continuity of the backgrounds in local gauges (Theorem BT), and the comparison of a regular configuration with its mirror image under the inversion in a site (with Proposition H.1).

These are stated in this section, each with the idea of its proof: the bound of the cubic remainder and its five inputs in Proposition 2.21 (b) and its sketch, the chains and the bound of the cumulants of insertions with distant carriers in the sketch of Proposition 2.21 (b), (c).

Of the volume, only the pressure gap of one unit cell at the source 0 and the lower limit over the sides in the domination enter: no limit in the side is taken, and no clustering of a limit, no gap and no uniqueness of a state is used.

2.4. **Auxiliary estimates.**

Lemma 2.7 (The pressure gap; transfer between sides)**.** Let $0 < g' \leq \gamma$, let (K, β) be a first-passage datum at g', and let $\ell_1 \leq \ell_2$ lie in $\mathfrak{L}(g')$. Then $0 \leq p_{\ell_1} - p_{\ell_2} \leq G_{g'}$. For a board of $\mathbb{L}_K$ of side l with $\ell_2 \geq \ell_1 \geq 2\mathsf{l}$ and every bounded function F of the bonds inside one cell, $\|F\|_{\mathrm{ch},\ell_2} \leq e^{\mathsf{l}^3 G_{g'}} \|F\|_{\mathrm{ch},\ell_1}$; for every $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, finitely many different cells and functions Φ_k of their bonds, $|\nu(\prod_k \Phi_k)| \leq \prod_k e^{\mathsf{l}^3 G_{g'}} \|\Phi_k\|_{\mathrm{ch},\ell_1}$. Finally, at the stopped coupling, $G_{g_{(i)}} - G_g = C_{g_{(i)}} - C_g \leq \frac{9}{2} i \log L + \frac{1}{8}$ for $1 \leq i \leq K-1$. ∎

Proof sketch. Theorems YMM1:AJ and YMM1:AD, at the source 0, give $-C_{g'} \leq p_\ell - E_{K,\ell,\beta}\, \ell^{-3} \leq C_{\mathrm{S}}$ at both sides $\ell = \ell_1, \ell_2$, uniformly in the cutoff, $E_{K,\ell,\beta}$ its normalising energy, and $|E_{K,\ell_1,\beta}\, \ell_1^{-3} - E_{K,\ell_2,\beta}\, \ell_2^{-3}| \leq 2C_{\mathrm{tt}} C'_{\mathrm{tt}} E_0$; together these give $p_{\ell_1} - p_{\ell_2} \leq C_{\mathrm{S}} + C_{g'} + 2C_{\mathrm{tt}} C'_{\mathrm{tt}} E_0 = G_{g'}$, and the chessboard estimate on the larger torus, applied to the constant function (Corollary B.1 (e)), gives $p_{\ell_1} \geq p_{\ell_2}$. The chessboard estimate converts the gap into the transfer of seminorms, and the domination of the periodic Gibbs states, with the lower limit taken along the sides of $\mathfrak{L}(g')$, into the bound in the states. Since C_{S}, C_{tt}, C'_{tt}, E_0 depend on no coupling, $G_{g_{(i)}} - G_g = C_{g_{(i)}} - C_g$, which (2) bounds. □

Lemma 2.8 (Change of the length scale)**.** Let $0 < g \leq \gamma^{\mathrm{sd}}_W$, (K, β) a first-passage datum at g, $1 \leq i \leq K-1$, $k = K - i$, $\ell \in \mathfrak{L}(g)$, $0 < \delta \leq \frac{1}{4}$.

(a) The map $x \mapsto L^i x$ carries $\mathbb{L}_K$ onto $\mathbb{L}_k$ and $\Lambda_{K,\ell}$ onto $\Lambda_{k,L^i\ell}$, bonds onto bonds and plaquettes onto plaquettes, the measure at (K, β) onto the measure at (k, β), and the board (i, o) onto the board $(0, L^i o)$ of side 1, with its cells and mirror maps; with $H' = L^i H(L^{-i}\cdot)$, $\mathcal{T}_K(H)$ goes over into $\mathcal{T}_k(H')$, so that $\|\mathcal{T}_K(H) - c\|^{(i,o)}_{\mathrm{ch},\ell}$ at (K, β) equals $\|\mathcal{T}_k(H') - c\|^{(0,L^i o)}_{\mathrm{ch},L^i\ell}$ at (k, β), and $|H'|_\infty / (L^i b) = |H|_\infty / b$.

(b) (k, β) is a first-passage datum at $g_{(i)} < g$ with label $L^i b$; $X_{g_{(i)}} = x_k$; $L^i \ell \in \mathfrak{L}(g_{(i)})$; and $L^{i-1}(g^{-2} - \bar{B}) - B_\sharp \leq g^{-2}_{(i)} \leq L^{i-1}(X_g + \bar{B}) - B_\sharp$.

(c) Let ℓ'' be the least side at $g_{(i)}$, $N = \ell''^3$, and $s = s(\delta)$ formed at $g_{(i)}$. Then $8 \leq N \leq (c' A_0^2/9)\, y_k^{2\mathfrak{p}_0 - 1} \leq (c' A_0^2/9)\, \mathsf{Y}_i^{2\mathfrak{p}_0 - 1}$, $\log g^{-2}_{(i)} \leq Y_s \leq \mathsf{Y}_i$, $L^s < L c_W \mathsf{Y}_i^{2\mathfrak{p}_0}/\delta$, $\bar{x}_s \leq L^2 c_W \delta^{-1} \mathsf{Y}_i^{2\mathfrak{p}_0} (X_g + \bar{B}) L^i$, and $s \leq s_E(i)$, the depth $s(\delta)$ formed at the coupling whose inverse square is $L^{i-1}(X_g + \bar{B}) - B_\sharp$.

(d) There is a number $\mathsf{x}_E(\delta)$, formed from the constants and δ alone, which may be taken equal to x^*/δ with x^* formed from the constants alone, such that the thresholds (T1) at $n = N$ and (T2) of Proposition 2.9 hold at $g' = g_{(i)}$, $K' = k$, ℓ'', $d = \delta$ as soon as $g_{(i)}^{-2} \geq \mathsf{x}_E(\delta)$; so for $i \geq i_E(g, \delta)$, the least $i \geq 1$ with $L^{i-1}(g^{-2} - \bar{B}) - B_\sharp \geq \mathsf{x}_E(\delta)$; and $L^{i_E} \leq c_i \delta^{-1}$ with $c_i = \max\{L,\, L^2(\mathsf{x}^* + B_\sharp)/(g^{-2} - \bar{B})\}$, a number formed from the constants and g.

■

Proof sketch. (a) is the exact dilation of the lattice model, Lemma K.1, a relabelling; since $a_K^{-1} = L^i a_k^{-1}$, the factor a_K^{-1} in Definition 2.1 turns H into $L^i H(L^{-i}\cdot)$. (b) is Corollary YMM1:74.3 and Lemma G.3, with the flow bound $|x_K - L^{-i}x_k| \leq \bar{B}(1 - L^{-i}) \leq \bar{B}$ of Proposition YMM1:74.1, YMM1:(1530). (c) Since $g_{(i)} \leq \gamma_W^{\mathrm{sd}}$, the least side ℓ'' is small over the running couplings of (k, β); (Sd.4) with the floor of B gives $\frac{9}{2} y_k N \leq \mathsf{B}(x_k)\ell''^3 \leq \frac{1}{2} c' A_0^2 y_k^{2\mathfrak{p}_0}$: the number of cells of the least torus is a power of a logarithm, not of the order a_i^{-3}. The depth satisfies $L^s\delta < LC_W(s) = Lc_W Y_s^{2\mathfrak{p}_0}$, so $\bar{x}_s = L^{s+1}(g_{(i)}^{-2} + \bar{B}) < L^2 c_W \delta^{-1} Y_s^{2\mathfrak{p}_0}(g_{(i)}^{-2} + \bar{B})$, and $2\mathfrak{p}_0 \log Y \leq \frac{1}{2}Y + 2\mathfrak{p}_0 \log(4\mathfrak{p}_0)$ gives $Y_s \leq \mathsf{Y}_i$ with (b). (d) By (c), N grows like the power $2\mathfrak{p}_0 - 1$ of Y_s while (T1) asks $2Y_s^{2\mathfrak{p}_0} \geq u_*(N)$, a quantity of the order $N \log N$; the quotient of the two sides tends to infinity with $Y_s \geq \log g_{(i)}^{-2}$. (T2) holds because L^{3s} is a power of a logarithm of $g_{(i)}^{-2}$, hence $\leq g_{(i)}^{-40} < x_k^{20}$ from a number on.

The threshold can be taken proportional to δ^{-1}, and then $L^{i_E} \leq c_i \delta^{-1}$ by (b). In numbers: put $x = g_{(i)}^{-2}$ and $Y = \log x$; then $x_k = L(x + B_\sharp) > x$, and $y_k \leq Y + \log 2L$ as soon as $x \geq B_\sharp$. Let $\mathsf{Y}^* \geq 1$ be the least number such that $2Y'^{2\mathfrak{p}_0} \geq u_*\big((c' A_0^2/9)(Y' + \log 2L)^{2\mathfrak{p}_0 - 1}\big)$ for all $Y' \geq \mathsf{Y}^*$, u_* being read at real arguments by its formula (the right member is of the order $Y'^{2\mathfrak{p}_0 - 1} \log Y'$), and put

$$\mathsf{c}_5 = \tfrac{74}{11}\, L^7 c_W^4\, (12\mathfrak{p}_0)^{6\mathfrak{p}_0} (4\mathfrak{p}_0)^{2\mathfrak{p}_0}, \qquad \mathsf{x}^* = \max\{1,\, B_\sharp,\, e^{\mathsf{Y}^*},\, L^2 3^{\mathfrak{p}_0},\, \mathsf{c}_5\},$$

numbers formed from the constants alone. Let $x \geq \mathsf{x}^*/\delta$. (T1) at $n = N$: by (c), $N \leq (c' A_0^2/9)(Y + \log 2L)^{2\mathfrak{p}_0 - 1}$ and $Y \leq Y_s$; as $t \mapsto t[c_1 + \log(c^* t)]$ increases on $[1, \infty)$, u_* does not decrease there, and $Y \geq \mathsf{Y}^*$ gives $u_*(N) \leq 2Y^{2\mathfrak{p}_0} \leq 2Y_s^{2\mathfrak{p}_0}$. (T2): $y_k > \log x \geq 2 \log L + \mathfrak{p}_0 \log 3$. By (c), $L^{3s} < (Lc_W/\delta)^3 \mathsf{Y}_i^{6\mathfrak{p}_0}$; the inequality $t^q \leq (2q)^q e^{t/2}$ $(t, q > 0)$ gives $\mathsf{Y}_i^{6\mathfrak{p}_0} \leq (12\mathfrak{p}_0)^{6\mathfrak{p}_0} e^{\mathsf{Y}_i/2} = (12\mathfrak{p}_0)^{6\mathfrak{p}_0} c_0 \delta^{-1} L^i$ with $c_0 = L^2 c_W (4\mathfrak{p}_0)^{2\mathfrak{p}_0}(X_g + \bar{B})$; by (b), $L^i \leq L(x + B_\sharp)/(g^{-2} - \bar{B}) \leq 2Lx/(g^{-2} - \bar{B})$; and $(X_g + \bar{B})/(g^{-2} - \bar{B}) = L(g^{-2} + \bar{B})/(g^{-2} - \bar{B}) \leq \frac{37}{11} L$, because $\bar{B} \leq \frac{13}{24} g^{-2}$ for $g \leq \gamma$ (Lemma G.3).

Together $L^{3s} < \mathsf{c}_5 \delta^{-4} x \leq x^{20} < x_k^{20}$, since $x^{19} \geq \max\{1, \mathsf{c}_5\}^{19} \delta^{-19} \geq \mathsf{c}_5 \delta^{-4}$. So $\mathsf{x}_E(\delta) = \mathsf{x}^*/\delta$: the reference coupling enters the threshold through the quotient $(X_g + \bar{B})/(g^{-2} - \bar{B})$ alone, and its bound $\frac{37}{11} L$ is independent of the coupling. By (b), $g_{(i)}^{-2} \geq L^{i-1}(g^{-2} - \bar{B}) - B_\sharp$, which increases with i; if $i_E \geq 2$, then $L^{i_E - 2}(g^{-2} - \bar{B}) - B_\sharp < \mathsf{x}^*/\delta$, whence $L^{i_E} < L^2(\mathsf{x}^* + B_\sharp)\delta^{-1}/(g^{-2} - \bar{B}) \leq c_i \delta^{-1}$; if $i_E = 1$, then $L \leq c_i \leq c_i \delta^{-1}$. □

Proposition 2.9 (As many sources as a small side has unit cubes)**.** There are numbers $A_\kappa > 0$, $A_\flat \in (0, 1]$, $c^* \geq 4$, c_2, C^I, C_2, C_1, formed from the constants alone, with $c_2 \geq c_1 := \log[(4/3)^{1/2} L^{1/2} 2^{\mathfrak{p}_0}]$; put

$$u_*(n) = \max\{4,\ (2/A_\kappa)(n[c_1 + \log(c^* n)] + \log 3)\}, \qquad u'_*(n) = \max\{4,\ (2/A_\flat)(n[c_2 + \log(4n)] + 3\log L + \log 3)\},$$

$$\mathsf{A}_n(s) = 2^{2\mathfrak{p}_0 + 1} n \max\{C^I, C_2 n^{3+\mathfrak{p}_0}\} (LC_W(s))^3\, \bar{x}_s\, Y_s^{2\mathfrak{p}_0}.$$

Let $0 < g' \leq \gamma_W^{\mathrm{ref}}$, (K', β) a first-passage datum at g' and ℓ a side small over its running couplings. A *source under the majorant* (s, S) is carried by the description of Theorem YMM1:D as a triple: a continuous gauge-invariant function F of the bonds with $|F| \leq a_{K'}^{-1} \sum_{p \in S} \mathsf{s}\, a_p$; a family of effective terms of the level 0; and families of the levels $1, \ldots, k$ up to the level k of the chain; each family sums to F up to a constant, vanishes on the polymers that miss S, and is bounded by the size that

the weight $\mathsf{s1}_S$ has at its level. F is the *first member* of the source; it is the function that is itself called the source when the triple is understood. A *source system* is a finite family of sources under majorants, entered with independent complex parameters. In (a) let $0 < d < 1$ with $s = s(d) \le K'$ (formed at g'), $k = \max\{K' - s, 2\}$, $\upsilon = 1/(a_{K'-k} x_k)$, so that $\upsilon^2 \le \frac{9}{8}(a_{K'}\beta)^{-2}$, and $\hat d = d/a_{K'-k}$, the distance d in the units of the level k; since $K' - k \in \{s-2, s-1, s\}$ and $C_W(s) \ge 4L^2 M Y_s^{2\mathfrak{p}_0}$, the definition of the depth gives $4MY_s^{2\mathfrak{p}_0} \le L^{-2} C_W(s) \le \hat d < L C_W(s)$.

(a) Let $2 \le n \le \ell^3$ and let $F_1, \dots, F_n$ be the first members of a source system under majorants (s_a, S_a) such that every plaquette of S_a has its barycentre within $\frac{7}{8}d$ of a point x_a and barycentres of plaquettes of different S_a are at distance $\ge \frac{5}{4}d$. Suppose

$$\text{(T1)}\quad 2Y_s^{2\mathfrak{p}_0} \ge u_*(n); \qquad \text{(T2)}\quad y_{K'} \ge 2\log L + \mathfrak{p}_0 \log 3 \ \text{ and } \ L^{3s} \le x_{K'}^{20}.$$

Then there are complex numbers c_a, the first-order terms of the sources at the trivial background summed up to the level k, such that for every non-empty $B \subset \{1, \dots, n\}$

$$\Big| \Big\langle \prod_{a \in B} (F_a - c_a) \Big\rangle_{K', \ell, \beta} \Big| \le \prod_{a \in B} \mathsf{A}_n(s)\, \upsilon\, \mathsf{s}_a .$$

(b) Let instead s be any integer with $2 \le k := K' - s \le K' - 1$, no distance being given, and $1 \le n \le \ell^3$; let the plaquettes of each S_a lie in the interior of a cell of its own of a board of side 1 of the torus, and, if $n \ge 2$, let the least sup distance between a corner of a plaquette of one S_a and a corner of a plaquette of another, in the units of the level k, be at least $M u'_*(n)$. Then, with the numbers c_a of (a) formed at this level k, for every non-empty $B \subset \{1, \dots, n\}$ with $r = \#B$ members

$$\Big| \Big\langle \prod_{a \in B} (F_a - c_a) \Big\rangle_{K', \ell, \beta} \Big| \le \prod_{a \in B} 2r\, C_1 L^{4s}\, \mathsf{s}_a \le \prod_{a \in B} 2n\, C_1 L^{4s}\, \mathsf{s}_a .$$

■

Proof sketch. Put $\sum_a \lambda_a F_a$ into the exponent. The normalized source sizes and mixed-derivative estimates used below are detailed in the proof of Lemma 5.6; the moment argument for (a) is given in Lemma D.6. By Theorem YMM1:D the effective actions $E_\lambda^{(j)}$ of the levels $j \le k$ are holomorphic in λ on a polydisc whose radii are governed by sizes $\hat g_{j,a}$, which grow by at most $L^{1/2}$ per step on the small fields. For $I \subset \{1, \dots, n\}$ with $r = \#I \ge 2$, the mixed derivative $\partial_I E_\lambda^{(j)}|_0$ vanishes on every polymer that misses some S_a, $a \in I$, and so carries the factor $e^{-A_\kappa [\mathsf{D}_j/M - 2]_+}$, D_j the least sup distance between a corner of a plaquette of one support and a corner of a plaquette of another, in the units of the level j; by the geometry of the majorants and the working level, $\mathsf{D}_k \ge (5/(4\sqrt{3}))\hat d - 1$ with $\hat d \ge 4MY_s^{2\mathfrak{p}_0}$, so that $u := \mathsf{D}_k/M \ge (5/\sqrt{3}) Y_s^{2\mathfrak{p}_0} - 1 \ge 2Y_s^{2\mathfrak{p}_0}$ ($Y_s \ge 7$), and (T1) gives $\mathsf{D}_j/M = L^{k-j} u \ge u_*(n)$ at all levels $j \le k$. An induction on r, and for each r on j, with the chain rule of all orders for the step map and Cauchy's estimate at the radius $1/(4r\hat g_{j,a})$, gives

$$\big\| \partial_I E_\lambda^{(j)}|_0 \big\| \le c_\theta\, (c^* r)^r \prod_{a \in I} \hat g_{j-1,a},$$

with a number c_θ formed from the constants alone, the same at every level j, for every n and every source system; the induction closes because $u \ge u_*(n)$ makes the series of the polymer sums times $(c^* m)^m$ at most 1 for $m \le n$, and because on the polydisc the perturbation of the arguments is at most 0.27 times the radius of the domain of the step map, so that they stay in it. The centred moment is a sum over the partitions of B of products of these derivatives on the history without large-field regions, plus the sum over the step t of the first creation of a large field with the weight w_t, in which every insertion loses at most L^4 per scale. On a small side this loss is paid: by (291),

(Sd.4) and the floor of B,

$$\tfrac12 c' p_0(g_t)^2 \ge \ell^3\Big[\tfrac92 y_{K'} + 2 + 9\mathfrak{p}_0(K'-t)\log\tfrac{L}{2}\Big],$$

and since $r \le n \le \ell^3$ and $9\log\frac{L}{2} > 4\log L$, the sum over t of $L^{4r(K'-t)}\mathsf{w}_t$ is at most $L^{3s}x_{K'}^{-20} \le 1$ by (T2). In (a) the number n enters at five places: through $u_*(n)$; through the number of partitions, $\mathrm{Bl}(r) \le r^r \le n^r$; through $r \le \ell^3$; through the domain in $\mathbb{C}^n$, of which only the derivatives at 0 are used; and through the sizes of the mixed derivatives of order $r \le n$, summed over the polymers and the levels, whose r-th root is at most $C_2 r^{3+\mathfrak{p}_0}$: the factor $(c^* r)^r$ of the Cauchy estimate gives one power of r, and the sum over the lag q between the level of a polymer and the level of the moment, $\sum_{q\ge0} L^{(3+r/2)q}(q+1)^{r\mathfrak{p}_0}e^{-3(L^q-1)} \le 5\,(r(2+\mathfrak{p}_0))^{r(2+\mathfrak{p}_0)}$, gives $r^{2+\mathfrak{p}_0}$.

With $\mathrm{Bl}(r) \le n^r$ these give the factor $n\max\{C^I, C_2 n^{3+\mathfrak{p}_0}\}$ of $\mathsf{A}_n(s)$, C^I bounding the sizes of the first order. In (b) the level $k = K' - s$ is given, and the threshold $u'_*(n)$ of the distance in its units takes the place of (T1): the polymer sums of the levels below k now carry the factor $L^{3n'}$ of the number of the cubes of the lag n', whence the term $3\log L$ and the exponent $A_\flat$. The sizes are taken crudely, $C_1 L^{4(K'-t)}\mathsf{s}_a$ for a source at the level t, and the exponential smallness of a polymer that joins two cells absorbs the factor $(4m)^m$ of the mixed derivatives of order m, so that in (b) the number n enters at the first four places alone.

The same sum over t then gives $|\langle\prod_B(F_a - c_a)\rangle| \le \mathrm{Bl}(r)\, C_1^r \prod_B \mathsf{s}_a\,[L^{4sr} + \sum_t L^{4(K'-t+1)r}\mathsf{w}_t]$, the bracket is at most $2L^{4sr}$, and $\mathrm{Bl}(r) \le r^r$. □

Proposition 2.10 (n sources with the sharper number)**.** Let $n \ge 2$ and $0 < g \le \gamma_W^{\mathrm{ref}}$. For $u > 0$ and $r \ge 1$ the numbers $T_r(u)$ are those of the paragraph *Sources* of the setting,

$$T_r(u) = \sum_{n'\ge1}(n'+1)L^{-(n'-1)}\big[(4/3)^{1/2}L^{n'/2}(1+n')^{\mathfrak{p}_0}\big]^r\, e^{-A_\kappa[L^{n'-1}u-2]_+},$$

with the number A_κ of Proposition 2.9, which is the number $4\beta_{\mathsf{s}}\kappa$ in the exponent of the function T of the definitions preceding (228). The series converges, the quotient of two consecutive terms tending to 0; $T_r(u)$ does not increase in u and does not decrease in r, the bracket being ≥ 1; and $T_2 = \frac43 L\,\mathsf{T}$. The condition (N.$\theta$) at (n,g,s) is $2T_n(3)\,\theta(L^{s-2}g^{-2}) \le 1$, $\theta(\cdot)$ the function of the definitions preceding (228); if it holds at (n,g,s), it holds at (n',g,s) for $2 \le n' \le n$. There is a function $s \mapsto k'_n(g,s) \in (0,\infty)$, formed from the constants, n, g and s alone, such that:

(a) for every first-passage datum (K,β) at g, $b = a_K\beta$, every side ℓ small over its running couplings, every $0 < d < 1$ with $s = s(d) \le K$ and (N.θ) at (n,g,s), all majorants (s_a, S_a) with the geometry of Proposition 2.9 (a), and every source system under them, real or not, with the first members $F_1,\dots,F_n$,

$$|\langle F_1;\dots;F_n\rangle_{K,\ell,\beta}| \le k'_n(g,s(d))\, b^{-n}\prod_a \mathsf{s}_a;$$

(a′) the same holds on every side $\ell = 2L^m$ with (Sd.1), $MR(x_K) \le L^m$, in particular on every $\ell \in \mathfrak{L}(g)$, with a number $k'^{,\ell}_n \le \max\{1,\mathsf{c}(\ell)\}^n k'_n$ in the place of k'_n;

(b) as $s \to \infty$, at fixed n and g, the leading size per entry is $162B_3^2A_0^2Y_s^{2\mathfrak{p}_0}(LC_W(s))^3$, B_3 a constant; there are numbers $C_n(g)$, $C(g)$ with $k'_n(g,s) \le C_n(g)Y_s^{8n\mathfrak{p}_0}$ for $s \ge 3$ and $Y_{s(d)} \le 2\log\frac1d + C(g)$; and uniformly in the coupling, at every depth $s = s(d)$ of a distance $0 < d < 1$: $k'_n(g,s(d)) \le C_n Y_{s(d)}^{8n\mathfrak{p}_0}$ with a number C_n formed from the constants and n alone, and $Y_{s(d)} \le 2\log(g^{-2}/d) + c$, c a constant;

(c) (N.θ) holds at (n,g,s) from a depth on, and at $n = 2$ for every $s \ge 3$.

■

Proof sketch. Let $k = \max\{K-s,2\}$, $y = y_k$, $\upsilon = 1/(a_{K-k}x_k)$ and $\hat d = d/a_{K-k}$ be formed as in Proposition 2.9, and $u = \mathsf{D}_k/M$, D_k the least sup distance of the supports in the units of the level

k as there. The proof has two layers. In the first, as in Proposition 2.9, the centred moments satisfy $|\langle\prod_B(F_a-c_a)\rangle| \le \mathrm{Bl}(r)[\mathsf{A}^r+\sum_{t\le k}\mathsf{bb}^r_{k-t+1}\mathsf{w}_t]\prod_{a\in B}\hat m_a$, with $\hat m_a=\upsilon\mathsf{s}_a$, $\mathrm{Bl}(r)$ the number of partitions, A the size on the history without large-field regions and $\mathsf{bb}_{n'}=\mathsf{c}_\mathsf{B}(n)\,\hat d^3 x_k y^{2\mathfrak{p}_0}L^{4n'}(n'+2)^{2\mathfrak{p}_0}$, $\mathsf{c}_\mathsf{B}(n)$ a number formed from the constants and n; here (N.θ) replaces (T1) in the induction for the mixed derivatives: at a level $j\le k$ the step carries the number $\theta(x_j)$ (the definitions preceding (228)), and $\theta(x_j)\le\theta(L^{s-2}g^{-2})$, since $x_j>L^{s-2}g^{-2}\ge g^{-2}\ge \mathsf{x}_W\ge x_\mathrm{J}\ge e^{2\mathfrak{p}_0}$ and θ does not increase on $[e^{2\mathfrak{p}_0},\infty)$, while $\mathsf{D}_j/M=L^{k-j}u\ge 3$; so (N.$\theta$) gives $\theta(x_j)\,T_m(\mathsf{D}_j/M)\le\frac12$ for $2\le m\le n$, and the series T_m of the polymer sums enter the induction exactly through this product.

At the level k the first-order size of one entry is $162B_3^2A_0^2y^{2\mathfrak{p}_0}\hat d^3$: of the exponent $8\mathfrak{p}_0$ per entry, $2\mathfrak{p}_0$ is the supremum of x_ka_p on the small fields and $6\mathfrak{p}_0$ comes from the number $\hat d^3<(LC_W(s))^3$ of unit cubes of the working level in a ball of radius d; the higher orders are smaller by $e^{-(u-2)}$, $u-2\ge(5/\sqrt3)Y_s^{2\mathfrak{p}_0}-3$. In the second layer the weights are bounded, $\mathsf{w}_t\le\mathsf{L}_0L^{3(K-t)}e^{-c''A_0^2y_t^{2\mathfrak{p}_0}}$, with $\mathsf{L}_0=M^{-3}c'A_0^2Y_s^{2\mathfrak{p}_0}$, $c''=\frac12c'$ on a small side and $\mathsf{L}_0=2M^{-3}\ell^3e^{\mathsf{B}(x_K)\ell^3}$, $c''=c'$ on a side with (Sd.1): this is the only place where the side enters.

Since $y_{k-a}\ge y+a\log\frac{3L}{4}$, and $\hat d<LC_W(s)$, $x_k\le\bar x_s$, $y\le Y_s$, the sum over the step of the first creation is at most

$$\mathsf{BB}^r\,\mathsf{L}_0\,L^{3s}\,S''_r\,e^{-c''A_0^2(Y_s-\log 2L^3)^{2\mathfrak{p}_0}},\qquad \mathsf{BB}=\mathsf{c}_\mathsf{B}(n)\,(LC_W(s))^3\,\bar x_s\,Y_s^{2\mathfrak{p}_0},$$

with $S''_r=\sum_{a\ge0}L^{3a+4r(a+1)}(a+3)^{2r\mathfrak{p}_0}e^{-\frac12c'A_0^2(a\log\frac{3L}{4})^2}$, a number formed from the constants and r. As $\bar x_s=e^{Y_s}$ and $L^{3s}\le e^{3Y_s}$, this is L_0 times a polynomial in Y_s times $e^{(r+3)Y_s-c''A_0^2(Y_s-\log 2L^3)^{2\mathfrak{p}_0}}$, which tends to 0 as $s\to\infty$ because $2\mathfrak{p}_0\ge2$; the factor L_0 is a power of Y_s on a small side, and on a side with (Sd.1) it reads the side and not s. Cumulants are obtained from the moments by the recursion over partitions, $\langle F_1;\dots;F_n\rangle=\langle\prod_a(F_a-c_a)\rangle-\sum_{\#\pi\ge2}\prod_{\gamma\in\pi}\langle\cdot\rangle^{\mathrm{cum}}_\gamma$, and $\prod_a\hat m_a\le(9/8)^{n/2}b^{-n}\prod_a\mathsf{s}_a$.

For (b), $Y_s<\log\frac1d+2\log L+\log c_W+\log(g^{-2}+\bar B)+2\mathfrak{p}_0\log Y_s$ at $s=s(d)$ by the definition of the depth, and $2\mathfrak{p}_0\log Y\le\frac12Y+2\mathfrak{p}_0\log(4\mathfrak{p}_0)$ gives $Y_{s(d)}\le2\log\frac1d+C(g)$; with $\log(g^{-2}+\bar B)\le\log g^{-2}+\log\frac{37}{24}$ (Lemma G.3) it gives $Y_{s(d)}\le2\log(g^{-2}/d)+c$. The bound uniform in the coupling holds at the depths of distances: at $s=s(d)$, $0<d<1$, one has $L^s\ge C_W(s)/d>C_W(s)\ge4L^2MY_s^{2\mathfrak{p}_0}$, so that $L^{s-1}/2\ge2LMY_s^{2\mathfrak{p}_0}$; besides, $gL^{-(s-2)/2}\le c\,e^{-Y_s/2}$, $L^{3s}\le e^{3Y_s}$ and $\bar x_s=e^{Y_s}$, c a constant. Besides through Y_s, the number $k'_n(g,s)$ reads the coupling only through the correction to the first-order size of one entry, which carries $gL^{-(s-2)/2}$ and $e^{-\mathsf{ds}(g,s)}$ with the number $\mathsf{ds}(g,s)=\min\{c_\mathrm{d}L^{(s-2)/2}/(A_0\,g\,Y_s^{\mathfrak{p}_0}),\ L^{s-1}/2-2\}-1$, c_d a constant.

This number bounds from below the quantity $\min\{c_\mathrm{d}\,\varepsilon_k^{-1},\ (\ell/(2a_{K-k})-4)/(2M)\}-1$ of the datum and the side that stands in its place in the size at the level k, $\varepsilon_k=A_0y^{\mathfrak{p}_0}x_k^{-1/2}$ being the size of the field there and ℓ/a_{K-k} the side of the torus in the units of that level: $\varepsilon_k\le A_0Y_s^{\mathfrak{p}_0}gL^{-(s-2)/2}$, as $y\le Y_s$ and $x_k>L^{s-2}g^{-2}$, and $\ell/(2a_{K-k})\ge LM\,L^{s-2}$, as $K-k\ge s-2$ and $\ell=2L^m\ge2LM$. So the size at the level k is at most the expression formed with $\mathsf{ds}(g,s)$ in the place of that quantity. At $s=s(d)$, by $L^{s-1}/2\ge2LMY_s^{2\mathfrak{p}_0}$ and $gL^{-(s-2)/2}\le c\,e^{-Y_s/2}$, one has $\mathsf{ds}(g,s)\ge\min\{(c_\mathrm{d}/(cA_0))\,e^{Y_s/2}Y_s^{-\mathfrak{p}_0},\,2LMY_s^{2\mathfrak{p}_0}-2\}-1$.

So at $s=s(d)$ every quantity of which $k'_n(g,s)$ is formed is bounded by a function of Y_s alone, which is of the order $Y_s^{8n\mathfrak{p}_0}$ for $Y_s\ge7$, and C_n is independent of the coupling. For (c), $\theta(t)$ is a constant times $t^{-1/2}(\log t)^{\mathfrak{p}_0}$, which decreases to 0; at $n=2$, $T_2(3)=\frac43L\,\mathsf{T}(3)$ with the function T of the definitions preceding (228), and since $L^{s-2}g^{-2}\ge g^{-2}\ge\mathsf{x}_W\ge x_\mathrm{J}$ for $s\ge2$ and θ does not increase, the condition $\frac43C_1^\flat L\,\mathsf{T}(3)\,\theta(x)\le1$ of the threshold x_J in (228), with $C_1^\flat\ge2$, gives $2T_2(3)\,\theta(L^{s-2}g^{-2})\le1$. □

Lemma 2.11 (The forms as sources)**.** Let $0<g'\le\gamma_W^{\mathrm{ref}}$, (K',β) a first-passage datum at g' and ℓ a side with (Sd.1), small over the running couplings or not; sources are those of the description of Theorem YMM1:D at these data. Let w be a complex function on the plaquettes and w a complex

function on the bonds, of finite supports. The plaquette form $\mathcal{O}(w)$ is the first member of a source under the majorant $(|w|_\infty, \operatorname{supp} w)$, and the bond form $Y[\mathsf{w}]$ of a source under $(59|\mathsf{w}|_\infty, S[\mathsf{w}])$, $S[\mathsf{w}]$ the plaquettes at the bonds where $\mathsf{w} \neq 0$; both sources are complex linear in the weight; and if $|w|_\infty \leq h$ and $|\mathsf{w}|_\infty \leq h$, then $\mathcal{O}(w)+Y[\mathsf{w}]$ is the first member of a source under $(60h, \operatorname{supp} w \cup S[\mathsf{w}])$.

A lattice isometry r with linear part $\operatorname{diag}(\sigma_1, \sigma_2, \sigma_3)$, $\sigma_\mu = \pm 1$, carries $\mathcal{O}(w)$ to $\mathcal{O}(w \circ \mathsf{r}^{-1})$ and $Y[\mathsf{w}]$ to $Y[\mathsf{r}^\flat \mathsf{w}]$, $(\mathsf{r}^\flat \mathsf{w})(\mathfrak{b}') = \sigma_\lambda \sigma_{\lambda'} \mathsf{w}(\mathsf{r}^{-1}\mathfrak{b}')$, and leaves the torus means invariant. Hence, for every bounded $H : \mathbb{R}^3 \to V_\mathbb{C}$ of bounded support, $\mathcal{T}_{K'}(H)$ is the first member of a source under $(60|H|_\infty, S_H)$, $S_H = \operatorname{supp} w_H \cup S[\mathsf{w}_H]$ the plaquettes on which it depends, and so are its mirror copies. ■

Proof. The plaquette-source assertion is the weighted progression of the construction. Lemma 6.12 supplies the bond-source families, including the action majorant, the height-zero and later-level norms, locality and the exact sum rule. Thus the bond conclusion uses the actual analytic source families, rather than boundedness of the bare polynomial alone. Source linearity follows from the linear dependence of these families on the weights. Increasing a majorant preserves all its defining inequalities, and adding sources adds their sizes and takes the union of their supports; $1 + 59 = 60$ gives the mixed-source bound.

Finally, $a_p \circ \mathsf{r}^{-1} = a_{\mathsf{r}p}$ and $q_\mathfrak{b} \circ \mathsf{r}^{-1} = \sigma_\lambda \sigma_{\lambda'} q_{\mathsf{r}\mathfrak{b}}$, with the reflected bond taken in its positive orientation. These identities give the stated reflection law and the assertion for mirror copies. □

Proposition 2.12 (Two consecutive cutoffs on one torus for the plaquette forms of one plane and the bond forms)**.** Let $0 < g \leq \gamma_W^{\mathrm{ref}}$, $b \in I(g)$, $\ell \in \mathfrak{L}(g)$, $n \geq 2$ and $\mathsf{d} > 0$; by Corollary YMM1:118.4 the pairs $(K, L^K b)$ are first-passage data at g with label b. For a bounded Borel function ψ on T_ℓ and $x \in \Lambda_{K,\ell}$ put $\psi^{(K)}(x) = a_K^{-3} \int_{x + a_K[-\frac{1}{2}, \frac{1}{2})^3} \psi$. A *cell insertion* at the cutoff K is one of the following: the plaquette form $\mathcal{O}(w)$ of one plane $\{\kappa, \kappa'\}$, with $w(p) = \psi^{(K)}(x)$ at the plaquette p spanned at x by $a_K e_\kappa$, $a_K e_{\kappa'}$ and $w = 0$ at the plaquettes of the two other planes; the sum of the three, the action density with the weight $\psi^{(K)}$; and the bond form $Y[\mathsf{w}]$ of one direction μ, with $\mathsf{w}(\langle x, x + a_K e_\mu \rangle) = \psi^{(K)}(x)$ and $\mathsf{w} = 0$ at the bonds of the two other directions. Let $\mathcal{E}_1, \dots, \mathcal{E}_n$ be cell insertions, of any kinds, whose functions ψ_a are real and vanish off closed sets at pairwise sup distances $\geq \mathsf{d}$, and $\kappa_K = \langle \mathcal{E}_1; \dots; \mathcal{E}_n \rangle_{K,\ell,L^K b}$.

(a) There are numbers C, p, formed from the constants, n and b, and a cutoff K_1, formed besides from g, ℓ and d, such that for $K \geq K_1$

$$|\kappa_{K+1} - \kappa_K| \leq C\, \ell^{3(n+1)} K^p L^{-\theta_n K} \prod_a \sup |\psi_a|, \qquad \theta_n = \frac{1}{1260\, n(8n+3)}.$$

So κ_K converges along the full sequence $K \to \infty$, and the limit is n-linear and symmetric. The same holds, with $\sup|\psi_a| + \operatorname{Lip}_\infty \psi_a$ in the place of $\sup|\psi_a|$, for the forms of the three kinds whose weights are real functions ψ_a with $\operatorname{Lip}_\infty \psi_a < \infty$ read at the barycentres of the plaquettes and at the midpoints of the bonds, $w(p) = \psi_a(x(p))$, $\mathsf{w}(\mathfrak{b}) = \psi_a(x_\mathfrak{b})$, under the same separation of the supports; and for such weights the two limits agree.

(b) In this clause the separation of the head is replaced by a weaker one. Let $\psi_1, \dots, \psi_n$ be real Lipschitz functions on T_ℓ, none of them 0, let $\mathcal{E}_1 = Y[\mathsf{w}]$ be the bond form of one direction μ with $\mathsf{w}(\mathfrak{b}) = \psi_1(x_\mathfrak{b})$ at the bonds $\mathfrak{b}$ of the direction μ and $\mathsf{w} = 0$ at the others, let $\mathcal{E}_a = \mathcal{O}(w_a)$, $w_a(p) = \psi_a(x(p))$, $2 \leq a \leq n$, be action densities, and let κ_K be the joint cumulant of these n forms. If the n supports have no common point and their spread is at least $\mathsf{d}_0 > 0$ (the definition preceding Lemma YMM1:114.6), then from a cutoff on $|\kappa_{K+1} - \kappa_K| \leq C\, K^p L^{-K/120} \prod_a \|\psi_a\|_\sharp$, $\|\psi\|_\sharp = \max\{\sup|\psi|, 40M \operatorname{Lip}\psi\}$, with C, p and the cutoff formed from the constants, n, ℓ, b and d_0.

(c) If all the $\mathcal{E}_a$ are action densities with real Lipschitz weights read at the barycentres, $\mathcal{E}_a = \mathcal{O}(w_a)$, $w_a(p) = \psi_a(x(p))$, and κ_K is their joint cumulant, the convergence is given by Theorem YMM1:AR, equation YMM1:(2203), Corollary YMM1:117.1 and Corollary YMM1:118.4: from a cutoff on, $|\kappa_{K+1} - \kappa_K| \leq C\, \ell^{3(n+1)} K^p L^{-K/10} \prod_a \|\psi_a\|_\sharp$.

Clauses (a) and (b) carry the convergence of Theorem YMM1:AR over to the plaquette form of one plane, to the bond form and to weights that are means over the lattice cubes; clause (c) is that theorem for the action density. ■

Proof sketch. (a) At the two cutoffs K and $K+1$, at the one label b on the one torus, put

$$\sigma = \lfloor K/(1260\,n)\rfloor, \qquad s = \lfloor \sigma/(8n+3)\rfloor;$$

then $\sigma \le \lceil K/1260\rceil$, $\sigma - s \ge (8n+2)s$, $s \ge \theta_n K - 2$ and $4n\sigma \le K/315$. Every insertion is the first member of a source under a majorant at both cutoffs (Lemma 2.11, which holds on every side with (Sd.1), so on every $\ell \in \mathfrak{L}(g)$ by Proposition YMM1:74.1): under (s_a, S_a) with $\mathsf{s}_a = \sup|\psi_a|$ for a plaquette form or an action density and $\mathsf{s}_a = 59\sup|\psi_a|$ for a bond form, S_a the plaquettes whose corners lie within $\frac{3}{2}a_K$ of the closed set off which ψ_a vanishes; a source under a majorant is one under every larger majorant, so that these majorants serve, and corners of plaquettes of different S_a are at sup distance $\ge \mathsf{d} - 3a_K \ge \mathsf{d}/2$ once $6a_K \le \mathsf{d}$. The two cumulants are compared through three errors, each bounded by a number formed from the constants and n times the factors written.

(i) *One cutoff.* By Theorem YMM1:D, on the small fields, the chain with the sources is run up to the level $K - s$, at which the n insertions have sizes at most $4\ell^3 L^{4s}\mathsf{s}_a$; each insertion is replaced by its *read-out*, its first member read at the background of the block field of the depth σ, a function of that block field alone. The cumulant of the n insertions and the cumulant of their n read-outs differ by at most

$$\Big[2L^{4n}V_\ell\, L^{-(4n+2)s} + n\,\epsilon(\sigma - s) + 2e^{3-L^s\mathsf{d}/(2M)}\Big]\prod_a 4\ell^3 L^{4s}\mathsf{s}_a.$$

The first term is the large-field term (Proposition YMM1:115.2), $V_\ell = 4M^{-3}\ell^3 e^{\mathsf{B}(X_g)\ell^3}$ times a number formed from the constants and n. The second is the loss of memory of the progression with sources between the depths s and σ: the sources switched on at the level $K - \sigma$ in the place of the level 0 change the effective terms of the level $K - s$ by at most $\epsilon(\sigma - s)$ times their sizes, $\epsilon(\nu) = C_{\mathrm{m}}(\nu+1)^{2\mathsf{p}_0+2}L^{-\nu/2}$ with a number C_{m} of the constants, because the linearised steps contract on the small fields, as the flows of Propositions YMM1:114.2, YMM1:114.3 forget their start. The third bounds the polymers that join two supports, whose linear size is at least $L^s\mathsf{d}/(2M) - 2$ in the units of the level $K - s$.

(ii) *The tie at the depth σ.* The read-outs of the two cutoffs are functions of one block field V of the depth σ, vanishing where V has large fields, of sizes at most $\frac{3}{2}B_3^2\ell^3 L^{4\sigma}\mathsf{s}_a$; over one such V they differ by at most

$$\tau_a = C_{\mathrm{t}}\,\ell^3 L^{4\sigma} K^{1/2} L^{-(K-\sigma)/2}\sup|\psi_a|$$

for weights that are means over the lattice cubes, and by the same with $\sup|\psi_a| + L^{-\sigma}\mathrm{Lip}_\infty\psi_a$ in the place of $\sup|\psi_a|$ for a weight read at the points of the two lattices, C_{t} a number of the constants; so, under one law of V, the cumulants of the read-outs of the two cutoffs differ by at most $\sum_a \tau_a \prod_{b\ne a}\frac{3}{2}B_3^2\ell^3 L^{4\sigma}\mathsf{s}_b$. The tie is a statement of its own, the counterpart of equation YMM1:(2156) for the products of two plaquette loops at a site. Let $(t, \varepsilon_{\mathrm{r}}, V)$ be data of the comparison (the setting preceding Lemma YMM1:113.8), $t = K - \sigma$, U^{A}, U^{B} the backgrounds over V of the bare lattices $\Lambda_{K,\ell}$, $\Lambda_{K+1,\ell}$, and $N_t = \ell^3 L^{3\sigma}$ the number of the sites of the level t; for two loops l, l' at a site x let $Q_x(l,l') = \langle w(W_{x,l}), w(W_{x,l'})\rangle$, $\langle X, Y\rangle = \frac{1}{2}\operatorname{tr} XY$, $W_{x,l}$ the plaquette loop of l at x. Then for $\xi \in [-1,1]^3$ and a complex function ϕ on T_ℓ with $\mathrm{Lip}_\infty\phi < \infty$,

$$\Big|L^{t+1}\sum_{x\in\Lambda_{K+1,\ell}}\phi(x + a_{K+1}\xi)\,Q_x(l,l')(U^{\mathrm{B}}) - L^t\sum_{y\in\Lambda_{K,\ell}}\phi(y + a_K\xi)\,Q_y(l,l')(U^{\mathrm{A}})\Big| \le C_{\mathrm{t}}\,\|\phi\|_{(t)}\,\varepsilon_{\mathrm{r}}^2 N_t\, t^{1/2}L^{-t/2},$$

$\|\phi\|_{(t)}$ the norm in equation YMM1:(2154); and for a weight v_{f} on the sites of $\Lambda_{K+1,\ell}$ and its block mean $\mathsf{v}_{\mathrm{c}}(y) = L^{-3}\sum_{x\in B(y)}\mathsf{v}_{\mathrm{f}}(x)$ on $\Lambda_{K,\ell}$, $B(y)$ the L^3 sites of the block of y, the same holds with v_{f}, v_{c} in the place of the two readings of ϕ and $\sup|\mathsf{v}_{\mathrm{f}}|$ in the place of $\|\phi\|_{(t)}$. The proof follows that of Proposition YMM1:113.9: in a gauge on a box about a site of the coarse lattice the background

is e^{ia} with a small 1-form a with values in the Lie algebra, the plaquette variables $w(W_{x,l})$ of the fine lattice are the curls of a up to the second order, and those of the coarse lattice their averages (one averaging step with values in the Lie algebra); the variance of the curls about their averages, plaquette by plaquette, is bounded by the defect of Jensen's inequality, whose sum over the plaquettes is $2L^{-2}$ times the difference $L\sum_p a_p - \sum_{p'} a_{p'}$ of the actions of the fine background and of its block average, a difference bounded through the comparison of the two background actions, equation YMM1:(2155), and the minimality of the background of the coarse lattice; and the background of the coarse lattice is compared with the block average of the fine background, a nearly minimal competitor, through its excess of action.

The bond density is a sum of four such products, $q_{\mathfrak{b}} = \frac{1}{4}\sum_{\varepsilon,\varepsilon'=\pm}\varepsilon\varepsilon' Q_x((\mu,\varepsilon\lambda),(\mu,\varepsilon'\lambda'))$ at $\xi = \frac{1}{2}e_\mu$, and the plaquette density of one plane is one such product up to a_p^2, by $a_p = \frac{1}{2}Q_x(l,l) + \frac{1}{2}a_p^2$ at the loop l of the plane, a_p^2 being of the fourth order in the field at the backgrounds; the action density is equation YMM1:(2156) itself. With $a_K^{-1} = L^\sigma L^t$ and $\varepsilon_{\mathrm{r}} \le 1$, $t \le K$, this gives τ_a; for means over the lattice cubes the weights of the two cutoffs are tied by the block mean, $\psi^{(K)}(y) = L^{-3}\sum_{x\in B(y)}\psi^{(K+1)}(x)$, since the cell of y is the union of the cells of the $x \in B(y)$, and the tie asks no regularity.

(iii) *The laws.* The laws of the block field of the depth $\sigma \le \lceil K/1260\rceil$ at the two cutoffs differ, on the bounded gauge-invariant functions, by at most $\mathsf{C}_{\mathrm{bf}}\ell^3 K^{\mathsf{p}_0}L^{-K/10}$ times their sup norm for $K \ge K_{\mathrm{bf}}$ (Corollary B.30), with the numbers C_{bf}, K_{bf} of Definition B.29 (5) at the label b and $\mathsf{p}_0 = 2\mathfrak{p}_0 + \frac{1}{2}$; for the cumulant of the read-outs this costs $\mathsf{C}_{\mathrm{bf}}\ell^3 K^{\mathsf{p}_0}L^{-K/10}\prod_a \frac{3}{2}B_3^2\ell^3 L^{4\sigma}\mathsf{s}_a$.

The balance. In (i), $\sigma - s \ge (8n+2)s$ gives $L^{4ns}\epsilon(\sigma-s) \le C_{\mathrm{m}}(\sigma+1)^{2\mathfrak{p}_0+2}L^{-s}$; and from a cutoff on $L^{4n}V_\ell L^{-s} \le 1$ and $2e^{3-L^s\mathsf{d}/(2M)}L^{(4n+1)s} \le 1$; so (i) is at most $(4\ell^3)^n[3 + nC_{\mathrm{m}}(\sigma+1)^{2\mathfrak{p}_0+2}]L^{-s}\prod_a \mathsf{s}_a$. In (ii) and (iii), $4n\sigma \le K/315$ gives $L^{4n\sigma}L^{-(K-\sigma)/2} \le L^{-K/3}$ and $L^{4n\sigma}L^{-K/10} \le L^{-K/11}$. As $L^{-s} \le L^2 L^{-\theta_n K}$, $\theta_n < \frac{1}{11}$, $\sigma + 1 \le K$ and $\mathsf{s}_a \le 59\sup|\psi_a|$, the three errors give (a) with $p = 2\mathfrak{p}_0 + 2$; the factor $\ell^{3(n+1)}$ comes from the n sizes and the law, and C is formed from the constants, n and C_{bf}, so from the constants, n and b.

The cutoff K_1 is the least from which $K \ge K_{\mathrm{bf}}$, $s \ge 1$, $L^s\mathsf{d} \ge 6M$, $6a_K \le \mathsf{d}$, $L^\sigma b \ge \Theta_\star$ (the number of equation YMM1:(2148)), the two inequalities above and the thresholds of the chain of n sources at the depth s hold; through V_ℓ, the distance and K_{bf} it reads besides g, ℓ and d, while C and p read neither. The Lipschitz numbers enter at one place, the tie, with the factor $L^{-\sigma}$. The two readings of a Lipschitz weight, at the points and through the means over the lattice cubes, differ by at most $a_K\mathrm{Lip}_\infty\psi_a$, the size of the weight of a source; the bound of the moments of first members of sources at one fixed depth then makes the two cumulants at the cutoff K differ by at most a number formed from the constants, n, g, ℓ and d times $a_K\sum_a \mathrm{Lip}_\infty\psi_a\prod_{b\ne a}\sup|\psi_b|$, which tends to 0; so the two limits agree.

Since $\sum_K K^p L^{-\theta_n K} < \infty$, κ_K converges along the full sequence; multilinearity and symmetry pass to the limit.

(b) Only the bond form needs a tie: the cumulant is the mixed derivative at 0, in the parameters of the action densities, of the mean of the bond form under the measure with these densities as sources; along the chain the derivative of the bond form obeys a linear recursion, whose sizes are those of a member of the level j and of what a step creates, so that no disc in a parameter of the bond form is needed; the polymers that meet all the n supports, which make the contact terms, have at a depth u a linear size of at least $\mathsf{d}_0 L^u/M - 2$ in the units of their level, as in the polymer estimate in Theorem YMM1:AR, so that the spread, and no pairwise distance, enters; and the comparison of the bond forms of the two backgrounds over one block field, the tie of (ii), gives the rate $L^{-K/120}$. (c) is Theorem YMM1:AR, equation YMM1:(2203) with Corollary YMM1:117.1 and Corollary YMM1:118.4. □

Lemma 2.13 (A board for n small sets)**.** Let $n \ge 1$, $\mathsf{l} > 0$, $0 < h < \mathsf{l}/(2n)$ with $\mathsf{l} \in h\mathbb{Z}$, and let $S_1, \dots, S_n \subset \mathbb{R}^3$ be non-empty sets of sup diameter $\le \mathsf{l}/(4n)$. There is $o \in h\mathbb{Z}^3$ such that every

point of every S_a is at distance $> \mathsf{l}/(8n)$ from every plane $\{x_\mu = o_\mu + \mathsf{l}(t' + \frac{1}{2})\}$, $\mu \in \{1,2,3\}$, $t' \in \mathbb{Z}$; so each S_a lies in the interior of one cube $o + \mathsf{l}\mathbf{k}_a + [-\frac{\mathsf{l}}{2}, \frac{\mathsf{l}}{2}]^3$. ■

Proof. Fix μ. The closed $\frac{\mathsf{l}}{8n}$-neighbourhoods of the projections of the S_a on the x_μ-axis have images on the circle $\mathbb{R}/\mathsf{l}\mathbb{Z}$ that are n closed arcs of total length $\le \frac{\mathsf{l}}{2}$. Their complement has measure $\ge \frac{\mathsf{l}}{2}$ and at most n components, so one of them is an open arc of length $\ge \frac{\mathsf{l}}{2n} > h$, and it contains a point of $\frac{\mathsf{l}}{2} + h\mathbb{Z}$; let $o_\mu + \frac{\mathsf{l}}{2}$ be such a point. The box of the neighbourhoods is connected and meets no wall plane. □

Lemma 2.14 (Dilation of the coupling; refinement)**.** (a) For $0 < g \le \gamma$ and $0 < \delta \le \frac{1}{4}$ let $z(g)$ be the least integer $z \ge 1$ with $\mathsf{G}_z^- := L^{z-1}(g^{-2} - \bar{B}) - B_\sharp \ge (\gamma_W^{\mathrm{sd}})^{-2}$, and $i_A(g,\delta) = z(g) + \tilde{\imath}$, $\tilde{\imath}$ the least integer ≥ 1 with $L^{\tilde{\imath}-1}(\mathsf{G}^-_{z(g)} - \bar{B}) - B_\sharp \ge \mathsf{x}_E(\delta)$, $\mathsf{x}_E(\delta)$ the number of Lemma 2.8 (d), formed from the constants and δ alone. For a first-passage datum (K,β) at g with $K \ge z+1$, $z = z(g)$, the stopped coupling $\tilde{g} = g_{(z)}$ satisfies $\tilde{g} \le \gamma_W^{\mathrm{sd}}$; $(K - z, \beta)$ is a first-passage datum at $\tilde{g}$ with label $L^z b$; $L^z\ell \in \mathfrak{L}(\tilde{g})$ for $\ell \in \mathfrak{L}(g)$; $X_{\tilde{g}} + \bar{B} \le L^z(X_g + \bar{B})$, $G_{\tilde{g}} \le G_g + \frac{9}{2} z \log L + \frac{1}{8}$; and for $i \ge z+1$, $\tilde{\imath} = i - z$: $\mathsf{Y}_{\tilde{\imath}}[\tilde{g}] \le \mathsf{Y}_i[g]$, $C_E[\tilde{g}] \le e^{1/8} L^{11z/2} C_E[g]$, $K_E(\tilde{\imath})[\tilde{g}] \le K_E(i)[g] - z$ and $i_E(\tilde{g},\delta) \le i_A(g,\delta) - z$, the bracket naming the coupling at which a number is formed.

(b) Let (K_j, β_j, ν_j) be first-passage data at g with periodic Gibbs states and labels converging to b_*, $z \ge 1$, $\Lambda = L^z$ and $g' = (2L^{z-1} b_*)^{-1/2}$. Then $g' < g$, and along a subsequence $(K_j - z, \beta_j)$ are first-passage data at g', with the dilated states, whose labels converge to Λb_*. For a weight H on $\mathbb{R}^3$ put $H^{(z)}(x) = H(\Lambda^{-1}x)$, for a tuple $X = (H_1, \dots, H_n)$ put $X^{(z)} = (H_1^{(z)}, \dots, H_n^{(z)})$, continued linearly to the combinations of tuples, and for a vector field η put $\eta^{[z]}(x) = \Lambda\, \eta(\Lambda^{-1}x)$. If they define the tensor limit σ', then σ exists and $\sigma(X) = \Lambda^n \sigma'(X^{(z)})$ for X with n entries.

The dilation $X \mapsto X^{(z)}$ of the tuples is a bijection, multiplicative for the concatenation, commutes with $\mathrm{O}(3)$, carries τ_v to $\tau_{\Lambda v}$ and $\theta_{n,c}$ to $\theta_{n,\Lambda c}$, and carries $H^{\mathrm{cons}}[\eta]$ to $H^{\mathrm{cons}}[\eta^{[z]}]$, that is $(H^{\mathrm{cons}}[\eta])^{(z)} = H^{\mathrm{cons}}[\eta^{[z]}]$, $\eta \mapsto \eta^{[z]}$ a bijection of C_c^2. If σ' satisfies $(\mathrm{Rec4})_V$ with $(C_V, p_V, \frac{1}{2})$, then σ satisfies it with $(3^{p_V}\Lambda^4 C_V, p_V, \frac{1}{2})$; if σ' satisfies it with (C_V, p_V, c_0), then σ satisfies it with $(\Lambda^4 C_V, p_V, \Lambda^{-1} c_0)$. All this holds as well with g' replaced by a reference coupling g'' such that Λb_* lies in the interior of $I(g'')$; with $g_1'^{-2} = \Lambda g^{-2}/2$ and $g_2'^{-2} = L\Lambda g^{-2}/4$, every label Λb, $b \in [g^{-2}, L(g^{-2} + \bar{B})]$, lies in the interior of $I(g_1')$ or of $I(g_2')$.

(c) Let (i,o) be a board of $\mathbb{L}_K$, $i + 2 \le i' \le K - 1$, $\mathfrak{s}$ a law on $\mathbb{L}_K$ invariant under the lattice isometries, $E \ge 0$, and let the eight boards $(i', o + wm)$, $m \in \{0,1\}^3$, $w = (a_{i'} - a_K)/2$, have the property: for every cell of them and every real h' vanishing at sup distance $< a_{i'}/8$ from its complement, $\|\mathcal{T}_K(h') - \mathfrak{s}(\mathcal{T}_K(h'))\|_{\mathrm{ch},\ell} \le E|h'|_\infty$. Then for every cell of (i,o) and every real h vanishing off it and within sup distance $a_i/32$ of its boundary, $\|\mathcal{T}_K(h) - \mathfrak{s}(\mathcal{T}_K(h))\|^{(i,o)}_{\mathrm{ch},\ell} \le 8(L^{i'-i} + 1)^3 E|h|_\infty$.

■

Proof sketch. (a) Corollary YMM1:74.3 and Lemma G.3 at the scale z, and the monotony of the explicit formulas of Theorem B (a) in the coupling: Y and C_E grow with X_g, and $G_{\tilde{g}} - G_g$ is bounded by (2). In detail: the flow bound YMM1:(1530) of Proposition YMM1:74.1 at the indices $K - z \le K$ reads $|x_K - L^{-z} x_{K-z}| \le \bar{B}(1 - L^{-z})$. With $g^{-2} < x_K \le X_g$ it gives $x_{K-z} > L^z(g^{-2} - \bar{B})$, so that $\tilde{g}^{-2} = L^{-1} x_{K-z} - B_\sharp > \mathsf{G}_z^- \ge (\gamma_W^{\mathrm{sd}})^{-2}$, and $x_{K-z} + \bar{B} \le L^z(x_K + \bar{B}) \le L^z(X_g + \bar{B})$; and $X_{\tilde{g}} = x_{K-z}$ by Corollary YMM1:74.3 and Lemma G.3, which give the datum at $\tilde{g}$, its label and its sides.

So $X_{\tilde{g}} + \bar{B} \le L^z(X_g + \bar{B})$; hence $\mathsf{Y}_{\tilde{\imath}}[\tilde{g}] \le \mathsf{Y}_i[g]$, and $C_E[\tilde{g}]/C_E[g] = e^{G_{\tilde{g}} - G_g}(X_{\tilde{g}} + \bar{B})/(X_g + \bar{B}) \le e^{1/8} L^{9z/2} L^z$. The depth $s(\delta)$ does not decrease with the inverse square of the coupling at which it is formed, because $C_W(s)$ grows with it; as $L^{\tilde{\imath}-1}(X_{\tilde{g}} + \bar{B}) - B_\sharp \le L^{i-1}(X_g + \bar{B}) - B_\sharp$, this gives

$s_E(\tilde{\imath})[\tilde{g}] \le s_E(i)[g]$ and the bound of K_E. As $\mathsf{x}_E(\delta)$ is independent of the coupling, $\tilde{g}^{-2} > \mathsf{G}_z^-$ gives $L^{j-1}(\tilde{g}^{-2} - \bar{B}) - B_\sharp > L^{j-1}(\mathsf{G}_z^- - \bar{B}) - B_\sharp$ for every $j \ge 1$, whence $i_E(\tilde{g}, \delta) \le i_A(g, \delta) - z$. (b) The exact dilation of the lattice model (Lemma K.1) gives $\mathcal{T}_K(H)$ as $\Lambda\, \mathcal{T}_{K-z}(H^{(z)})$ after transport, for the dilated weight $H^{(z)}$, as in Lemma 2.8 (a), where $L^i H(L^{-i}\cdot) = \Lambda H^{(z)}$ at $i = z$, and carries periodic Gibbs states to periodic Gibbs states; the labels are placed by the first-passage windows of Corollary YMM1:74.2, at g' and at every g'' of the kind named, for the labels Λb_j lie in the interior of $I(g'')$ from an index on; the formula of $q_\mathfrak{b}$ shows that the dilation commutes with the action of O(3) on the labels, and the identity for H^{cons} is the chain rule: $\nabla(\eta^{[z]})(x) = \Lambda\, \Lambda^{-1}(\nabla\eta)(\Lambda^{-1}x) = (\nabla\eta)^{(z)}(x)$, so $\nabla \cdot \eta^{[z]} = (\nabla \cdot \eta)^{(z)}$ and $H^{\mathrm{cons}}[\eta^{[z]}] = (H^{\mathrm{cons}}[\eta])^{(z)}$.

For the two couplings: with $y = \Lambda g^{-2}$ the interiors of $I(g_1')$, $I(g_2')$ are $(y/2 + \bar{B}, Ly/2 + (L-2)\bar{B})$ and $(Ly/4 + \bar{B}, L^2 y/4 + (L-2)\bar{B})$, which overlap and cover $[y, Ly + L\Lambda\bar{B}]$, as $\bar{B} \le \frac{13}{24} g^{-2}$. For $(\mathrm{Rec4})_V$: the map $F \mapsto \Lambda^{|F|} F^{(z)}$, $|F|$ the number of entries, is multiplicative, commutes with θ and the conjugation, carries $\tau_{-\eta e_3}$ to $\tau_{-\Lambda\eta e_3}$ and the classes of σ isometrically onto those of σ', and $\|\Lambda h^{(z)}\|_{L^1} = \Lambda^4 \|h\|_{L^1}$. So for $\eta \le \Lambda^{-1}$ the bound of σ' at the distance $\Lambda\eta \le 1$ gives that of σ with $\Lambda^{4-p_V} C_V$, in either form; for $\Lambda^{-1} < \eta \le 1$ and h carried by $\{|x_3| < \Lambda^{-1} c_0 \eta\}$ the bound of σ' at the distance 1 applies, and the semigroup e^{-tH} is a contraction: the second triple.

For the first, let $0 < \eta \le 1$, h be carried by $\{|x_3| < \eta/2\}$ and $\eta_1 = \min\{\Lambda^{-1}, \eta/3\}$; cut h in x_3 by a partition of unity into pieces h_k carried by the slabs of width η_1 about the heights $y_k = k\eta_1/2$, and translate each piece, with the two tuples beside it, to the height 0, σ being invariant under the translations. The translated tuples lie at heights $> \eta - |y_k| > \eta_1$; the bound at the distance η_1, the contraction of the semigroup, $\sum_k \|h_k\|_{L^1} = \|h\|_{L^1}$ and $\eta_1^{-1} \le 3\Lambda/\eta$ give the number $3^{p_V} \Lambda^4 C_V$. (c) Let $\xi_\mu(x)$ be the coordinate of x in the direction μ measured from a wall plane of the coarse board (i, o); put $m_\mu(x) = 0$ if $\mathrm{dist}(\xi_\mu(x), a_{i'}\mathbb{Z}) \ge a_{i'}/8$ and $m_\mu(x) = 1$ otherwise, and $E_m = \{x : m(x) = m\}$, $m \in \{0,1\}^3$: eight Borel sets that part $\mathbb{R}^3$.

As a_i is an odd multiple of $a_{i'}$, a mirror map of the coarse board changes each ξ_μ modulo $a_{i'}$ at most by its sign, so it keeps every E_m. In the coordinate ξ_μ the walls of the fine board $(i', o + wm)$ are the points of $wm_\mu + a_{i'}\mathbb{Z}$; so the points of E_m, and with them their coarse mirror images, lie at sup distance $\ge a_{i'}/8$ from the walls of this board, and the coarse mirror image of a piece $h\mathbf{1}_{E_m \cap \square'}$, $\square'$ a cell of the board $(i', o + wm)$, lies in one cell of the same board. Copies of a piece in different coarse cells are at sup distance $\ge a_i/16 > a_{i'}$, hence in fine cells that are different modulo the side. The pieces $h\mathbf{1}_{E_m \cap \square'}$ that meet the coarse cell, at most $8(L^{i'-i} + 1)^3$ of them, add up to h; the chessboard estimate on the fine board, for a subset of a period box (Corollary B.1 (b)), bounds the coarse seminorm of each piece by the fine seminorms of its copies, each at most $E|h|_\infty$, and the seminorm is subadditive. □

Lemma 2.15 (From the sup norm on a cube to L^1; for data)**.** Let $\mathcal{H}$ be a Hilbert space, $\mathcal{P}$ a projection-valued measure on $[0,\infty) \times \mathbb{R}^2$ carried by the square cone, $e^{-tH}\mathcal{U}(v) = \int e^{-tE + iv\cdot q} d\mathcal{P}$. Let W be a complex normed space of finite dimension, $Q = \{|x - z|_\infty \le \rho\}$, b a linear map from the continuous W-valued functions carried by Q to the bounded operators with $\|\mathsf{b}(g)\| \le \mathsf{c} \sup|g|$, $\varepsilon \ge 12\rho$, and $\mathsf{B}^\varepsilon(g) = e^{-\varepsilon H}\mathsf{b}(g)e^{-\varepsilon H}$. Suppose that $\mathsf{B}^\varepsilon(\tau_u g) = e^{-(\varepsilon + u_3)H}\mathcal{U}(\vec{u})\mathsf{b}(g)\mathcal{U}(-\vec{u})e^{-(\varepsilon - u_3)H}$ whenever $|u|_\infty \le 2\rho$ and g, $\tau_u g$ are carried by Q. Then $\|\mathsf{B}^\varepsilon(h)\| \le 4\mathsf{c}\rho^{-3}\|h\|_{L^1}$ for every continuous h carried by Q. ■

Proof. Let χ be the product of the tents $\rho^{-1}(1 - |t|/\rho)_+$ about the coordinates of z; then $\int \chi = 1$, $\sup \chi = \rho^{-3}$, and with $g_u = \chi\, h(\cdot + u)$,

$$h = \int \tau_u g_u \, du,$$

$$\langle \psi', \mathsf{B}^\varepsilon(h)\psi\rangle = \int_{|u|_\infty \le 2\rho} \langle \psi'_u, \mathsf{b}(g_u)\psi_u\rangle \, du,$$

$\psi_u = \mathcal{U}(-\vec{u})e^{-(\varepsilon-u_3)H}\psi$, $\psi'_u = \mathcal{U}(-\vec{u})e^{-(\varepsilon+u_3)H}\psi'$. On the square cone $|q_k| \le E$, so

$$\|P_1^{\alpha_1}P_2^{\alpha_2}H^{\alpha_3}e^{-\varepsilon H}\| \le |\alpha|!\,\varepsilon^{-|\alpha|};$$

this is the only use of the cone. Expanding ψ_u, ψ'_u in power series in u (convergent since $|u|_1 \le 6\rho \le \varepsilon/2$), exchanging sum and integral, and using

$$\sup|\int u^\gamma g_u\,du| \le \rho^{-3}(2\rho)^{|\gamma|}\|h\|_{L^1},$$

one obtains the bound

$$\mathsf{c}\rho^{-3}\|h\|_{L^1}(\sum_m (6\rho/\varepsilon)^m)^2 \le 4\mathsf{c}\rho^{-3}\|h\|_{L^1}.$$

□

Proposition 2.16 (Reconstruction for data with labels)**.** (a) Let σ be reconstruction data with labels with the numbers C_V, $p = p_V$, c_0; (Rec5) is not supposed. Then $\mathcal{H}(\sigma)$ is separable, and there are a strongly continuous unitary representation U of $\mathbb{R}^{1+2} \rtimes \mathcal{L}$ with $U(x,1) = e^{itH}\mathcal{U}(\vec{x})$, operators $\phi(f)$, $f \in \mathcal{S}_V$, on the span $\mathcal{D}_0$ of Ω and of the vectors $\phi(f_1)\cdots\phi(f_n)\Omega$, functions $\mathbf{W}_n(\mathfrak{z};e)$ holomorphic on $\{d_\circ > 0\}^{n-1}$ and n-linear in e, and vectors $\Psi_n(z;e)$ with $[X] = \int \Psi_n(x; h_1(x_1),\dots,h_n(x_n))\,dx$ for the tuples in $\mathbb{E}_+$ ordered in the third coordinate, such that: (i) the spectral measure of $U(\cdot,1)$ is carried by the closed forward cone and $U(a,\Lambda)\Omega = \Omega$; with (Rec5), the invariant vectors are the multiples of Ω; (ii) $\phi(f)\mathcal{D}_0 \subset \mathcal{D}_0$, $U(a,\Lambda)\mathcal{D}_0 = \mathcal{D}_0$, $f \mapsto \langle\psi,\phi(f)\psi'\rangle$ is tempered, and $\langle\psi,\phi(f)\psi'\rangle = \langle\phi(f^*)\psi,\psi'\rangle$; (iii) $U(a,\Lambda)\phi(f)U(a,\Lambda)^{-1} = \phi(D(\Lambda)f(\Lambda^{-1}(\cdot - a)))$ on $\mathcal{D}_0$, where $D(\Lambda) = \rho_{\mathbb{C}}(\hat{\Lambda})$ and $\rho_{\mathbb{C}}$ is the holomorphic continuation of $\rho|_{\mathrm{SO}(3)}$ to $\mathrm{SO}(3,\mathbb{C})$; at $V = \mathrm{Sym}_3(\mathbb{R})$, $D(\Lambda)A = \hat{\Lambda}A\hat{\Lambda}^{\mathrm{T}}$; (iv) $\phi(f)\phi(f')\psi = \phi(f')\phi(f)\psi$ on $\mathcal{D}_0$ at spacelike separated supports, for all components; (v) $\mathcal{D}_0$ is dense; (vi) $|\mathbf{W}_n(\mathfrak{z};e)| \le (C_V\eta^{-p})^n\prod_k|e_k|$ for $e \in V^n$, $d_\circ(\mathfrak{z}_k) \ge 2\eta$, $0 < \eta \le 1$; $\langle\Omega,\phi(f_1)\cdots\phi(f_n)\Omega\rangle = \lim_{\epsilon\downarrow 0}\int \mathbf{W}_n(\iota(x_2 - x_1 + i\epsilon\alpha_1),\dots;f_1(x_1),\dots,f_n(x_n))\,dx$ for all α_k in the open forward cone; $\sigma(X) = \int \mathbf{W}_n(x_2 - x_1,\dots;h_1(x_1),\dots)\,dx$ at the tuples ordered in the third coordinate; (vii) there is exactly one function $\mathbf{S}_n$, holomorphic on the union of the tubes $\{d_\circ(\mathsf{R}^{-1}(z_{\varsigma(k+1)} - z_{\varsigma(k)})) > 0,\ 1 \le k < n\}$ over $\mathsf{R} \in \mathrm{SO}(3)$ and the permutations ς, which on each of them is $\mathbf{W}_n$ written in the frame R at the labels $\rho(\mathsf{R})^{-1}e_{\varsigma(k)}$; its restriction s_n to the real non-coinciding configurations is real-analytic, is the only continuous kernel of σ, is symmetric in points and labels together, and is invariant under every isometry; (viii) Ω and the vectors $\Psi_n(x;e)$ at real x with $0 < x_{13} < \cdots < x_{n3}$ are total, and so are Ω and the classes of the tuples whose entries lie in disjoint slabs.

Clauses (i)–(vi) hold as well for complex symmetric functionals invariant under the orientation-preserving isometries, with $\overline{\sigma(W)} = \sigma(\theta\bar{W})$ and with $(\mathrm{Rec2})_V$–$(\mathrm{Rec4})_V$.

(b) For data as in (a) the two-fold plateau $m_2(X,Y) = \lim_{|v|\to\infty}\sigma(X\cdot\tau_v Y)$ exists, and σ has a Hermitian canonical decomposition: a compact metrisable X, a Borel probability measure λ with support X, and complex symmetric functionals σ_ξ with $\overline{\sigma_\xi(X)} = \sigma_\xi(\theta X)$, continuous and injective in ξ, such that the iterated plateaux of σ (Definition 2.2 (5)) are $\int\prod_i \sigma_\xi(X^i)\,d\lambda$; it is unique up to exactly one homeomorphism, and its components are real, so that it is a canonical decomposition, if and only if $m_2(F,F) \ge 0$ for the real combinations F of tuples.

Every component has $(\mathrm{Rec2})_V$–$(\mathrm{Rec4})_V$ with the numbers of σ and (Rec5), is reflection positive at every mirror, and $|\sigma_\xi(X\cdot\tau_v Y) - \sigma_\xi(X)\sigma_\xi(Y)| \le K(X,Y)|v|^{-1}$ for $|v| \ge r(X,Y)$, with K, r formed from C_V, p, c_0 and the two tuples, the same for all ξ. Let V_0 be a subrepresentation such that the classes of the tuples with entries in V_0 are total, and let $(\mathsf{X}_0,\lambda_0,(\sigma_{0,\zeta}))$ be the Hermitian canonical decomposition of $\sigma|_{V_0}$, which is reconstruction data with labels in V_0 with the numbers of σ. There is exactly one map $\pi : \mathsf{X} \to \mathsf{X}_0$ with $\sigma_\xi|_{V_0} = \sigma_{0,\pi(\xi)}$ for every ξ; it is continuous and onto, $\pi_*\lambda = \lambda_0$, and $g \mapsto g\circ\pi$ is a unitary map of $L^2(\mathsf{X}_0,\lambda_0)$ onto $L^2(\mathsf{X},\lambda)$.

So for every tuple X there is a bounded Borel function g_X on X_0 with $\sigma_\xi(X) = g_X(\pi(\xi))$ for λ-almost every ξ, and the iterated plateaux of σ are $\int \prod_i g_{X^i}\, d\lambda_0$: the decomposition of $\sigma|_{V_0}$ bears that of σ as measure spaces. The map π is a homeomorphism if and only if every g_X agrees λ_0-almost everywhere with a continuous function, in particular if $\dim\ker H < \infty$. ∎

Proof sketch. (a) On the circular cone $|e^{-\mathfrak{z}_3 E + i(\mathfrak{z}_1 q_1 + \mathfrak{z}_2 q_2)}| \le e^{-d_\circ(\mathfrak{z})E}$; this gives the contractions $\mathcal{T}(\mathfrak{z})$, holomorphic inside the tube. By $(\mathrm{Rec4})_V$ the forms $(F, F') \mapsto \sigma(\theta\bar{F}\cdot(h)\cdot F')$ are bounded, whence insertion operators $B_\eta(h)$ with $\|B_\eta(h)\| \le C_V \eta^{-p}\|h\|_{L^1}$, covariant under the translations, $B_\eta(\tau_y h') = \mathcal{T}(y + (\eta-\eta')e_3) B_{\eta'}(h') \mathcal{T}(-y + (\eta-\eta')e_3)$. Since translations act on them Lipschitz-continuously (on the cone each derivative of $e^{-(\eta/2+y_3)E + i\vec{y}\cdot q}$ is at most $4/(e\eta)$), the limits $\mathsf{B}(\eta,\eta;e) = \lim_{\epsilon\downarrow 0} B_\eta(\delta_\epsilon e)$, $\delta_\epsilon = \epsilon^{-3}\chi(\cdot/\epsilon)$ with $\chi \ge 0$ radial of integral 1, exist in norm, and $\mathsf{b}(w|e|w') = \mathcal{T}(w - se_3)\mathsf{B}(s,s;e)\mathcal{T}(w' - se_3)$ are holomorphic point operators with $B_\eta(h) = \int \mathsf{b}(y+\eta e_3 | h(y) | -y+\eta e_3)\, dy$.

Ordered tuples are products of insertion operators and semigroup factors; this gives $\mathbf{W}_n$, Ψ_n and the integral formulas. Any n distinct points are ordered in some frame $\mathsf{R} \in \mathrm{SO}(3)$ whose cap $\{\mathsf{R}e_3 \cdot \hat{v} > \frac{1}{2}\}$ contains a given direction (the zones $\{|u\cdot(x_a - x_b)| < \gamma_N |x_a - x_b|\}$, $\gamma_N = 1/(2N^2)$ with $N \ge n$, cover less than a quarter of the sphere); the pieces in two frames agree at the real points of the intersection of two convex tubes, hence on it, and they form one function $\mathbf{S}_n$. Totality: the map $y \mapsto \Phi(y)$, the limit of the classes of tuples of bumps at y, has the real-analytic Gram kernel $\mathsf{s}_{2n}(\theta y, y')$, so its matrix elements are real-analytic; for a vector orthogonal to the Ψ_n they vanish on the ordered configurations, hence on the connected set of the non-coinciding ones.

The fields are defined by the forms q_0 with $\mathsf{A}_l(e) = \Gamma(l)^{-2} \iint (ss')^{l-1} e^{-s-s'} \mathsf{B}(s,s';e)\, ds\, ds'$, $\mathsf{B}(s,s';e) = \mathsf{b}(se_3|e|s'e_3)$, convergent for $l > p$; then $\mathcal{T}(w)\phi(f)\mathcal{T}(w') = \int \mathsf{b}(w + \iota x | f(x) | w' - \iota x)\, dx$ for w, w' in the open tube, and $\|(1+H)^j \phi(f)\psi\| \le c_j(f)\|(1+H)^{2l+j}\psi\|$. *Boundary values* (vi): with $c_k = \iota(\frac{i}{2}\epsilon\alpha_k)$, α_k in the open forward cone, the contractions $\mathcal{T}(2c_k)$ commute with H and tend strongly to 1 as $\epsilon \downarrow 0$; inserted between the fields, they turn $\langle\Omega, \phi(f_1)\cdots\phi(f_n)\Omega\rangle$ into $\int \mathbf{W}_n(\iota(x_2 - x_1 + i\epsilon\alpha_1), \ldots; f_1(x_1), \ldots, f_n(x_n))\, dx$, up to an error that the energy bounds, applied from the right to the left, send to 0.

The density of $\mathcal{D}_0$ (v): let $\psi \perp \mathcal{D}_0$. For a word w in the operators $\phi(f)$ and $\mathcal{T}(w)$, $\psi \perp \mathsf{w}\Omega$, by induction on the number of the letters $\mathcal{T}$: the matrix element is continuous on the closed tube and holomorphic inside in the argument w of the leftmost such letter; it vanishes at $w = \iota a$, $a \in \mathbb{R}^{1+2}$, because $\mathcal{T}(\iota a) = U(a)$ moves the rest of the word into a word with translated test functions and one such letter fewer; so it vanishes on the half planes in time by the reflection principle, and on the tube by the identity theorem in the space variables. As $\mathcal{T}(w)\phi(g_k e)\mathcal{T}(w') \to \mathsf{b}(w|e|w')$ in norm for $g_k \ge 0$ of integral 1 whose supports shrink to a point, $\psi \perp \Psi_n(z;e)$, and $\psi = 0$ by (viii).

The representation D: with the covering $\mathsf{p} : \mathrm{SL}(2,\mathbb{C}) \to \mathrm{SO}(3,\mathbb{C})$, the differential of $\rho \circ \mathsf{p}$ on $\mathrm{SU}(2)$ continues complex-linearly to $\mathfrak{sl}(2,\mathbb{C})$ and integrates to a holomorphic representation of the simply connected $\mathrm{SL}(2,\mathbb{C})$, trivial on ± 1, hence to a holomorphic representation $\rho_{\mathbb{C}}$ of $\mathrm{SO}(3,\mathbb{C})$ that continues ρ; $\Lambda \mapsto \hat{\Lambda}$ is a homomorphism of $\mathcal{L}$ into $\mathrm{SO}(3,\mathbb{C})$, so $D(\Lambda) = \rho_{\mathbb{C}}(\hat{\Lambda})$ is a representation, and $D(\Lambda)e^* = (D(\Lambda)e)^*$. Every $\Lambda \in \mathcal{L}$ is $(1 \oplus \mathsf{R}_1)B(s)(1 \oplus \mathsf{R}_2)$ with rotations $\mathsf{R}_1, \mathsf{R}_2$ of the space plane and the boost $B(s)$: a spatial rotation and a boost send the future unit vector e_0 to Λe_0, and their inverse followed by Λ fixes e_0 and acts as a rotation of its orthogonal spatial plane; $\widehat{1 \oplus \mathsf{R}} = \mathsf{R} \oplus 1$, and $\widehat{B(s)}$ is the rotation in the plane (e_1, e_3) by the imaginary angle is.

Lorentz covariance: $\mathbf{W}_n$ is invariant under the real rotations about e_3 and under those in the plane (e_1, e_3), and this last invariance continues holomorphically in the angle to imaginary angles, the boosts, the labels being moved by $e^{is\, d\rho(\omega_1)}$, $\omega_1 = E_{13} - E_{31}$, $d\rho$ the differential of ρ; no bound on this factor is needed. So $\mathbf{W}_n(\hat{\Lambda}\mathfrak{z}; D(\Lambda)e) = \mathbf{W}_n(\mathfrak{z}; e)$, and the boundary values at the cone vectors $\Lambda^{-1}\alpha_k$ give $\langle\Omega, \phi(\Lambda f_1)\cdots\phi(\Lambda f_n)\Omega\rangle = \langle\Omega, \phi(f_1)\cdots\phi(f_n)\Omega\rangle$ with $(\Lambda f)(x) = D(\Lambda) f(\Lambda^{-1}x)$.

As $(\Lambda f)^* = \Lambda(f^*)$, the map $\phi(f_1)\cdots\phi(f_n)\Omega \mapsto \phi(\Lambda f_1)\cdots\phi(\Lambda f_n)\Omega$ is isometric on the dense $\mathcal{D}_0$ and extends to a unitary operator $U(\Lambda)$; these form a representation with $U(\Lambda)U(a)U(\Lambda)^{-1} = U(\Lambda a)$,

whose strong continuity reads of D only that it is locally bounded. With the spectrum of $U(\cdot,1)$, the image of $\mathcal{P}$, carried by the closed forward cone by $(\mathrm{Rec3})_V$, this gives (i)–(iii). *Locality*: the componentwise argument is that of Proposition YMM1:110.2. Fix the labels and compactly supported scalar tests with two adjacent supports spacelike separated. The height deformation used there stays in tilted tubes with every consecutive margin at least 3η. The Cauchy–Riemann equations and integration by parts move derivatives onto the tests, and Lemma YMM1:109.4 gives a finite smeared bound $Q_e(g)$ uniform along the deformation. For g the product test, the integrals for the two adjacent orders differ by at most $2\eta Q_e(D'g)$, where $D' = \frac{1}{2}(\partial_{t_{k+1}} - \partial_{t_k})$ and $k, k+1$ are the exchanged entries. Their endpoint boundary values therefore agree as $\eta \to 0$. Graph-norm continuity extends the equality to Schwartz tests, as in the cited proof.

These are the proofs for scalar data of Propositions YMM1:108.3, YMM1:109.1, YMM1:110.1, YMM1:110.2 and Theorem YMM1:AO among the construction results, with a label at each entry and with D in the place of the trivial representation; besides them they read the spectral theorem, the identity theorem, the reflection principle in one variable and the covering of $\mathrm{SO}(3,\mathbb{C})$ by $\mathrm{SL}(2,\mathbb{C})$. They read the reality of σ and its invariance under an orientation-reversing isometry at one place only, the adjoint $B_\eta(h)^* = B_\eta(\theta\bar{h})$, where $\overline{\sigma(W)} = \sigma(\theta\bar{W})$ is all that is used; this gives (i)–(vi) for the complex functionals of the last sentence of (a). (b) For a combination Y of tuples put $\mathsf{e}(Y) = P_0[\tau_{se_3}Y]$, P_0 the projection onto $\ker H$ and s so large that $\tau_{se_3}Y$ lies over $\mathbb{E}_+$: it does not depend on s, it is invariant under the translations, and these vectors are dense in $\ker H$.

In a frame R, by the cone, $\sigma(A\cdot\tau_w Y) \to \langle \mathsf{e}(\theta\bar{A}'), \mathsf{e}(Y')\rangle$, $A' = \mathsf{R}^{-1}A$, $Y' = \mathsf{R}^{-1}Y$, uniformly as $|w| \to \infty$ with $\mathsf{R}e_3\cdot w \geq \frac{1}{2}|w|$; two frames whose caps meet give the same limit, and the caps cover the sphere; so the two-fold plateau exists, $m_2(A,Y) = \langle \mathsf{e}(\theta\bar{A}), \mathsf{e}(Y)\rangle$. *The rotations are trivial at infinity*: for a unit vector u, $\beta_u(F,G) = m_2(\theta_u\bar{F}, G)$ is a positive Hermitian form; for $u' \perp u$ the involution $\theta_u\theta_{u'}$ acts on its space as a self-adjoint unitary operator ≥ 0, which is 1; hence $m_2(\theta_u A, Y)$ does not depend on u, $m_2(\mathsf{r}A, Y) = m_2(A,Y)$ and $\mathsf{e}(\mathsf{r}Y) = \mathsf{e}(Y)$ for the orientation-preserving isometries r, and $J\mathsf{e}(Y) = \mathsf{e}(\theta Y)$ defines a unitary involution J of $\ker H$ with $m_2(\bar{A}, Y) = \langle J\mathsf{e}(A), \mathsf{e}(Y)\rangle$.

The operators at infinity: $M(X)$ is the bounded operator of $\ker H$ with $\langle \mathsf{e}(Z), M(X)\mathsf{e}(Y)\rangle = \lim_{|v|\to\infty} m_2(\theta\bar{Z}, X\cdot\tau_v Y)$, the limit of $\sigma(\tau_w\theta\bar{Z}\cdot X\cdot\tau_v Y)$ as w and v go to infinity on opposite sides of X; for X ordered in a frame, $M(X) = P_0\mathsf{b}_X|_{\ker H}$, b_X the product of the insertion operators and semigroup factors of the ordered tuple, and a partition of unity reduces every tuple to such ones. Then $M(F)^* = M(\theta\bar{F})$, $M(\mathsf{r}X) = M(X)$ for the orientation-preserving and $M(\mathsf{r}X) = JM(X)J$ for the other isometries, $M(X\cdot\tau_v Y) \to M(X)M(Y)$ strongly as $|v| \to \infty$, and, σ being symmetric, the $M(X)$ commute.

They generate a separable commutative C^*-algebra; its space of characters is X, the vacuum gives λ, whose support is X because Ω is cyclic, hence separating, for the algebra; $\ker H$ is carried unitarily onto $L^2(\mathsf{X},\lambda)$, $\sigma_\xi(X)$ is the Gelfand transform of $M(X)$, so that $\overline{\sigma_\xi(X)} = \sigma_\xi(\theta X)$, and the iterated plateaux of σ are $\langle\Omega, \prod_i M(X^i)\Omega\rangle$. Uniqueness follows from the density of the polynomials in the $\sigma_\xi(X)$ and their conjugates. *Reality*: $m_2(\bar{F}, F) = \langle J\mathsf{e}(F), \mathsf{e}(F)\rangle$, so $m_2(F,F) \geq 0$ for the real combinations F if and only if $J \geq 0$, that is $J = 1$, that is $M(X)^* = M(X)$ for every tuple, that is every σ_ξ is real.

The components: an inequality of σ at the tuples $F\cdot\tau_{tu}Y$, the spectator Y sent to infinity along u, becomes an inequality between elements of the algebra on a dense set of $\ker H$, and, the Gelfand transforms being continuous and $\operatorname{supp}\lambda = \mathsf{X}$, an inequality at every ξ (test it with $\lambda(O)^{-1/2}\mathbf{1}_O$ for small neighbourhoods O of ξ); so every σ_ξ is reflection positive at every mirror, has $(\mathrm{Rec4})_V$ with the numbers of σ, and the translations act on its space by contractions and unitary operators, which gives $(\mathrm{Rec2})_V$, one countable family of tuples making all these spaces separable.

The spectral measures disintegrate, $\mu_F = \int \mu_F^\xi\, d\lambda(\xi)$ for F over $\mathbb{E}_+$; so $\mu_F^\xi(\{E < |q|\}) = 0$ for λ-almost every ξ, and, this number being lower semicontinuous in ξ, for every ξ: $(\mathrm{Rec3})_V$. At $\{(0,0)\}$ the disintegration gives $\int \|P_0^\xi[F]_\xi\|^2 d\lambda = \|P_0[F]\|^2 = \int |\sigma_\xi(F)|^2 d\lambda$, while $\|P_0^\xi[F]_\xi\| \geq |\sigma_\xi(F)|$, P_0^ξ

the projection onto $\ker H_\xi$: so $\ker H_\xi = \mathbb{C}\Omega_\xi$ for almost every ξ. *The rate*: for data, and for Hermitian data, $|\sigma(X \cdot \tau_v Y) - m_2(X,Y)| \le K(X,Y)|v|^{-1}$ for $|v| \ge r(X,Y)$, with K, r formed from C_V, p, c_0 and the two tuples alone.

In each frame of a finite family whose caps cover the sphere and in which X and Y are ordered, the difference $f(v)$ is the integral of $e^{-(v_3'-c)E+i\vec{v}'\cdot q}$, $v' = \mathsf{R}^{-1}v$, against a complex measure off $(0,0)$ whose variation is at most the product of the numbers $C_V\eta^{-p}\|h\|_{L^1}$ of the entries of X and Y. The image κ_v of this measure, with the exponential, under $(E,q) \mapsto s = E^2 - |q|^2$ has the moments $\Delta^k f(v)$, which are independent of the frame. Its damping gives $\int e^{a\sqrt{s}}\, d|\kappa_v|(s) < \infty$ for every $a > 0$ below the positive time margin, since $0 \le \sqrt{s} \le E$. This square-root exponential condition determines complex measures within this class by their moments. Indeed, the real and imaginary parts of the difference of two such measures have zero moments, including order zero. Their positive and negative parts have equal masses and moments and inherit the same integrability condition; after normalization when the common mass is nonzero, Hardy's criterion applies to them [2, Theorem 1]. Thus κ_v is independent of the frame, and its masses $f_{\mathsf{B}}(v) = \kappa_v(\mathsf{B})$ on windows B are functions outside a ball $\{|v| < r_2\}$, with $\Delta f_{\mathsf{B}}(v) = \int_{\mathsf{B}} s\, \kappa_v(ds)$.

For $\mathsf{B} = [m_1^2, m_2^2)$, $|(\Delta - m_1^2)\operatorname{Re}(e^{i\varphi} f_{\mathsf{B}})| \le (m_2^2 - m_1^2)\mathsf{V}_{\mathsf{B}}$, V_{B} the variation of the part, and the comparison principle for $\Delta - m_1^2$ outside the ball, with the radial solution $\frac{r_2}{r}e^{-m_1(r-r_2)}$ of the dimension three, gives $|f_{\mathsf{B}}(v)| \le \mathsf{V}_{\mathsf{B}}(\frac{r_2}{|v|} + \frac{m_2^2 - m_1^2}{m_1^2})$; the harmonic part at the mass 0, which tends to 0 at infinity, is at most $\mathsf{V}_{\{0\}}\frac{r_2}{|v|}$; the sum over the windows $[(1+\epsilon)^j, (1+\epsilon)^{j+1})$, $j \in \mathbb{Z}$, with $\epsilon \downarrow 0$, gives the rate. One rate serves all the components, which are Hermitian data with the numbers of σ; with the continuity in ξ and $\operatorname{supp}\lambda = \mathsf{X}$ the bound by $\sigma_\xi(X)\sigma_\xi(Y)$ holds at every ξ, so that $\langle [F]_\xi, e^{-tH_\xi}[F]_\xi\rangle \to |\sigma_\xi(F)|^2$ and $\ker H_\xi = \mathbb{C}\Omega_\xi$ for every ξ.

The subrepresentation: the defining limits of the operators at infinity of $\sigma|_{V_0}$ and of σ agree at the tuples with entries in V_0; when their classes are total, $\sigma|_{V_0}$ and σ have one space and one $\ker H$, the operators of these tuples generate a C^*-subalgebra with the same unit, for which Ω is cyclic too, π is the restriction of the characters, the only map with $\sigma_\xi|_{V_0} = \sigma_{0,\pi(\xi)}$ because $\zeta \mapsto \sigma_{0,\zeta}$ is injective, $\pi_*\lambda = \lambda_0$ by the vacuum state, π is onto because its image is compact of full measure, and $g \mapsto g \circ \pi$ is unitary because both decompositions carry the one space $\ker H$ unitarily onto their L^2; π is injective if and only if the subalgebra is the whole algebra, by the theorem of Stone and Weierstrass, that is if and only if every g_X agrees almost everywhere with a continuous function; and if $\dim\ker H = N < \infty$, then X and X_0 have N points each. □

Lemma 2.17 (The circular cone from five mirrors; for data)**.** Let σ be a real symmetric multilinear functional on labelled tuples, with $\sigma(\varnothing) = 1$ and bounds independent of the position, invariant under the translations. For a unit vector u at whose mirror $\{u \cdot x = 0\}$ σ is reflection positive, let $\mathcal{H}_u$, H_u, $\mathcal{P}_u$ be formed as in Definition 2.2 (3) with u in the place of e_3.

(a) Let u' be a unit vector orthogonal to u. If σ is reflection positive at the mirrors with the normals u and $(u+u')/\sqrt{2}$, then $H_u \ge |u' \cdot P_u|$.

(b) Let (u, u', u'') be an orthonormal basis and $n_\beta = \cos\beta\, u + \sin\beta\, u'$. If σ is reflection positive at the four planes through the axis $\mathbb{R}u''$ with the normals $n_0, n_{\pi/4}, n_{\pi/2}, n_{3\pi/4}$ and at one plane with the normal $(n_{\beta_1} + u'')/\sqrt{2}$, $\beta_1 \in \frac{\pi}{4}\mathbb{Z}$, then $\mathcal{P}_{n_\beta}(\{E < |q|\}) = 0$ for every $\beta \in \frac{\pi}{4}\mathbb{Z}$.

(c) *(Eight measures in one plane; analysis alone.)* Let $R > 0$, $\kappa > 0$, $C < \infty$, $\mathsf{V} = \{(E,q) \in \mathbb{R}^2 : E \ge |q|\}$, and for each of the eight angles $\beta \in \frac{\pi}{4}\{0, 1, \dots, 7\}$ let m_β be a complex Borel measure on V with $|m_\beta|(\mathsf{V}) \le C$; for $\rho > 0$ and complex c put

$$f_\beta(c;\rho) = \int_{\mathsf{V}} \exp(2RE - \rho[E\cos(c-\beta) - iq\sin(c-\beta)])\, dm_\beta(E,q)$$

where the integrand is bounded. Suppose that $f_\beta(t;\rho) = f_{\beta'}(t;\rho)$ for any two of the eight angles β, β', all $\rho > 0$ and all real t with $\rho\cos(t-\beta) > 2R$ and $\rho\cos(t-\beta') > 2R$; that

$\mu = e^{2RE} m_0$ is a finite positive measure; and that for one of the eight angles, β_1, the measure m_{β_1} is carried by $\{E \geq \kappa\}$. Then $\mu(\{(E,q) \in \mathsf{V} : E^2 - q^2 < \kappa^2\}) = 0$.

No invariance under W_3, under a reflection or under a rotation is supposed. ■

Proof sketch. (a) is the argument of Proposition YMM1:94.4, applied at the mirrors with the normals u and $(u+u')/\sqrt{2}$; the labels ride along, the one number $\sigma(\theta_u \bar{F} \cdot \tau_w F)$ being read in the two pictures. (b) By the symmetry of σ (the entries commute) one and the same number $\sigma(A \cdot \tau_x B)$ is a matrix element in every picture whose mirror separates A from $\tau_x B$, also when x has gone around A. After a cut $|q \cdot u''| \geq \kappa$ in the momentum normal to the plane of the eight normals n_β, which is common to the eight pictures, this gives eight complex measures m_β, $\beta \in \frac{\pi}{4}\mathbb{Z}$, carried by V by (a) in each picture, whose Laplace–Fourier transforms $\int \exp(2RE - \rho[E\cos(c-\beta) - iq\sin(c-\beta)])\, dm_\beta$ agree wherever two of them are defined, by the uniqueness of the Fourier transform in the common momentum; the one of the picture u is positive after the weight e^{2RE}, and by (a) at the fifth mirror the one of the picture n_{β_1} is carried by $\{E \geq |q \cdot u''|\} \subset \{E \geq \kappa\}$.

Clause (c) gives $\mu(\{E^2 - q^2 < \kappa^2\}) = 0$ for every $\kappa > 0$, and so the circular cone in each picture. (c) Write $c = t + i\gamma$. On V, $E\cosh\gamma + q\sinh\gamma \geq Ee^{-|\gamma|}$; so on $S_\beta(\rho) = \{\rho\cos(t-\beta)e^{-|\gamma|} > 2R\}$ the integrand of f_β is bounded by 1, and $f_\beta(\cdot;\rho)$ is holomorphic there (Morera), bounded by C and of the period 2π. The sets $S_\beta(\rho)$ cover the band $\{|\gamma| < \Gamma(\rho)\}$, $\Gamma(\rho) = \log(\rho\cos\frac{\pi}{8}/2R)$, and two of the functions agree on real intervals of the overlaps, hence on the overlaps (identity theorem): they glue to one holomorphic function $f(\cdot;\rho)$ on the band, $|f| \leq C$.

Near β_1, $|f(c;\rho)| \leq Ce^{-\kappa\rho_\delta}$ for $|c - \beta_1| \leq \delta$, $\rho_\delta = \rho e^{-\delta}\cos\delta - 2R$, by the carrier of m_{β_1}. With $N(c) = \log|2\sin((c-\beta_1)/2)|$, harmonic off $\beta_1 + 2\pi\mathbb{Z}$, the function $\log|f| - \log C + \kappa\rho_\delta h$, $h = (\mathsf{M} - N)/(\mathsf{M} + \log(2/\delta))$, $\mathsf{M} = \log(2\sinh(\Gamma'/2))$, $\Gamma' = \Gamma(\rho) - 1$, is subharmonic on the band $\{|\gamma| < \Gamma'\}$ without the discs $|c - \beta_1 - 2\pi k| \leq \delta$ and ≤ 0 on its boundary; by the maximum principle $|f| \leq Ce^{-\kappa\rho_\delta h}$ there. At the points $i\gamma_0$, $f(i\gamma_0;\rho) = \int \exp(-\rho(E\cosh\gamma_0 + q\sinh\gamma_0))\, d\mu$ is the Laplace transform of the positive measure μ, and $h(i\gamma_0) \to 1$ as $\rho \to \infty$. For fixed $\gamma_0 \neq 0$, choose $\delta > 0$ small enough that $i\gamma_0$ lies outside the excluded discs. First letting $\rho \to \infty$ and then $\delta \downarrow 0$ gives $E\cosh\gamma_0 + q\sinh\gamma_0 \geq \kappa$ almost everywhere. Apply this first on a countable dense subset of $\mathbb{R} \setminus \{0\}$ and use continuity in γ_0; the inequality then holds for every real γ_0 on one set of full measure, and the infimum over γ_0 of the left member is 0 if $E = |q|$ and $(E^2 - q^2)^{1/2}$ if $E > |q|$. □

Proposition 2.18 (Ordered classes and kernels; for data with the square cone)**.** Let σ be a real symmetric multilinear functional on labelled tuples with bounds $C_n(d;R)\prod_a |H_a|_\infty$ independent of the position, invariant under $\mathbb{R}^3 \rtimes W_3$, with $\sigma(\theta\bar{F} \cdot F) \geq 0$ on $\mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$ and with $\mathcal{P}$ carried by the square cone.

(a) $\mathcal{H}^{\mathrm{ord}}(\sigma) = \mathcal{H}(\sigma)$; two such functionals that agree on the tuples ordered in the third coordinate are equal.

(b) If σ^1 satisfies besides $(\mathrm{Rec4})_V$ with C_V, p and $c_0 = \frac{1}{2}$, then the slab operators of tuples with entries side by side, the kernels and the bounds of Theorem C (g) hold for σ, with $\mathsf{K}_n = (10n)^{\lceil pn\rceil n(n-1)/2}$; σ does not charge the configurations with two equal heights.

(c) If moreover the scalar part of σ is scalar reconstruction data, the kernel of one tensor entry among m scalar entries is real-analytic at all non-coinciding points, for every m.

■

Proof sketch. (a) By the bounds the class of a tuple depends continuously, in the sup norm, on its entries; so it suffices to show $[X] \in \mathcal{H}^{\mathrm{ord}}(\sigma)$ for $X \in \mathfrak{S}_V(\mathbb{E}_+)$ with smooth entries. A partition of unity of a small mesh cuts X into tuples $Y = (g_1, \ldots, g_n)$ on *frames*: g_a is carried by a box Q_a with sides at most $2r$, the boxes lie in $\{x_3 \geq 2t_1\}$ and are pairwise at sup distance $\geq 4nr$, for some $r, t_1 > 0$. A pair $\{a,b\}$ is *bad* if the intervals of the heights of Q_a and Q_b meet; without bad pairs Y is ordered. Induction on the number of the bad pairs. A bad pair $\{a,b\}$ is parted by a vertical cut, a plane $\{x_\mu = c\}$, $\mu \in \{1,2\}$, at a distance $\geq r$ from every box, with Q_a and Q_b on different sides:

in the direction μ in which Q_a and Q_b are $4nr$ apart, the gap between them leaves an interval of length $\geq (4n-2)r$ for c, of which the other $n-2$ boxes forbid at most $(4n-8)r$.

Let Y_{L}, Y_{R} be the groups of the entries on the two sides, Y_{R} holding g_b. The lifted vector $u(\mathsf{h}) = [Y_{\mathsf{L}} \cdot \tau_{\mathsf{h}e_3} Y_{\mathsf{R}}]$, $\mathsf{h} > -t_1$, lies in $\mathcal{H}^{\mathrm{ord}}(\sigma)$ for large h by the induction, as the lifted frame has a bad pair fewer. Its Gram kernel across the diagonal is $\langle u(\mathsf{h}_0+x-y), u(\mathsf{h}_0+x+y)\rangle = \sigma(A \cdot \tau_{ye_3} B_{\mathsf{h}_0+x})$ with $A = \theta Y_{\mathsf{L}} \cdot Y_{\mathsf{L}}$ and $B_s = \tau_{-se_3}\theta Y_{\mathsf{R}} \cdot \tau_{se_3} Y_{\mathsf{R}}$: as θ reverses the heights, y moves each group rigidly together with its mirror copy. The plane $\{x_\mu = c\}$ parts A from B_s; in the picture of its normal e_μ, which an element of W_3 turns into e_3, this number is $\langle \Phi_A, e^{-rH}\mathcal{U}(ye_\mu)\Phi_B\rangle$, the norms of Φ_A, Φ_B being bounded by the position-free bounds at $4\#\mathsf{L}$ and $4\#\mathsf{R}$ entries, and by the square cone $|\partial_y^j \sigma(A \cdot \tau_{ye_3} B_s)| \leq (j/er)^j \|\Phi_A\| \|\Phi_B\|$ for every j: this is the only use of the cone.

The norm of the Fourier transform of a windowed curve reads the Gram kernel at the frequencies $(p, -p)$ alone, that is across the diagonal; with windows that are $(2q+1)$-fold convolutions of indicator functions, whose derivatives of the orders $j \leq 2q$ are at most $(24q)^j$ on the unit scale, Lemma 5.28 (b) gives real-analyticity of u in norm on $(-\frac{5}{8}t_1, \infty)$. So for $\psi \perp \mathcal{H}^{\mathrm{ord}}(\sigma)$ the real-analytic function $\mathsf{h} \mapsto \langle \psi, u(\mathsf{h})\rangle$ vanishes for large h, hence at $\mathsf{h} = 0$: $\psi \perp [Y]$. For the second clause let σ' be the other functional. Then $\frac{1}{2}(\sigma + \sigma')$ satisfies what the Proposition supposes: its classes are carried isometrically into $\mathcal{H}(\sigma) \oplus \mathcal{H}(\sigma')$ by $[F] \mapsto 2^{-1/2}([F]_\sigma, [F]_{\sigma'})$, which intertwines the translations, so that its spectral measure is carried by the square cone.

A combination G of ordered tuples whose class is close to that of X for $\frac{1}{2}(\sigma + \sigma')$ is close to it in $\mathcal{H}(\sigma)$ and in $\mathcal{H}(\sigma')$ at once; $|\sigma(F)| = |\langle \Omega, [F]\rangle| \leq \|[F]\|$ for F over $\mathbb{E}_+$, and $\sigma(G) = \sigma'(G)$; so $\sigma(X) = \sigma'(X)$ for X over $\mathbb{E}_+$, and for every X by a translation. (b) For points $z_a = (\vec{x}_a, t_a)$, t_a complex, whose real heights lie in $(0, l)$ and are pairwise different, $\mathsf{G}_l(z; e)$ is the product, in the order of increasing height, of the point operators $\mathsf{b}(\cdot|e_a|\cdot)$ with the semigroup factors between them, the first factor taking the lowest point and the last factor le_3 minus the highest point; the point operators are those that $(\mathrm{Rec4})_V$ gives on the square tube $\{d_\square > 0\}$, as in the sketch of Proposition 2.16 (a) with the square cone in the place of the circular one, with the bound of Theorem C (d) (ii); so G_l is holomorphic on the union of the tubes of the orders in height and bounded by a power of the least gap.

Two fields side by side, at the horizontal sup distance $\gamma = |\vec{x}_a - \vec{x}_b|_\infty > 0$, are one holomorphic function of their two heights across the wall $\operatorname{Re} t_a = \operatorname{Re} t_b$, for $|\operatorname{Im}(t_a - t_b)| < \gamma$. At a point of the wall, $\operatorname{Re} t_a = \operatorname{Re} t_b = T_0$, put $\zeta = t_a - t_b$, $\tau_0 = \operatorname{Im}\zeta \in (-\gamma, \gamma)$, $\kappa = \frac{1}{2}\min\{1, T_0, l - T_0, \gamma - |\tau_0|\}$, m_1 the least integer $\geq 2p$, and $\mu(\zeta) = (\zeta - i\tau_0)^2 + \kappa^2$. On the circle $|\zeta - i\tau_0| = \kappa$ one has $|\mu(\zeta)| = 2\kappa|\operatorname{Re}\zeta|$; so $\mu(\zeta)^{-m_1}$ times the Cauchy integral of $\mu^{m_1}\mathsf{G}_l$ over this circle is formed, the bound $C|\operatorname{Re}\zeta|^{-2p}$ of G_l off the wall being absorbed, and it is holomorphic inside.

It is the continuation: its matrix elements between $\mathcal{U}(v)[F']$ and $\mathcal{U}(w)[F]$ are holomorphic in v, w for $|\operatorname{Im} v_1| + |\operatorname{Im} v_2| < \frac{\kappa}{2}$, and so are those of G_l, by the square cone; for real v, w far out along e_k in opposite senses, $k \in \{1, 2\}$ the direction with $|x_{a,k} - x_{b,k}| = \gamma$, the spectators and the two fields are ordered along e_k, and in the frame of W_3 that turns e_k into e_3 the kernel is holomorphic across $\operatorname{Re}\zeta = 0$ for $|\operatorname{Im}\zeta| < \gamma$, so that the two agree there; the identity theorem in (v, w) carries the agreement to $v = w = 0$. *The bound by the least distance.* Let $0 < d \leq 1$ with $d \leq \operatorname{Re} t_a \leq l - d$ for all a and, for every pair $\{a, b\}$, $|\operatorname{Re}(t_a - t_b)| \geq d$ or $|\vec{x}_a - \vec{x}_b|_\infty - |\operatorname{Im}(t_a - t_b)| \geq d$.

On the disc $t_a(\lambda) = t_a + a\lambda$, $|\lambda| < d/(3n)$, on which the a-th point moves with the velocity a, the walls of the pairs $\{a, b\}$ with $|\operatorname{Re}(t_a - t_b)| < d$ are the lines $\operatorname{Re}\lambda = -r_{ab}$, $r_{ab} = \operatorname{Re}(t_a - t_b)/(a - b)$, which may be supposed pairwise different. With $d_n = d/(4n)$ and $m_2 = \lceil pn \rceil$ the multiplier $Q(\lambda) = \prod_{\{a,b\}}(\lambda^2 + 2r_{ab}\lambda + d_n^2)^{m_2}$, the product over these pairs, has the modulus $\prod(2d_n|\operatorname{Re}\lambda + r_{ab}|)^{m_2}$ on the circle $|\lambda| = d_n$ and $d_n^{2m_2 P}$ at $\lambda = 0$, P the number of these pairs; $Q\mathsf{G}_l$ continues across the walls by the clause on two fields, and the maximum principle at $\lambda = 0$ gives the factor K_n.

The slab operators. Every family of small sets at mutual distances larger than n times their diameters can be cut by a coordinate plane into two non-empty groups; with this, an induction on n

shows $[M \cdot \tau_{le_3} F] = \mathsf{I}_l(M)[F]$, $\mathsf{I}_l(M)$ the integral of G_l over the configurations with different heights, whose complement is a null set. For a cut by a plane $\{x_3 = c_1\}$ the two groups give a product of two operators of the induction. For a cut by $\{x_k = c_1\}$, $k \in \{1,2\}$, let $\eta > 0$ with $\operatorname{supp} M \subset \{\eta < x_3 < l - \eta\}$: the difference of $\sigma(\theta\overline{\tau_{(v,0)}F'} \cdot M \cdot \tau_{le_3}\tau_{(w,0)}F)$ and $\langle \mathcal{U}(v)[F'], \mathsf{I}_l(M)\mathcal{U}(w)[F]\rangle$ is holomorphic in v for $|\operatorname{Im} v_1| + |\operatorname{Im} v_2| < \eta$ at real w, and in w at real v, by the square cone; it vanishes when v and w are far out along e_k in opposite senses, where the groups and the spectators are ordered along e_k and the induction applies, in the frame that turns e_k into e_3, to the turned groups; the identity theorem, first in v and then in w, gives it at $v = w = 0$. (c) Fix non-coinciding points $x^0, y^0_1, \dots, y^0_m$.

For each k choose a coordinate plane $\{x_{\mu_k} = c_k\}$ strictly between x^0 and y^0_k, in the direction μ_k in which they are farthest apart, at a positive distance from all the points; an element of $\mathbb{R}^3 \rtimes W_3$ turns it into $\{x_3 = 0\}$ with y^0_k above, and on that side stand scalar points alone. For entries $h, f_1, \dots, f_m$ carried by small cubes about the points, $W(v) = \sigma(h, \tau_{v_1} f_1 \mathbf{1}, \dots, \tau_{v_m} f_m \mathbf{1})$ is, in the picture of that plane, the scalar product of the class of the entries below it, the tensor entry among them, with the class $[F_v]$ of the scalar entries above it. The latter is an integral of scalar point vectors, which are holomorphic in their points, in norm and uniformly on compact sets, because their Gram kernel $\mathsf{s}_{2n}(\theta\eta, \eta')$ is real-analytic (Proposition YMM1:108.3, the scalar part being scalar data) and Cauchy's estimates of a Gram kernel bound the derivatives of the vectors; the former is bounded by the position-free sup bounds at two tensor entries.

So W is holomorphic in each v_k apart, the others being real, with one bound $C \sup|h| \prod_k \sup|f_k|$; by the bound of the Chebyshev coefficients (Bernstein), a continuous function on a cube that is holomorphic in each variable apart, on ellipses about the real intervals, with one bound, is holomorphic in all the variables together on a smaller polyellipse. The translations move the tensor point as well. Cauchy's estimate for the derivatives in a shift, with $\int \omega(u)\tau_u H \, du = \omega * H$, replaces the sup norm of one entry by its L^1 norm, entry after entry; so the values of σ at bumps of shrinking width about the points converge uniformly on a polydisc about (x^0, y^0), and the limit is a real-analytic kernel there.

These neighbourhoods cover the non-coinciding configurations; a partition of unity gives the formula of the kernel for all tuples, and the bumps its uniqueness. □

Proposition 2.19 (Covariance of the tensor limits under O(3))**.** (a) Let $0 < g \le \gamma^{\mathrm{sd}}_W$. Every tensor limit σ at g satisfies $\sigma(\mathsf{R}X) = \sigma(X)$ for all $\mathsf{R} \in \mathrm{O}(3)$ and all $X \in \mathfrak{S}_V(\mathbb{R}^3)$. By Lemma 2.14 (b), since the dilations commute with O(3), the same holds for the tensor limits at every $0 < g \le \gamma$.

(b) *(For data.)* Let σ be a real symmetric multilinear functional on labelled tuples with $\sigma(\varnothing) = 1$, $\sigma((H)) = 0$, bounds independent of the position, invariant under $\mathbb{R}^3 \rtimes W_3$, reflection positive at the coordinate and diagonal mirrors, with $H \ge |P_1|, |P_2|$. Suppose: (i) bounded slab operators $\mathsf{B}_l(h)$ exist; (ii) for every off-diagonal label $o = e_\mu e_\nu^{\mathrm{T}} + e_\nu e_\mu^{\mathrm{T}}$, $\mu \ne \nu$, every $0 < d < 1$ and every real continuous h carried by a ball $B(x_0, d)$ with $x_{0,3} \in [\frac{3}{2}d, 2d]$, $\sigma(\theta(ho), (ho)) \le C|h|^2_\infty$; (iii) for the scalar part: there are a real $a < 4$ and, for every real $\varphi \in C^1_c(\mathbb{R})$, a number C_φ with $\sigma(\theta(f\mathbf{1}), (f\mathbf{1})) \le C_\varphi t^{-a}$ for all $t \in (0,1]$ and all $f(x) = \alpha(x_3, x_1)\varphi(x_2)$, α a real C^1_c function carried by $[t, 2t] \times [-t, t]$ with $|\alpha| \le 3$ and $\operatorname{Lip}\alpha \le 12/t$; (iv) the class of the tuple $(H^{\mathrm{cons}}[\eta])$ vanishes in $\mathcal{H}(\sigma)$ for η carried by $\mathbb{E}_+$; (v) for one $p < \infty$, $\|\mathsf{B}_{2d}(\tau_{de_3}h)\| \le C \min\{1, d - d'\}^{-p} \|h\|_{L^1}$ for h carried by $\{|x_3| \le d'\}$.

Then $\sigma(\mathsf{R}X) = \sigma(X)$ for all $\mathsf{R} \in \mathrm{O}(3)$ and all X, and $\sigma((H^{\mathrm{cons}}[\eta]) \cdot X) = 0$ for every X off $\operatorname{supp}\eta$. In (v) a weaker growth suffices. Write $y = (y^0, y^1) = (x_3, x_1)$ for the points of the plane of e_3, e_1, $\xi^\pm = \xi^0 \pm i\xi^1$ for $\xi \in \mathbb{C}^2$, $d(\xi) = \min \operatorname{Re}\xi^\pm$, $\mathrm{Tb} = \{\xi : d(\xi) > 0\}$, $\mathsf{Z}(\kappa) = \int e^{-\kappa^0 E + i\kappa^1 q_1} \, d\mathcal{P}$ for κ in the closure of Tb, and R_ζ for the rotation about e_2 by the angle ζ, continued to complex ζ by $(\mathsf{R}_\zeta\xi)^\pm = e^{\pm i\zeta}\xi^\pm$. Under (i) there is, for every label $\lambda = (\varphi, a)$, $\varphi \in C^1_c(\mathbb{R})$ real and $a \in V_{\mathbb{C}}$, exactly one family of bounded operators $\mathsf{B}_\lambda(\xi, \xi')$, $(\xi, \xi') \in \mathrm{Tb}^2$, holomorphic in norm, with $\mathsf{Z}(\kappa)\mathsf{B}_\lambda(\xi, \xi')\mathsf{Z}(\kappa') = \mathsf{B}_\lambda(\kappa + \xi, \xi' + \kappa')$

and $\mathsf{B}_l(h) = \int \alpha(y)\, \mathsf{B}_\lambda(y, le_3 - y)\, dy$ for the plates $h(x) = \alpha(x_3, x_1)\varphi(x_2)a$ with α carried by $\{0 < y^0 < l\}$: the *point plates*.

The *plate vectors* are $\Psi(z; \lambda_1, \dots, \lambda_j) = \mathsf{B}_{\lambda_1}(z_1, \frac{1}{2}(z_2 - z_1)) \cdots \mathsf{B}_{\lambda_j}(\frac{1}{2}(z_j - z_{j-1}), \kappa)\Omega$, which do not depend on $\kappa \in \mathrm{Tb}$. It suffices that for every j there is $A_j \geq 0$ with $\sup_{s\in\mathbb{R}} e^{-A_j|s|}\|\Psi(\mathsf{R}_{is}z; \lambda_1, \dots, \lambda_j)\| < \infty$ uniformly on the compact sets of real z whose z_1 and differences $z_{i+1} - z_i$ lie at angles $< \frac{5\pi}{16}$ from e_3, the labels running over a basis of $V_{\mathbb{C}}$ of eigenvectors of the rotations about e_2, with $\liminf_j (A_j - j^2)/j = -\infty$; with the diagonal mirrors, $\liminf_j A_j/j^2 < 2$ suffices. Of the scalar part only the bound (iii) is used, at one step of the proof; its covariance is a case of the conclusion.

The free model formed by the tensor of free photon fields with $\epsilon\, \delta_{\lambda\lambda'}\partial_\lambda^2\chi$ added, χ a free massive scalar field and $\epsilon \neq 0$, has the other properties and fails exactly (iv).

■

Proof. In (b), the normalization, multilinearity, bounds, cubic invariance, reflection positivity and square spectral cone are precisely (D1)–(D4) of Definition 5.1. Conditions (i), (ii), (iv) and (v) give (S), (O), (N) and (P), respectively. Theorem T proves the two conclusions. For the alternative growth hypotheses, Proposition 5.31(a) first gives covariance at pairs from (O) and (N), and Proposition 5.34 gives covariance at every order. The final conservation assertion follows from the null-vector identity by Lemma 5.30(c).

For (a) at $g \leq \gamma_W^{\mathrm{sd}}$, Theorem C supplies the slab and integrable insertion bounds. Theorem G(E4)(i) supplies the scale-independent off-diagonal bound. Theorem E(c), applied to $H^{\mathrm{cons}}[\eta]$ and its reflected member, gives (N). Theorem C and its proof supply (D1)–(D4), so Theorem T applies. Lemma 2.14(b) gives the assertion at every $g \leq \gamma$, since dilations commute with rotations. These inputs use the cutoff estimates and conservation argument, before the Wightman reconstruction of Theorem D. □

Lemma 2.20 (Mirrors)**.** (a) For unit vectors m, n, $\mathsf{R} \in \mathrm{O}(3)$ with $\mathsf{R}m = n$, $c \in \mathbb{R}$ and $\mathsf{g}x = \mathsf{R}x + cn$: $\mathsf{g}\{m \cdot x > 0\} = \{n \cdot x > c\}$ and, with $\theta_m = \theta_{m,0}$, $\theta_{n,c} = \mathsf{g}\theta_m\mathsf{g}^{-1}$ on points, on labelled tuples and on their combinations. $\rho(\Theta_n)$ is $+1$ on $\mathbb{R}nn^{\mathrm{T}} \oplus \{E : En = 0\}$ and -1 on $\{nm^{\mathrm{T}} + mn^{\mathrm{T}} : m \perp n\}$; a mirror outside the nine lattice families mixes the diagonal and the off-diagonal labels, and $\Theta_n \in W_3$ if and only if n is one of the eighteen normals of these families.

(b) A functional invariant under the translations and under $\mathrm{O}(3)$ and reflection positive at one plane is reflection positive at every plane.

(c) Let σ be a real symmetric multilinear functional with bounds, invariant under the translations and reflection positive at the nine lattice families of mirrors. A functional reflection positive at a mirror is invariant under its reflection, labels turned; a closed subgroup of $\mathrm{O}(3)$ that contains W_3 and one element more is $\mathrm{O}(3)$. Hence reflection positivity at a single plane whose normal is not one of the eighteen is equivalent to covariance under $\mathrm{O}(3)$; the set of the mirrors of σ is the nine families or all planes, and there are functionals with exactly the nine.

■

Proof sketch. (a) is linear algebra: $\Theta_n E \Theta_n = E - 2n(\underline{En})^{\mathrm{T}} - 2(En)n^{\mathrm{T}} + 4(n \cdot En)nn^{\mathrm{T}}$. (b) follows from (a): $\sigma(\theta_{n,c}\bar{F} \cdot F) = \sigma(\mathsf{g}(\theta_m\overline{\mathsf{g}^{-1}F} \cdot \mathsf{g}^{-1}F)) = \sigma(\theta_m\overline{\mathsf{g}^{-1}F} \cdot \mathsf{g}^{-1}F) \geq 0$. (c) Positivity at the mirror $\{n \cdot x = c\}$ makes the form $(F, F') \mapsto \sigma(\theta_{n,c}\bar{F} \cdot F')$ Hermitian; at $F' = \varnothing$, σ being real, this gives $\sigma(\theta_{n,c}X) = \sigma(X)$ for the tuples X carried by $\{n \cdot x > c\}$, and for every tuple X, with s so large that $\tau_{sn}X$ is carried there, $\sigma(X) = \sigma(\tau_{sn}X) = \sigma(\theta_{n,c}\tau_{sn}X) = \sigma(\tau_{-sn}\theta_{n,c}X) = \sigma(\theta_{n,c}X)$ by the invariance under the translations.

So σ is invariant under the reflection at every mirror at which it is reflection positive, labels turned, and with the translations under the reflection Θ_n in the parallel plane through 0. The nine

reflections of the lattice families generate W_3; so the group of the elements of O(3) under which σ is invariant, which is closed by the bounds, contains W_3; the octahedral group W_3 is a maximal finite subgroup of O(3), so a closed subgroup containing one element more is infinite and contains a one-parameter group of rotations; since W_3 acts irreducibly on $\mathbb{R}^3$, the conjugates of its axis generate SO(3), and with $-1 \in W_3$ the group is O(3).

For the last clause let σ be a tensor limit at $g \le \gamma_W^{\mathrm{sd}}$, covariant by Theorem D (a), let $z \neq \pm 1$ be real and Z_z the linear map of V that is the identity on the diagonal and the factor z on the off-diagonal matrices. It commutes with $\rho(W_3)$, so $\sigma \circ Z_z$, Z_z applied to every entry, is real, symmetric and multilinear, keeps the bounds and the translations, and is reflection positive at the nine families. Were it covariant, the rotation by $\frac{\pi}{4}$ about e_3, which carries $o = e_1 e_2^{\mathrm{T}} + e_2 e_1^{\mathrm{T}}$ to the diagonal label $e_2 e_2^{\mathrm{T}} - e_1 e_1^{\mathrm{T}}$, would give $(z^2-1)\sigma(h_1 o, h_2 o) = 0$ for all real h_1, h_2 with disjoint supports, against the free law (E6) of Theorem G, by which $\sigma(\theta(\varphi o), \varphi o) > 0$ for a small bump φ.

So the mirrors of $\sigma \circ Z_z$ are exactly the nine families. □

Proposition 2.21 (The lattice stress identity; the remainder; one cell)**.** Let $0 < g \le \gamma$, let $\ell' = 2\mathsf{l}$ be one side of $\mathfrak{L}(g)$, fixed once, and let (K, β) be first-passage data at g.

(a) *(Identity.)* For $\eta \in C_c^2(\mathbb{R}^3; \mathbb{R}^3)$ there is an exact identity of functions on the configurations of the torus

$$b\,\mathcal{T}_K(H^{\mathrm{cons}}[\eta]) = \mathcal{N}_\eta - \tfrac{1}{4}\mathfrak{N}[\mathsf{k}_\eta] - c_\eta - \sum_{e=1}^{9} \mathfrak{J}_e[\eta],$$

where $\mathcal{N}_\eta$ and $\mathfrak{N}[\mathsf{k}_\eta]$ are null terms: every joint cumulant of order ≥ 2 on $T_{\ell'}$ with a null term in one slot and, in the others, bounded functions of the bonds at sup distance $> a_K$ from $\operatorname{supp}\eta$, vanishes; c_η is a constant; and the $\mathfrak{J}_e[\eta]$ are nine local lattice remainders, entries of order ≥ 2 in the field strength, with real weights at most $(3 + 60L(g^{-2} + \bar{B}))L^{2K}\|\eta\|_{C^2}$, carried within sup distance $4a_K$ of $\operatorname{supp}\eta$. Among them is the renormalised remainder of the stress identity, with a size $\mathsf{H}(\eta)$ at most a multiple of $\|\eta\|_{C^2}$.

(b) *(Remainder.)* Let $0 < \phi \le \frac{1}{84}$, $u = \lceil \phi K \rceil$, $t = K - u$, and let $\omega_t(\mathfrak{J})$ be the distance from the constants, in the sup norm on the configurations without large fields, of the conditional mean of $\mathfrak{J}$ given the block fields at the level t. There are C_ω, p_ω (formed from the constants, g, ℓ', ϕ) and, for a margin $0 < \delta \le \frac{1}{8}\mathsf{l}$, a cutoff K_{B} (formed from these and δ) such that for $K \ge K_{\mathrm{B}}$, every board of side l whose offset lies in $a_{K-t}\mathbb{Z}^3$, every cell, every η with $\|\eta\|_{C^2} \le 1$ carried in it with margin δ, and every mirror copy: $\sum_e \omega_t(\mathfrak{J}_e[\eta]) \le \varpi_{\mathrm{s}} = C_\omega K^{p_\omega} L^{3u - K/28}$, while for $\mathcal{T}_K(H)$ with $|H|_\infty \le 1$, $\omega_t \le \varpi_{\mathrm{T}} = C_\omega K^{p_\omega} L^{4u}$; and $L^{-K} \le \varpi_{\mathrm{s}} \le \varpi_{\mathrm{T}} \le L^K$. The renormalised remainder $\mathcal{S}[b\eta]$ of the stress identity, a density of the third order, has a conditional mean that is a number up to a small error: for $0 < \tau \le \frac{1}{4}$ there are C_{HR}, p_{HR} (formed from the constants, g, ℓ', ϕ, τ) and a number $\mathsf{a}[\eta]$, linear in η, with

$$\big|(\mathsf{Q}_{t\leftarrow 0}\mathcal{S}[b\eta])(V) - \mathsf{a}[\eta]\big| \le C_{\mathrm{HR}}\,\mathsf{H}(\eta)\,K^{p_{\mathrm{HR}}} L^{-c_0' K}, \qquad c_0' = \min\{\tfrac{1}{14} - \tfrac{\tau}{7},\ \tfrac{1}{14} - 3\phi\},$$

for almost every block field V of the level t without large fields, $\mathsf{Q}_{t\leftarrow 0}$ the conditional mean given the block field of the level t and $\mathsf{H}(\eta) = \max_\rho \sup|\eta^\rho| + \max_\rho \operatorname{Lip}\eta^\rho$. This holds also when sources enter the chain; at the source 0, the case here, $\min\{\frac{1}{10} - \frac{\tau}{5}, \frac{1}{10} - 3\phi\}$ may be taken in the place of c_0'. At $\tau = \frac{1}{4}$, $c_0' \ge \frac{1}{28}$, so that $\omega_t \le C_{\mathrm{HR}}\mathsf{H}(\eta)K^{p_{\mathrm{HR}}}L^{-K/28}$.

(c) *(One cell.)* Let $m \ge 1$, $0 < \delta \le \frac{1}{8}\mathsf{l}$. There are pure numbers C_m and a cutoff K_{P} (constants, g, ℓ', ϕ, m, δ) such that for $K \ge K_{\mathrm{P}}$, every $d > 0$ with $dL^u \ge K^2$, every board and cell as in (b), and slots $\mathsf{X}_1, \dots, \mathsf{X}_m$ in the cell with margin δ, each of them $\mathcal{T}_K(H_a)$ or $\mathcal{T}_K(H^{\mathrm{cons}}[\eta_a])$ or one of the terms of (a), with supports pairwise at sup distance $\ge d$,

$$\Big\| \prod_{a=1}^{m} \big(\mathsf{X}_a - \langle \mathsf{X}_a \rangle_{K,\ell',\beta}\big) \Big\|_{\mathrm{ch},\ell'} \le \mathsf{C}_m \prod_{a=1}^{m} \varpi(\mathsf{X}_a)\,\mathsf{n}(\mathsf{X}_a),$$

$\varpi = \varpi_{\mathrm{T}}$ for the tensor slots and ϖ_{s} for the others, n the norm $|H_a|_\infty$ or $\|\eta_a\|_{C^2}$.

■

Proof sketch. (a) is the Ward identity of the lattice stress tensor: the Haar measure is invariant under the local variation $U(\mathfrak{b}) \mapsto e^{tX_\mathfrak{b}} U(\mathfrak{b})$ along the field k_η obtained from η, and the derivative at $t = 0$ of the mean of a product with this variation in one place, integrated by parts on SU(2) against the Wilson weight, is the null term; the variation of the action is $b\,\mathcal{T}_K(H^{\mathrm{cons}}[\eta])$ up to the remainders, which are of order ≥ 2 in the field strength or carry a factor a_K. (b) In the setting (Th) of Section B.13 with the top level t (Lemma YMM1:118.1), the conditional means $\mathsf{Q}_{t\leftarrow 0}$ given the block fields form a tower of averages along the small-field chain of Proposition YMM1:115.2, with the flows of Proposition YMM1:114.2; they contract in the sup norm over the field cuts (the definitions preceding Lemma YMM1:113.10, Lemma YMM1:113.10).

The renormalised remainder $\mathcal{S}[b\eta]$ is an insertion of the third order; carried through the tower to first order in its parameter, it is the sum of its value at the background of a level $n_0 = K - \lceil K/7 \rceil$ and of the births of the steps, carried on by chains of averaging operators that are stopped at levels fixed by the count of their members. Five inputs enter. (1) The linearisation of a step: the derivative of the output of one step (Proposition E.7) with respect to the parameter of the family of the cubic potential, added to the fourth argument of the step, is a pointed family of the next level, linear in the weight; these derivatives are the births. (2) The size of the insertion at the background of the level n_0: at most a multiple of $\ell'^3 L^{3K-6n_0}$ times the cube of the radius of the field cuts there and the weight. (3) Parity: the part of a birth that is even in the fluctuation field vanishes to the second order, and the odd part enters evenly; this bounds the norm of the birth of the step $k+1$ by $C(\log x_k)^{\mathfrak{p}_0} g_k^2 L^{-3k}$ times the weight. (4) The Hölder continuity of the backgrounds: in a local gauge on a cube about a site (Theorem BT) a regular configuration is e^{ihA} with A, ∇A small and ∇A Hölder continuous. (5) The comparison of a regular configuration with its mirror image under the inversion in a site: the cubic density is odd under this inversion (Proposition H.1(c)), and in the gauge of (4) the part of the potential that is even under the inversion is of the second order in the ratio of the scales, the odd part smaller by a further power of it, so that the local terms at a site vanish to the second order.

The least of the rates of the parts so bounded is c'_0. The nine entries of (a) are bounded one by one, and so are their mirror copies, the mirror maps of a board whose offset lies in $a_{K-t}\mathbb{Z}^3$ preserving the lattices of the levels up to t. The entry $\mathcal{S}[b\eta]$, of the third order with weights of the order L^{2K}, is bounded as just described, at $\tau = \frac{1}{4}$. Five entries of the second order with weights bounded independently of K, a multiple of a_K times a plaquette form among them, and two entries of the third and the fourth order with weights of the order L^K, are bounded by power counting along the chain with one insertion: an entry of the second order has $\omega_t \leq C K^{2\mathfrak{p}_0} L^{4u-K}$ times its weight, an entry of a higher order $\omega_t \leq C K^{3\mathfrak{p}_0} L^{4u-3K/2}$ times its weight.

For the last entry, of the second order with a weight of the order L^K, power counting gives only the size L^{4u} of a tensor entry; its conditional mean is first cut at the level $n_\Delta = K - y$, $y = \lceil K/14 \rceil$, where $\omega_t \leq \epsilon_X + C K^{3\mathfrak{p}_0} L^{3u-K-y/2}$ times the weight, ϵ_X being its supremum on the regular backgrounds of the level n_Δ. By the Hölder continuity of the backgrounds with the exponent $\frac{1}{2}$ (input (4)), $\epsilon_X \leq C K^{2\mathfrak{p}_0} L^{7y/2-K/2} b \sup|\nabla\eta|$, and the second member is at most $C K^{3\mathfrak{p}_0} L^{3u-y/2} b$. As $u \leq \frac{13}{28} K$, all these are at most $C K^p L^{3u-K/28} \|\eta\|_{C^2}$: the rate $\frac{1}{28}$ is fixed by this last entry, through $L^{3u-y/2}$, and by $\tau = \frac{1}{4}$ in the bound of $\mathcal{S}[b\eta]$.

A tensor entry only grows, by at most L^4 per scale over the last u steps: power counting gives $\omega_t \leq C K^{2\mathfrak{p}_0} L^{4u} |H|_\infty$. (c) The eighth power of the seminorm is the mean on $T_{\ell'}$, whose board has eight cells, of the $8m$ mirror copies $Y_{(a,\kappa)}$, all centred. The mean is the sum over the partitions into blocks of at least two members of products of cumulants; in each cumulant every slot may be replaced by its list of entries of (a), since the null terms and constants drop out of cumulants of order ≥ 2 whose other slots depend only on bonds away from their support. The carriers of the

entries of different copies are at sup distance at least $d_\times = \min\{d, 2\delta\} - 8a_K \geq \frac{1}{2}\min\{d, 2\delta\}$, and $d_\times L^{K-i} \geq d_\times L^u \geq \frac{1}{2}K^2$ at the levels $i \leq t$, because $dL^u \geq K^2$ and K_{P} is so large that $2\delta L^{\phi K} \geq K^2$.

A cumulant of $r+1 \leq N = 8m$ such entries is at most $\mathsf{op}_{r+1}\prod_i \omega_t(\cdot)$, with $\mathsf{op}_N = \sum_\pi (|\pi| - 1)!$ over the partitions π of N members, plus two members: $C^N (K^{3\mathfrak{p}_0} L^{2K})^N \mathsf{t}_\times$, with $\mathsf{t}_\times = \sum_{i\leq t} \ell'^3 L^{3(K-i)} e^{-d_\times L^{K-i}/M} \leq CK\ell'^3 L^{3u} e^{-K^2/2M}$, under the condition $32(N+1)C_8\mathsf{t}_\times \leq 1$, C_8 a number formed from the constants; and $4\,\mathsf{op}_{r+1}\mathsf{R}_t \prod \sup|\mathfrak{J}|$, with $\mathsf{R}_t \leq CL^{3u}\exp[-c'A_0^2(\phi K \log L)^{2\mathfrak{p}_0}]$ the weight of the creation of a large field up to the level t, $\mathfrak{p}_0 \geq 1$, and $\sup|\mathfrak{J}| \leq CL^{5K}$: the configurations with large fields, which ω_t does not see, enter here.

This bound comes from the chain with several insertions of disjoint carriers, whose exponents differ from the sum of the exponents with one insertion only by polymers that hold boxes of two insertions; such a polymer has a linear size at least the sup distance of the carriers in the units of its level divided by M, less 2 ((321)), and the sum over these polymers is bounded by the entropy bound of (320). The logarithms of both members are $-cK^2 + O(K\log K)$ with $c > 0$; so for $K \geq K_{\mathrm{P}}$ they are at most $\mathsf{c}_N L^{-2NK}$, c_N a pure number. Every copy lies in exactly one block, so the sum is $\mathsf{Op}_{8m}\prod_a \varpi(\mathsf{X}_a)^8$, Op_N being the sum over the partitions of N members into blocks of at least two members of the products of the numbers op of the blocks, up to a term $\leq L^{-8mK} \leq \prod_a \varpi(\mathsf{X}_a)^8$; take the eighth root, which gives $\mathsf{C}_m = (\mathsf{Op}_{8m} + 1)^{1/8}$. □

Lemma 2.22 (Conservation of kernels and of operators; for data)**.** Let σ' be scalar reconstruction data with a unique vacuum on $\mathcal{H}$, with a tensor of one label satisfying (M1), (M2), forms $\mathfrak{q}_{ij}$ and kernels s_{ij}.

(a) A subspace $\mathcal{V} \subset \mathcal{D}_\infty$, dense in $\mathcal{H}$ and invariant under $e^{-\tau H}$, $\tau > 0$, is a core of $(1+H)^N$ for every N.

(b) $\mathcal{V}_1$, the span of the $e^{-\tau H}[F']$, and, if $\mathcal{H} \neq \mathbb{C}\Omega$, $\mathcal{V}_2$, the span of the $\mathcal{U}(v)\mathsf{B}_0(s,s')[F]$, B_0 the scalar point operators, are such subspaces.

(c) If $\sum_i \int \partial_i\zeta(x)\,\mathsf{s}_{ij}(x;y)\,dx = 0$ for all $m \geq 1$, $y \in (\mathbb{R}^3)^m_{\neq}$ and $\zeta \in C_c^\infty$ off the y_k, then the form $CL_j(\psi',\psi) = \mathfrak{q}_{3j}(H\psi',\psi) - \mathfrak{q}_{3j}(\psi', H\psi) - i\sum_k[\mathfrak{q}_{kj}(P_k\psi',\psi) - \mathfrak{q}_{kj}(\psi', P_k\psi)]$, $P_k = \int q_k\,d\mathcal{P}$, vanishes on $\mathcal{D}_\infty \times \mathcal{D}_\infty$, and $T_{0\nu}(\partial_0 F)\psi = \sum_{k=1,2} T_{k\nu}(\partial_k F)\psi$ on $\mathcal{D}_\infty$. Conversely (M4) (a) gives the identity of the kernels.

■

Proof sketch. (a) A vector orthogonal to $\mathcal{V}$ in the graph norm of $(1+H)^N$ gives a finite measure $(1+E)^N\mu$ that annihilates all the functions $e^{-\tau E}$, hence vanishes by the Stone–Weierstrass theorem. (b) The closure of $\mathcal{V}_2$ reduces H and $\mathcal{U}$ and contains $\phi(f)\mathcal{D}_\infty$, hence all the $\phi(f_1)\cdots\phi(f_n)\Omega$; if it were proper, its orthogonal complement would hold an invariant vector, hence Ω by the unique vacuum, and $\phi(f)\Omega = 0$ would follow. (c) Let $a > 0$, let F', G be scalar tuples over $\mathbb{E}_+$ with smooth entries, $F'(z')$, $G(z)$ the products of their entries at the points z', z, and $P_k = \int q_k\,d\mathcal{P}$, so that $\mathcal{U}(v) = e^{iv\cdot P}$. For $x \neq y$ in $\{|x_3| < a\}$ with $x_3 < y_3$ put

$$\mathsf{s}_{ij}^{F',G}(x,y) = \int \overline{F'(z')}\,G(z)\,\mathsf{s}_{ij}(x;y,\theta(z'+ae_3),z+ae_3)\,dz'\,dz;$$

the operator formula of (M2), the product of the point operator of $\mathfrak{q}_{ij}$ at x and of the scalar point operator at y between $[F']$ and $[G]$, reads $\mathsf{s}_{ij}^{F',G}(x,y) = \mathfrak{q}_{ij}(\psi'_x,\psi_x)$ with $\psi'_x = \mathcal{U}(-\vec{x})e^{-(a+x_3)H}[F']$ and $\psi_x = \mathcal{U}(-\vec{x})e^{-(h_*-x_3)H}\mathcal{U}(\vec{y})\mathsf{B}_0(y_3-h_*, a-y_3)\mathcal{U}(-\vec{y})[G]$, for any $h_* \in (x_3,y_3)$. As $\partial_{x_3}\psi'_x = -H\psi'_x$, $\partial_{x_3}\psi_x = H\psi_x$, $\partial_{x_k}\psi'_x = -iP_k\psi'_x$ and $\partial_{x_k}\psi_x = -iP_k\psi_x$ for $k = 1,2$, one has $\sum_i \partial_{x_i}\mathsf{s}_{ij}^{F',G}(x,y) = -CL_j(\psi'_x,\psi_x)$, and $|CL_j(\psi',\psi)| \leq 6c_T\|(1+H)^{l+1}\psi'\|\,\|(1+H)^{l+1}\psi\|$.

Given $\tau, s, s' > 0$, $v \in \mathbb{R}^2$ and F, the choice $a = \frac{1}{2}(\tau+s+s')$, $x = (0, \tau - a)$, $y = (v, a - s')$, $G = \tau_{(v,0)}F$ gives $\psi'_x = e^{-\tau H}[F']$ and $\psi_x = \mathcal{U}(v)\mathsf{B}_0(s,s')[F]$. The identity of the kernels supposed in (c), integrated against $\overline{F'}G$, kills the divergence near x; so $CL_j = 0$ on $\mathcal{V}_1 \times \mathcal{V}_2$, and on $\mathcal{D}_\infty \times \mathcal{D}_\infty$

by (a), (b) and the bound. Read at $U(b)^{-1}\psi'$, $U(b)^{-1}\psi$, $b \in \mathbb{R}^{1+2}$, multiplied by the test function of the operator identity and integrated by parts in b, this is that identity. Conversely, $\mathcal{D}_0$ is invariant under the operators $U(b)$, so it is a core of every $(1+H)^N$, as in (a) with the group in the place of the semigroup, the finite measure $(1+E)^N\mu$ having a vanishing Fourier transform; the bounds $\|T_{\mu\nu}(F_1)\psi\| \le C\|(1+H)^{2l}\psi\|$ of the operators of (M1) carry (M4) (a) from $\mathcal{D}_0$ to $\mathcal{D}_\infty$, and, the test function being arbitrary, $CL_j = 0$ on $\mathcal{D}_\infty \times \mathcal{D}_\infty$.

At a configuration $(x, y_1, \dots, y_m)$ with pairwise different heights take a slab that holds x and the point next to it in height and no other point; the other points are smeared by bumps into G above and, through their mirror images, into F' below; the divergence of $\mathsf{s}_{ij}^{F',G}$ is $-CL_j(\psi'_x, \psi_x) = 0$, and approximate units for the bumps give $\sum_i \int \partial_i\zeta(x)\,\mathsf{s}_{ij}(x;y)\,dx = 0$ for ζ carried near x. A rotation that makes the heights pairwise different reaches every configuration, by the covariance of the kernels in (M2), and a partition of unity every ζ. □

Lemma 2.23 (Plateaux on the lattice)**.** Let $0 < g \le \gamma_W^{\mathrm{ref}}$, let (K_j, β_j, ν_j) be first-passage data at g with periodic Gibbs states and $K_j \to \infty$, $A_j(X) = A^{\nu_j}_{K_j}(X)$, and $\mathcal{I}$ the invariant σ-field. In (c) let moreover $\sigma(X) = \lim_j \nu_j(A_j(X))$ exist for every $X \in \mathfrak{S}_V(\mathbb{R}^3)$: σ is the tensor limit of the sequence, as in the head of Theorem F.

(a) For n, δ, ϱ there are $c_n(\delta;\varrho)$ and $j_n(\delta;\varrho)$ such that for tuples X, X' of n entries carried by one family of cubes of radius ϱ at distances $\ge \delta$, $j \ge j_n$ and $\rho \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$: $|\rho(A_j(X)) - \rho(A_j(X'))| \le c_n \mathsf{D}(X,X')$, $|E_\rho[A_j(X)|\mathcal{I}]| \le c_n|X|_\infty$ and $|E_\rho[A_j(X) - A_j(X')|\mathcal{I}]| \le c_n \mathsf{D}(X,X')$ almost surely, with $|X|_\infty = \prod_a |H_a|_\infty$ and $\mathsf{D}(X,X') = \sum_a |H_a - H'_a|_\infty \prod_{b<a}|H'_b|_\infty \prod_{b>a}|H_b|_\infty$.

(b) For tuples X, Y in a cube $(-\bar R, \bar R)^3$, j large and lattice vectors v with $|v| \ge 4\sqrt{3}\bar R$: $|\rho(A_j(X \cdot \tau_v Y)) - \rho(E_\rho[A_j(X)|\mathcal{I}]\, E_\rho[A_j(Y)|\mathcal{I}])| \le \mathfrak{k}_0 \mathsf{N}(X)^{1/2}\mathsf{N}(Y)^{1/2}\bar R/|v|$, with numbers N formed from the tuples.

(c) For $X^1, \dots, X^q$ the means $\nu_j(\prod_i \mathsf{e}_j(X^i))$, $\mathsf{e}_j(X)$ a real-valued choice of $E_{\nu_j}[A_j(X)|\mathcal{I}]$, converge, and the limit is the iterated plateau of σ at $(X^1, \dots, X^q)$ (Definition 2.2 (5)): with $G^{(1)}(v_2, \dots, v_q) = \sigma(X^1 \cdot \tau_{v_2} X^2 \cdots \tau_{v_q} X^q)$ where this tuple is formed, the limits $G^{(p)}(v_{p+1}, \dots, v_q) = \lim_{|v_p|\to\infty} G^{(p-1)}(v_p, v_{p+1}, \dots, v_q)$, $p = 2, \dots, q$, exist at every $(v_{p+1}, \dots, v_q)$ for which $X^1 \cdot \tau_{v_{p+1}} X^{p+1} \cdots \tau_{v_q} X^q$ is formed, and the number $G^{(q)}$ is the iterated plateau.

(d) Let $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$, and let σ' be a functional with $\|E_{\rho_j}[A_j(X)|\mathcal{I}] - \sigma'(X)\|_{L^\infty(\rho_j)} \to 0$ for every X, so that $\sigma'(X) = \lim_j \rho_j(A_j(X))$, the products $A_j(X)$ being centred by ν_j and integrated by ρ_j. Then $\lim_{|v|\to\infty} \sigma'(X \cdot \tau_v Y) = \sigma'(X)\sigma'(Y)$.

■

Proof sketch. (a) Multilinearity and the uniform bound of Theorem B (c) (iii), which holds at every $0 < g \le \gamma$ for any two periodic Gibbs states, the one integrating and the other centring, give the first inequality, $j_n(\delta;\varrho)$ being an index from which on K_j is at least the cutoff K^A of that clause at the order n and the distance δ, which exists because $K_j \to \infty$; the invariant-conditioning argument in the proof of Proposition YMM1:100.1, for the class of the periodic Gibbs states at one cutoff, carries it to the conditional expectations given $\mathcal{I}$. (b) is the clustering on one lattice at the rate $ra/|x|_\infty$, Proposition YMM1:99.7, from reflection positivity at the nine families of mirrors of one lattice, applied to the centred products as in Proposition YMM1:100.1; no mass enters, only a power. (c) follows from (a), (b) by induction on q, the plateaux being taken one translation after another. (d) is (b) with the conditional means replaced by constants. □

Lemma 2.24 (Identification of the limits; recentring)**.** (a) A sequence of first-passage data (K_j, β_j) at g, with $K_j \to \infty$ and periodic Gibbs states, whose labels and centred moments on the tuples with C^1_c entries converge has a tensor limit that agrees with its limit on these tuples, with the same label; the restriction of a tensor limit to C^1_c entries is such a limit;

a limit along data whose labels do not converge has a subsequence whose labels converge, since they lie in a compact interval. The lattice observables of the plaquette and bond forms are the same in all these limits.

(b) Let σ^c be a limit of periodic Gibbs states and $m(H) = \frac{c}{3}\int \operatorname{tr} H$. Then $\sigma^{\#}(X) = \sum_S \prod_{a\notin S} m(H_a)\,\sigma^c(X_S)$ is a symmetric functional; since $m(\mathsf{r}H) = m(H)$ for every isometry and $m(H^{\mathrm{cons}}[\eta]) = \frac{c}{3}\int \nabla\cdot\eta = 0$, covariance and conservation pass from σ^c to $\sigma^{\#}$.

(c) For a functional σ_ξ with $s_\xi(H) = \sigma_\xi((H)) = \frac{c_\xi}{3}\int \operatorname{tr} H$, the map $\mathsf{S}_\xi X = \sum_J \prod_{a\notin J} s_\xi(H_a) X_J$ is a bijection of the combinations of tuples, multiplicative for the concatenation, commuting with the conjugation and with every isometry, and $\sigma_\xi = \sigma^c_\xi \circ \mathsf{S}_\xi$ for the recentred σ^c_ξ; $[F]\mapsto[\mathsf{S}_\xi F]$ is unitary and intertwines e^{-tH} and $\mathcal{U}$, and the point operators correspond as $\mathsf{B}(s,s';e) \cong \mathsf{B}^c(s,s';e) + \frac{c_\xi}{3}(\operatorname{tr} e)e^{-(s+s')H}$.

■

Proof sketch. (a) Extraction along a countable family of tuples dense for the uniform norm on each product of compact sets, with the continuity of Theorem C (b); the labels lie in $[g^{-2}, L(g^{-2}+\bar B)]$. (b), (c) are algebra: $\operatorname{tr} H^{\mathrm{cons}}[\eta] = 3\nabla\cdot\eta - 2\nabla\cdot\eta = \nabla\cdot\eta$, and the inverse of S_ξ is the same sum with $-s_\xi$. □

Lemma 2.25 (Extension over the diagonals; contact terms)**.** Let $\mathbb{M}$ be $\mathbb{R}^3$ or a torus T_ℓ, $n\ge 2$, and V a real vector space of finite dimension with a norm. A *functional of n entries* is a map u on the tuples $(f_1,\dots,f_n)$ of functions $f_a \in C_c^\infty(\mathbb{M};V_{\mathbb{C}})$ with pairwise disjoint supports that is n-linear on $\prod_a C_c^\infty(O_a;V_{\mathbb{C}})$ for all open sets O_a with pairwise disjoint closures; the entries may as well take their values in n different spaces $V_1,\dots,V_n$, with $\bigotimes_a V_{a,\mathbb{C}}$ in the place of $V_{\mathbb{C}}^{\otimes n}$ below, and nothing else changes (this is used in (e)). We write $\|G\|_{(h),r} = \max_{|\gamma|\le r} h^{|\gamma|}\sup|\partial^\gamma G|$, on $\mathbb{M}$ and on $\mathbb{M}^n$; $\mathsf{d}_\infty(x) = \min_{a\neq b}|x_a - x_b|_\infty$ for $x\in\mathbb{M}^n$; and $\Delta = \{\mathsf{d}_\infty = 0\}$, the union of the diagonals.

(1) *Strata.* For a partition π of $\{1,\dots,n\}$ with $k = |\pi|$ blocks, $B(a)$ the block of a and $a_B = \min B$: $\Delta_\pi = \{x : x_a = x_b \text{ whenever } B(a) = B(b)\}$, and $\Sigma_k = \bigcup_{|\pi|\le k}\Delta_\pi$, so that $\Sigma_{n-1} = \Delta$. The coordinates at π are $y_B = x_{a_B}\in\mathbb{M}$ and $\xi_a = x_a - x_{a_{B(a)}}$ for $a\neq a_{B(a)}$; $\iota_\pi(y)_a = y_{B(a)}$, so that $\Delta_\pi = \{\xi = 0\} = \iota_\pi(\mathbb{M}^k)$. For a distribution T' on $\mathbb{M}^k$ and a multi-index α of ξ, $(\partial_\xi^\alpha\delta_\pi\otimes T')(F) = (-1)^{|\alpha|}\,T'((\partial_\xi^\alpha F)\circ\iota_\pi)$.

(2) *The bound* $(\mathrm{W};\kappa,q,r)$, $\kappa\in\mathbb{R}$, $q\ge 0$, $r\in\mathbb{N}_0$, with numbers $A, h_0 > 0$ (on T_ℓ: $h_0\in\ell 2^{-\mathbb{N}}$, $h_0\le \ell/(64n)$): for every $0<h\le h_0$, all closed cubes $Q_1^*,\dots,Q_n^*\subset\mathbb{M}$ of the side $\frac{3}{2}h$, wherever they lie, at pairwise sup distances $\ge\frac{5}{2}h$, this lower bound being the only condition on their distances, and all $f_a\in C_c^\infty(\operatorname{int}Q_a^*;V_{\mathbb{C}})$,

$$|u(f_1,\dots,f_n)| \le A\,h^\kappa\,l(h)^q\prod_a \|f_a\|_{(h),r}, \qquad l(h) = 1+\log(h_0/h).$$

(3) *The class.* A function F on $\mathbb{M}^n$ is λ-*supported* if $\operatorname{supp}F\subset\prod_a\{|x_a - z_a|_\infty\le\lambda\}$ for some $z\in\mathbb{M}^n$, the z_a coinciding or not. $\mathfrak{E}_n(\kappa)$ is the set of the $(V_{\mathbb{C}}^{\otimes n})^*$-valued distributions T on $\mathbb{M}^n$ for which there are C, q, m, h_1 with $|T(F)|\le C\lambda^\kappa(1+\log\frac{h_1}{\lambda})^q\|F\|_{(\lambda),m}$ for all $0<\lambda\le h_1$ and all λ-supported F: the *power counting* κ, up to logarithms, also where the points meet. On $\mathbb{M} = T_\ell$ the norms $\|\cdot\|_{(\lambda),m}$, the λ-supported functions, the classes $\mathfrak{E}_n(\kappa)$, the coordinates at π and the distributions $\partial_\xi^\alpha\delta_\pi\otimes T'$ of (1) are those of Definition 2.4. We put $\omega_k = \lfloor 3k-\kappa\rfloor$.

(4) *Whitney products.* A product $Q = \prod_a Q_a$ of half-open cubes $Q_a\subset\mathbb{M}$ of one side $h(Q)\le h_0$ is *admissible* if $\operatorname{dist}_\infty(Q_a,Q_b)\ge 3h(Q)$ for $a\neq b$; $c(Q)$ is its centre, and Q^+, Q^* are the closed concentric products of the sides $\frac{5}{4}h(Q)$ and $\frac{3}{2}h(Q)$, so that the cubes Q_a^* are at pairwise sup distances $\ge\frac{5}{2}h(Q)$. Let $h_j = 2^{-j}h_0$, $j\ge 0$, and let $\mathcal{Q}$ be the set of the admissible products of dyadic cubes of the sides h_j that lie in no larger admissible product of dyadic cubes.

For $Q \in \mathcal{Q}$, $\pi(Q)$ is the partition of $\{1,\dots,n\}$ into the connected components of the graph $a \sim b \iff |c(Q)_a - c(Q)_b|_\infty \le 12h(Q)$, and $k(Q) = |\pi(Q)|$.

Then $\mathcal{Q}$ is a partition of $\mathbb{M}^n \setminus \Delta$; on Q, $\mathsf{d}_\infty \ge 3h(Q)$, and if $h(Q) < h_0$, $\mathsf{d}_\infty < 10h(Q)$ and $k(Q) \le n-1$; there are $\varphi_Q \in C^\infty_c(\operatorname{int} Q^+)$, $\varphi_Q \ge 0$, with $\sum_{Q\in\mathcal{Q}} \varphi_Q = 1$ on $\mathbb{M}^n \setminus \Delta$ and $|\partial^\gamma \varphi_Q| \le c_\gamma h(Q)^{-|\gamma|}$. Fix a smooth μ on $\mathbb{R}^3$ carried by $\{|y|_\infty < 1\}$ with $\int \mu = 1$. For $Q \in \mathcal{Q}$ with $h = h(Q)$, $\pi = \pi(Q)$, $k = k(Q) \le n-1$ and $\omega_k \ge 0$ put $\mu_Q(y') = \prod_{B\in\pi} h^{-3}\mu((y'_B - c(Q)_{a_B})/h)$ for $y' \in \mathbb{M}^k$ and

$$P_Q F(x) = \int \mu_Q(y') \sum_{|\gamma|\le\omega_k} \frac{(x - \iota_\pi(y'))^\gamma}{\gamma!}\, \partial^\gamma F(\iota_\pi(y'))\, dy',$$

the Taylor polynomial of F of total order ω_k averaged over the piece of the size h of the stratum Δ_π next to Q; $P_Q = 0$ for the other Q.

Let u be a functional of n entries with $(\mathrm{W};\kappa,q,r)$, and put $N_0 = \lfloor \frac{3n}{2} \rfloor + 1 + nr$ and $m = \max\{\omega_{n-1}+1, N_0\}$.

(a) For every admissible product Q, dyadic or not, in particular for every $Q \in \mathcal{Q}$, there is exactly one linear functional u_Q on $C^\infty_c(\operatorname{int} Q^+; V_{\mathbb{C}}^{\otimes n})$ with $u_Q(g_1 \otimes \cdots \otimes g_n) = u(g_1,\dots,g_n)$ and

$$|u_Q(G)| \le C_{\mathrm{F}}\, A\, h(Q)^\kappa\, l(h(Q))^q\, \|G\|_{(h(Q)),N_0},$$

C_{F} formed from n, r and the norm of V; it reads (W) at the side $h(Q)$ alone, and two of these functionals agree where both are defined. There is exactly one distribution u° on $\mathbb{M}^n \setminus \Delta$ with $u^\circ(f_1 \otimes \cdots \otimes f_n) = u(f_1,\dots,f_n)$ for the tuples of the definition, and $u^\circ = u_Q$ on $C^\infty_c(\operatorname{int} Q^+)$: off the diagonals u is given by exactly one distribution.

(b) The sum

$$\tilde u(F) = \sum_{Q\in\mathcal{Q}} u_Q(\varphi_Q(F - P_Q F))$$

converges absolutely for $F \in C^m_c(\mathbb{M}^n; V_{\mathbb{C}}^{\otimes n})$, and $\tilde u$ is a distribution of order at most m that extends u°. At $\kappa = 0$, $r = 0$: $\omega_k = 3k$ and $m = 3n-2$.

(c) For $0 < \lambda \le h_0$ and every λ-supported F,

$$|\tilde u(F)| \le C_{\mathrm{ext}}\, A\, \lambda^\kappa\, l(\lambda)^{q+\epsilon}\, \|F\|_{(\lambda),m},$$

where $\epsilon = 1$ if $3k - \kappa$ is an integer ≥ 0 for some $k \in \{1,\dots,n-1\}$, $\epsilon = 0$ otherwise, and C_{ext} is formed from n, κ, q, r, the norm of V and μ, and does not depend on u; so $\tilde u \in \mathfrak{E}_n(\kappa)$. *(A range of sides.)* If u has the inequality of $(\mathrm{W};\kappa,q,r)$ at the sides $h_\flat \le h \le h_0$ alone, for some $h_\flat \in (0, h_0]$, then the sum $\tilde u^\flat(F)$ over the $Q \in \mathcal{Q}$ with $h(Q) \ge h_\flat$ has the same bound, with the same C_{ext}, for $8h_\flat \le \lambda \le h_0$ and every λ-supported F.

(d) If u is invariant under a group generated by permutations of the entries, translations of $\mathbb{M}$ acting on all the entries at once, and a closed subgroup of $\mathrm{O}(3)$ that maps $\mathbb{M}$ onto itself, acting by $f \mapsto \rho(\mathsf{R}) f(\mathsf{R}^{-1}\cdot)$, then u° has an extension in $\mathfrak{E}_n(\kappa)$ of order at most m that is invariant under this group.

(e) *(Contact terms.)* A distribution T on $\mathbb{M}^n$ with support in Δ lies in $\mathfrak{E}_n(\kappa)$ if and only if

$$T = \sum_{|\pi|\le n-1} \sum_{|\alpha|\le\omega_{|\pi|}} \partial^\alpha_\xi \delta_\pi \otimes T_{\pi,\alpha} \qquad \text{with} \quad T_{\pi,\alpha} \in \mathfrak{E}_{|\pi|}(\kappa + |\alpha|),$$

the sum over the partitions π with at most $n-1$ blocks and the multi-indices α of ξ at π. So two extensions of u° in $\mathfrak{E}_n(\kappa)$ differ by such a sum, and every such sum may be added to an extension. A term with $|\alpha| > \omega_{|\pi|}$ and a coefficient in $\mathfrak{E}_{|\pi|}(\kappa + |\alpha|)$ vanishes, and for every π and every α with $|\alpha| \le \omega_{|\pi|}$ there are nonzero examples when $V \ne \{0\}$. The coefficients in this representation need not be unique. If $\kappa > 3(n-1)$, the extension in $\mathfrak{E}_n(\kappa)$ is unique.

(f) *(Two points.)* Let $n = 2$, $\kappa = 0$, $V = \mathrm{Sym}_3(\mathbb{R})$ with $\rho(\mathsf{R})H = \mathsf{R}H\mathsf{R}^{\mathrm{T}}$, and let $T \in \mathfrak{E}_2(0)$ have its support in $\{x_1 = x_2\}$, be invariant under the translations, real, and symmetric under the exchange of the two entries. Then $T(f_1 \otimes f_2) = \sum_{|\alpha|\le 3} \int \mathsf{c}_\alpha(\partial^\alpha f_1(x), f_2(x))\,dx$ with bilinear forms c_α on $V_{\mathbb{C}}$. If $\mathbb{M} = \mathbb{R}^3$ and T is covariant under $\mathrm{O}(3)$, the symbol $\hat{T}(p)(H, H') = \sum_\alpha \mathsf{c}_\alpha(H, H')(ip)^\alpha$ is a real combination of the six forms

$$\operatorname{tr} H \operatorname{tr} H', \quad \operatorname{tr} HH', \quad p^2 \operatorname{tr} H \operatorname{tr} H', \quad p^2 \operatorname{tr} HH', \quad (p \cdot Hp) \operatorname{tr} H' + (p \cdot H'p) \operatorname{tr} H, \quad (Hp) \cdot (H'p);$$

if T is covariant under the cubic group W_3, on $\mathbb{R}^3$ or on T_ℓ, then $\hat{T}$ is a real combination of twelve forms.

■

Proof sketch. (4) The facts on $\mathcal{Q}$: if Q is admissible, so is the product of the next generation that holds a given point; $|x_a - x_b|_\infty \ge \mathsf{d}_\infty(x) - 2h_j \ge 3h_j$ once $5h_j \le \mathsf{d}_\infty(x)$, so every $x \notin \Delta$ lies in exactly one member of $\mathcal{Q}$; if $h(Q) < h_0$ the parent of Q is not admissible, whence $\mathsf{d}_\infty < 10h(Q)$ on Q and two points in one block of $\pi(Q)$ are linked by a chain of centres at most $12h(Q)$ apart. Members of $\mathcal{Q}$ whose sets Q^+ meet have sides in the ratio $\frac12$, 1 or 2, and a point lies in at most $3 \cdot 2^{3n}$ sets Q^+; φ_Q is a normalised product of cutoffs of the scale $h(Q)$. A count used below: at most $\mathrm{Bl}(n)(24n)^{3n}(3R/h_j)^{3k}$ members of $\mathcal{Q}$ have the side h_j, k clusters and all the coordinates of their centres within $R \ge h_j$ of those of a given point of $\mathbb{M}^n$, a partition, one cube for each block and the cubes of the other indices within $12(n-1)h_j$ of it being chosen.

(a) Let $h = h(Q)$, $\mathsf{s} = \frac32 h$, $c = c(Q)$. A $G \in C_c^\infty(\operatorname{int} Q^+; V_{\mathbb{C}}^{\otimes n})$, continued periodically with the cell Q^*, is the sum of its Fourier series in the modes $\mathsf{E}_{\mathbf{k}}(x) = \prod_a e^{2\pi i \mathbf{k}_a \cdot (x_a - c_a)/\mathsf{s}}$, $\mathbf{k} \in \mathbb{Z}^{3n}$, with all derivatives, uniformly; with cutoffs $\chi_a \in C_c^\infty(\operatorname{int} Q_a^*)$, equal to 1 on Q_a^+, fixed once at the scale h, $\|\chi_a e^{2\pi i \mathbf{k}_a \cdot (\cdot - c_a)/\mathsf{s}}\|_{(h),r} \le C_r(1 + |\mathbf{k}_a|)^r$, and every mode times $\prod_a \chi_a$ is a product of entries carried by the cubes Q_a^*, of the side $\frac32 h$ and at pairwise sup distances $\ge \frac52 h$.

Put $u_Q(G) = \sum_{\mathbf{k}} \hat{G}_{\mathbf{k}}\, u(\chi_1 e^{2\pi i \mathbf{k}_1 \cdot (\cdot - c_1)/\mathsf{s}}, \dots, \chi_n e^{2\pi i \mathbf{k}_n \cdot (\cdot - c_n)/\mathsf{s}})$, componentwise in a basis of V. By (W) the terms are at most $Ah^\kappa l(h)^q C_r^n (1 + |\mathbf{k}|)^{nr} |\hat{G}_{\mathbf{k}}|$; by the Cauchy–Schwarz inequality, with $\sum_{\mathbf{k}} (1 + |\mathbf{k}|)^{-2s} < \infty$ for $2s > 3n$, and by Parseval, $\sum_{\mathbf{k}} (1 + |\mathbf{k}|)^{nr} |\hat{G}_{\mathbf{k}}| \le C \|G\|_{(h),N_0}$: this is the origin of $N_0 = \lfloor \frac{3n}{2} \rfloor + 1 + nr$. At a product $G = g_1 \otimes \cdots \otimes g_n$ the coefficients are products, the series of the entries converge in $\|\cdot\|_{(h),r}$, and $u_Q(G) = u(g_1, \dots, g_n)$.

A function carried by a product of open sets O_a is a limit in every C^N, within one compact subset of $\prod_a O_a$, of finite sums of products of functions carried by the O_a (truncated Fourier series times cutoffs); so two functionals that are bounded by a C^N norm and equal to u on products agree, which gives the uniqueness of u_Q and the agreement of u_Q, $u_{Q'}$ on $\operatorname{int} Q^+ \cap \operatorname{int} Q'^+$. Then $u^\circ(G) = \sum_Q u_Q(\varphi_Q G)$ is a finite sum on every compact subset of $\mathbb{M}^n \setminus \Delta$, a distribution; on a tuple with disjoint supports, a partition of unity of $\mathbb{M}$ by dyadic cubes of a side h_j with $6h_j$ below the least distance of the supports and the multilinearity of u give $u^\circ = u$, the products of the cubes that meet the supports being admissible; and u° is unique by the same density.

(b) Four facts on P_Q, at $Q \in \mathcal{Q}$ with $h = h(Q)$, $\pi = \pi(Q)$, $k = k(Q) \le n - 1$, $\omega = \omega_k \ge 0$. (P1) For $x \in Q^+$ and y' in the support of μ_Q, $|x_a - y'_{B(a)}|_\infty \le \frac58 h + 12(n-1)h + h \le 12nh$. (P2) $P_Q F = 0$ if F vanishes near Δ_π: it reads the derivatives of F on Δ_π alone. (P3) For $h \le \lambda$ and $|\gamma| \le N_0$, on Q^+, $h^{|\gamma|} |\partial^\gamma (F - P_Q F)| \le C(h/\lambda)^{\omega+1} \|F\|_{(\lambda),m}$: since $\int \mu_Q = 1$ and ∂^γ of the Taylor polynomial of order ω is the Taylor polynomial of order $\omega - |\gamma|$ of $\partial^\gamma F$, Taylor's formula with (P1) gives $(36n^2 h)^{\omega+1-|\gamma|} \lambda^{-\omega-1} \|F\|_{(\lambda),\omega+1}$ for $|\gamma| \le \omega$, and for $|\gamma| > \omega$, $\partial^\gamma P_Q F = 0$. (P4) If F is λ-supported at z and $\lambda \le h$, then, in the coordinates at π and after an integration by parts in y', $h^{|\gamma|} |\partial^\gamma P_Q F| \le C \sum_{j \le \omega} (h/\lambda)^{j-3k} \|F\|_{(\lambda),\omega}$ on Q^+, because μ_Q and its derivatives are of the size h^{-3k} and $(\partial_\xi^\alpha F) \circ \iota_\pi$, of the size $\lambda^{-|\alpha|}$, is carried by a set of volume $\le (2\lambda)^{3k}$; and $P_Q F = 0$ unless $|c(Q)_a - z_a|_\infty \le 12nh$ for all a.

Now let $F \in C^m_c$ be carried by a ball of radius $R_F \geq h_0$. By (P3) at $\lambda = h_0$, (a), the count of (4) and $\|\varphi_Q G\|_{(h),N_0} \leq C\|G\|_{(h),N_0}$ on Q^+, the terms of the members of the side h_j with k clusters add up to at most $C\,A\,\|F\|_{(h_0),m}((R_F+12nh_0)/h_j)^{3k}h_j^{\kappa}l(h_j)^q(h_j/h_0)^{(\omega_k+1)_+}$; the exponent of h_j is $\varepsilon_k = \kappa-3k+(\omega_k+1)_+ > 0$, equal to $\lfloor 3k-\kappa\rfloor+1-(3k-\kappa) \in (0,1]$ if $\omega_k \geq 0$ and to $\kappa-3k$ if $\omega_k < 0$; for $k = n$ only $h_j = h_0$ occurs. So the series converges absolutely, $\tilde u$ is bounded by a C^m norm on every compact set, and by (P2) $\tilde u = u^\circ$ off Δ. At $\kappa = 0$, $r = 0$: $\omega_{n-1}+1 = 3n-2 \geq \lfloor \frac{3n}{2}\rfloor + 1$.

(c) Let F be λ-supported at z. Only finitely many members with $h(Q) > \lambda$ give a term, and

$$\tilde u(F) = \underbrace{\sum_{h(Q)\leq\lambda} u_Q\big(\varphi_Q(F-P_QF)\big)}_{\text{I}} + \underbrace{u^\circ\Big(\sum_{h(Q)>\lambda}\varphi_Q F\Big)}_{\text{II}} - \underbrace{\sum_{h(Q)>\lambda} u_Q(\varphi_Q P_Q F)}_{\text{III}}.$$

In I the members that give a term have their centres within $13n\lambda$ of z, and (P3) at the scale λ with the count gives $C\,A\,\lambda^{\kappa}\|F\|_{(\lambda),m}\sum_k\sum_{h_j\leq\lambda}(h_j/\lambda)^{\varepsilon_k}l(h_j)^q$, which is at most $C\,A\,\lambda^{\kappa}l(\lambda)^q\|F\|_{(\lambda),m}$, as $l(2^{-i}\lambda) \leq 2(1+i)l(\lambda)$. In II the function is smooth, carried where $\mathsf{d}_\infty \geq \frac{11}{4}\lambda$, with $\|\cdot\|_{(\lambda),N_0} \leq C\|F\|_{(\lambda),N_0}$; a partition of unity by all the products of dyadic cubes of one side $h' \in (\frac{\lambda}{8},\frac{\lambda}{4}]$ meets its support only in admissible products, at most 19^{3n} of them, and (a) bounds each term by $C\,A\,\lambda^{\kappa}l(\lambda)^q\|F\|_{(\lambda),N_0}$.

In III, by (P4), at most $(24n+1)^{3n}$ members of each side $h_j > \lambda$ give a term, each at most $C\,A\,\lambda^{\kappa}l(\lambda)^q(h_j/\lambda)^{\kappa+\omega_k-3k}\|F\|_{(\lambda),\omega_k}$; the exponent $\kappa+\omega_k-3k$ is ≤ 0, and it is 0 exactly when $3k-\kappa$ is an integer; so the sum over $\lambda < h_j \leq h_0$ is a convergent geometric series or has at most $1+\log_2(h_0/\lambda) \leq 2\,l(\lambda)$ equal terms: this is the one logarithm more. *A range of sides:* if (W) holds only at the sides $\geq h_\flat$ and $8h_\flat \leq \lambda$, I loses its members below $h_\flat$ and was bounded term by term; III is unchanged; and II, now $\sum_{h(Q)>\lambda} u_Q(\varphi_Q F)$, is the sum over the products of the side $h' > \frac{\lambda}{8} \geq h_\flat$ of the partition of II, by the agreement in (a) at sides $\geq h_\flat$, and is bounded in the same way.

(d) The grids, so $\mathcal{Q}$ and $\pi(Q)$, and with covariant choices φ_Q, μ_Q, are invariant under the translations by $h_0\mathbb{Z}^3$, so $\tilde u$ is; the mean of $\tilde u(\tau_t\,\cdot)$ over $t \in [0,h_0)^3$ is invariant under all the translations, and the mean over the permutations and over the Haar measure of the closed subgroup of O(3) keeps this invariance. Each of these maps carries λ-supported functions to $\sqrt{3}\lambda$-supported ones and changes $\|\cdot\|_{(\lambda),m}$ by a factor formed from n and m; so it maps $\mathfrak{E}_n(\kappa)$ to itself with uniform numbers and extensions of the invariant u° to extensions, and means of extensions with one bound are such extensions.

(e) *If:* for λ-supported F the function $g = (\partial^\alpha_\xi F)\circ\iota_\pi$ on $\mathbb{M}^k$ is λ-supported, and $\|g\|_{(\lambda),m'} \leq n^{m'}\lambda^{-|\alpha|}\|F\|_{(\lambda),m'+|\alpha|}$, as $\partial_{y_B} = \sum_{a\in B}\partial_{x_a}$; so $|T_{\pi,\alpha}(g)| \leq C\lambda^{\kappa+|\alpha|}(1+\log\frac{h_1}{\lambda})^q\,n^{m'}\lambda^{-|\alpha|}\|F\|_{(\lambda),m'+|\alpha|}$, the power counting κ. A distribution $T' \in \mathfrak{E}_k(\kappa')$ with $\kappa' > 3k$ is 0: a test function on $\mathbb{M}^k$ is the sum of at most $C\lambda^{-3k}$ pieces carried by balls of radius λ, each of value $\leq C\lambda^{\kappa'}$ up to logarithms, and $\lambda \to 0$; this is the case $|\alpha| > \omega_k$, where $\kappa+|\alpha| > 3k$.

The Lebesgue measure of $\mathbb{M}^k$ times a fixed nonzero element of the dual lies in $\mathfrak{E}_k(\kappa')$ exactly when $\kappa' \leq 3k$, that is, at $\kappa' = \kappa+|\alpha|$, exactly when $|\alpha| \leq \omega_k$; this supplies a nonzero example for every allowed pair (π,α) when $V \neq \{0\}$. *Only if:* a descent over $k = n-1,\dots,1$ for $T \in \mathfrak{E}_n(\kappa)$, with its numbers C, q, m, h_1, carried by Σ_k. Off Σ_{k-1} the strata Δ_π with $|\pi| = k$ are disjoint; in the tube $U_\pi = \{|\xi|_\infty < \frac{1}{4}\min\{\mathsf{d}_\infty(y), h_1\}\}$ about the open stratum, which meets no other of them, and with a cutoff χ carried by $\{|\xi|_\infty < 1\}$ and equal to 1 on $\{|\xi|_\infty \leq \frac{1}{2}\}$, the coefficients

$$t_{\pi,\alpha}(g) = (-1)^{|\alpha|}\,T\Big(\chi(\xi/\varepsilon)\,\frac{\xi^\alpha}{\alpha!}\,g(y)\Big), \qquad |\alpha| \leq \omega_k, \quad 0 < \varepsilon \leq \tfrac{1}{4}\min\Big\{\min_{\operatorname{supp} g}\mathsf{d}_\infty, h_1\Big\},$$

do not depend on ε and are distributions on $\mathbb{M}^k \setminus \Delta^{(k)}$ alone, $\Delta^{(k)}$ the diagonals of $\mathbb{M}^k$. *Claim A:* if G is carried by U_π and $\partial^\alpha_\xi G(y,0) = 0$ for $|\alpha| \leq \omega_k$, then $T(G) = 0$; for $(1-\chi(\xi/\varepsilon))G$ vanishes near Δ_π and is carried by U_π, which meets the support of T in the open stratum alone, so that

$T(G) = T(\chi(\xi/\varepsilon)G)$ for small ε, and a partition of unity at the scale ε in y cuts $\chi(\xi/\varepsilon)G$ into at most $C\varepsilon^{-3k}$ pieces, each 2ε-supported with $\|\cdot\|_{(2\varepsilon),m} \le C\varepsilon^{(\omega_k+1)_+}$, so that $|T(G)| \le C\varepsilon^{\kappa-3k+(\omega_k+1)_+}$ times logarithms, which tends to 0.

Claim B: on $C_c^\infty(\mathbb{M}^n\backslash\Sigma_{k-1})$, by Taylor's formula in ξ and Claim A, $T = \sum_{|\pi|=k}\sum_{|\alpha|\le\omega_k}\partial_\xi^\alpha\delta_\pi\otimes t_{\pi,\alpha}$. The coefficients have a power counting of their own: for cubes R_B^* of the side $\frac{3}{2}h$ at pairwise sup distances $\ge\frac{5}{2}h$, $h\le\frac{1}{4}h_1$, and g carried by $\prod_B R_B^*$, the function $\chi(2\xi/h)\frac{\xi^\alpha}{\alpha!}g(y)$ is $2h$-supported with $\|\cdot\|_{(2h),m}\le Ch^{|\alpha|}\|g\|_{(h),m}$; so $t_{\pi,\alpha}$ is a functional of k entries with $(\mathrm{W};\kappa+|\alpha|,q,m)$, with derivatives of the order m in the norms, which is why (a)–(c) are stated for every r.

For $k\ge 2$, (a)–(c) at $r=m$ extend $t_{\pi,\alpha}$ to $T_{\pi,\alpha}\in\mathfrak{E}_k(\kappa+|\alpha|)$; for $k=1$ there are no diagonals in $\mathbb{M}^1$ and $T_{\pi,\alpha}=t_{\pi,\alpha}$ lies in $\mathfrak{E}_1(\kappa+|\alpha|)$ by the same inequality. By Claim B, $T-\sum_{|\pi|=k}\sum_{|\alpha|\le\omega_k}\partial_\xi^\alpha\delta_\pi\otimes T_{\pi,\alpha}$ vanishes off Σ_{k-1}, and it lies in $\mathfrak{E}_n(\kappa)$ by the first part; the descent ends at $\Sigma_0=\varnothing$. If $\kappa>3(n-1)$, all ω_k with $k\le n-1$ are negative and the sum is empty.

(f) At $n=2$ the one stratum has $k=1$, $y=x_1$, $\xi=x_2-x_1$ and $\omega_1=3$; the coefficients T_α are translation-invariant distributions on $\mathbb{M}$, hence constants $\mathsf{c}_\alpha\,dy$, and an integration by parts gives the form; conversely a constant lies in $\mathfrak{E}_1(\kappa')$ for $\kappa'\le 3$. Covariance reads $\hat T(\mathsf{R}p)(\rho(\mathsf{R})H,\rho(\mathsf{R})H')=\hat T(p)(H,H')$, and the exchange $\hat T(-p)(H',H)=\hat T(p)(H,H')$. Since -1 lies in both groups and $\rho(-1)=1$, $\hat T$ is even in p; so only the terms of the orders 0 and 2 in p occur, with real coefficients, $\hat T(p)$ is symmetric in (H,H'), and the number of the independent terms is that of the invariants of $\mathrm{Sym}^2V^*\otimes\mathrm{Sym}^j(\mathbb{R}^3)^*$, $j=0,2$. Under SO(3), $V=[0]\oplus[2]$, $\mathrm{Sym}^2V=2[0]\oplus 2[2]\oplus[4]$ and $\mathrm{Sym}^2\mathbb{R}^3=[0]\oplus[2]$: $2+4=6$; the six forms are invariant. Separating the homogeneous terms of degrees 0 and 2, their independence follows by evaluating at $H=H'\in\{\mathrm{diag}(1,-1,0),\mathrm{diag}(1,0,0)\}$ and $p\in\{e_1,e_2,e_3\}$ within each degree. Under the cubic group $V=A_1\oplus E\oplus T_2$, $\mathrm{Sym}^2V=3A_1\oplus 3E\oplus 3T_2\oplus T_1$ and $\mathrm{Sym}^2\mathbb{R}^3\cong V$: $3+9=12$; the characters give the same numbers, and 0 for the odd orders. □

Remark 2.26 (The point bound and the bounds of kernels, for data). For reconstruction data with labels the point bound gives pointwise bounds of the kernels by powers of the least distance of the points (Proposition 2.16 and Theorem D (d) (i)). The converse fails: at $V=\mathbb{R}$, $\sigma(f_1,\dots,f_n)=n!\prod_k\int f_k$ is symmetric and has constant kernels, hence every bound of the kind of (E1), but no bound of one insertion between two vectors. The reconstruction uses nothing at coinciding points.

2.5. **Proofs of the theorems.**

Proof of Theorem B. Step 1: reduction. It suffices to treat real H; for complex H the real and the imaginary part are treated separately, at the price of a factor 2. By Lemma 2.8 (a),

$$\|\mathcal{T}_K(H)-c\|_{\mathrm{ch},\ell}^{(i,o)}\ \text{at}\ (K,\beta)\ =\ \|\mathcal{T}_k(H')-c\|_{\mathrm{ch},L^i\ell}^{(0,L^io)}\ \text{at}\ (k,\beta),\qquad |H'|_\infty/b'=|H|_\infty/b,$$

so the seminorm is taken at the stopped datum (k,β), $k=K-i$, at the coupling $g'=g_{(i)}\le\gamma_W^{\mathrm{sd}}$, on a board of side 1, for $H'=L^iH(L^{-i}\cdot)$, which vanishes within sup distance δ of the walls of its cell; the label is $b'=L^ib$, the least side ℓ'' at g' is small over the running couplings of (k,β), and $s=s(\delta)\le s_E(i)\le k$, so that at the working level $a_k\le\delta/C_W(s)\le\delta/2197$.

Step 2: pieces. The points of the cell at sup distance $\ge\delta$ from its walls form a cube of side $1-2\delta$, a union of at most $2\delta^{-3}$ boxes of sides $\le\frac{99}{100}\delta$, each in the ball of radius $0.8574\,\delta$ about its centre. Restricting $w_{H'}$ and $\mathsf{w}_{H'}$ to the plaquettes and bonds with barycentres and midpoints in a box $\mathfrak{b}$,

$$\mathcal{T}_k(H')=\sum_{\mathfrak{b}}[\mathcal{O}(w_{\mathfrak{b}})+Y[\mathsf{w}_{\mathfrak{b}}]],$$

a sum of at most $4\delta^{-3}$ functions of the bonds of the cell.

Step 3: one piece and its copies. Let F be one of these pieces, taken on $T_{\ell''}$, whose board has $N=\ell''^3$ cells, and F_κ its mirror copies. By Lemma 2.11 each F_κ is the first member of a source under (s,S_κ) with $\mathsf{s}\le 59|H'|_\infty$. The barycentres of the plaquettes of S_κ lie within

$0.8574\,\delta + 0.71\,\delta/2197 \le \frac{7}{8}\delta$ of the centre of the copy of the box; two points in different cells, each at sup distance $\ge \delta$ from the walls, are parted on the circle by a wall on either side, so their distance is $\ge 2\delta$, and the barycentres of different copies are at distance $\ge 2\delta - \sqrt{2}a_k \ge \frac{5}{4}\delta$.

Step 4: the moments of the copies. For $i \ge i_E$ the thresholds (T1) at $n = N$ and (T2) hold (Lemma 2.8 (d)), and $N = \ell''^3$ is admissible in Proposition 2.9 (a), whose condition $n \le \ell^3$ is exactly the number of cells. So there are $c_\kappa \in \mathbb{C}$ with

$$\Big|\Big\langle \prod_{\kappa\in B} (F_\kappa - c_\kappa)\Big\rangle_{k,\ell'',\beta}\Big| \le (\mathsf{A}_N(s)\,\upsilon\,\mathsf{s})^{\#B} \qquad \text{for every non-empty set } B \text{ of cells.}$$

Step 5: one constant. The torus mean is invariant under the diagonal isometries, so all the copies have one mean m_F, and $|m_F - c_\kappa| \le \mathsf{A}_N(s)\upsilon\mathsf{s}$ by Step 4 at $B = \{\kappa\}$. Expanding about the c_κ,

$$\|F - m_F\|_{\ell''}^N = \Big\langle \prod_\kappa (F_\kappa - m_F)\Big\rangle = \sum_B \Big\langle \prod_{\kappa\in B}(F_\kappa - c_\kappa)\Big\rangle \prod_{\kappa\notin B}(c_\kappa - m_F) \le (2\mathsf{A}_N(s)\upsilon\mathsf{s})^N.$$

Step 6: the sum, and every side. By subadditivity and $\upsilon \le (9/8)^{1/2}/b'$, $\|\mathcal{T}_k(H') - m\|_{\ell''} \le 2\delta^{-3}\cdot 2\mathsf{A}_N(s)\upsilon(1+59)|H'|_\infty \le 255\,\delta^{-3}\mathsf{A}_N(s)|H|_\infty/b$, $m = \sum m_F$. For $\ell \in \mathfrak{L}(g)$, $L^i\ell \in \mathfrak{L}(g')$ and $L^i\ell \ge \ell''$; Lemma 2.7 at g', with cells of side 1, gives

$$\|\cdot\|_{L^i\ell} \le e^{G_{g'}}\|\cdot\|_{\ell''}, \qquad G_{g'} \le G_g + \tfrac{9}{2} i \log L + \tfrac{1}{8},$$

so $\|\mathcal{T}_K(H) - m\|_\ell \le \mathsf{E}_i b^{-1}|H|_\infty$ with $\mathsf{E}_i = 510\,\delta^{-3}e^{G_g + 1/8}L^{9i/2}\mathsf{A}_N(s)$ for complex H.

Step 7: the centrings. The mean on a torus T_{ℓ_1} differs from m by at most the seminorm on T_{ℓ_1}; the mean in $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ differs from m by at most the lower limit of the seminorms, by the domination along the sides ℓ_k of $\mathfrak{L}(g)$:

$$|\nu(\mathcal{T}_K(H)) - m| \le \liminf_k \|\mathcal{T}_K(H) - m\|_{\ell_k} \le \mathsf{E}_i b^{-1}|H|_\infty;$$

with the triangle inequality, $\|\mathcal{T}_K(H) - c\|_\ell \le 2\mathsf{E}_i b^{-1}|H|_\infty$.

Step 8: the numbers. Lemma 2.8 (c) in the formula of $\mathsf{A}_N(s)$ gives

$$N\max\{C^I, C_2 N^{3+\mathfrak{p}_0}\} \le \max\{C^I, C_2\}(1 + c' A_0^2/9)^{4+\mathfrak{p}_0}\mathsf{Y}_i^{(4+\mathfrak{p}_0)(2\mathfrak{p}_0-1)}, \quad (LC_W(s))^3$$
$$\le L^3 c_W^3 \mathsf{Y}_i^{6\mathfrak{p}_0}, \quad \bar{x}_s \le L^2 c_W \delta^{-1}\mathsf{Y}_i^{2\mathfrak{p}_0}(X_g + \bar{B})L^i,$$

and $Y_s^{2\mathfrak{p}_0} \le \mathsf{Y}_i^{2\mathfrak{p}_0}$; hence $\mathsf{E}_i \le C_E \mathsf{Y}_i^{q_E} L^{11i/2}$, which is (4). Of the power $\frac{11}{2}$, $\frac{9}{2}$ is the increment of the pressure gap of one unit cell at the stopped coupling, and 1 is the crude size $\bar{x}_s \sim L^i$ of one insertion at the working level. With $\mathsf{x}_E(\delta) = \mathsf{x}^*/\delta$, x^* formed from the constants alone (Lemma 2.8 (d)), $L^{i_E} \le c_i\delta^{-1}$, and $\mathsf{Y}_i^{q_E} \le (2q_E)^{q_E}c_0\delta^{-1}L^i$ with $c_0 = L^2 c_W(4\mathfrak{p}_0)^{2\mathfrak{p}_0}(X_g + \bar{B})$; so $C_E\mathsf{Y}_i^{q_E}L^{11i/2} \le c_3\delta^{-5}L^{13i/2}$, C_E being δ^{-4} times a number free of δ.

Step 9: the second form (b). The same steps with Proposition 2.9 (b) in the place of (a), at the stopped datum $(K - i, \beta)$ and at $s = s_i$, so that the level $k = K - i - s_i \in [2, K - i - 1]$ is chosen by the distance alone and the depth $s(\delta)$ plays no part. The whole cell is one source, and by (Sd.1) and the definition of the admissible sides the least torus at $g_{(i)}$, of side $\ell'' \le 2L^2 M C_{\mathrm{s}}(\frac{1}{2}\mathsf{Y}_i')^r$, has few cells:

$$N = \ell''^3 \le c_N \mathsf{Y}_i'^{3r}, \qquad \delta L^{s_i} \ge M u_*'(\lceil c_N \mathsf{Y}_i'^{3r}\rceil) \ge M u_*'(N);$$

two corners of plaquettes of different copies are at sup distance $\ge \delta$, that is $\ge \delta L^{s_i}$ in the units of the level k. No threshold on i is then needed, and the pressure gap enters as in Step 6. As $u_*'(\lceil c_N \mathsf{Y}_i'^{3r}\rceil) \le c_u \mathsf{Y}_i'^{3r+1}$ and, by the minimality of s_i, $L^{s_i} \le (LMc_u/\delta)\mathsf{Y}_i'^{3r+1}$, this gives C_E' and $q_E' = 15r + 4$.

Step 10: all couplings $\le \gamma$ and all scales (c). (i) By Lemma 2.14 (a) the datum stopped at $z = z(g)$ is a first-passage datum at $\tilde{g} \le \gamma_W^{\mathrm{sd}}$, the board (i, o) becomes a board of side a_{i-z}, and (a) at $\tilde{g}$, $\tilde{\imath} = i - z \ge i_E(\tilde{g}, \delta)$, with the monotony of the numbers gives

$$\|\mathcal{T}_K(H) - c\|_\ell \le 2C_E[\tilde{g}]\mathsf{Y}_{\tilde{\imath}}[\tilde{g}]^{q_E}L^{11\tilde{\imath}/2}(L^z b)^{-1}L^z|H|_\infty \le 2e^{1/8}C_E[g]\mathsf{Y}_i[g]^{q_E}L^{11i/2}b^{-1}|H|_\infty.$$

(ii) For $i \geq i_A(g, \frac{1}{32})$ this is (i) at $\delta = \frac{1}{32}$; for the finitely many smaller i, Lemma 2.14 (c) with $i' = \max\{i+2, i_A(g, \frac{1}{8})\}$ and (i) at $\delta = \frac{1}{8}$ on the eight shifted fine boards give $\mathsf{N}_i = 8(L^{i'-i}+1)^3$ times the number of (i) at i'. Since $\mathsf{N}_i \leq C\mathsf{Y}_i^{q_E} L^{11i/2}$ for large i and $b^{-1} < g^2$, $C_T < \infty$ for every $p_T > \frac{11}{2}$. (iii) Let $i = i^A$. Cut each H_a by a smooth partition of unity of mesh $a_i/(8n)$ into at most $(16nR/a_i + 3)^3$ pieces of sup diameter $\leq a_i/(4n)$; by multilinearity it suffices to bound one choice of a piece for each entry. Lemma 2.13 at the mesh a_K (possible since $L^{K-i} \geq 8n$) gives one board of side a_i in which each of the n pieces lies in a cell at the margin $a_i/(8n) = \delta_n a_i$, pieces of different entries in different cells, since two points of one cell are at distance $\leq \sqrt{3}a_i < d$. The domination of the state ν, with (i) at δ_n for each piece centred by its mean in ν', bounds the product of the pieces by $\prod_a 2e^{1/8} C_E(\delta_n) \mathsf{Y}_i^{q_E} a_i^{-11/2} b^{-1} |h_a|_\infty$; the sum over the pieces gives $C_n^A(d; R)$. □

Proof of Theorem C. Step 1: the uniform bound (a). Let $i = i^G$, so that $2a_i \leq d$. Cut each H_a by a smooth partition of unity of mesh $a_i/(8n)$ into pieces of sup diameter $\leq a_i/(4n)$, at most $(16nR/a_i + 3)^3$ of them per entry; by multilinearity it suffices to bound one choice of a piece for each entry. Lemma 2.13, at a mesh of the lattice (possible since $L^{K-i} \geq 8n$), gives one board of side a_i in which each of the n pieces lies in a cell at margin $a_i/(8n) = \delta_n a_i$; since two points of one cell are at distance $\leq \sqrt{3}a_i < d$, the pieces of different entries lie in different cells. The domination and (4) at $\delta = \delta_n$, centred in the state ν, give

$$\Big|\nu\Big(\prod_a [\mathcal{T}_K(h_a) - \nu(\mathcal{T}_K(h_a))]\Big)\Big| \leq \prod_a 2C_E(\delta_n) \mathsf{Y}_i^{q_E} a_i^{-11/2} b^{-1} |h_a|_\infty;$$

no order of the cells is used. On a torus the chessboard estimate takes the place of the domination. For $d \leq 2a_{i_E}$, $a_{i^G} \geq d/(2L)$.

Step 2: extraction and the properties (b). Along a countable family of tuples, dense for the uniform norm on every product of compact sets, the bound (a), uniform in the datum and the state, gives bounded sequences, and a diagonal subsequence converges; multilinearity and (a) give the continuity under the motion of the entries, which carries the convergence to all tuples; the labels lie in the compact interval $[g^{-2}, L(g^{-2} + \bar{B})]$ by YMM1:(1531). Reality, symmetry and multilinearity pass to the limit, and $\sigma((H)) = 0$ by the centring. The periodic Gibbs states are invariant under the isometries of the lattice and reflection positive at its mirrors (Proposition YMM1:103.4), the plaquette and bond forms being carried to their images with the signs of Lemma 2.11; as $a_K \to 0$ these isometries approach all of $\mathbb{R}^3 \rtimes W_3$, and the entries are continuous. The five-point inequality, Lemma F.5, from the positivity at the diagonal mirrors,

$$\mathsf{S}(0) - 4\mathsf{S}(te_3) + \mathsf{S}(2te_3) + \mathsf{S}(te_3 + te_k) + \mathsf{S}(te_3 - te_k) \geq 0,$$

gives $\mathcal{P}(\{E < \max_k |q_k|\}) = 0$. $\mathcal{H}_0$ is invariant under e^{-tH} and $\mathcal{U}$. The basic inequality comes from the multiple reflections in the periodic Gibbs states (Proposition YMM1:104.2, using the domination inequality YMM1:(1832)),

$$|\rho_j(\overline{\theta_c A'}\, D\, \tau_{a_i e_3} A)| \leq \liminf_\ell \|D\|_\ell \, \|A'\| \, \|A\|,$$

for D the centred $\mathcal{T}_{K_j}(h)$ in a cell over the mirror, whose seminorms (4) at $\delta = \frac{1}{16}$ bounds uniformly in the side (the support is at sup distance $\geq a_i/8 - a_{K_j}/2 \geq a_i/16$ from the walls); letting $j \to \infty$ gives $|\sigma(\theta \bar{F}' \cdot (h) \cdot \tau_{a_i e_3} F)| \leq \mathsf{c}_E(i) b_*^{-1} |h|_\infty \|[F']\| \, \|[F]\|$.

Step 3: the point bound (c). Let $i = i(\vartheta)$ be the least $i \geq i_1$ with $a_i \leq \vartheta$, $\rho = a_i/32$ and $\varepsilon = 12\rho$. Cut $\tau_{de_3} h$ by the tent partition of unity on $\rho\mathbb{Z}^3$; for a piece carried by Q_z put $\mathsf{b}(g) = \mathsf{B}_{a_i}(\tau_{-ce_3} g)$, $c = z_3 - a_i/2$ and $c' = 2d - z_3 - a_i/2$. Since Q_z meets the support of $\tau_{de_3} h$, both gaps are at least $\vartheta - a_i/2 - \rho \geq 15a_i/32 > \varepsilon$. Thus $\|\mathsf{b}(g)\| \leq \mathsf{c}_E(i) b_*^{-1} |g|_\infty$ by Step 2; the relations of the slab operators give the covariance asked in Lemma 2.15, and $\mathsf{B}_{2d}(g) = e^{-(c-\varepsilon)H} \mathsf{B}^\varepsilon(g) e^{-(c'-\varepsilon)H}$ with two

contractions. Summing over the pieces,

$$\|\mathsf{B}_{2d}(\tau_{de_3}h)\| \le 4{\cdot}32^3 a_i^{-3}\mathsf{c}_E(i)\, b_*^{-1}\|h\|_{L^1}, \qquad a_i^{-3}\mathsf{c}_E(i) = 2C_E\mathsf{Y}_i^{q_E}a_i^{-17/2} \le C_p\min\{1,\vartheta\}^{-p}\ (p>\tfrac{17}{2}).$$

For $(\mathrm{Rec4})_V$: $\sigma(\theta\bar F\cdot(h)\cdot F') = \langle[\tau_{-\eta e_3}F], \mathsf{B}_{2\eta}(\tau_{\eta e_3}h)[\tau_{-\eta e_3}F']\rangle$ with $\vartheta > \eta/2$, and $|A|_\infty \le |A|$; $b_* \ge g^{-2}$ gives the one triple. The price of the passage to L^1 is a_i^{-3}: $\frac{17}{2} = \frac{11}{2} + 3$.

Step 4: real time (d). The proofs of Proposition 2.16 (a) that give the semigroup on the tube, the insertion and point operators, the ordered tuples, $\mathbf{W}_n$, Ψ_n, the fields and their boundary values use, of the isometries, the translations and θ alone, besides $(\mathrm{Rec2})_V$ and $(\mathrm{Rec4})_V$; they use the cone at five places, and each remains valid with $d_\square$ and the square cone, because on it

$$|\operatorname{Im}\mathfrak{z}_1\, q_1 + \operatorname{Im}\mathfrak{z}_2\, q_2| \le (|\operatorname{Im}\mathfrak{z}_1| + |\operatorname{Im}\mathfrak{z}_2|)\, E :$$

the bound $|e^{-\mathfrak{z}_3 E + i(\mathfrak{z}_1 q_1 + \mathfrak{z}_2 q_2)}| \le e^{-d_\square(\mathfrak{z})E}$, the estimate $|-\zeta_3 E + i(\zeta_1 q_1 + \zeta_2 q_2)| \le 2|\zeta|E$ for the holomorphy, $\mathcal{P}(\{0\}\times\mathbb{R}^2) = \mathcal{P}(\{(0,0)\})$, the bound $Ee^{-\eta E/4}$ of the derivatives of the translations, and the convexity of the square tube. The invariance under W_3 gives the covariance under the signed permutations fixing e_3. For (vi), $\mathcal{H}_0$ reduces H, $\|\mathsf{A}_l(E)\| \le \|\mathsf{A}_l\|\,|E|$, $\overline{q_0(\psi,\psi';e)} = q_0(\psi',\psi;e^*)$ with $E^* = \rho(\theta)E$ for a constant real label, so that $\mathsf{m}^*_{ij} = \vartheta_i\vartheta_j\mathsf{m}_{ij}$ and $|\mathsf{m}_{ij}| \le \sqrt{3}$, and $q_0(\Omega,\Omega;E)$ is an integral of $\mathbf{W}_1 = 0$, since $\sigma((h)) = 0$; the operator formula of (M2) is the product $\mathsf{b}(x + ae_3|\mathsf{m}_{ij}|\frac12(y-x))\,\mathsf{b}(\frac12(y-x)|\mathbf{1}| - y + ae_3)$ at $x_3 < y_3$, between the vectors $[F']$, $[F]$.

Step 5: the circular cone (e). A tensor limit is reflection positive at the coordinate mirrors and at the diagonal mirrors $\{x_\mu \pm x_\nu = c\}$ of the lattice. Lemma 2.17 (b) at $u = e_3$, $u' = e_1$, $u'' = e_2$, with the four mirrors of normals e_3, $(e_3 \pm e_1)/\sqrt{2}$, e_1 through the axis $\mathbb{R}e_2$ and the fifth with normal $(e_3+e_2)/\sqrt{2}$, all of them lattice mirrors, gives the circular cone in the picture e_3 (the case $\beta = 0$), and likewise in each of the nine pictures, the axis of the four mirrors being the coordinate axis normal to the plane that holds the normal of the picture, and the fifth mirror a diagonal one; in each picture u the contractions $\mathcal{T}_u(\mathfrak{z})$ on the circular tube follow.

In the picture e_3 the product formula for $\mathbf{W}_n$ written in (e), with these contractions, gives the continuation and its bound with $C_{\mathrm{pt}}(\varepsilon) = 3\sqrt{2}\,C_V\min\{1,\varepsilon\}^{-p}$; the invariance under W_3 carries them to the pictures e_1, e_2. *The boosts.* σ is invariant under the quarter turn $\mathsf{q}x = (x_3, x_2, -x_1)$ in the plane of e_1, e_3, an element of W_3; it is reflection positive at the mirror $\{x_3 = 0\}$ and at the diagonal mirror $\{x_1 = x_3\}$, of the normal $n_- = (e_3 - e_1)/\sqrt{2}$, whose reflection is $\mathsf{q}^{-1}\theta$; and $H \ge |P_1|$, so that $H_\pm = H \pm P_1 \ge 0$. Let $\mathcal{C}_-$, $\mathcal{C}_+$ be the sets of the classes of the tuples carried by the quadrants $\{x_1 < 0,\ x_3 > 0\}$ and $\{x_1 > 0,\ x_3 > 0\}$.

Both are total: if $\psi \perp \mathcal{C}_-$, then for $F \in \mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$ and $\varepsilon > 0$ the function

$$v \mapsto \langle\psi, \mathcal{U}(ve_1)e^{-\varepsilon H}[F]\rangle = \langle\psi, [\tau_{(v,0,\varepsilon)}F]\rangle$$

continues holomorphically to $|\operatorname{Im} v| < \varepsilon$, because $|P_1| \le H$, and vanishes for v far to the left, where $\tau_{(v,0,\varepsilon)}F$ is carried by the quadrant; so it vanishes, and $\varepsilon \downarrow 0$ gives $\psi \perp [F]$; likewise for $\mathcal{C}_+$. For F, F' carried by $\{x_1 < 0,\ x_3 > 0\}$, $\mathsf{q}F$ is carried by $\{x_1 > 0,\ x_3 > 0\}$, and, $[\cdot]_{n_-}$ denoting the classes of the picture n_-, the invariance of σ under q gives

$$\langle[F']_{n_-}, [F]_{n_-}\rangle = \sigma(\mathsf{q}^{-1}\theta\bar F'\cdot F) = \sigma(\theta\bar F'\cdot \mathsf{q}F) = \langle[F'], [\mathsf{q}F]\rangle.$$

So the map $I : [F] \mapsto [F]_{n_-}$ on the span of $\mathcal{C}_-$ is well defined, its form $\|I\psi\|^2$ is the form of the positive symmetric operator $[F] \mapsto [\mathsf{q}F]$, and the form is closable: I is closable, and with its closure $\bar I$, $D = \bar I^*\bar I$ is the Friedrichs extension of that operator, a positive self-adjoint operator with $D[F] = [\mathsf{q}F]$ on $\mathcal{C}_-$ and $D\Omega = \Omega$; $\ker D = (\operatorname{ran} D)^\perp = 0$, since $\operatorname{ran} D \supset \mathcal{C}_+$. For $x = (-a, 0, t)$, $a, t \ge 0$, the translation by x maps $\{x_1 < 0,\ x_3 > 0\}$ into itself; $\mathcal{T}(x) = e^{-tH}\mathcal{U}(-ae_1)$ is the operator of this translation, and $\bar I\,\mathcal{T}(x) \supset \mathcal{T}^{n_-}(x)\,\bar I$ with the translation $\mathcal{T}^{n_-}(x)$ of the picture n_-, a contraction since $n_-\cdot x \ge 0$; taking adjoints in this relation at $x' = -\theta_{n_-}x = (-t, 0, a)$, which is of the same kind, and using $\mathcal{T}^{n_-}(x')^* = \mathcal{T}^{n_-}(x)$ and $\mathcal{T}(x')^* = \mathcal{T}(\mathsf{q}x)$, one gets $D\,\mathcal{T}(x) \supset \mathcal{T}(\mathsf{q}x)\,D$; in the same way D commutes with $\mathcal{U}(ve_2)$.

With $\Xi(\alpha,\beta)=\exp(-\frac{\alpha}{2}H_+-\frac{\beta}{2}H_-)$, $\operatorname{Re}\alpha,\operatorname{Re}\beta\ge 0$, and $z=t+ia$, this reads $D\,\Xi(z,\bar z)\supset \Xi(-iz,i\bar z)\,D$ for z in the closed first quadrant. For $\phi,\psi\in\operatorname{dom}D$ both members of $\langle D\phi,\Xi(\alpha,\beta)\psi\rangle=\langle\phi,\Xi(-i\alpha,i\beta)D\psi\rangle$ are holomorphic for α in the open first and β in the open fourth quadrant, continuous up to the boundary, and they agree on the totally real set $\{\beta=\bar\alpha\}$; so they agree everywhere, and letting $\beta\to 0$, $D\,e^{-\alpha H_+/2}\supset e^{i\alpha H_+/2}D$ for $0\le\arg\alpha\le\frac{\pi}{2}$. For ϕ,ψ in the spectral subspace of $\log D$ of a bounded set and $r>0$, the function

$$h(z)=\langle D^{-\bar z}\phi,\exp(-\tfrac{r}{2}e^{-i\pi z/2}H_+)D^z\psi\rangle$$

is holomorphic and bounded on $|\operatorname{Re}z|\le 1$, as $\operatorname{Re}e^{-i\pi z/2}\ge 0$ there, and the last relation at $\alpha=re^{-i\pi z/2}$ gives $h(z+1)=h(z)$ for $-1\le\operatorname{Re}z\le 0$; so h continues to a bounded entire function and is constant. At $z=is$ this says $D^{is}e^{-rH_+/2}D^{-is}=e^{-re^{\pi s/2}H_+/2}$ for all $r>0$, that is $D^{is}H_+D^{-is}=e^{\pi s/2}H_+$; in the same way, from the relation for H_- with β in the closed fourth quadrant, $D^{is}H_-D^{-is}=e^{-\pi s/2}H_-$, and D^{is} commutes with P_2. So $V_1(s)=D^{is}$ is a strongly continuous unitary group with $V_1(s)\Omega=\Omega$ and $V_1(s)\mathcal{P}(B)V_1(s)^{-1}=\mathcal{P}(\Lambda^{(1)}_{-\pi s/2}B)$, where the boost $\Lambda^{(1)}_\varsigma$ multiplies $E\pm q_1$ by $e^{\pm\varsigma}$ and keeps q_2; V_2 is its conjugate by the exchange of e_1 and e_2, an element of W_3 that fixes e_3, and $\Lambda^{(2)}_\varsigma$ multiplies $E\pm q_2$ by $e^{\pm\varsigma}$. Two boosts in independent directions generate $\mathrm{SO}_0(1,2)$, so the null sets and the support of $\mathcal{P}$ are invariant under it.

Step 6: ordered classes and kernels (f), (g). The suppositions of Proposition 2.18 hold by (a)–(c); its clause (a) gives $\mathcal{H}^{\mathrm{ord}}(\sigma)=\mathcal{H}(\sigma)$, and the density of $\mathcal{D}_0$ in $\mathcal{H}^{\mathrm{ord}}(\sigma)$ follows as in Proposition 2.16: a vector orthogonal to $\mathcal{D}_0$ is orthogonal to the holomorphic vectors $\Psi_n(z;e)$, which span a dense subspace of $\mathcal{H}^{\mathrm{ord}}$. Its clause (b) gives (g) but for its last sentence; the bound for tuples in balls follows from the bound of the kernels with

$$\|h_a\|_{L^1}\le\tfrac{4\pi}{3}R^3\sup|h_a|,\qquad |x|_\infty\ge|x|/\sqrt{3}.$$

The last sentence of (g) is clause (c), whose supposition holds: the restriction of σ to the tuples with entries in V_0 is the limit, along the sequence (K_j,β_j,ρ_j) of first-passage data at g and periodic Gibbs states that defines σ, of the centred products of the action densities $\mathcal{T}_{K_j}(f\mathbf{1})=\mathcal{O}(f)$ (Definition 2.1). This sequence is a Gibbs sequence at g in the sense of Definition 15.4(2), and it converges at the scalar tuples with C^1_c entries, which are the tuples among the construction results; by Theorem YMM1:AP its limit, the scalar part of σ on C^1_c entries, is invariant under all the isometries of $\mathbb{R}^3$ and is scalar reconstruction data, (Rec) with the numbers $16\,C^g_{\mathrm{pt}}$, 4, $\frac12$ of that theorem. Of the rotations outside W_3, this reads the invariance of the scalar limit alone, on no tensor entry.

Step 7: growth (h). Let i be as in (h), so that $a_i\le d/4$; as $L^{i_E(g,\delta_n)}\le c_i\delta_n^{-1}=8nc_i$ (Theorem B (a)) and $L^{i(d)}\le 4L/d$ for the least $i(d)$ with $a_{i(d)}\le d/4$, and c_i may be taken ≥ 1,

$$L^i\le\max\{8nc_i,\,4L/d\}\le 8c_iLn/d,\qquad \mathsf{E}_i(\delta_n)\le c_3(8n)^5L^{13i/2}.$$

Cut each H_a by a smooth partition of unity of mesh $a_i/(8n)$ into pieces of sup diameter $\le a_i/(4n)$, at most a number times $(n/a_i)^3$ of them, the supports lying in balls of radius 1. Lemma 2.13 at $h=a_K$, possible as $8na_K\le a_i$, puts the n pieces of one choice, one of each entry, on one board of side a_i in cells at the margin $a_i/(8n)=\delta_na_i$, and in n different cells, since two points of one cell are at distance $\le\sqrt{3}a_i<d$; the domination with (4) at δ_n bounds the centred product of the pieces in any two states by $(2\mathsf{E}_i(\delta_n)b^{-1})^n\prod|h_a|_\infty$, without a factorial and without an order of the cells. One entry thus contributes at most a number times $n^3L^{3i}\cdot n^5L^{13i/2}=n^8L^{19i/2}\le c\,n^{35/2}d^{-19/2}$; this is the first bound of (h), and with $n^{35n/2}\le e^{35n/2}(n!)^{35/2}$ and $b_*^{-1}\le g^2$ it gives the bound of σ, for every tensor limit and, by Theorem F (b) (i), for every component.

The finer count. By the formulas of Theorem B (a), $C_E(\delta_n)=(8n)^4C_E(1)$, and $\mathsf{Y}_i=2[c_E(\delta_n)+i\log L]\le c\,(1+\log(n/d))$, as $c_E(\delta_n)=\log(8n)+c_E(1)$ and $L^i\le 8c_iLn/d$; so $\mathsf{Y}_i^{q_E}\le c\,(n/d)^{1/2}$, in the place of the crude bound by a number times $\delta_n^{-1}L^i$ of Step 8 of the proof of Theorem B, and $\mathsf{E}_i(\delta_n)\le C_E(\delta_n)\mathsf{Y}_i^{q_E}L^{11i/2}\le c\,n^4(n/d)^{1/2}L^{11i/2}$. For entries of any size at pairwise sup distances

$\geq 2d$, cut each H_a into its restrictions to the boxes $\mathfrak{b} = \frac{a_i}{4n}(\mathbf{n} + [0,1)^3)$, $\mathbf{n} \in \mathbb{Z}^3$, of the mesh $a_i/(4n) \leq d/(16n)$; the pieces of two different entries are at sup distance $\geq 2d > a_i$, hence in different cells of the board of Lemma 2.13; and $\sum_{\mathfrak{b}} \sup_{\mathfrak{b}} |H_a|_\infty = (4n/a_i)^3 \|H_a\|_\natural$ with the upper Riemann sum $\|H\|_\natural = \sum_{\mathfrak{b}} |\mathfrak{b}| \sup_{\mathfrak{b}} |H|_\infty$. One entry then contributes

$$2\mathsf{E}_i(\delta_n) b^{-1} (4n/a_i)^3 \|H_a\|_\natural \leq c\, n^7 (n/d)^{1/2} L^{17i/2}\, b^{-1} \|H_a\|_\natural \leq c'\, n^{16} d^{-9}\, b^{-1} \|H_a\|_\natural,$$

which, in the limit along the data of σ and with $b_*^{-1} \leq g^2$, is the bound of (h) with $\|\cdot\|_\natural$, ordered or not. Entries in balls of radius 1 at Euclidean distances $\geq d$ are at sup distances $\geq d/\sqrt{3} = 2d'$, and the bound at d' with $\|H_a\|_\natural \leq 27 |H_a|_\infty$ gives $|\sigma(X)| \leq (c\, g^2 n^{16} d^{-9})^n \prod_a |H_a|_\infty$ for $0 < d \leq 1$.

The extension. Proposition YMM1:93.3, applied to each of the 6^n components of the labels with a bound $\mathsf{c_T} \max\{1, d^{-\mathsf{a}}\} \prod_a \|f_a\|_\sharp$ at radius ≤ 1 and distances $\geq d$, gives exactly one functional, bounded for $|\cdot|_{8n+\mathsf{a}-1}$ with the factor $C^n (n!)^8 \mathsf{c_T}$. With the first bound, $\mathsf{a} = \lceil 19n/2 \rceil$ and $\mathsf{c_T} = (c_4 g^2 e^{35/2})^n (n!)^{35/2}$: the norm $|\cdot|_{18n}$ and the factorial power $\frac{51}{2}$. With the finer bound, $\mathsf{a} = 9n$ and $\mathsf{c_T} = (c\, g^2 n^{16})^n \leq (c\, g^2 e^{16})^n (n!)^{16}$: the norm $|\cdot|_{17n}$ and the factorial power $24 \leq \frac{49}{2}$, so that the pair $(17n, \frac{49}{2})$ serves.

The pair $(15n, \frac{43}{2})$ comes from an extension that reads the bound on small cubes itself. Let $i_n = i_E(g, \delta_n)$, and for an integer $i \geq i_n$ let $P_1, \dots, P_n$ be closed cubes of the side $a_i/(4n)$, with edges along the axes, at pairwise sup distances $\geq a_i$, and h_a continuous, with values in $V_\mathbb{C}$ and carried by P_a. At the cutoffs with $K \geq K_E(i)$ (at δ_n) and $8n a_K \leq a_i$, Lemma 2.13 at $h = a_K$ puts the P_a on one board of side a_i, in cells at the margin $\delta_n a_i$ and in n different cells, since two points of one cell at this margin are at sup distance $< a_i$; the domination with (4) at δ_n, at complex entries as in (a), and $b_*^{-1} \leq g^2$ give, for σ and, by Theorem F (b) (i), for each of its components,

$$|\sigma(h_1, \dots, h_n)| \leq \big(\mathsf{u}\, L^{\mathsf{v}i}\big)^n \prod_a |h_a|_\infty, \qquad \mathsf{u} = 2c_3 g^2 (8n)^5, \quad \mathsf{v} = \tfrac{13}{2}.$$

With an orthonormal basis $(\varepsilon_\alpha)_{1 \leq \alpha \leq 6}$ of V for the trace form, $|\varepsilon_\alpha|_\infty \leq |\varepsilon_\alpha| = 1$; so each of the 6^n components of the labels, $\Lambda(f_1, \dots, f_n) = \sigma(f_1 \varepsilon_{\alpha_1}, \dots, f_n \varepsilon_{\alpha_n})$, continued linearly to complex f_k, has the same bound for every $i \geq i_n$ and all f_k carried by such cubes. A multilinear Λ with this bound has exactly one extension S, bounded for one Schwartz norm, to the complex Schwartz functions on $\mathbb{R}^{3n}$ vanishing with all their derivatives on the diagonals, and

$$|\mathsf{S}(\varphi)| \leq 2 \big(C_*\, \mathsf{u}\, n^7 L^{(\mathsf{v}+3)i_n}\big)^n |\varphi|_{(\lceil \mathsf{v} \rceil + 8)n},$$

C_* a number formed from v and two cutoff functions of one variable fixed once. Differences of products over the pairs $a < b$ of cutoffs in $|x_a - x_b|$ at the scales L^{-s}, $s \geq 0$, cut the non-coinciding configurations into shells on which the least distance of the points lies between L^{-s} and $\sqrt{2} L^{1-s}$, and is ≥ 1 at $s = 0$; a partition of unity of the mesh $w_s = L^{-i_s}/(16n)$, $i_s = \max\{i_n, s+1\}$, cuts each shell into pieces carried by products of boxes of the side $2w_s$ whose concentric cubes of the side $L^{-i_s}/(4n)$ lie at pairwise sup distances $\geq L^{-i_s}$, as $L \geq 13$. A piece is the sum of its Fourier series of the period $4w_s$ in each coordinate, and each mode times fixed cutoffs is a product of entries carried by these cubes, of sup norm ≤ 1; the operator $\prod_k (1 - (2w_s/\pi)^2 \Delta_k)^2$, four derivatives in each entry, bounds the sum of the moduli of the coefficients of a piece by 62^n times the supremum of its image under the operator, in which Leibniz's formula has at most $(n+1)^{4n}$ terms and the powers of $2w_s/\pi$ pay for the derivatives of the cutoffs.

The sum over the boxes of a shell, with the weight $(1 + |x|^2)^{-m/2}$ of the norm $|\cdot|_m$, $m = (\lceil \mathsf{v} \rceil + 8)n$, costs $(16n)^{3n} L^{3i_s n}$, and the bound on the cubes gives $(\mathsf{u} L^{\mathsf{v}i_s})^n$: in all $L^{(\mathsf{v}+3)i_s n} \leq L^{(\mathsf{v}+3)(i_n + s + 1)n}$. On the shell $s \geq 1$, Taylor's formula of the order $(\lceil \mathsf{v} \rceil + 4)n$ at a point of the diagonals at distance $\leq L^{1-s}$, where φ vanishes with all its derivatives, gives, up to a number to the power n, the factor $L^{-(s-1)(\mathsf{v}+4)n}$; so the shell s carries $L^{(\mathsf{v}+3)i_n n} L^{(2\mathsf{v}+7)n} L^{-sn}$, and the series over s converges. The index is $4n + (\lceil \mathsf{v} \rceil + 4)n = m$, and $(n+1)^{4n} (16n)^{3n} \leq 16^{4n} n^{7n}$.

At $\mathsf{v} = \frac{13}{2}$ the index is $15n$, and with $L^{i_n} \le 8nc_i$ one entry carries $n^5 \cdot n^7 \cdot n^{19/2} = n^{43/2}$; as $n^{43n/2} \le (e^n n!)^{43/2}$, the sum over the 6^n components of the labels gives

$$|\mathsf{S}_n(\varphi)| \le 2\big(6\,C_* \cdot 2c_3 g^2\, 8^5 (8c_i)^{19/2} e^{43/2}\big)^n (n!)^{43/2}\, |\varphi|_{15n}$$

for the one functional S_n of (h), this sum being bounded for a Schwartz norm and equal to σ at the smooth tuples: the pair $(15n, \frac{43}{2})$ serves. The kernel theorem, Proposition YMM1:93.1, gives the order $\le 4n+1$ on compact sets. □

Proof of Theorem D. Step 1: covariance (a) is Proposition 2.19 (a): with $(\mathsf{R}H)(x) = \mathsf{R}H(\mathsf{R}^{-1}x)\mathsf{R}^{\mathrm{T}}$,

$$\sigma(\mathsf{R}H_1, \dots, \mathsf{R}H_n) = \sigma(H_1, \dots, H_n) \qquad (\mathsf{R} \in \mathrm{O}(3)).$$

Step 2: every mirror (b). By Theorem C (b), σ is invariant under the translations and reflection positive at $\{x_3 = 0\}$; with (a), Lemma 2.20 (b) gives, for $\mathsf{g}x = \mathsf{R}x + cn$, $\mathsf{R}e_3 = n$,

$$\sigma(\theta_{n,c}\bar{F} \cdot F) = \sigma\big(\theta\, \overline{\mathsf{g}^{-1}F} \cdot \mathsf{g}^{-1}F\big) \ge 0.$$

Step 3: data (c). $(\mathrm{Rec1})_V$ is the composition of the translations (Theorem C (b)) with (a); $(\mathrm{Rec2})_V$ is Theorem C (b), the space being separable by the bounds and a countable dense family of tuples; $(\mathrm{Rec3})_V$ is Theorem C (e), or follows from (a) and $H \ge |P_1|$ by the unitary rotations about e_3, which turn $\mathcal{P}$; $(\mathrm{Rec4})_V$ is Theorem C (c). The classes of the C_c^1 tuples are dense, because a continuous entry is the uniform limit of its mollifications and σ is continuous under such limits; so the map of the two spaces is unitary. Since $g^{-2} \le b_*$, the numbers do not depend on σ:

$$C_V = 2^{p_V} C_{p_V} b_*^{-1} \le 2^{p_V} C_{p_V} g^2.$$

Step 4: kernels, representation, locality (d). Proposition 2.16 (a) at $V = \mathrm{Sym}_3(\mathbb{R})$ applies to σ^1. Its clause (vii) gives the kernels, extended to continuous entries by the continuity of Step 3; for the bound at every point, a direction u with $|u \cdot (x_a - x_b)| \ge |x_a - x_b|/n^2$ for all pairs exists, and the bound of $\mathbf{S}_n$ in the tube of the frame of u at $\eta = \frac{1}{2}\min\{1, \mathsf{d}(x)\}/n^2$ gives

$$|\mathsf{s}_n(x; e)| \le \big(C_V (2n^2/\min\{1, \mathsf{d}(x)\})^{p_V}\big)^n \prod_a |e_a|;$$

integrating gives the bound of σ, and $\mathsf{S}_n(\varphi) = \int \mathsf{s}_n \varphi$ with the Taylor bound of φ near the diagonals gives the growth with the norm $|\cdot|_{(\lceil p_V \rceil + 4)n}$. Its clauses (i)–(iii) and (v) give the representation, with $D(\Lambda)A = \hat{\Lambda} A \hat{\Lambda}^{\mathrm{T}}$, and (iv) the locality. The fields of Proposition 2.16 are the $T(f)$ of Theorem C (d): both are determined on $\mathcal{D}_\infty$ by $\langle \psi, T(f)\psi' \rangle = \int \lim_{s \downarrow 0} \langle U(x)^{-1}\psi, \mathsf{B}(s, s; f(x)) U(x)^{-1}\psi' \rangle\, dx$, which involves σ alone, and the totality used in Proposition 2.16 (a) (viii) is $\mathcal{H}^{\mathrm{ord}} = \mathcal{H}(\sigma)$, Theorem C (f).

Step 5: all couplings (e). Let $0 < g \le \gamma$. Extract a subsequence with converging labels, $b_j \to b_*$, and let z, g_1', g_2' be as in (e); $g_2' < g_1' \le \gamma_W^{\mathrm{sd}}$, and by Lemma 2.14 (b) the label $L^z b_*$ lies in the interior of $I(g')$ for one $g' \in \{g_1', g_2'\}$. By the same Lemma the dilated data are, from an index on, first-passage data at g', Theorem C (b) at g' gives a further subsequence with a tensor limit σ', and

$$\sigma(X) = L^{zn} \sigma'(X^{(z)})$$

exists. The dilation commutes with O(3), carries mirrors to mirrors and $H^{\mathrm{cons}}[\eta]$ to $H^{\mathrm{cons}}[\eta^{[z]}]$; so (a), (b) and the conservation pass from σ' to σ, and by Lemma 2.14 (b) $(\mathrm{Rec4})_V$ holds with $(3^{p_V} L^{4z} C_V[\sigma'], p_V, \frac{1}{2})$, where $C_V[\sigma'] \le 2^{p_V} C_{p_V}[g']\, g'^2$ by Theorem C (c) at g'; this is at most the number C_V of (e), which does not depend on the sequence. Then (c), (d) follow as in Steps 3, 4. □

Proof of Theorem E. Step 1: the identity. By Proposition 2.21 (a), for $a \le n_1$,

$$X_a = b^{-1}\Big[\mathcal{N}_{\eta_a} - \tfrac{1}{4}\mathfrak{N}[\mathsf{k}_{\eta_a}] - c_{\eta_a}\Big] - b^{-1} \sum_{e=1}^{9} \mathfrak{J}_e[\eta_a] :$$

null terms and a constant, and nine small entries. The same holds for each of the terms of the identity in the place of X_a.

Step 2: pieces. Fix the side $\ell' = 2\mathsf{l}$, put $s = \mathsf{l}/(8n)$, and cut every datum by a smooth partition of unity (χ_i) of mesh s, into pieces of sup diameter $\le \mathsf{l}/(4n)$; a ball of radius R meets at most $N_\chi = (2R/s+3)^3$ of the supports, and

$$|\chi_i H|_\infty \le |H|_\infty, \qquad \|\chi_i\eta\|_{C^2} \le C_\chi \|\eta\|_{C^2}, \qquad C_\chi = 1 + 2\sup|\nabla\chi_i| + \sup|\nabla^2\chi_i|.$$

By multilinearity it suffices to bound one choice of a piece for each slot.

Step 3: the board. Lemma 2.13 with $h = a_{K-t} = L^{-u} < \mathsf{l}/(2n)$ gives a board of side l with offset in $a_{K-t}\mathbb{Z}^3$ in which each piece lies in one cell at the margin δ,

$$\operatorname{dist}_\infty(\operatorname{supp}(\text{piece}), \text{wall planes}) > \delta = \frac{\mathsf{l}}{8n};$$

several pieces may share a cell.

Step 4: one cell, then the state. For $B \subset \{1,\dots,n\}$ group the factors $X_a - c_a$, $c_a = \langle X_a\rangle_{K,\ell',\beta}$, by cells. Lemma 2.7 with the pressure gap, $\mathsf{Q} = e^{\mathsf{l}^3 G_g}$, and Proposition 2.21 (c) in each cell give, for every $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$,

$$\Big|\nu\Big(\prod_{a\in B}(X_a - c_a)\Big)\Big| \le \prod_{a\in B}\mathsf{e}_a, \qquad \mathsf{e}_a = \mathsf{Q}\,\mathsf{C}_n\,\varpi(X_a)\,\mathsf{n}(X_a);$$

at $B = \{a\}$, $|\nu(X_a) - c_a| \le \mathsf{e}_a$.

Step 5: the centring in n factors. With $\delta_a = \nu(X_a) - c_a$,

$$\prod_a A^\nu[X_a] = \sum_B \prod_{a\in B}(X_a - c_a)\prod_{a\notin B}(-\delta_a),$$

and each of the 2^n terms has a ν-mean of modulus $\le \prod_a \mathsf{e}_a$: every term carries the factor of every slot, the small ones among them. A joint cumulant of order $n \ge 2$ does not change when constants are subtracted from its entries; as a sum over the partitions of products of the means of Step 4, it is at most $\mathsf{op}_n \prod_a \mathsf{e}_a$, $\mathsf{op}_n = \sum_\pi (|\pi|-1)!$.

Step 6: the exponent. By Proposition 2.21 (b), $\prod_a \varpi(X_a) = C_\omega^n K^{np_\omega} L^E$ with $u \le \phi K + 1$ and

$$E = n_1(3u - \tfrac{K}{28}) + 4u(n-n_1) \le -K\big[n_1(\tfrac{1}{28} - (4n-1)\phi)\big] + 4n = -c\,n_1 K + 4n,$$

since $n - n_1 \le n_1(n-1)$. This gives (a), with $p = np_\omega$ and $C = N_\chi^n \max\{2^n, \mathsf{op}_n\}(\mathsf{Q}\mathsf{C}_n C_\omega C_\chi)^n L^{4n}$.

Step 7: the second form (b). Change the scale by $z = z_C(g,d)$ steps, the least integer $z \ge 1$ with $L^z g^{-2}/2 \ge \mathsf{x}_W = (\gamma_W^{\mathrm{ref}})^{-2}$, the number of equation YMM1:(2326), and $\mathsf{l}_2 \le L^z d/2$, $2\mathsf{l}_\iota$ the least side at g'_ι, to the couplings

$$g_1'^{-2} = L^z g^{-2}/2, \qquad g_2'^{-2} = L^{z+1} g^{-2}/4,$$

at which the first-passage windows hold the dilated data. In the units of g the eight-cell board of the least torus at g'_ι then has a side smaller than d, and every piece gets a cell of its own; the conservation slot is bounded by Proposition 2.21 at the dilated datum, and the spectators by Proposition 2.10 at the orders $2,\dots,8$, uniformly in the cutoff. The rate becomes $L^{-K/36}$ in the original cutoff index. On a torus T_ℓ the same argument is made with the torus mean.

Step 8: the limit (c). At $n_1 = 1$ the bound of (a) tends to 0 along the data of σ, while the left side tends to $\sigma(H^{\mathrm{cons}}[\eta], H_2, \dots, H_n)$; continuous entries with compact disjoint supports off $\operatorname{supp}\eta$ are at a positive distance from each other, and $dL^u \ge K^2$ holds for large K. The second form of (5) is the identity of V

$$\sum_i (\partial_i\zeta)\mathsf{m}_{ij} = H^{\mathrm{cons}}[\zeta e_j].$$

On a torus, (b) and the convergence of Theorem G (E3) (ii) give the vanishing of the limit.

Step 9: kernels and operators (d) is Lemma 2.22: the identity of the kernels gives, and is given by,

$$T_{0\nu}(\partial_0 F)\psi = \sum_{k=1,2} T_{k\nu}(\partial_k F)\psi \qquad (\psi \in \mathcal{D}_\infty).$$

□

Proof of Theorem F. Step 1: the space (a). By Lemma 2.23 (a) the conditional means $\mathsf{e}_j(X)$ take values in compact intervals and depend continuously on X, uniformly in j; for a countable dense family $\mathfrak{F}$ of tuples, the images of ν_j under $\omega \mapsto (\mathsf{e}_j(X)(\omega))_{X\in\mathfrak{F}}$ are probability measures on a countable product of compact intervals, compact and metrisable, and along a subsequence they converge to a measure; by Lemma 2.23 (c) its moments are the iterated plateaux of σ, which do not depend on the subsequence. X is its support, $\sigma_\xi(X)$ the coordinate of ξ at X, extended by continuity, and

$$m(X^1,\dots,X^q) = \int_{\mathsf{X}} \prod_i \sigma_\xi(X^i)\, d\lambda(\xi).$$

The continuity of $\xi \mapsto \sigma_\xi(X)$ and the injectivity hold by construction, the coordinates of $\mathfrak{F}$ separating the points of X.

Step 2: the approximants (b) (i). For $\xi \in \mathsf{X}$ and finitely many $X \in \mathfrak{F}$, the set of the ω at which $\mathsf{e}_j(X)(\omega)$ is within ε of $\sigma_\xi(X)$ is an invariant event of positive ν_j-measure for large j, since ξ lies in the support of λ; a periodic Gibbs state conditioned on an invariant event is again one. Letting the finite set grow and $\varepsilon \downarrow 0$ slowly along the full sequence gives $\rho_j = \nu_j(\cdot \,|\, E_j)$ with

$$\big\| E_{\rho_j}[A_j(X) \,|\, \mathcal{I}] - \sigma_\xi(X) \big\|_{L^\infty(\rho_j)} \to 0.$$

Step 3: one entry; recentring (b) (ii). $H \mapsto \sigma_\xi((H))$ is linear, continuous for the sup norm on compact sets, and invariant under $\mathbb{R}^3 \rtimes W_3$; so it is $\int \operatorname{tr}(AH)$ with a matrix A invariant under W_3, that is $A = \frac{c}{3}\mathbf{1}$; and c is determined by the scalar entries, so it depends on $\pi(\xi)$ alone. Replacing in the lattice entries the centring by ν_j with the centring by ρ_j changes each factor by a quantity that tends to $\sigma_\xi((H_a))$ uniformly; so σ^c_ξ is the tensor limit of (K_j, β_j, ρ_j), and Lemma 2.24 (c) gives the unitary map.

Step 4: the unique vacuum (b) (iii). By Lemma 2.23 (d), $\lim_{|v|\to\infty} \sigma_\xi(X \cdot \tau_v Y) = \sigma_\xi(X)\sigma_\xi(Y)$, so for $F \in \mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$

$$\|P_0^\xi [F]_\xi\|^2 = \lim_{t\to\infty} \langle [F]_\xi, e^{-tH_\xi}[F]_\xi\rangle = |\sigma_\xi(F)|^2 = |\langle \Omega_\xi, [F]_\xi\rangle|^2,$$

on a dense set, hence everywhere: $\ker H_\xi = \mathbb{C}\Omega_\xi$.

Step 5: the map to the scalar decomposition (b) (iv). The restrictions $\sigma_\xi|_{V_0}$ form, with (X, λ), a decomposition of the scalar part with the plateau formula; by the uniqueness of the canonical decomposition of the scalar limits, Proposition YMM1:101.1, $\xi \mapsto \sigma_\xi|_{V_0}$ factors through exactly one map π to X_0, continuous and onto,

$$\sigma_\xi(f_1\mathbf{1},\dots,f_n\mathbf{1}) = \sigma_{0,\pi(\xi)}(f_1,\dots,f_n),$$

and the plateau formulas give $\pi_*\lambda = \lambda_0$.

Step 6: Wightman fields (c). By (b) (ii), σ^c_ξ is a tensor limit at g, so Theorem D (c), (d) apply to it with the same numbers; it has (Rec5) by (b) (iii) and the unitary map of (b) (ii). Proposition 2.16 (a) (i) with (Rec5) gives the uniqueness of the invariant vector; the Hermiticity is

$$\langle \psi, T(f)\psi'\rangle = \langle T(f^*)\psi, \psi'\rangle, \qquad f^* = \rho(\theta)\bar f,$$

under which a component with r indices equal to 3 is Hermitian after the factor i^r; the representation, the spectrum, the locality and the cyclicity are Theorem D (d) and Theorem C (f) for σ^c_ξ. The growth is Theorem C (h), whose numbers do not depend on the limit.

Step 7: the frame over a component (d). The frame is formed at the label matrices m_{ij} of the stress tensor, the labels of $\frac12\delta_{ij}\operatorname{tr} T - T_{ij}$; (M1), (M2), (M3), (M5) are linear in the label. (M1) and the operator formula of (M2) are Theorem C (d) (vi) for σ^c_ξ, and the covariance of the kernels is Theorem D (d) (i) with $\rho(\mathsf{R})\mathsf{m}_{ij} = \sum_{i'j'} \mathsf{R}_{i'i}\mathsf{R}_{j'j}\mathsf{m}_{i'j'}$, at $\mathsf{s}_{ij}(x;y) = \mathsf{s}_{1+m}(x,y;\mathsf{m}_{ij},\mathbf{1},\dots,\mathbf{1})$. The scalar subspace reduces H, $\mathcal{U}$, $\mathcal{P}$, and it is invariant under the families $\mathcal{T}(\mathfrak{z})$ and $\mathsf{b}(w|\mathbf{1}|w')$, which

are closed under the adjoint; so its projection Π_0 commutes with $\phi(f) = T(f\mathbf{1})$ on $\mathcal{D}_\infty$, and with $T^E_{ij}(F_1) = \Pi_0 T(F_1 \mathsf{m}_{ij})\Pi_0$,

$$T^E_{ij}(F_1)\phi(f)\psi = \Pi_0 T(F_1\mathsf{m}_{ij})\phi(f)\psi = \Pi_0\phi(f)T(F_1\mathsf{m}_{ij})\psi = \phi(f)T^E_{ij}(F_1)\psi$$

at spacelike separation by the locality: (M3). The scalar subspace reduces $U(a,\Lambda)$ as well: the restriction of $(\sigma^c_\xi)^1$ to the tuples with entries in V_0 is reconstruction data with the label space V_0, whose space is the scalar subspace, and by Proposition 2.16 (a) (v) the span of Ω and of the vectors $\phi(f_1)\cdots\phi(f_n)\Omega$ is dense in it; as $\hat\Lambda\mathbf{1}\hat\Lambda^{\mathrm{T}} = \hat\Lambda\hat\Lambda^{\mathrm{T}} = \mathbf{1}$, Theorem D (d) (ii) gives $U(a,\Lambda)\phi(f)U(a,\Lambda)^{-1} = \phi(f(\Lambda^{-1}(\cdot - a)))$ on $\mathcal{D}_0$, and with $U(a,\Lambda)\Omega = \Omega$ every $U(a,\Lambda)$ maps this span onto itself; U being a unitary representation, the scalar subspace and its orthogonal complement are invariant, and Π_0 commutes with every $U(a,\Lambda)$.

So U restricts to a representation on the scalar subspace, and (M5) is Π_0 applied to the Lorentz covariance on Ω of Theorem D (d) (ii), with the passage from the Euclidean labels to $T_{\mu\nu}$ of Definition 2.3 (3). (M4) (a): conservation passes to σ^c_ξ by Lemma 2.24 (b), so Theorem E (c), in the second form of (5) with ζ vanishing near the scalar points, gives $\sum_i \int \partial_i\zeta(x)\,\mathsf{s}_{ij}(x;y)\,dx = \sigma^c_\xi(H^{\mathrm{cons}}[\zeta e_j], \text{the scalar entries}) = 0$; the scalar subspace has a unique vacuum, by (b) (iii); and Lemma 2.22 gives (M4) (a). At the labels $e_ie_j^{\mathrm{T}} + e_je_i^{\mathrm{T}} = \delta_{ij}\mathbf{1} - \mathsf{m}_{ij}$ the identity of the kernels fails: among one scalar entry their divergence is $\partial_{x_j}\mathsf{s}_2(x,y;\mathbf{1},\mathbf{1})$, which does not vanish identically by the free law (E6) of Theorem G; the components T_{ij} themselves are not conserved.

Step 8: the frame on $\mathcal{H}_0$ (e). For σ itself the same compression applies without the unique vacuum: (M1) is Theorem C (d) (vi), the covariant kernels come from Theorem D (d) (i), and (M3), (M5) are the compressions of Theorem D (d) (iii), (ii), as identities between scalar vectors, for instance

$$\langle\Omega, \phi(f_1)\cdots\phi(f_n)T[\Lambda t](F\circ\Lambda^{-1})\Omega\rangle = \langle\Omega, \phi(f_1\circ\Lambda)\cdots\phi(f_n\circ\Lambda)T[t](F)\Omega\rangle.$$

□

Proof of Proposition 2.5. The argument follows the proofs of Propositions YMM1:108.3, YMM1:110.2 and YMM1:110.1 for scalar data, with one entry carrying a label; its steps are these.

Step 1: the scalar part and one label. Let $e' \in V \setminus V_0$. For a tuple whose entries all lie in V_0, $f_1\mathbf{1} = f_1(\mathbf{1} - e') + f_1e'$ writes it as the sum of two tuples with exactly one entry outside V_0, at which $\sigma(\mathsf{R}X) = \sigma(X)$ is supposed; so the scalar part of σ is invariant under O(3), and with the translations it is invariant under all the isometries. With Theorem C (b), (c), (e), which give the positivity, the point bound and the circular cone, the space being separable by the bounds and a countable dense family of tuples, its restriction to C^1_c entries is scalar reconstruction data (Rec); Theorem YMM1:AP gives this as well, as in Step 6 of the proof of Theorem C. The insertion and point operators with one tensor label and their energy bounds are those of Theorem C (d), and Proposition 2.18 (c) gives the kernel $\mathsf{s}_{1+m}(x,y;e,\mathbf{1},\dots,\mathbf{1})$ of one tensor entry among m scalar entries, continuous and real-analytic at all non-coinciding points; by continuity, the supposed covariance at one label is $\mathsf{s}_{1+m}(\mathsf{R}x+v,\mathsf{R}y+v;\rho(\mathsf{R})e,\mathbf{1},\dots,\mathbf{1}) = \mathsf{s}_{1+m}(x,y;e,\mathbf{1},\dots,\mathbf{1})$ for $\mathsf{R}\in\mathrm{O}(3)$, $v\in\mathbb{R}^3$.

Step 2: one holomorphic function at one label; (M2). For a frame $\mathsf{R}_u \in \mathrm{SO}(3)$ with $\mathsf{R}_u e_3 = u$ and an order ς of the $1+m$ points along u, the piece on the tube of the configurations ordered along u in the order ς is the function $\mathbf{W}_{1+m}$ of Theorem C (d) (iii) written in the frame R_u at the label $\rho(\mathsf{R}_u)^{-1}e$; in the components of the label it is

$$\sum_{i',j'}(\mathsf{R}_u)_{ii'}(\mathsf{R}_u)_{jj'}\,\mathbf{W}_{1+m}\big(\mathsf{R}_u^{-1}\cdot; E_{i'j'},\mathbf{1},\dots,\mathbf{1}\big),$$

$E_{i'j'}$ the symmetrised matrix units, that is $\rho(\mathsf{R}_u)\mathbf{W}_{1+m}(\mathsf{R}_u^{-1}\cdot)$ at the one label. At the real points of the intersection of two tubes, the configurations ordered in both frames, both pieces are equal to the kernel of Step 1, by the covariance at one label; the intersection is convex and these real points

form an open subset of its real section, so the two pieces agree on it, and they form one holomorphic function on the union of the tubes. As $|(\mathsf{R}_u)_{ii'}| \le 1$, its bound is that of $\mathbf{W}_{1+m}$ times at most 9, the number of the terms (i', j'). Its restriction to the real non-coinciding configurations is the kernel; so the kernels $\mathsf{s}_{ij}(x;y) = \mathsf{s}_{1+m}(x, y; \mathsf{m}_{ij}, \mathbf{1}, \dots, \mathbf{1})$ are covariant at all non-coinciding points, and with the product formula of Theorem C (d) (vi) this is (M2).

Step 3: locality; (M3). The matrix elements of products of the fields between vectors of $\mathcal{D}_\infty$ are the boundary values of the one function of Step 2 from the tubes of the orders of the real times. For a pair of spacelike separated points, one of them carrying the label, the tubes of the two orders are joined by the tubes of the frames tilted by an angle of the order η towards the direction of the separation, on which the function is one and the same; apply the uniform smeared-bound argument in the proof of Proposition 2.16 (a) to the holomorphic kernel and polynomial bound of Step 2, with its single tensor label fixed and the remaining labels scalar. The Cauchy–Riemann identities and integration by parts give the same bound $2\eta Q_e(D'g)$ for the difference of the two orders, with $Q_e(D'g)$ independent of η; hence the boundary values agree as $\eta \to 0$. So $\langle \psi', [T(F_1 \mathsf{m}_{ij}), \phi(f)]\psi\rangle = 0$ at spacelike separation for ψ', ψ in the span of the vectors $e^{-\tau H}[F]$, $\tau > 0$, F scalar, which lie in $\mathcal{D}_\infty$, are dense in $\mathcal{H}_0$ and form a core of every power of $1 + H$ there (Lemma 2.22 (a), (b), at the span $\mathcal{V}_1$); the bound of (M1) and the commutation of Π_0 with $\phi(f)$ on $\mathcal{D}_\infty$, as in Step 7 of the proof of Theorem F, carry this to $T^E_{ij}(F_1)\phi(f)\psi = \phi(f)T^E_{ij}(F_1)\psi$ on $\mathcal{D}_0$: (M3).

Step 4: Lorentz covariance; (M5). The invariance of $\mathbf{W}_{1+m}$ at one label under the real rotations R_ζ in the plane of e_1, e_3, the label being turned by $\rho(\mathsf{R}_\zeta)$, continues holomorphically in the angle ζ to the imaginary angles $\zeta = is$, which act on the arguments, through ι, as the boosts of rapidity s in the plane of (t, x_1); the label is then moved by $\rho_{\mathbb{C}}(\mathsf{R}_{is})$, $\rho_{\mathbb{C}}$ the holomorphic continuation of $\rho|_{\mathrm{SO}(3)}$, that is by $e \mapsto \hat\Lambda e \hat\Lambda^{\mathrm{T}}$, and no bound on this factor is needed, the identity being one of holomorphic functions at fixed arguments. With the real rotations in the plane of e_1, e_2, which fix e_3, this gives the invariance of $\langle \Omega, \phi(f_1)\cdots\phi(f_m)T(F)\Omega\rangle$, the tensor entry at the last place, under $(f_k, F) \mapsto (f_k \circ \Lambda^{-1}, \hat\Lambda F(\Lambda^{-1}\cdot)\hat\Lambda^{\mathrm{T}})$ for all $\Lambda \in \mathcal{L}$.

The scalar data of Step 1 carry the representation U of $\mathbb{R}^{1+2} \rtimes \mathcal{L}$ on $\mathcal{H}_0$ with

$$U(\Lambda)\phi(f_1)\cdots\phi(f_m)\Omega = \phi(f_1 \circ \Lambda^{-1})\cdots\phi(f_m \circ \Lambda^{-1})\Omega$$

(Proposition 2.16 (a) at V_0); these vectors are dense in $\mathcal{H}_0$, and the invariance reads $U(\Lambda)\Pi_0 T(F)\Omega = \Pi_0 T(\hat\Lambda F(\Lambda^{-1}\cdot)\hat\Lambda^{\mathrm{T}})\Omega$. At the label matrices m_{ij}, with the passage from the Euclidean labels to $T_{\mu\nu}$ of Definition 2.3 (3), this is (M5). □

Proof of Theorem G. Step 1: (E1). By Lemma 2.11, which holds for complex weights, $\mathcal{T}_K(H_a)$ is the first member of a source under $(60|H_a|_\infty, S_{H_a})$ for H_a with values in $V_{\mathbb{C}}$, and Proposition 2.10 (a) holds for source systems real or not; so the number 60^n holds for complex H_a. Since $s(d) \le K$, $a_K \le d/C_W(s(d)) \le d/2197$, and a plaquette of S_{H_a} lies within $a_K/\sqrt{2}$ of the points of Σ_a; so (Geo) at d gives the geometry of Proposition 2.10:

$$0.87\,d + 0.71\,d/2197 \le \tfrac{7}{8}d, \qquad 1.26\,d - 1.42\,d/2197 \ge \tfrac{5}{4}d.$$

Proposition 2.10 (a), (b) give the bound and its logarithmic form, and (a′) the factor off the small sides.

Step 2: (E2). A box of side $\le 0.99\,d''$ lies in a ball of radius $0.8574\,d''$, and boxes that meet different Σ_a are at distance $\ge d \ge \frac{4}{3}d'' \ge 1.26\,d''$; by multilinearity the cumulant is a sum over the choices of boxes, each bounded by (E1) at d'', which gives (i), the number of boxes being at most $(2\ell/d'')^3$. For $K < s''$ a box holds at most $3(d''/a_K + 1)^3$ points of plaquettes and bonds, $|a_p| \le 2$, $|q_{\mathfrak{b}}| \le 4$, $L^K d'' < C_W(s'')$ and $b \le \bar x_0$:

$$|\mathcal{T}_K(h)| \le 18\,\bar x_0\,(C_W(s'') + 1)^4/d'' \cdot b^{-1} \sup|h| \quad \text{for } h \text{ carried by one box},$$

and the cumulant is a sum over the partitions of products of means, which gives (ii) with f_n. For (iii), at low cutoffs an exponential moment $\mu(e^{\beta a_p}) \le C$ of one plaquette gives a bound $C_n^{\mathrm{cr}}(6\ell^3 C_W (s'')^3/d''^3)^n$, and at high cutoffs (i) applies.

Step 3: (E3). (i) The dilation of the lattice by L^z (Proposition YMM1:119.1) gives the identity of the cumulants

$$\langle \mathcal{T}_K(H_1); \dots ; \mathcal{T}_K(H_n)\rangle_{K,\ell,\beta} = L^{zn} \langle \mathcal{T}_{K_\star}(H_1(L^{-z}\cdot)); \dots \rangle_{K_\star, L^z\ell, \beta},$$

at the label $a_{K_\star}\beta = L^z b$, and (E1) at $g_\star$ and the distance $L^z d$; the bounds of the label at $g_\star$ give $\delta_\star b \le L^{-z} < g_\star^2 b$, and $\log(1/(L^z d)) \le \log(b/d) + C(g_\star)$. The statement is invariant under $(K, \ell, b, d) \mapsto (K-1, L\ell, Lb, Ld)$. (ii) By Corollary YMM1:74.2 the pairs $(K, L^K b)$, $b \in I(g)$, are first-passage data at g with label b, and every $\ell \in \mathfrak{L}(g)$ has (Sd.1) by Proposition YMM1:74.1; the convergence along the full sequence, n-linear and symmetric, with the rates of its clauses (a) and (b), is Proposition 2.12, applied to the six cell insertions of each entry, real and imaginary parts apart, the cumulant being a sum of at most 12^n cumulants of cell insertions (6^n at real entries), and the bound is (E1) with (a′), the radii $0.86\,d$ and $1.27\,d$ leaving room for the lattice corrections.

Step 4: (E4). (i) At two points the leading term of the cumulant at the working level is the Gaussian value of the effective density, which is free of d, and the other terms are smaller; it is computed on the least torus with the moments of eight and sixteen mirror copies of the pair, and carried to every side and every state by Lemma 2.7, which gives, for real weights,

$$|\langle \mathcal{T}_K(H_1); \mathcal{T}_K(H_2)\rangle| \le 180^2 C^\diamond(g)\, b^{-2} |H_1|_\infty |H_2|_\infty,$$

with the number $C^\diamond(g) = \max\{2\,\mathsf{c}_\diamond(g)^2, C_2^T(\frac12; 1)\}$ of (E4) (i), and with the factor 4 for complex weights, their real and imaginary parts being taken apart; on one torus the same holds from the first depth $s_1(g,\ell)$ on. (ii) Cut each of the three cubes into 4^3 cubes of side $\delta/4$; the cumulant is a sum of 64^3 cumulants of pieces, and three pieces, one from each cube, are at pairwise sup distances $\ge 2\delta = 8 \cdot \frac{\delta}{4}$, so that a coordinate mirror parts one of them from the other two. The third cumulant is the third centred moment, and the Schwarz inequality at this mirror gives $|\kappa|^2 \le \langle \text{pair} \cdot \text{its mirror image}\rangle \langle \text{single} \cdot \text{its mirror image}\rangle$.

The pair with its mirror image is a centred moment of four entries, the sum over the partitions into blocks of at least two members of products of cumulants, at most $60^4(k_4' + 3k_2'^2) b^{-4}$ times the sup norms by Proposition 2.10, with the power $32\mathfrak{p}_0$ of the logarithm; the single entry with its mirror image is a two-point function on the one torus, bounded by the second statement of (i), with a number free of the distance and of the logarithm. After the square root the power of the logarithm is $16\mathfrak{p}_0$, and the bound carries b^{-3}. (iii) The history without large-field regions is entered at the level T of (E4) (iii), in the place of the working level of (E1), and the smallness of the side is replaced by the ceiling $y_K \ge \mathsf{Y}^\natural$ of Definition L.1, under which Proposition L.6 bounds the large-field regions uniformly in the volume, with its constant $c_2^\natural$.

By the flow bound YMM1:(1530) at the indices $0 \le T$, $|x_T - L^{K-T} b| \le \bar B$, and $\bar B \le \frac{13}{24} g^{-2} < \frac{13}{24} b$ (Lemma G.3); with $L^{K-T} = \hat d/d$, $\hat d \ge 3$ and $d < 1$ this gives $x_T \ge 3b/d - \bar B > 2b/d$ and $\bar B \le \frac14 x_T$, so that $d \le b\, e^{-y^\sharp}$ gives $y_T \ge y^\sharp$, and the conditions that define $y^\sharp$ hold at $y = y_T$. At the levels $j \le T$, $x_j \ge x_T \ge x_{\mathrm{J}}$ and $\theta(x_j) \le \theta(e^{y_T})$, a number formed from the constants and p; this closes the induction of the mixed derivatives, as (N.θ) does in the proof of Proposition 2.10. By the choice of T the least sup distance D_T of two supports in the units of the level T is at least $M(2 + \frac{p}{2} y_T)$, so that a polymer that joins two supports has there a linear size of at least $\mathsf{D}_T/M - 2 \ge \frac{p}{2} y_T$.

The correction to the first-order size of one entry at the level T carries $e^{-d_*(T)}$, $d_*(T)$ being the counterpart at the level T of the quantity $\min\{c_{\mathrm{d}}\, \varepsilon_k^{-1}, (\ell/(2a_{K-k}) - 4)/(2M)\} - 1$ of the proof of Proposition 2.10, and $d_*(T) \ge \frac12 y_T$ makes it at most $x_T^{-1/2}$. The configurations with a large field enter through the level $t \le T$ of its first creation, with the weight of Proposition L.6 per unit cube of that level; with the count of the unit cubes of the torus at the level T, $(\ell L^{K-T})^3 \le (\frac54)^3 (\ell/b)^3 e^{3y_T}$,

as $L^{K-T}b \le x_T + \bar B \le \frac{5}{4}x_T$, and with the sizes of the p insertions, they add at most a number formed from the constants and p times

$$e_T = 4\cdot 24^3\big(\tfrac{5}{4}\big)^3(\ell/b)^3\exp\big((3+p^2)y_T - c_2^\natural A_0^2 y_T^{2\mathfrak{p}_0}\big) \le 1$$

times the term of the history without large-field regions, the terms of the levels $t<T$, at which $y_t > y_T$, decreasing geometrically by $2\mathfrak{p}_0 c_2^\natural A_0^2 y^{2\mathfrak{p}_0-1} \ge 4+(3+p)p$. At the level T the size of a plaquette source carries $y_T^{2\mathfrak{p}_0}$, the supremum of $x_T a_p$ on the small fields, and the count of the unit cubes of that level in a ball of radius d the factor $\hat d^3$: this is the first form of the bound. By the maximality of T, $\hat d < L(M(2+\frac{p}{2}y_{T+1})+1) \le L(M(2+\frac{p}{2}y_T)+1)$, which gives the second form; and $x_T \le L^{K-T}b + \bar B < \frac{4}{3}L(M(2+\frac{p}{2}y_T)+1)\,b/d$ gives the bound of y_T.

Step 5: (E5). (i) The cumulant of order $n\ge 2$ is the sum over the partitions π of $\{1,\dots,n\}$ without singletons of $(-1)^{|\pi|-1}(|\pi|-1)!$ times the products over the blocks B of the moments of the entries of B centred in the state. For $K \ge \max_m K^G(m)$ each of these moments is bounded by Theorem C (a) at its own order $\#B$, which gives the second bound; on a torus the chessboard estimate takes the place of the domination, the pieces of different entries lying in cells different modulo the side; for the finitely many smaller cutoffs the crude bound of Step 2 holds. Together these give a number $C_n^T(d;R)$. (ii) Extraction as in Theorem C (b); on the scalar entries the limit is the scalar limit; on one torus the full sequence converges by (E3) (ii), and the bounds of (i) do not depend on the side. (iii) The cumulant does not change when each entry is centred by its mean m_a on the least torus $T_{\ell'}$; by the moment–cumulant formula it is then the sum over the partitions π of $\{1,\dots,n\}$ of $(-1)^{|\pi|-1}(|\pi|-1)!$ times the products over the blocks B of the moments of the entries of B, centred by these numbers.

Since $s(d)\le K$, $a_K \le d/2197 < \mathsf{l}/(2n)$, the distance d being $\le \mathsf{l}/(6.96\,n)$, and $\mathsf{l} = \ell'/2 \in a_K\mathbb{Z}$; so Lemma 2.13 at $h = a_K$ gives a board of side l in which the n balls of radius $0.87\,d$ that hold the sets Σ_a, of sup diameter $\le 1.74\,d \le \mathsf{l}/(4n)$, lie in cells at the margin $\mathsf{l}/(8n)$; on a torus T_ℓ, $\ell\in\mathfrak{L}(g)$, the lemma is applied to lifts, ℓ being a multiple of $2\mathsf{l}$, and the cells are taken modulo the side. Let $\mathcal{C}$ be the partition of the entries whose sets share a cell, modulo the side on a torus. The moment of a block B is the mean of the product of the functions $\Phi_C = \prod_{a\in B\cap C}(\mathcal{T}_K(H_a) - m_a)$ of different cells, one for each class $C\in\mathcal{C}$ that meets B, each a function of the bonds inside its cell, as the margin $\mathsf{l}/(8n)$ exceeds a_K; and the domination with the pressure gap, Lemma 2.7 at $\ell_1 = \ell' = 2\mathsf{l}$,

$$\Big|\nu\Big(\prod_C \Phi_C\Big)\Big| \le \prod_C e^{\mathsf{l}^3 G_g}\|\Phi_C\|_{\mathrm{ch},\ell'},$$

bounds it in every periodic Gibbs state, and on every torus of $\mathfrak{L}(g)$ with the chessboard estimate, the cells being different modulo the side. The board of side l has eight cells on $T_{\ell'}$; so the eighth power of $\|\Phi_C\|_{\mathrm{ch},\ell'}$ is the mean on $T_{\ell'}$ of the product of the $8m$ mirror copies of the $m = \#(B\cap C)$ centred entries of the cell, at complex weights with the conjugations of the reflections, $\overline{\mathcal{T}_K(H)} = \mathcal{T}_K(\bar H)$ being a source under the same majorant. The copies are centred, the mean on $T_{\ell'}$ being invariant under the lattice isometries (Lemma 2.11); so this mean is the sum over the partitions of the copies into blocks of at least two members of products of cumulants.

The copies in one cell are the images of the entries under one isometry, so their sets lie in balls of radius $0.87\,d$ and are $\ge 1.26\,d$ apart; the copies in different cells lie at sup distance $\ge \mathsf{l}/(8n)$ from the walls, hence at distance $\ge \mathsf{l}/(4n) \ge 1.74\,d$ from each other: the $8m$ copies have (Geo) at d. The least side at $g\le\gamma_W^{\mathrm{sd}}$ is small over the running couplings of every first-passage datum, so Proposition 2.10 (a) applies on $T_{\ell'}$ at every order $r = \#I \le 8n$: (N.θ) at $(8n, g, s(d))$ gives (N.θ) at $(r, g, s(d))$ for $2\le r\le 8n$, the numbers $T_r(3)$ not decreasing in r, as each term of the series that forms $T_r(3)$ carries the r-th power of a number ≥ 1.

With the majorants $60|H_a|_\infty$ of Step 1, at complex weights too, it needs no upper bound on the distances and bounds each cumulant by $60^{\#I} k'_{\#I}(g, s(d))\, b^{-\#I}$ times the sup norms. So

$$\|\Phi_C\|_{\mathrm{ch},\ell'} \le 60^m\, \mathfrak{m}_{8m}(g, s(d))^{1/8}\, b^{-m} \prod_{a \in B \cap C} |H_a|_\infty,$$

and the sum over the partitions π, with the maximum over $\mathcal{C}$, gives the number k_n^{fold}. By Proposition 2.10 (b), $\mathfrak{m}_{8m}(g, s)$ is at most a number times $Y_s^{64m\mathfrak{p}_0}$; so each eighth root carries the power $8\mathfrak{p}_0$ of $Y_{s(d)} \le 2 \log \frac{1}{d} + C(g)$ per entry of the cell, and the powers add up to $8n\mathfrak{p}_0$, as the classes $B \cap C$ part $\{1, \dots, n\}$ for each π. The cumulants of a tensor limit are the limits of the lattice cumulants, which gives the last bound.

Step 6: (E6). At the working level of the distance d the effective density is, up to the non-Gaussian part, that of three free photon fields B_λ; the Wick value of the cumulant of $\langle B_\lambda, B_{\lambda'} \rangle(x)$ and $\langle B_\mu, B_{\mu'} \rangle(y)$ is

$$b^{-2} \cdot \tfrac{3}{2} \operatorname{tr}\big[E_1 K_3(x - y) E_2 K_3(x - y)\big] \quad \text{for the labels } E_1, E_2,$$

since the propagator of the field strength of a free photon in three dimensions is K_3 up to a contact term. The non-Gaussian part is smaller by a negative power of $\log \frac{1}{d}$, which gives $e_g(d)$. The transfer from the least torus to every side and every state uses the chessboard estimate with eight and sixteen mirror copies. Since $\mathsf{W} \ne 0$, the limit determines b_*. For the bump of (E6), $0 \le \varphi \le 1$, $\varphi = 1$ on $B(x_0, d/128)$ and $\varphi = 0$ off $B(x_0, d/64)$, $x_0 = \frac{3}{2} d\, e_3$, the explicit evaluation of $\mathsf{W}(\theta(\varphi E), \varphi E)$ gives at least $w_0 \operatorname{tr} E^2$; with the remainder, at most $e_g(d) b_*^{-2} \operatorname{tr} E^2$, this gives the positivity at the d with $e_g(d) < w_0$.

Step 7: (E7). Let $\ell \in \mathfrak{L}(g)$, $b \in I(g)$, and let u be the limit cumulant of (E3) (ii), continued complex linearly and restricted to smooth entries: a functional of n entries on $\mathbb{M} = T_\ell$ with $V = \mathrm{Sym}_3(\mathbb{R})$, in the sense of Lemma 2.25. *The bound* (W). Closed cubes of the side $\frac{3}{2}h$ lie in the balls of radius $\frac{3\sqrt{3}}{4} h < 1.3\, h \le 0.86\, d$ about their centres, $d = 1.52\, h$, and cubes at pairwise sup distances $\ge \frac{5}{2} h$ are $\ge 1.27\, d$ apart; if $1.52\, h \le L^{-s_{\mathrm{th}}(n)}$, then $d < 1$ and $L^{s(d)} \ge C_W(s(d))/d \ge L^{s_{\mathrm{th}}(n)}$, so that (N.$\theta$) holds at $(n, g, s(d))$, $s_{\mathrm{th}}(n)$ being the number of (E2). So the bound of the limit in (E3) (ii), with Proposition 2.10 (b) and

$$2 \log \tfrac{1}{1.52\, h} + C(g) \le \big[2 + 2 \log \tfrac{1}{h_0} + C(g)\big]\, l(h) \qquad (0 < h \le h_0),$$

gives $(\mathrm{W}; 0, 8n\mathfrak{p}_0, 0)$ for u, with $h_0 \in \ell 2^{-\mathbb{N}}$, $h_0 \le \min\{\ell/(64n), \frac{1}{2} L^{-s_{\mathrm{th}}(n)}\}$, and

$$A = 60^n \max\{1, \mathsf{c}(\ell)\}^n C_n(g) \big[2 + 2 \log \tfrac{1}{h_0} + C(g)\big]^{8n\mathfrak{p}_0} b^{-n},$$

at complex entries as well, (E1) holding at complex weights (Step 1) and the limit being continued complex linearly. *The extension.* Lemma 2.25 (a)–(c) at $\kappa = 0$, $q = 8n\mathfrak{p}_0$, $r = 0$ give

$$\tilde{S}_n(F) = \sum_{Q \in \mathcal{Q}} u_Q(\varphi_Q(F - P_Q F)), \qquad P_Q F \text{ of total order} \le 3k \text{ at a stratum of } k \text{ clusters},$$

a distribution of order at most $3n - 2$, as $\lfloor \frac{3n}{2} \rfloor + 1 \le 3n - 2$; and $\epsilon = 1$, every $3k$ being an integer, so that $|\tilde{S}_n(F)| \le C\, b^{-n} l(\lambda)^{8n\mathfrak{p}_0 + 1} \|F\|_{(\lambda), 3n-2}$ for $0 < \lambda \le h_0$ and every λ-supported F, with $C = C(n, g, \ell)$, which depends on the side through $\mathsf{c}(\ell)$ and h_0. *The lattice cumulants.* Let $u_K(F)$ be the lattice cumulant at $(K, \ell, L^K b)$ with the weights read at the barycentres of the plaquettes and the midpoints of the bonds, continued to functions F on T_ℓ^n as a finite sum of values of F. By (E1) with the factor $\max\{1, \mathsf{c}(\ell)\}^n$ of the sides with (Sd.1), u_K has the inequality of $(\mathrm{W}; 0, 8n\mathfrak{p}_0, 0)$, with the same A and h_0, at the sides $h \le h_0$ with $s(1.52\, h) \le K$, an interval $[h'_K, h_0]$ since $s(\cdot)$ does not increase; and $(u_K)_Q(G) = u_K(G)$, the Fourier series converging at every point. With

$\mathcal{Q}_K = \{Q \in \mathcal{Q} : s(1.52\, h(Q)) \le K\}$ and h_K the least side in $\mathcal{Q}_K$, the subtracted lattice cumulant is

$$\tilde{u}_K(F) = \sum_{Q \in \mathcal{Q}_K} (u_K)_Q(\varphi_Q(F - P_Q F));$$

it differs from $u_K(F)$ by $\sum_{Q\in\mathcal{Q}_K} u_K(\varphi_Q P_Q F)$, which reads of F the derivatives of the orders $\le 3k$ on the strata of k clusters alone, and by a term that reads F where $\mathsf{d}_\infty < 6h_K$ alone. The clause of Lemma 2.25 (c) on a range of sides, at $h_\flat = h_K$, gives $|\tilde{u}_K(F)| \le C\, b^{-n} l(\lambda)^{8n\mathfrak{p}_0+1} \|F\|_{(\lambda),3n-2}$ for all K, all $8h_K \le \lambda \le h_0$ and all λ-supported F: one bound for all the cutoffs. For one Q, $(u_K)_Q(G)$ is the series over the Fourier modes of G of the values of u_K at products of smooth entries carried by the cubes Q_a^*; each of these values converges to that of u, by (E3) (ii) at Lipschitz entries read at the points, and the series is dominated, uniformly in K, by $C\, A\, l(h(Q))^{8n\mathfrak{p}_0} \sum_{\mathbf{k}} |\hat{G}_{\mathbf{k}}| < \infty$, $\hat{G}_{\mathbf{k}}$ the Fourier coefficients of the proof of Lemma 2.25 (a); so $(u_K)_Q(G) \to u_Q(G)$.

The sum over Q is dominated, uniformly in K, by the series that gives the absolute convergence in Lemma 2.25 (b); hence $\tilde{u}_K(F) \to \tilde{S}_n(F)$ for every smooth F. *The contact terms.* The list is Lemma 2.25 (e) at $\kappa = 0$: $\omega_k = 3k$, the coefficients $T_{\pi,\alpha} \in \mathfrak{E}_{|\pi|}(|\alpha|)$, $|\alpha| \le 3|\pi|$, and two extensions of the cumulant functional in the class $\mathfrak{E}_n(0)$ differ exactly by such a sum. The translation-invariant, real, symmetric two-point contact terms are classified in Lemma 2.25 (f): the invariant space has dimension six under $\mathrm{O}(3)$ on $\mathbb{R}^3$, and twelve under the cubic group on $\mathbb{R}^3$ or T_ℓ. □

2.6. **Scope of the conclusions.** The theorems concern the components $\operatorname{tr} F_{ij}F_{kl}$ at separated points; at coinciding points they give the extensions of Theorem G (E7), on one torus. The Wightman property and the unique vacuum are asserted for each component of the canonical decomposition. Free of the side of the torus and of the state are the bounds of Theorem B, of Theorem C (a) and (h), of Theorem E (a) and of the first display of its clause (b), and, in Theorem G, those of the first statement of (E4) (i), of (E5), and of (E6) with its numbers $d_0(g)$ and $e_g(d)$. The numbers of (E1), of the first member of (E2) (i) and of (E3) (i) contain no side, the side being one that is small over the running couplings, and (E2) (ii) holds on any side with a number free of it. The side enters the numbers of (E1) off the small sides, through the factor $\max\{1, \mathsf{c}(\ell)\}^n$; of the second member of (E2) (i), through $(2\ell/d'')^{3n}$; of (E2) (iii), through $C(n, g, \ell)$; of (E3) (ii), through the numbers of Proposition 2.12 and the factor of the bound of the limit; of the second statement of (E4) (i), through the first depth $s_1(g, \ell)$; of (E4) (ii), through $C(g, \ell)$ and $\delta_\star(g, \ell)$; of (E7), whose number is $C = C(n, g, \ell)$; and of the torus form of Theorem E (b).

3. Conservation of the stress tensor

The curvature bilinears form a symmetric tensor T. The associated stress tensor is

$$S_{ij} = \tfrac{1}{2}\delta_{ij} \operatorname{tr} T - T_{ij}.$$

We prove its conservation inside correlations by estimating the remainder in an exact lattice identity. The argument separates two tasks: making the orbital remainder small under the renormalisation steps, and identifying the remaining insertion with the divergence of S.

The main estimates hold at finite cutoff in every periodic Gibbs state and on a fixed torus. Theorems H and I give the rates and their dependence on the separation of the supports. Theorem J passes the identity to every convergent tensor sequence. We retain the alternative null-form argument because it isolates the collapse estimate needed for the reflection-positive null vector.

3.1. **Notation and hypotheses.** *Constants, couplings, sides.* Take the admitted constant choice of Proposition YMM1:69.1 and Section YMM1:82. Its constants include the blocking factor L (odd, $L \ge 13$), the cube size M, an exponent $\mathfrak{p}_0 \ge 1$, the bound $\gamma \in (0, \frac{1}{2}]$ of the reference couplings, $B_\sharp \ge 0$, $\bar{B} = B_\sharp L/(L-1)$, and the further letters fixed there. A number is a *function* of some data if it depends on these data and on the constants alone; C and p denote such numbers, which may change from line to line. The cutoff is $K \in \mathbb{N}$, $a_K = L^{-K}$, $\mathbb{L}_K = a_K\mathbb{Z}^3$; $\beta > 0$ is the inverse

coupling of the Wilson weight $\rho_0 = e^{-\beta\sum_p a_p}$, where $a_p = 1 - \frac{1}{2}\mathrm{tr}\,\partial U(p)$ is the action density of the plaquette p (equations YMM1:(6)–(7)); $b = a_K\beta$ is the *label*.

For $0 < g \le \gamma$, $\mathfrak{d}(g)$ is the set of first-passage data (K,β) at g (YMM1:74.2, with the canonical data of YMM1:74), $\mathfrak{L}(g)$ the set of sides at g (YMM1:(1528)), all of the form $2L^m$, $X_g = L(g^{-2} + B_\sharp)$, $\mathsf{b}_+ = X_g + \bar B = L(g^{-2} + \bar B)$ (YMM1:74, with $\bar B = B_\sharp L/(L-1)$, YMM1:(1526)), and $I(g) = (g^{-2} + \bar B, X_g - \bar B]$. Lemmas 3.14 (c), (d) and 3.16 and Propositions 3.5 and 3.21 take a number $\mathsf{b}_+ \ge \gamma^{-2}$, and some of them a number $\gamma^{-2} \le \mathsf{b}_- \le \mathsf{b}_+$, as free data; there b_+ is any such number, and first-passage data at g are the case $\mathsf{b}_- = \gamma^{-2}$, $\mathsf{b}_+ = X_g + \bar B$ (Lemma 3.12 (a)).

A side $\ell' = 2\mathsf{l} \in \mathfrak{L}(g)$, $\mathsf{l} = L^{m_1}$, is fixed once and for all; the least side at g will do. $\gamma_W^{\mathrm{ref}} \le \gamma$ is the ceiling of the reference couplings of equation YMM1:(2326), and $\gamma_W^{\mathrm{sd}} \le \gamma_W^{\mathrm{ref}}$ is the smaller ceiling of equation YMM1:(2327); both are fixed in the choices in equations YMM1:(2326)–(2327).

States. For a side ℓ, the torus $T_\ell = \mathbb{R}^3/\ell\mathbb{Z}^3$ carries the lattice of spacing a_K, the torus measure $\langle\cdot\rangle_{K,\ell,\beta}$ with the Wilson weight, its partition function $Z_{K,\ell,\beta}$ and the pressure $p_\ell = \ell^{-3}\log Z_{K,\ell,\beta}$; a function on the configurations of $\mathbb{L}_K$ that depends on the bonds of a cube of side $< \ell$ is regarded as a function on the configurations of T_ℓ through its periodisation. $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ is the set of periodic Gibbs states on $\mathbb{L}_K$; they are invariant under the reflections in the lattice mirrors of the nine families $\{\mathsf{n}\cdot x = c\}$, $\mathsf{n} \in \{e_\mu, e_\mu \pm e_\lambda\}$, and reflection positive at these mirrors (YMM1:103.4); products of two such reflections give translations of the lattice. Torus measures are invariant under all isometries of the lattice of the torus. For a state ν, $A^\nu[X] = X - \nu(X)$, $\langle X;Y\rangle_\nu = \nu(A^\nu[X]A^\nu[Y])$, and $\langle X_1;\dots;X_n\rangle_\nu$ is the joint cumulant. Over the partitions π of $\{1,\dots,n\}$ we put $\mathsf{op}_n = \sum_\pi(|\pi|-1)!$ and $\mathsf{op}'_n = \sum_\pi|\pi|!$; Bl_n is the number of these partitions.

Test objects. $\eta \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ (or a C^2 vector field on a torus), with $\|\eta\| = \sup|\eta| + \sup|\nabla\eta| + \sup|\nabla^2\eta|$ (largest entries); $H : \mathbb{R}^3 \to V = \mathrm{Sym}_3(\mathbb{R})$ bounded Borel (or $H : T_\ell \to V$), $|H|_\infty = \sup_x \max_{\lambda,\lambda'}|H_{\lambda\lambda'}(x)|$. Distances and diameters are sup distances. With $\Theta = \mathrm{diag}(1,1,-1)$: $(\theta\eta)(x) = \Theta\eta(\Theta x)$, $(\theta H)(x) = \Theta H(\Theta x)\Theta$.

The Lie algebra. $\mathfrak{g}$ is the space of Hermitian 2×2 matrices of trace 0, with $\langle X,Y\rangle = \frac{1}{2}\mathrm{tr}\,XY$ and $|X|^2 = \langle X,X\rangle$; $\mathbf{w}(V) = \frac{1}{2i}(V - V^{-1})$ is the vector part of $V \in SL(2,\mathbb{C})$. On matrices $|\cdot|$ is the operator norm; $|V^{-1} - \mathbf{1}| = |V - \mathbf{1}|$ for $V \in SL(2,\mathbb{C})$.

Petals, bonds, differences. For a site x and signed directions $\alpha,\alpha' \in \{\pm1,\pm2,\pm3\}$ with $|\alpha| \ne |\alpha'|$, $W_x(\alpha,\alpha')$ is the holonomy of the plaquette loop from x, first along e_α; the pair $\pi = (\alpha,\alpha')$ is a *petal* at x, $m(\pi) = \{|\alpha|,|\alpha'|\}$ is its plane and $\mathsf{s}(\pi) = \pm1$ its orientation, and $q_x(\pi,\pi') = \langle\mathbf{w}(W_x(\pi)),\mathbf{w}(W_x(\pi'))\rangle$. For a positively oriented bond $\mathfrak{b} = \langle x, x + a_K e_\mu\rangle$, $\mu = \mu_\mathfrak{b}$, with midpoint $x_\mathfrak{b}$, and a direction $\rho \ne \mu$, $p(\mathfrak{b},\pm\rho)$ are the two plaquettes that contain $\mathfrak{b}$ in the plane of e_μ, e_ρ; $W_{\mathfrak{b},p}$ is the holonomy of the plaquette $p \ni \mathfrak{b}$ from x, starting with $\mathfrak{b}$, so that $W_{\mathfrak{b},p(\mathfrak{b},\pm\rho)} = W_x(\mu,\pm\rho)$; $\mathbf{u}_{\mathfrak{b},\rho} = -\frac{1}{2}[\mathbf{w}(W_x(\mu,\rho)) - \mathbf{w}(W_x(\mu,-\rho))]$ and $\mathbf{y}_{\mathfrak{b},\rho} = \mathbf{w}(W_x(\mu,\rho)) + \mathbf{w}(W_x(\mu,-\rho))$; $\lambda_\mathfrak{b} < \lambda'_\mathfrak{b}$ are the two directions normal to $\mathfrak{b}$, and $q_\mathfrak{b} = \langle\mathbf{u}_{\mathfrak{b},\lambda_\mathfrak{b}}, \mathbf{u}_{\mathfrak{b},\lambda'_\mathfrak{b}}\rangle$.

For a plaquette p, $x(p)$ is its centre, $\rho(p)$ its normal direction, $\mathsf{P}(p)$ the two directions of its plane; for a direction ρ, $p_\pm = p \pm a_K e_\rho$ wherever $p_\pm$ stands beside the index ρ, as in $\mathfrak{r}^\sharp_\rho(p)$ and $\mathfrak{e}_\rho(p)$, so that at $\rho = \rho(p)$ it is the shift along the normal; and $p_m(x)$ is the plaquette of the plane m with the lowest corner x. Differences: $(\nabla^\pm_\rho f)(y) = \pm a_K^{-1}[f(y \pm a_K e_\rho) - f(y)]$, $(\nabla^{\mathrm{c}}_\rho f)(y) = a_K^{-1}[f(y + \frac{1}{2}a_K e_\rho) - f(y - \frac{1}{2}a_K e_\rho)]$, $(\nabla^{\mathrm{s}}_\rho f)(y) = (2a_K)^{-1}[f(y + a_K e_\rho) - f(y - a_K e_\rho)]$, $\nabla^{\mathrm{s}}\cdot\eta = \sum_\rho \nabla^{\mathrm{s}}_\rho\eta^\rho$, and $(\Delta_\rho f)(y) = 4a_K^{-2}[f(y + \frac{1}{2}a_K e_\rho) - 2f(y) + f(y - \frac{1}{2}a_K e_\rho)]$.

Definition 3.1 (Lattice fields)**.** The derivations $\mathfrak{v}_\mathbf{X}$ along fields of directions $\mathbf{X}$ on the bonds and their divergence $\mathrm{div}\,\mathfrak{v}_\mathbf{X}$, the orbital potential $\Psi_\rho(p)$, the orbital remainder $\mathfrak{r}_\rho(p)$ and its part of third order $\mathfrak{r}^\sharp_\rho(p) = \mathfrak{r}_\rho(p) - \Psi_\rho(p) + \Psi_\rho(p_-)$ are those of equation YMM1:(2103), J, J and equations YMM1:(2104)–(2105), Section H; $\mathfrak{v}_\eta$ is the displacement along η.

(1) For a weight w of the plaquettes $\mathcal{O}(w) = a_K^{-1}\sum_p w(p)a_p$; for a weight w of the positively oriented bonds $Y[\mathsf{w}] = -a_K^{-1}\sum_{\mathfrak{b}} \mathsf{w}(\mathfrak{b})q_{\mathfrak{b}}$; and for a bounded Borel H

$$\mathcal{T}_K(H) = \mathcal{O}(w_H) + Y[\mathsf{w}_H], \qquad w_H(p) = H_{\rho(p)\rho(p)}(x(p)), \quad \mathsf{w}_H(\mathfrak{b}) = H_{\lambda_{\mathfrak{b}}\lambda'_{\mathfrak{b}}}(x_{\mathfrak{b}}).$$

Formally $\mathcal{T}_K(H) = \frac{1}{2}\int \mathrm{Tr}(HT)$ with $T_{\lambda\lambda'} = \langle B_\lambda, B_{\lambda'}\rangle$, $B_\lambda = \frac{1}{2}\varepsilon_{\lambda\mu\nu}F_{\mu\nu}$; and $\mathcal{T}_K(f\mathbf{1}) = \mathcal{O}(w_{f\mathbf{1}})$ is the action density field of the main theorems.

(2) $H^{\mathrm{cons}}[\eta] = (\nabla\cdot\eta)\mathbf{1} - \nabla\eta - (\nabla\eta)^{\mathrm{T}}$, $(\nabla\eta)_{\nu\rho} = \partial_\nu\eta^\rho$, $H^{\mathrm{c}}_\eta = -H^{\mathrm{cons}}[\eta]$, and $\mathcal{T}^{\mathrm{c}}[\eta] = \mathcal{T}_K(H^{\mathrm{cons}}[\eta])$; formally $\mathcal{T}^{\mathrm{c}}[\eta] = -\int \eta_j\partial_i S_{ij}$.

(3) The insertion field is $\Theta_\beta[\eta] = \beta a_K^{-1}\sum_p\sum_{\mathfrak{b}\subset\partial p}\sum_\rho(\eta^\rho(x_{\mathfrak{b}}) - \eta^\rho(x(p)))\langle \mathbf{u}_{\mathfrak{b},\rho}, \mathbf{w}(W_{\mathfrak{b},p})\rangle$, with $\mathbf{u}_{\mathfrak{b},\mu_{\mathfrak{b}}} = 0$. The general-field formula (301) at the constant weight β splits $\mathfrak{v}_\eta(\beta\sum_p a_p) = \mathfrak{K}[\eta] + \mathsf{St}[\eta]$ into the *orbital remainder* $\mathfrak{K}[\eta]$, the coupling of $\beta\eta$ to the orbital remainders $\mathfrak{r}_\rho(p)$, and the *stress insertion* $\mathsf{St}[\eta] = \Theta_\beta[\eta] - b\,\mathcal{O}(\nabla^{\mathrm{s}}\cdot\eta)$. The *defect* is $\Delta[\eta] = \mathsf{St}[\eta] - b\,\mathcal{T}^{\mathrm{c}}[\eta]$.

(4) $\mathsf{k}^\rho_\eta = \nabla^+_\rho\eta^\rho$ and $w_\eta(p) = \sum_{\rho\in\mathsf{P}(p)}(\nabla^{\mathrm{c}}_\rho\eta^\rho)(x(p))$. For a complex weight $\varkappa$ of the plaquettes $\mathcal{S}_\varkappa = \sum_p \varkappa(p)\,\mathfrak{r}^\sharp_{\rho(p)}(p)$; a *field* Ξ is a triple of real functions on the centres of the plaquettes, $\mathsf{H}(\Xi) = \max_\rho \sup|\Xi_\rho| + \max_\rho \mathrm{Lip}\,\Xi_\rho$, and $\mathcal{S}[\Xi] = \mathcal{S}_\varkappa$ at $\varkappa(p) = L^{2K}\Xi_{\rho(p)}(x(p))$. The *cubic half* is $\mathcal{S}[b\eta] = \sum_p L^{2K} b\,\eta^{\rho(p)}(x(p))\mathfrak{r}^\sharp_{\rho(p)}(p)$, the *bilinear half* $\mathfrak{J}^{\mathrm{II}}[\mathsf{k}] = \beta\sum_{p,\rho}\mathsf{k}^\rho(x(p))\Psi_\rho(p)$.

(5) For a field of directions $\mathbf{X}$ that vanishes off a finite set Λ of bonds, $\mathsf{N}_{\mathbf{X}} = \beta\,\mathfrak{v}_{\mathbf{X}}(\sum_p a_p) - \mathrm{div}\,\mathfrak{v}_{\mathbf{X}}$ is a *null term*; $\mathcal{N}_\eta$ is the null term of $\mathfrak{v}_\eta$, and $\mathfrak{N}[\mathsf{k}]$ that of the field of directions $\sum_\rho \mathsf{k}^\rho(x_{\mathfrak{b}})\mathbf{y}_{\mathfrak{b},\rho}$.

(6) The *remainder* is $\mathsf{Rm}[\eta] = \mathcal{S}[b\eta] - \sum_{v=1}^5 \mathfrak{J}_{0,v}[\mathsf{k}_\eta] + \frac{3}{2}a_K\mathcal{O}(w_\eta)$, with the insertions $\mathfrak{J}_{0,v}$ of Lemma 3.9.

■

Definition 3.2 (Insertions, rough insertions, oscillations)**.** (1) A *box* is $Q = \{x + a_K\sum_\mu n_\mu e_\mu : 0 \le n_\mu \le r_\mu\}$, $r \in \{0,1,2\}^3$ with at least two $r_\mu \ge 1$; x is its lowest site. A *density* on Q is a polynomial j in the entries of complex configurations $\mathbf{U}(\mathfrak{b}) \in SL(2,\mathbb{C})$, $\mathbf{U}(\bar{\mathfrak{b}}) = \mathbf{U}(\mathfrak{b})^{-1}$, on the bonds of Q, invariant under the gauge transformations of Q; it has *height* $\hat{c}$ if $|\mathsf{j}| \le \hat{c}$ whenever all $|\mathbf{U}(\mathfrak{b})| \le 2$, and *order* m with *constant* c if moreover $|\mathsf{j}| \le c\,r^m$ whenever all plaquette variables of Q, taken from one corner and in one sense, satisfy $|\partial\mathbf{U}(q) - \mathbf{1}| \le r \le 1$. An *insertion* of type $(m, c, \hat{c}, N)$ is $\mathfrak{J} = \sum_\iota \varkappa_\iota \mathsf{j}_\iota(U|_{Q_\iota})$ with such densities on boxes Q_ι, complex weights $\varkappa_\iota$, $|\varkappa|_\infty = \max_\iota|\varkappa_\iota|$, and at most N indices with one lowest site (N is the *counting number*); indices of weight 0 are struck before the type is formed, the *carrier* is the set of the sites of the remaining boxes, and $\mathfrak{J}$ *meets* a set X if one of these boxes lies in X.

(2) A *rough insertion* is $F(k,v) = a_K^{-1}\sum_x\sum_{\pi,\pi'} k_{\pi\pi'}(x)q_x(\pi,\pi') + \mathcal{O}(v)$, the sums over the sites and the petals at them, with $|k|_1 = \sup_x\sum_{\pi,\pi'}|k_{\pi\pi'}(x)|$. Its *symbol* at x is the quadratic form in $F_{12}, F_{13}, F_{23} \in \mathfrak{g}$ obtained by putting $\mathsf{s}(\pi)F_{m(\pi)}$ for $\mathbf{w}(W_x(\pi))$ and $\frac{1}{2}|F_m|^2$ for $a_{p_m(x)}$; $F(k,v)$ is *null* if its symbol vanishes at every site.

(3) In the small-field setting (Th) of B.13 on a torus T_ℓ, $\ell = 2L^m$, with the data $(K, \mathfrak{b}', m, t_*)$, a level t with $1 \le t \le t_*$ (in most uses the top level $t = t_*$) and the line $x_k = L^{K-k}\mathfrak{b}'$: $\mathcal{V}_k$ is the space of the configurations of the block lattice of level k, $\mathcal{V}_0$ that of the configurations of the bare lattice, $\mathcal{M}^k : \mathcal{V}_0 \to \mathcal{V}_k$ is the k-fold block averaging, $\mathsf{Cut}_k \supset \mathsf{In}_k$ are the field cuts (YMM1:113.10), with the radii $\mathsf{e}^{\mathrm{c}}_k = c_\rho A_0 x_k^{-1/2}(\log x_k)^{\mathfrak{p}_0}$ of the definitions preceding Lemma YMM1:113.10, c_ρ the constant defined in Section B.13 of the field cuts. For $0 \le j < t_*$, $\mathfrak{G}_j[x_j]$ is the gauge-fixing factor, the *gauge factor*, and $\chi^{\mathrm{sf}}_{x_j}$ the fluctuation test, the *small-field indicator*, of the step of height j at the inverse coupling x_j (Section B.2), written $\mathfrak{G}_j$ and χ^{sf} for short: functions on $\mathcal{V}_j$, the first bounded Borel with values in $[0,\infty)$, the second Borel with the values 0 and 1. The *small-field weights* of the chain up to the

level k, $0 \le k \le t_*$, are

$$\mathsf{p}_k(U) = \mathbf{1}_{\mathsf{Cut}_k}(V_k) \prod_{j=0}^{k-1} [\mathbf{1}_{\mathsf{Cut}_j}\, \mathfrak{G}_j[x_j]\, \chi^{\mathrm{sf}}_{x_j}](V_j), \qquad V_j = \mathcal{M}^j U,$$

the product over $j < k$ of the indicator of Cut_j, of the gauge factor and of the small-field indicator at the level j, times the indicator of Cut_k: bounded Borel functions ≥ 0 on $\mathcal{V}_0$, with $\mathsf{p}_0 = \mathbf{1}_{\mathsf{Cut}_0}$ and $\mathsf{p}_{k+1} = (\mathbf{1}_{\mathsf{Cut}_{k+1}} \circ \mathcal{M}^{k+1})\, ((\mathfrak{G}_k[x_k]\chi^{\mathrm{sf}}_{x_k}) \circ \mathcal{M}^k)\, \mathsf{p}_k$. The measures $\nu_k = (\mathcal{M}^k)_*(\mathsf{p}_k \rho_0 dU)$ are those of the chain at zero source, given by the measure recursion in Proposition YMM1:114.2 at $t_0 = 0$: $\nu_0 = \mathbf{1}_{\mathsf{Cut}_0}\rho_0 dU$ and $\nu_{k+1} = \mathbf{1}_{\mathsf{Cut}_{k+1}} \mathbf{T}(\mathfrak{G}_k[x_k]\chi^{\mathrm{sf}}_{x_k}\nu_k)$, $\mathbf{T}$ the image of complex measures under one block averaging $\mathcal{M} : \mathcal{V}_k \to \mathcal{V}_{k+1}$ (Proposition YMM1:114.2); this follows from the recursion of the p_k, by induction on k with the rules of images of measures, as in the proof of Proposition YMM1:115.2, its image-identity proof.

For $0 \le k \le t_*$ let $\mathbf{B}_k$ be the determining set of the constant sequence $T_\ell = \Omega_0 = \cdots = \Omega_k$, whose averaging map is $\mathcal{M}^k$, and for $V \in \mathcal{V}_k$ let $\mathcal{C}(\mathbf{B}_k, V)$ be the set of the configurations U with $\mathcal{M}^k U = V$ that are critical for the action under this constraint and regular (Definitions YMM1:7.1, YMM1:9.3 and YMM1:9.5). For $V \in \mathsf{Cut}_k$ this set is one orbit of the residual gauge group, formed by the gauge transformations of the bare lattice that equal $\mathbf{1}$ at the sites of the block lattice of level k (YMM1:113.10; for $k = 0$ it is $\{V\}$, by the definition preceding Proposition YMM1:114.2): $\mathcal{C}(\mathbf{B}_k, V)$ is the minimal orbit over $V \in \mathsf{Cut}_k$ (Section P), its elements are the *backgrounds over* V, and $U_k(V)$, the background of V (Section YMM1:9, immediately before equation YMM1:(77)), is any of them.

A configuration U is *over* V, and *over* Cut_k, if $V \in \mathsf{Cut}_k$ and $U \in \mathcal{C}(\mathbf{B}_k, V)$; so a configuration over Cut_k is a background over some $V \in \mathsf{Cut}_k$, and a *background of level* k is a configuration over Cut_k. A function of the bare configuration that is invariant under its gauge transformations takes one value at the configurations over V, that is, on the orbit, and so is a function of V there. $\mathsf{Q}_{k\leftarrow 0}Y$ is the conditional mean of a bounded Borel Y given the block field of the level k (Lemma 3.14). The *small-field functional* is $\Lambda^{\mathrm{sf}}(F) = \int F\, (\mathbf{1}_{\mathsf{In}_t} \circ \mathcal{M}^t)\, \mathsf{p}_t\, \rho_0\, dU$ for bounded Borel F; as $\mathsf{In}_t \subset \mathsf{Cut}_t$ YMM1:(2159), its weight $(\mathbf{1}_{\mathsf{In}_t} \circ \mathcal{M}^t)\, \mathsf{p}_t$ is the weight $\mathfrak{w}^{\mathrm{sf}}_t$ of level t of the small-field chain defined before Proposition YMM1:115.2; the image of the measure $F\, (\mathbf{1}_{\mathsf{In}_t} \circ \mathcal{M}^t)\, \mathsf{p}_t\, \rho_0\, dU$ under $\mathcal{M}^t$ is $\mathbf{1}_{\mathsf{In}_t}(\mathsf{Q}_{t\leftarrow 0}F)\, \nu_t$ (Lemma 3.14 (a)), and cumulants under the small-field functional are those of the normalised functional $\Lambda^{\mathrm{sf}}(\cdot)/\Lambda^{\mathrm{sf}}(1)$.

For a pointed family f among the construction results of level $j \le k$ (with the norm $\|\cdot\|$ of rate $\kappa + 1$ in which Proposition YMM1:45.1 and Lemma O.1 control the sums over polymers: on the domain of the local terms its member at a polymer X of level j is at most $\|\mathsf{f}\| e^{-(\kappa+1)d_j(X)}$, $d_j(X)$ the linear size of X), $\mathsf{Sum}[\mathsf{f}](U) = \sum_X \sum_z \mathsf{f}(X, U, z)$ is the sum of its members at U, and $\Sigma_k[\mathsf{f}](V) = \mathsf{Sum}[\mathsf{f}](U_k(V))$ on Cut_k, 0 off it. The *oscillation* of an insertion is $\omega_t(\mathfrak{J}) = \inf_{c\in\mathbb{C}} \|\mathsf{Q}_{t\leftarrow 0}\mathfrak{J} - c\|_{L^\infty(\mathbf{1}_{\mathsf{In}_t}\nu_t)}$.

■

Definition 3.3 (Tensor limits)**.** Let $(K_j, \beta_j) \in \mathfrak{d}(g)$, $K_j \to \infty$, and $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$. A functional σ is a *tensor limit at* g *along* (K_j, β_j, ρ_j) if for all $n \ge 1$ and all $H_1, \dots, H_n \in C_c(\mathbb{R}^3; V)$ with pairwise disjoint supports

$$\sigma(H_1, \dots, H_n) = \lim_j \rho_j\Big(\prod_{a=1}^n A^{\rho_j}[\mathcal{T}_{K_j}(H_a)]\Big),$$

the limits being assumed to exist. For the conservation statements in this section, tensor limit refers only to this moment convergence; convergence of the labels $a_{K_j}\beta_j$ is not required. ■

3.2. **Results.**

Theorem H (Conservation among n entries at finite cutoff)**.** Let $0<g\le\gamma$, $n\ge 2$, $1\le n_1\le n$, $R>0$. For $a\le n_1$ let $\eta_a\in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and let X_a be one of $\mathcal{T}^{\mathrm{c}}[\eta_a]$, $\mathsf{St}[\eta_a]$, $\mathfrak{K}[\eta_a]$, $\Delta[\eta_a]$, $\mathsf{Rm}[\eta_a]$; for $n_1<a\le n$ let $H_a:\mathbb{R}^3\to V$ be bounded Borel and $\mathsf{X}_a=\mathcal{T}_K(H_a)$. Let the n supports lie in a ball of radius R, pairwise at sup distance $\ge\mathsf{d}>0$, and put $\Pi=\prod_{a\le n_1}\|\eta_a\|\prod_{a>n_1}|H_a|_\infty$.

(i) For every $0<c<\frac{1}{14}$ there are C,p,K_0, functions of g,ℓ',n,d,R,c, such that for all $(K,\beta)\in\mathfrak{d}(g)$ with $K\ge K_0$ and all $\nu\in\mathcal{G}^{\mathrm{per}}_{K,\beta}$, if each X_a, $a\le n_1$, is one of the first three,

$$\Big|\nu\Big(\prod_{a=1}^{n}A^\nu[\mathsf{X}_a]\Big)\Big|\le CK^pL^{-cn_1K}\,\Pi.$$

(ii) The bound of (i) holds also when $\Delta[\eta_a]$ or $\mathsf{Rm}[\eta_a]$ are among the X_a, $a\le n_1$, and for the joint cumulant $\langle\mathsf{X}_1;\dots;\mathsf{X}_n\rangle_\nu$.

(iii) Let $0<c<\frac{1}{28}$ and $\phi=(\frac{1}{28}-c)/(4n-1)$. There are C,p, functions of g,ℓ',n,R,c, and K_0, a function of g,ℓ',n,c, such that the bounds of (i), (ii) hold for all $(K,\beta)\in\mathfrak{d}(g)$ with $K\ge K_0$, all $\nu\in\mathcal{G}^{\mathrm{per}}_{K,\beta}$ and all data as above whose supports are pairwise at sup distance $\ge\mathsf{d}$ for some $\mathsf{d}>0$ with $\mathsf{d}\,L^{\lceil\phi K\rceil}\ge K^2$.

(iv) Under the hypotheses of (i), also $|\nu(\mathfrak{K}[\eta_1])|\le CK^pL^{-cK}\|\eta_1\|$ and, if $n_1\ge 2$, also $|\nu(\mathfrak{K}[\eta_1]\mathfrak{K}[\eta_2])|\le CK^pL^{-2cK}\|\eta_1\|\|\eta_2\|$.

■□

Corollary 3.4 (Two points)**.** Let $0<g\le\gamma$, $0<c<\frac{1}{14}$, $R,\mathsf{d}>0$; let $\eta,\eta'\in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and a bounded Borel $H':\mathbb{R}^3\to V$ have their supports in a ball of radius R, with $\operatorname{supp}\eta$ at sup distance $\ge\mathsf{d}$ from $\operatorname{supp}\eta'$ and from $\operatorname{supp}H'$. There are C,p,K_0, functions of g,ℓ',d,R,c, such that for all $(K,\beta)\in\mathfrak{d}(g)$ with $K\ge K_0$ and all $\nu\in\mathcal{G}^{\mathrm{per}}_{K,\beta}$:

(a) $|\langle\mathsf{St}[\eta'];\mathsf{St}[\eta]\rangle_\nu|=|\langle\mathsf{Rm}[\eta'];\mathsf{Rm}[\eta]\rangle_\nu|\le CK^pL^{-2cK}\|\eta'\|\|\eta\|$; $|\nu(\mathfrak{K}[\eta'])|\le CK^pL^{-cK}\|\eta'\|$; and $|\nu(\mathfrak{K}[\eta']\mathfrak{K}[\eta])|+|\nu(\mathfrak{K}[\eta'])\nu(\mathfrak{K}[\eta])|\le CK^pL^{-2cK}\|\eta'\|\|\eta\|$;

(b) $|\langle\mathcal{T}^{\mathrm{c}}[\eta'];\mathcal{T}^{\mathrm{c}}[\eta]\rangle_\nu|\le CK^pL^{-2cK}\|\eta'\|\|\eta\|$;

(c) (the collapse)

$$|\langle\Delta[\eta];\mathcal{T}_K(H')\rangle_\nu|\le CK^pL^{-cK}\|\eta\||H'|_\infty,$$

and $|\langle\Delta[\eta];Z\rangle_\nu|\le CK^pL^{-2cK}\|\eta\|\|\eta'\|$ for $Z=\mathsf{St}[\eta']$ and for $Z=\Delta[\eta']$;

(d) $|\langle\mathcal{T}^{\mathrm{c}}[\eta];\mathcal{T}_K(H')\rangle_\nu|\le CK^pL^{-cK}\|\eta\||H'|_\infty$.

At $\eta'=\theta\eta$, $\eta\in C^2_c(\{x_3>0\};\mathbb{R}^3)$, the last bound of (a) bounds the mirrored two-point function $\langle\mathfrak{K}[\theta\eta];\mathfrak{K}[\eta]\rangle_\nu$ of the orbital remainder, which gives (N) by Theorem J (iii); and (b) is the lattice form of (N) below. ■□

Theorem I (Conservation among bounded tensor fields, by a change of scale)**.** Let $0<g\le\gamma$, $q\ge 2$, $\mathsf{d}>0$.

(S) Let $R>0$. There are C,p,K_0, functions of g,q,d,R, such that for all $(K,\beta)\in\mathfrak{d}(g)$ with $K\ge K_0$, all $\nu\in\mathcal{G}^{\mathrm{per}}_{K,\beta}$, every $\eta\in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and all bounded Borel $H_2,\dots,H_q:\mathbb{R}^3\to V$ whose q supports lie in a ball of radius R, pairwise at sup distance $\ge\mathsf{d}$,

$$\Big|\nu\Big(A^\nu[\mathcal{T}^{\mathrm{c}}[\eta]]\prod_{a=2}^{q}A^\nu[\mathcal{T}_K(H_a)]\Big)\Big|\le CK^pL^{-K/36}\|\eta\|\prod_{a=2}^{q}|H_a|_\infty,$$

and the same bound holds for the joint cumulant of the q functions under ν.

(T) Let $\ell\in\mathfrak{L}(g)$. There are C,p,K_0, functions of g,q,d,ℓ, such that for all $(K,\beta)\in\mathfrak{d}(g)$ with $K\ge K_0$, every C^2 vector field η on T_ℓ and all bounded Borel $H_2,\dots,H_q:T_\ell\to V$ whose q

supports are pairwise at sup distance $\geq \mathsf{d}$ on T_ℓ,

$$|\langle \mathcal{T}_K(H^{\mathrm{cons}}[\eta]); \mathcal{T}_K(H_2); \dots; \mathcal{T}_K(H_q)\rangle_{K,\ell,\beta}| \leq CK^p L^{-K/36}\|\eta\| \prod_{a=2}^{q} |H_a|_\infty.$$

■□

Proposition 3.5 (The remainder at every rate below $\frac{1}{10}$)**.** Let $m_1 \in \mathbb{N}$, $\mathsf{l} = L^{m_1}$, $\gamma^{-2} \leq \mathsf{b}_- \leq \mathsf{b}_+$ with $MR(\mathsf{b}_+) \leq L^{m_1}$ (R the cube-size function of YMM1:74), $r > 0$, and let parameters $0 < \psi < \frac{2}{9}$, $0 \leq \kappa_\star < 1$, $0 < \tau < \frac{1}{2}$, $0 < \phi < \frac{1}{6}\psi$ be given with

$$c'' = \min\{1 - \tfrac{9}{2}\psi,\ \kappa_\star - (3+\kappa_\star)\psi,\ (\tfrac{1}{2} - \tau)\psi,\ \tfrac{1}{2}\psi - 3\phi\} > 0.$$

(a) There are $C, p, K_\star$, functions of these data, such that for all $K \geq K_\star$, all $\beta = L^K \mathsf{b}'$ with $\mathsf{b}' \in [\mathsf{b}_-, \mathsf{b}_+]$, every board of eight cells of side l on $T_{2\mathsf{l}}$ with an offset in $a_K\mathbb{Z}^3$, every cell of it and every $\eta \in C^2(\mathbb{R}^3;\mathbb{R}^3)$ carried by the points of that cell at sup distance $\geq r$ from its walls, with $c_0 = \langle \mathsf{Rm}[\eta]\rangle_{K,2\mathsf{l},\beta}$,

$$0 \leq \Big\langle \prod_{\kappa} (\mathsf{Rm}[\eta] - c_0) \circ \mathsf{r}_\kappa^{-1} \Big\rangle_{K,2\mathsf{l},\beta} = \|\mathsf{Rm}[\eta] - c_0\|^8_{\mathrm{ch},2\mathsf{l}} \leq \big(CK^p L^{-c''K}\|\eta\|\big)^8,$$

the product over the eight mirror maps r_κ of the board. Moreover, let $u = \lceil \phi K \rceil$ and $t = K - u$, so that, $K_\star$ being taken $\geq K_\phi$, (Th) holds on $T_{2\mathsf{l}}$ with (K, b', m_1, t) (Lemma 3.12 (b), as $MR(\mathsf{b}') \leq MR(\mathsf{b}_+) \leq L^{m_1}$, R being non-decreasing), and attach to the seven insertions of $\mathsf{Rm}[\eta]$ (Definition 3.1 (6)) the numbers

$$\epsilon_1 = C\mathsf{b}_+\mathsf{H}(\eta)K^p L^{-c''K}, \qquad \epsilon_2 = CK^{2\mathfrak{p}_0} L^{4u-K}\|\eta\|, \qquad \epsilon_3 = CK^{3\mathfrak{p}_0} L^{4u-K/2}\|\eta\|,$$

ϵ_1 to $\mathcal{S}[b\eta]$, ϵ_2 to $\mathfrak{J}_{0,1}[\mathsf{k}_\eta]$, $\mathfrak{J}_{0,2}[\mathsf{k}_\eta]$, $\mathfrak{J}_{0,3}[\mathsf{k}_\eta]$ and $\frac{3}{2}a_K\mathcal{O}(w_\eta)$, ϵ_3 to $\mathfrak{J}_{0,4}[\mathsf{k}_\eta]$ and $\mathfrak{J}_{0,5}[\mathsf{k}_\eta]$, with $C \geq 1$ and p those of the display and $\mathsf{H}(\eta) = \max_\rho \sup|\eta^\rho| + \max_\rho \mathrm{Lip}\,\eta^\rho$ (Definition 3.1 (4)); these numbers depend neither on the board, its offset and its cell nor on the mirror map. For every mirror copy $\mathfrak{J} \circ \mathsf{r}_\kappa^{-1}$ of one of the seven insertions $\mathfrak{J}$, with the number ϵ attached to $\mathfrak{J}$, there is a number a with $|\mathsf{Q}_{t\leftarrow 0}(\mathfrak{J} \circ \mathsf{r}_\kappa^{-1}) - \mathsf{a}| \leq \epsilon$ almost everywhere for $\mathbf{1}_{\mathsf{In}_t}\nu_t$ (Definition 3.2 (3)); and every joint cumulant under $\langle\cdot\rangle_{K,2\mathsf{l},\beta}$ of 2 to 8 such mirror copies, in pairwise different cells, is at most $1 + \mathsf{op}'_8\mathsf{Bl}_8$ times the product of the numbers ϵ attached to the insertions of which they are copies.

(b) Without the cubic half: for $0 < \phi < \frac{1}{8}$ there are $C, K_\star$ with $\|\mathsf{Rm}[\eta] - \mathcal{S}[b\eta] - c_0\|_{\mathrm{ch},2\mathsf{l}} \leq CK^{3\mathfrak{p}_0} L^{-(\frac{1}{2}-4\phi)K}\|\eta\|$ in the situation of (a), the torus mean of $\mathcal{S}[b\eta]$ being 0; and $\|\mathcal{S}[\Xi]\|_{\mathrm{ch},2\mathsf{l}} \leq C\mathsf{H}(\Xi)K^p L^{-c''K}$ for every field Ξ carried by a cell at sup distance $\geq r$ from its walls.

(c) Let $0 < g \leq \gamma$, $2\mathsf{l} \in \mathfrak{L}(g)$, $\mathsf{b}_- = \gamma^{-2}$, $\mathsf{b}_+ = X_g + \bar{B}$. Then (a), (b) hold for all $(K,\beta) \in \mathfrak{d}(g)$ with $K \geq K_\star$; at $\psi = \frac{1}{5}$, $\kappa_\star = \frac{9}{10}$, $c'' = \frac{1}{10} - \max\{\frac{1}{5}\tau, 3\phi\}$, so every $c'' < \frac{1}{10}$ is reached. For every $c < \frac{1}{10}$ and $R, \mathsf{d} > 0$ there are C, p, K_0, functions of g, c, R, d, such that for all $(K,\beta) \in \mathfrak{d}(g)$ with $K \geq K_0$, all $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ and all $\eta \in C^2_c(\{x_3 > 0\};\mathbb{R}^3)$ with support in the ball of radius R at sup distance $\geq \frac{1}{2}\mathsf{d}$ from $\{x_3 = 0\}$:

$$|\langle \mathsf{St}[\theta\eta]; \mathsf{St}[\eta]\rangle_\nu| = |\langle \mathsf{Rm}[\theta\eta]; \mathsf{Rm}[\eta]\rangle_\nu| \leq CK^p L^{-2cK}\|\eta\|^2, \qquad |\langle \mathfrak{K}[\theta\eta]; \mathfrak{K}[\eta]\rangle_\nu| \leq CK^p L^{-2cK}\|\eta\|^2.$$

■

Theorem J (The limit)**.** Let $0 < g \leq \gamma$, let σ be a tensor limit at g along (K_j, β_j, ρ_j), and $b_j = a_{K_j}\beta_j$.

(i) $\sigma(H^{\mathrm{cons}}[\eta], H_2, \dots, H_n) = 0$ for every $n \geq 2$, every $\eta \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and all $H_2, \dots, H_n \in C_c(\mathbb{R}^3; V)$ whose supports are pairwise disjoint and disjoint from $\mathrm{supp}\,\eta$.

(ii) In particular: (C) $\sigma(H^{\mathrm{cons}}[\eta], H') = 0$ whenever $\operatorname{supp}\eta \cap \operatorname{supp} H' = \emptyset$; (N)

$$\sigma(\theta H^{\mathrm{cons}}[\eta], H^{\mathrm{cons}}[\eta]) = 0$$

for $\eta \in C^2_c(\{x_3 > 0\}; \mathbb{R}^3)$.

(iii) For $\eta \in C^2_c(\{x_3 > 0\}; \mathbb{R}^3)$, with $\gamma^{-2} \le b_j \le \mathsf{b}_+$,

$$b_j^2 \langle \mathcal{T}^{\mathrm{c}}[\theta\eta]; \mathcal{T}^{\mathrm{c}}[\eta]\rangle_{\rho_j} - \langle \mathfrak{K}[\theta\eta]; \mathfrak{K}[\eta]\rangle_{\rho_j} \to 0.$$

So $\langle \mathfrak{K}[\theta\eta]; \mathfrak{K}[\eta]\rangle_{\rho_j} \to 0$, which holds by Corollary 3.4 (a), gives (N) by itself; and (N) for σ gives $\langle \mathfrak{K}[\theta\eta]; \mathfrak{K}[\eta]\rangle_{\rho_j} \to 0$ and $\langle \mathsf{St}[\theta\eta]; \mathsf{St}[\eta]\rangle_{\rho_j} \to 0$ along (K_j, β_j, ρ_j). The comparison does not use Proposition 3.21.

No positivity, covariance or growth of σ is used. ■□

Theorem K (One torus; the cutoff removed first)**.** (i) Let $0 < g \le \gamma$, $\ell \in \mathfrak{L}(g)$, $q \ge 2$, $\mathsf{d} > 0$, $0 < c < \frac{1}{28}$. There are C, p, K_0, functions of $g, \ell, q, \mathsf{d}, c$, such that for all $(K, \beta) \in \mathfrak{d}(g)$ with $K \ge K_0$, every C^2 vector field η on T_ℓ and all bounded Borel $H_2, \dots, H_q : T_\ell \to V$ such that $\operatorname{supp}\eta, \operatorname{supp} H_2, \dots, \operatorname{supp} H_q$ are pairwise at sup distance $\ge \mathsf{d}$ on T_ℓ,

$$|\langle \mathcal{T}_K(H^{\mathrm{cons}}[\eta]); \mathcal{T}_K(H_2); \dots; \mathcal{T}_K(H_q)\rangle_{K,\ell,\beta}| \le C K^p L^{-cK} \|\eta\| \prod_{a=2}^{q} |H_a|_\infty.$$

(ii) Let $0 < g \le \gamma_W^{\mathrm{ref}}$, $\ell \in \mathfrak{L}(g)$ and $b \in I(g)$. Then $(K, L^K b) \in \mathfrak{d}(g)$ for every K, and for $\eta, H_2, \dots, H_q$ as in (i) the cumulants of (i) at $\beta = L^K b$ tend to 0 as $K \to \infty$. For Lipschitz $H_2, \dots, H_q$ whose supports are pairwise disjoint and disjoint from $\operatorname{supp}\eta$ this says that the torus limit functional $\mathcal{S}_q^{\ell,b}$, the limit of the joint cumulants $\langle \mathcal{T}_K(H_1); \dots; \mathcal{T}_K(H_q)\rangle_{K,\ell,L^K b}$ at Lipschitz weights with pairwise disjoint supports (statement (iii) of the subsection on the input), vanishes:

$$\mathcal{S}_q^{\ell,b}(H^{\mathrm{c}}_\eta, H_2, \dots, H_q) = 0, \qquad H^{\mathrm{c}}_\eta = \nabla\eta + (\nabla\eta)^{\mathrm{T}} - (\nabla\cdot\eta)\mathbf{1}.$$

In particular, with scalar spectators, $\mathcal{S}_{m+1}^{\ell,b}(H^{\mathrm{c}}_\eta, h_1\mathbf{1}, \dots, h_m\mathbf{1}) = 0$ for every $m \ge 1$ and all real Lipschitz $h_1, \dots, h_m$ on T_ℓ whose supports are pairwise disjoint and disjoint from $\operatorname{supp}\eta$, at every pair (ℓ, b) with $\ell \in \mathfrak{L}(g)$, $b \in I(g)$.

■□

Corollary 3.6 (Tensor limits at small coupling)**.** Let $0 < g \le \gamma_W^{\mathrm{ref}}$.

(i) Every sequence (K_j, β_j, ν_j) with $(K_j, \beta_j) \in \mathfrak{d}(g)$, $K_j \to \infty$, $\nu_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$, has a subsequence along which $a_{K_j}\beta_j$ converges to some $b_* \in [g^{-2}, L(g^{-2} + \bar{B})]$ and which defines a tensor limit. A subsequence of a defining sequence defines the same tensor limit; so every tensor limit at g is a limit along a sequence with convergent labels. Every tensor limit σ at g is symmetric in its entries and vanishes at a single entry; it is covariant, $\sigma(\mathsf{r}H_1, \dots, \mathsf{r}H_n) = \sigma(H_1, \dots, H_n)$ for every $\mathsf{r}x = \mathsf{R}x + v$, R in the cubic group, $v \in \mathbb{R}^3$, $(\mathsf{r}H)(x) = \mathsf{R}H(\mathsf{r}^{-1}x)\mathsf{R}^{\mathrm{T}}$; for weights that vanish off closed subsets of a ball of radius R_0 at pairwise sup distances $\ge 2\delta_0$, $|\sigma(H_1, \dots, H_n)| \le C_n \prod_a |H_a|_\infty$ with C_n a function of g, n, δ_0, R_0, and the same holds with a number that depends on g, n, δ_0 and the sup diameters of the single supports, not on R_0; and $\sigma(f_1\mathbf{1}, \dots, f_n\mathbf{1})$ is the limit, along the same sequence, of the centred products of the action density fields $\mathcal{O}(w_{f_a\mathbf{1}})$ of the main theorems.

The limits at g of statement (iv) of the subsection on the input are tensor limits in the sense of Definition 3.3.

(ii) Every tensor limit σ at g is reflection positive at the nine families of mirrors: $\sigma(\theta_{\mathsf{n},c}\bar{F} \cdot F) \ge 0$ for $\mathsf{n} \in \{e_\mu, e_\mu \pm e_\lambda\}$, $c \in \mathbb{R}$, $\theta_{\mathsf{n},c}$ the reflection in $\{\mathsf{n}\cdot x = c\}$ acting on arguments and indices, and F a finite complex combination of tuples of C^1_c tensor fields with pairwise disjoint supports in $\{\mathsf{n}\cdot x > c\}$. The form $\langle [F'], [F]\rangle = \sigma(\theta_{e_3,0}\bar{F'} \cdot F)$ gives a separable Hilbert space

$\mathcal{H}(\sigma)$ with a unit vector $\Omega=[\emptyset]$, a strongly continuous semigroup $e^{-tH}[F]=[\tau_{te_3}F]$, $t\ge 0$, of self-adjoint contractions, $H\ge 0$, $H\Omega=0$, and a strongly continuous unitary representation $e^{i(v_1P_1+v_2P_2)}[F]=[\tau_{(v,0)}F]$ of the translations parallel to the mirror, which commutes with H and fixes Ω; and $H\ge|P_1|$, $H\ge|P_2|$. Here τ_v translates every entry of a tuple by v.

(iii) For $\eta\in C^2_c(\{x_3>0\};\mathbb{R}^3)$ and every such F in $\{x_3>0\}$ whose supports do not meet $\operatorname{supp}\eta$, the vector $[(H^{\mathrm{cons}}[\eta])\cdot F]\in\mathcal{H}(\sigma)$ is zero; at $F=\emptyset$ this is (N). In particular $\sigma(\theta_{e_3,0}\bar F'\cdot(H^{\mathrm{cons}}[\eta])\cdot F)=0$ for every such F'; for tuples separated by the plane $\{x_3=0\}$ this is contained in Theorem J (i), which holds in general position and without the Hilbert space.

■□

Proposition 3.7 (A second road: null forms)**.** For weights $v=(v_\rho(\mathfrak{b}))_{\rho\neq\mu_\mathfrak{b}}$ and $z=(z_{\rho\tau}(\mathfrak{b}))_{\rho,\tau\neq\mu_\mathfrak{b}}$ of the positively oriented bonds and w of the plaquettes, with $a_\pm=a_{p(\mathfrak{b},\pm\rho)}$ and ρ' the direction normal to $e_{\mu_\mathfrak{b}}$ and e_ρ, put

$$\mathcal{Y}[v]=a_K^{-1}\sum_{\mathfrak{b}}\sum_{\rho\neq\mu_\mathfrak{b}}v_\rho(\mathfrak{b})|\mathbf{y}_{\mathfrak{b},\rho}|^2,\quad \mathcal{A}[v]=a_K^{-1}\sum_{\mathfrak{b},\rho}v_\rho(\mathfrak{b})(a_+^2+a_-^2),\quad \mathcal{A}^2[w]=a_K^{-1}\sum_p w(p)a_p^2,$$
$$\mathcal{R}[z]=a_K^{-1}\sum_{\mathfrak{b}}\sum_{\rho,\tau}z_{\rho\tau}(\mathfrak{b})\langle\mathbf{u}_{\mathfrak{b},\rho},\mathbf{y}_{\mathfrak{b},\tau}\rangle;$$

the *planar null form* is $\mathcal{P}_K[v,w]=\mathcal{Y}[v]+\mathcal{A}^2[w]$, with $|(v,w)|_\infty=\max\{\sup|v|,\sup|w|\}$; for six bounded real functions $\kappa=(\kappa_{\mu\nu})_{\mu\neq\nu}$, $\mathfrak{Y}[\kappa]=\frac{\beta}{4}\sum_\mathfrak{b}\sum_{\nu\neq\mu_\mathfrak{b}}\kappa_{\mu_\mathfrak{b}\nu}(x_\mathfrak{b})|\mathbf{y}_{\mathfrak{b},\nu}|^2=\mathcal{P}_K[\frac{b}{4}v^\kappa,0]$, $v^\kappa_\nu(\mathfrak{b})=\kappa_{\mu_\mathfrak{b}\nu}(x_\mathfrak{b})$. For a vector field η: $v^\eta_\rho(\mathfrak{b})=(\nabla^{\mathrm{c}}_\rho\eta^\rho)(x_\mathfrak{b})$, $z^\eta_{\rho\tau}(\mathfrak{b})=\frac{a_K}{8}(\Delta_\tau\eta^\rho)(x_\mathfrak{b})$, $\mathfrak{Y}[\eta]=\mathfrak{Y}[\kappa]$ at $\kappa_{\mu\nu}=\nabla^{\mathrm{c}}_\nu\eta^\nu$; and $H^{\mathrm{cons}}_K[\eta]$ is the lattice symbol whose diagonal entry $\lambda\lambda$ at $x(p)$, $\lambda=\rho(p)$, is $(\nabla^{\mathrm{s}}\cdot\eta-2\nabla^{\mathrm{s}}_\lambda\eta^\lambda)(x(p))$ and whose entry $\lambda_\mathfrak{b}\lambda'_\mathfrak{b}$ at $x_\mathfrak{b}$ is $-(\nabla^{\mathrm{c}}_{\lambda'_\mathfrak{b}}\eta^{\lambda_\mathfrak{b}}+\nabla^{\mathrm{c}}_{\lambda_\mathfrak{b}}\eta^{\lambda'_\mathfrak{b}})(x_\mathfrak{b})$, inserted in $\mathcal{T}_K$ as in Definition 3.1 (1); $H''_K[\eta]=H^{\mathrm{cons}}_K[\eta]-H^{\mathrm{cons}}[\eta]$ has $|H''_K[\eta]|_\infty\le\frac{3}{2}a_K\sup|\nabla^2\eta|$.

(a) (An exact identity.) For every K, $\beta>0$, every vector field η of bounded support (or on a torus) and every configuration,

$$\mathsf{St}[\eta]=b\,\mathcal{T}_K(H^{\mathrm{cons}}_K[\eta])-b\{\tfrac14\mathcal{Y}[v^\eta]+\tfrac12\mathcal{A}[v^\eta]+\mathcal{R}[z^\eta]\}.$$

(b) (One bond.) Let ν be a Gibbs state at (a_K,β), z a weight of bounded support, Y a bounded Borel local function that does not depend on the bonds $\mathfrak{b}$ with $z(\mathfrak{b})\neq0$; let $\zeta_\rho(\mathfrak{b})=z_{\rho\rho}(\mathfrak{b})-z_{\rho\rho'}(\mathfrak{b})$, $\zeta'_\rho(\mathfrak{b})=z_{\rho\rho'}(\mathfrak{b})$, and $(\delta\xi)(p)=\sum_{(\mathfrak{b},\rho)\colon p(\mathfrak{b},\rho)=p}\xi_\rho(\mathfrak{b})-\sum_{(\mathfrak{b},\rho)\colon p(\mathfrak{b},-\rho)=p}\xi_\rho(\mathfrak{b})$ for a weight ξ of the pairs. Then

$$\langle\mathcal{R}[z];Y\rangle_\nu=\big\langle\mathcal{O}(\delta[-\zeta+\tfrac{3}{2\beta}\zeta'])\,;Y\big\rangle_\nu+\tfrac12\langle\mathcal{A}^2[\delta\zeta];Y\rangle_\nu.$$

(c) (Eight copies of a null form.) Let $0<g\le\gamma$, $\ell\in\mathfrak{L}(g)$, $r>0$, and let parameters $0<\kappa_\star<1$, $0<\phi<\psi<1$, $\phi\le\frac{1}{84}$, have $c_{\mathrm{Y}}=\min\{2\kappa_\star-(3+2\kappa_\star)\psi,\ \frac12\psi-4\phi\}>0$. There are C,K_0, functions of g,ℓ,r and these parameters, such that for all $(K,\beta)\in\mathfrak{d}(g)$ with $K\ge K_0$, every board of eight cells of side $\frac12\ell$ on T_ℓ with an offset in $a_K\mathbb{Z}^3$ and all real weights (v,w) carried by the points of one cell at sup distance $\ge r$ from its walls, with $F=\mathcal{P}_K[v,w]$ and $c=\langle F\rangle_{K,\ell,\beta}$: every joint cumulant of $q\ge2$ mirror copies of F in different cells is at most $(\frac32+\mathsf{op}'_q\mathsf{BI}_q)(CK^{2\mathfrak{p}_0}L^{-c_{\mathrm{Y}}K}|(v,w)|_\infty)^q$, and

$$0\le\Big\langle\prod_\kappa(F-c)\circ\mathsf{r}_\kappa^{-1}\Big\rangle_{K,\ell,\beta}\le\big(CK^{2\mathfrak{p}_0}L^{-c_{\mathrm{Y}}K}|(v,w)|_\infty\big)^8.$$

For every $c'<\frac{2}{11}$ there are parameters with $c_{\mathrm{Y}}>c'$; at $(\kappa_\star,\psi,\phi)=(\frac12,\frac18,\frac{1}{256})$, $c_{\mathrm{Y}}=\frac{3}{64}$. For $\mathfrak{Y}[\kappa]$ the same holds with $\frac14\mathfrak{b}_+\sup|\kappa|$ for $|(v,w)|_\infty$.

(d) (The collapse in the limit.) Let $0<g\le\gamma^{\mathrm{sd}}_W$, and take for the fixed side $\ell'=2\mathsf{l}$ the least side at g. For $0<r\le\frac{1}{16}\mathsf{l}$ there are C,K_0, functions of g,r, such that for all $(K,\beta)\in\mathfrak{d}(g)$ with

$K \geq K_0$, all $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, every direction μ_0, every $c \in a_K(\mathbb{Z}+\frac{1}{2})$, θ_c the reflection in $\{x_{\mu_0} = c\}$, and all real weights (v,w) carried in a cube of side r in $\{c+2r-2a_K \leq x_{\mu_0} < c+3r\}$ or in its image under θ_c,

$$\|\mathcal{P}_K[v,w]\|_{\nu,c} := \langle \theta_c \mathcal{P}_K[v,w]; \mathcal{P}_K[v,w]\rangle_\nu^{1/2} \leq C K^{2\mathfrak{p}_0} L^{-3K/64} |(v,w)|_\infty;$$

and for every tensor limit σ at g along (K_j,β_j,ρ_j) with $b_j \to b_*$, every $\eta \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and every $H' \in C_c(\mathbb{R}^3;V)$ with disjoint supports,

$$\lim_j \langle \mathsf{St}[\eta]; \mathcal{T}_{K_j}(H')\rangle_{\rho_j} = b_*\, \sigma(H^{\mathrm{cons}}[\eta], H').$$

Proposition 3.21 is not used for (d).

(e) ((N) at a lattice mirror.) Let $0 < g \leq \gamma_W^{\mathrm{sd}}$, $h_0, R_0 > 0$ and $c < \frac{1}{10}$. There are C, p, K_0, functions of g, h_0, R_0, c, such that for all $(K,\beta) \in \mathfrak{d}(g)$ with $K \geq K_0$, all $\rho \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ and all $\eta \in C^2(\mathbb{R}^3;\mathbb{R}^3)$ with support in $\{x_3 \geq h_0\} \cap \{|x|_\infty \leq R_0\}$, θ_K being the reflection in the bond mirror $\{x_3 = \frac{1}{2}a_K\}$,

$$0 \leq \big\langle \theta_K \mathcal{T}_K(H_K^{\mathrm{cons}}[\eta]); \mathcal{T}_K(H_K^{\mathrm{cons}}[\eta])\big\rangle_\rho \leq b^{-2}\big(C K^p L^{-cK} \|\eta\|\big)^2.$$

This gives (N) again for every tensor limit at g.

■

Proposition 3.8 (Two instances)**.** (a) (The free value.) Let $K_3(u) = \nabla\nabla \frac{1}{4\pi|u|}$ be the matrix of second derivatives, $y_1, y_2 \in \mathbb{R}^3$, B a real 3×3 matrix and $M(x) = K_3(x-y_1)\, B\, K_3(x-y_2)$. On $\mathbb{R}^3 \setminus \{y_1, y_2\}$

$$\sum_\nu \partial_\nu (M_{\nu\rho} + M_{\rho\nu}) = \partial_\rho \operatorname{tr} M.$$

Hence $\int \operatorname{tr}[H^{\mathrm{cons}}[\eta](x) M(x)]\, dx = 0$ for $\eta \in C^2_c(\mathbb{R}^3 \setminus \{y_1,y_2\};\mathbb{R}^3)$, and for three free photon fields, $\langle B^{\mathsf{a}}_\alpha(x) B^{\mathsf{b}}_\gamma(y)\rangle = \delta^{\mathsf{ab}} K_3(x-y)_{\alpha\gamma}$ for $x \neq y$, and for bounded $H_1, \dots, H_q$ with compact supports that are pairwise disjoint, the value of the joint cumulant of $\frac{1}{2}\int \mathrm{Tr}(H_a T)$, $a = 1,\dots,q$,

$$\tfrac{3}{2} \sum_{\pi \in S_{q-1}} \int\!\cdots\!\int \operatorname{tr}\big[H_1(x_1) K_3(x_1 - x_{\pi 2}) H_{\pi 2}(x_{\pi 2}) K_3(x_{\pi 2} - x_{\pi 3}) \cdots H_{\pi q}(x_{\pi q}) K_3(x_{\pi q} - x_1)\big]\, dx_1 \cdots dx_q,$$

in which every integrand is bounded, vanishes at $H_1 = H^{\mathrm{cons}}[\eta]$ for every $q \geq 2$, every $\eta \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and all bounded $H_2, \dots, H_q$ with compact supports that are pairwise disjoint and disjoint from $\operatorname{supp}\eta$.

(b) (Stress bounds without (N).) On $\mathbb{L}_K$ let (U, χ_K) have the law $\nu \otimes \gamma_K$, $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, γ_K the free lattice scalar field of mass 1, and $\mathcal{T}^{\mathsf{X}}_K(H) = \mathcal{T}_K(H) + \epsilon\, \mathsf{X}_K[H]$, $\mathsf{X}_K[H] = a_K^3 \sum_x \sum_\lambda H_{\lambda\lambda}(x)(\nabla^-_\lambda \nabla^+_\lambda \chi_K)(x)$, $\epsilon \neq 0$. The functions $\mathsf{St}[\eta]$, $\mathsf{Rm}[\eta]$, $\mathfrak{K}[\eta]$ depend on U alone, so Corollary 3.4 (a) holds word for word under $\nu \otimes \gamma_K$; but $b\,\mathcal{T}^{\mathsf{X}}_K(H^{\mathrm{cons}}[\eta]) - \mathsf{St}[\eta] = -\Delta[\eta] + b\epsilon\, \mathsf{X}_K[H^{\mathrm{cons}}[\eta]]$, and the last member is no function of the gauge field. At $\eta = h e_3$, $0 \leq h \in C^\infty_c(\{x_3 > 0\})$, $h \neq 0$, the mirrored two-point function $\gamma_K(\mathsf{X}_K[H^{\mathrm{cons}}[\theta\eta]]\, \mathsf{X}_K[H^{\mathrm{cons}}[\eta]])$ tends, as $K \to \infty$, to

$$\int |\hat h(p)|^2 E(p)^2 \big(2E(p)^2 - 1\big)^2\, d\rho(p) > 0, \qquad E(p) = (1+|p|^2)^{1/2}, \quad d\rho(p)$$
$$= \frac{d^2p}{(2\pi)^2\, 2E(p)}, \quad \hat h(p) = \int e^{-E(p)x_3 + ip\cdot(x_1,x_2)} h(x)\, dx.$$

So along every sequence of first-passage data and states as in Corollary 3.4 the mirrored two-point function of $\mathcal{T}^{\mathsf{X}}_K(H^{\mathrm{cons}}[\eta])$ tends to ϵ^2 times this positive number: the dressed field violates (N), while the bounds for St, Rm, $\mathfrak{K}$ hold.

■

3.3. **Input.** Lemma YMM1:118.1 supplies the constants satisfying (Th1), (Th2) of the calibrated small-field setting (Th) of B.13, whose admissible top levels are those of B.13, with the number $c_{\log} = \log L/\log\gamma^{-2}$ of Section B.13. In this setting we use one renormalisation step with its locality (Proposition E.7, with the admitted local data and the radius $\varepsilon_{\mathrm{src}}$ of the sources (274)) and with its parity: if the four families of a step depend holomorphically on a parameter μ, the other data of the step not, and the reflection $B \mapsto -B$ of the fluctuation field carries the four families at μ into those at $-\mu$, the output of the step is holomorphic, bounded and even in μ (Proposition E.8), and the three interaction families of a step are families in the fourth place of size at most $K_P\delta(x_k)$ ((273)), which bounds their even and odd parts; the potentials of local functions (equation YMM1:(870)), with their sum rule and decay (Proposition YMM1:51.15, equations YMM1:(872) and YMM1:(871)); the chain on one torus with its runs and its numbers (YMM1:114, YMM1:(2163), YMM1:(2176)), its exponent and measure recursion in Proposition YMM1:114.2, the bound in Proposition YMM1:114.2 on its families, with the step identity and the actions on a field cut there, the field cuts (YMM1:113.10, YMM1:113.10, the definitions preceding Lemma YMM1:113.10), the gauge-fixing factor and the fluctuation test of a step (Section B.2), the small-field weights, the weight defined before Proposition YMM1:115.2 of the small-field chain and the chart integrals, and the discarding of large fields (YMM1:115.2) with the number R_t of YMM1:115.2; the sums over polymers of Proposition YMM1:45.1 and Lemma O.1; minimal orbits and backgrounds (Definitions YMM1:9.3 and YMM1:9.5; Section P); local terms and their evaluation in a local gauge (Section P.1), with the usable radius YMM1:(933); the number $\varepsilon_{\mathcal{W}}$ (Proposition YMM1:52.3), regular configurations and the current of a level (Definition P.3); local regular gauges (Theorem YMM1:F, with its constants $c_{*,\mathrm{rg}} = c_*$ and B_*) and the gauge of a regular configuration on a cube about a polymer (Lemma P.4); and local gauges with a Hölder bound on cubes (Theorem BT).

Theorems YMM1:AJ and YMM1:AD enter only through the transfer statement N.1 with (319), taken at zero source: it bounds the difference of the pressures of two sides at g uniformly in the cutoff and in the larger side. We use besides the labels and the sides at a reference coupling (Corollary YMM1:74.2, YMM1:(1535), the side definition YMM1:(1528), at the common choice of Section YMM1:82); the lattice fields of equation YMM1:(2103), J, J and equations YMM1:(2104)–(2105), Section H, with the densities (293), (298); the general-field formula (301), the calculus J.1 and the divergence (302) of the derivations, the summation by parts in the orbital remainder and its covariance (Proposition H.1), and the vanishing of its torus means (8.10(b)); the equations of Dobrushin, Lanford and Ruelle for Gibbs states (YMM1:(1819)); the chessboard seminorm on tori (Section B.1), the chessboard estimate and the comparison of two sides (B.1), and the domination of periodic Gibbs states (Proposition YMM1:91.9); the reflection positivity and invariance of periodic Gibbs states (YMM1:103.4); and the invariance of torus measures under lattice isometries.

For the chain with insertions, its sources and its covariance under lattice isometries we use further: the bound of the action of a bare array at a background field (Proposition YMM1:113.13), with the number C_{old} of equation YMM1:(2163); the loss of memory of a run, that is, its Lipschitz bound in its early members (the proof of Proposition YMM1:114.3); the bound $\frac{15}{16}E_0$ on the family produced by every run whose early members have norms $\le E_0$ (the proof of Proposition YMM1:114.2), with the constant YMM1:(2173) of a step and the step identity YMM1:(2174); the classes of covariance, with their heredity, their window and their invariance (Lemma B.4); the covariance of the chart, of its Gaussian normaliser and of the minimal orbits under the isometries of the coarser lattices (the chart and push-forward calculation in the proof of Proposition YMM1:52.4, the minimal-orbit argument in Proposition YMM1:52.3, and Lemma G.1), with the chart integral (191) and the Gaussian normaliser of Section B.2; and the radius and the sets of the sources ((274), (274), the half-radius and rate conditions following (274)), with the size (272) of the families in the fourth place.

The square cone of Corollary 3.6 (ii) uses the five-point inequality of periodic Gibbs states (Lemma F.5), which rests on the lattice energy–momentum inequality (Proposition YMM1:99.3 and Lemma F.5), and the lemma of slope one at small steps (Lemma F.5).

From Section C on the six fields $\operatorname{tr} F_{ij}F_{kl}$, their continuum limits and a Wightman tensor field, in which the six fields form one tensor field and whose statements rest on Theorems YMM1:D, YMM1:AJ and YMM1:AD, we use the following three statements, restated in the notation of this section; the lattice field of that section, $O_K^T(H) = a_K^{-1}\big[\sum_p H_{\rho(p)\rho(p)}(x(p))\,a_p - \sum_{\mathfrak{b}} H_{\lambda_{\mathfrak{b}}\lambda'_{\mathfrak{b}}}(x_{\mathfrak{b}})\,q_{\mathfrak{b}}\big]$, is $\mathcal{T}_K(H)$ of Definition 3.1 (1), its bond form being $q_{\mathfrak{b}} = \langle \mathbf{u}_{\mathfrak{b},\lambda_{\mathfrak{b}}}, \mathbf{u}_{\mathfrak{b},\lambda'_{\mathfrak{b}}}\rangle = \frac{1}{4}\sum_{\epsilon,\epsilon'=\pm}\epsilon\epsilon'\langle \mathbf{w}(W_x(\mu,\epsilon\lambda_{\mathfrak{b}})), \mathbf{w}(W_x(\mu,\epsilon'\lambda'_{\mathfrak{b}}))\rangle$ at the bond $\mathfrak{b} = \langle x, x + a_K e_\mu\rangle$.

(i) (The lemma on exact symmetries and separated insertions of that section, part (b).) Let $0 < g \le \gamma_W^{\mathrm{ref}}$, $\ell \in \mathfrak{L}(g)$, $q \ge 2$ and $\delta > 0$. There are a depth $s_q(\delta)$, a function of g, q and δ, and a number $\mathsf{K}_q^{\mathrm{ub}}(g,\ell,\delta)$, neither of which depends on the cutoff or on β, such that for all $(K,\beta) \in \mathfrak{d}(g)$ with $K \ge s_q(\delta) + 2$ and $3a_K \le \delta$ and all bounded Borel $H_1, \dots, H_q : T_\ell \to V$ vanishing off closed sets that are pairwise at sup distance $\ge 2\delta$ on T_ℓ,

$$|\langle \mathcal{T}_K(H_1); \dots; \mathcal{T}_K(H_q)\rangle_{K,\ell,\beta}| \le \mathsf{K}_q^{\mathrm{ub}}(g,\ell,\delta) \prod_{a=1}^{q} 60|H_a|_\infty .$$

(ii) (The theorem on periodic Gibbs states and limits on $\mathbb{R}^3$ of that section, part (a).) Let $0 < g \le \gamma_W^{\mathrm{ref}}$, $n \ge 2$ and $\delta_0, \varrho_0 > 0$. There are a number $C_n^{\mathrm{lc}}(g,\delta_0,\varrho_0)$ and a threshold, functions of g, n, δ_0 and ϱ_0, such that for all $(K,\beta) \in \mathfrak{d}(g)$ beyond the threshold, all $\nu, \nu' \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ and all real bounded Borel $H_1, \dots, H_n : \mathbb{R}^3 \to V$ vanishing off closed sets of sup diameter $\le \varrho_0$ that are pairwise at sup distance $\ge 2\delta_0$,

$$\Big|\nu\Big(\prod_{a=1}^{n}(\mathcal{T}_K(H_a) - \nu'(\mathcal{T}_K(H_a)))\Big)\Big| \le C_n^{\mathrm{lc}}(g,\delta_0,\varrho_0)\prod_{a=1}^{n}|H_a|_\infty ;$$

the number depends neither on the cutoff, the states and the positions of the supports nor on their distances beyond $2\delta_0$.

(iii) (The theorem on the tori of that section, part (a).) Let $0 < g \le \gamma_W^{\mathrm{ref}}$, $\ell \in \mathfrak{L}(g)$, $b \in I(g)$ and $q \ge 2$. For Lipschitz $H_1, \dots, H_q : T_\ell \to V$ with pairwise disjoint supports the joint cumulants $\langle \mathcal{T}_K(H_1); \dots; \mathcal{T}_K(H_q)\rangle_{K,\ell,L^K b}$ converge as $K \to \infty$; the limit is the torus limit functional $\mathcal{S}_q^{\ell,b}(H_1, \dots, H_q)$.

Besides, Corollary 3.6 uses two further statements of that section, for $0 < g \le \gamma_W^{\mathrm{ref}}$: the limits at g with their reflection positivity at the nine families of mirrors, (iv), and the Hilbert space of such a limit with its forward cone, (v).

(iv) (The theorem on periodic Gibbs states and limits on $\mathbb{R}^3$ of that section, part (c).) Let $0 < g \le \gamma_W^{\mathrm{ref}}$. A *Gibbs sequence* at g is (K_j, β_j, ν_j) with $(K_j,\beta_j) \in \mathfrak{d}(g)$, $K_j \to \infty$ and $\nu_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$; a *limit* at g is the functional

$$\sigma(H_1, \dots, H_n) = \lim_j \nu_j\Big(\prod_{a=1}^{n} A^{\nu_j}[\mathcal{T}_{K_j}(H_a)]\Big),$$

for all $n \ge 0$ and all continuous $H_1, \dots, H_n : \mathbb{R}^3 \to V$ of compact support with pairwise disjoint supports, along a Gibbs sequence whose labels $a_{K_j}\beta_j$ converge, these limits existing. Every Gibbs sequence at g has a subsequence along which $a_{K_j}\beta_j$ converges to a number in $[g^{-2}, L(g^{-2} + \bar{B})]$ and all these limits exist. A limit at g is real, symmetric and multilinear, $\sigma(\emptyset) = 1$, and σ vanishes at a single entry; it obeys the bounds of (ii); it is invariant under every $\mathsf{r}x = \mathsf{R}x + v$, R in the cubic group, $v \in \mathbb{R}^3$, acting on points and indices; and $\sigma(\theta_{\mathsf{n},c}\bar{F} \cdot F) \ge 0$ for the reflection $\theta_{\mathsf{n},c}$ in every plane $\{\mathsf{n} \cdot x = c\}$, $\mathsf{n} \in \{e_\mu, e_\mu \pm e_\lambda\}$, $c \in \mathbb{R}$, acting on points and indices, and every finite complex combination F of such tuples with

supports in $\{\mathsf{n}\cdot x > c\}$, where σ is extended linearly, $\bar F$ has the conjugate coefficients and $F'\cdot F$ is formed by concatenating the tuples. Its trace part $\sigma(f_1\mathbf{1},\dots,f_n\mathbf{1})$ is the scalar limit of the action density of the main theorems along the same sequence.

(v) (The theorem on invariance, the Wightman field and the decomposition of that section, part (a).) Let σ be a limit at $0<g\le\gamma_W^{\mathrm{ref}}$ as in (iv), θ the reflection in $\{x_3=0\}$ and τ_v the translation of every entry of a tuple by v. The form $\langle[F'],[F]\rangle=\sigma(\theta\bar F'\cdot F)$ on the finite complex combinations of tuples with supports in $\{x_3>0\}$ gives, by quotient and completion, a separable Hilbert space $\mathcal{H}(\sigma)$ with the unit vector $\Omega=[\emptyset]$; $e^{-tH}[F]=[\tau_{te_3}F]$, $t\ge0$, and $\mathcal{U}(v)[F]=[\tau_{(v,0)}F]$, $v\in\mathbb{R}^2$, define a self-adjoint $H\ge0$ with $H\Omega=0$ and a unitary group $\mathcal{U}(v)=e^{i(v_1P_1+v_2P_2)}$ that commutes with it; and the joint spectral measure $\mathcal{P}$ of (H,P_1,P_2) is carried by the forward cone, $\mathcal{P}(\{(E,q):E<|q|\})=0$, which contains $H\ge|P_1|$ and $H\ge|P_2|$. The same holds with every mirror of the nine families in the place of $\{x_3=0\}$.

The covariance of tensor limits under $O(3)$ in the Remarks uses two further inputs, which rest, like the scalar theory, on Theorems YMM1:D, YMM1:AJ and YMM1:AD. A scalar limit is invariant under all isometries of $\mathbb{R}^3$ (Theorem YMM1:AP). And for $0<g\le\gamma_W^{\mathrm{sd}}$ Section 6 on reflection positivity at every plane, the forward light cone and Wightman fields for the tensor $\operatorname{tr}F_{ij}F_{kl}$ gives a bound on off-diagonal entries near a mirror that depends neither on the scale nor on the cutoff (Proposition 6.15 (e)): there is $C_\infty(g)$, a function of g, such that every tensor limit σ at g has $\sigma(\theta h,h)\le C_\infty(g)\,b_*^{-2}|h|_\infty^2$, θ the reflection in $\{x_3=0\}$ and b_* the limit of the labels along a defining sequence of σ with convergent labels, for $0<d<1$ and every real $h=h_0(E_{\mu\nu}+E_{\nu\mu})$, $E_{\mu\nu}$ the matrix units, $\mu\ne\nu$, with h_0 supported in the ball of radius d about a point x_0 with $x_{0,3}\in[\frac32 d,2d]$.

3.4. **Estimates and proofs.**

Lemma 3.9 (Null terms and the remainder)**.** Let $K\in\mathbb{N}$, $\beta>0$, and let η be a vector field of bounded support on $\mathbb{R}^3$, evaluated at the points of $\mathbb{L}_K$, or a vector field on a torus.

(a) Put $\mathsf{e}^{\mathsf{k}}_{\mathsf{P}}(y)=\sum_{\rho\in\mathsf{P}}[\mathsf{k}^\rho(y+\frac12 a_K e_\rho)+\mathsf{k}^\rho(y-\frac12 a_K e_\rho)]$ and, with $\rho=\rho(p)$, $\mathfrak{e}_\rho(p)=\sum_{\mathfrak{b}\subset\partial p}\langle\mathbf{y}_{\mathfrak{b},\rho},\mathbf{w}(W_{\mathfrak{b},p})\rangle+2[\Psi_\rho(p)+\Psi_\rho(p_-)]+[a_{p_+}+a_{p_-}-2a_p]$, and let the insertions $\mathfrak{J}_{0,v}[\mathsf{k}]$, linear in a vector field k, be

$$\begin{aligned}
\mathfrak{J}_{0,1}[\mathsf{k}]&=\sum_p\Big[\tfrac34\mathsf{e}^{\mathsf{k}}_{\mathsf{P}(p)}(x(p))-\tfrac14 b\,a_K\sum_\rho(\nabla_\rho^-\nabla_\rho^+\mathsf{k}^\rho)(x(p))\Big]a_p,\\
\mathfrak{J}_{0,2}[\mathsf{k}]&=\tfrac{b}{4}\sum_{p,\rho}\sum_{\mathfrak{b}\subset\partial p}\frac{\mathsf{k}^\rho(x_{\mathfrak{b}})-\mathsf{k}^\rho(x(p))}{a_K}\\
&\qquad\langle\mathbf{y}_{\mathfrak{b},\rho},\mathbf{w}(W_{\mathfrak{b},p})\rangle,\\
\mathfrak{J}_{0,3}[\mathsf{k}]&=-\tfrac{b}{2}\sum_{p,\rho}(\nabla_\rho^+\mathsf{k}^\rho)(x(p))\,\Psi_\rho(p),\\
\mathfrak{J}_{0,4}[\mathsf{k}]&=\tfrac{\beta}{4}\sum_p\mathsf{k}^{\rho(p)}(x(p))\,\mathfrak{e}_{\rho(p)}(p),\\
\mathfrak{J}_{0,5}[\mathsf{k}]&=-\tfrac{\beta}{2}\sum_p\Big(\sum_{\rho\in\mathsf{P}(p)}\mathsf{k}^\rho(x(p))\Big)a_p^2.
\end{aligned}$$

There is a number c_{k} such that, identically in the configuration,

$$\mathfrak{J}^{\mathrm{II}}[\mathsf{k}]=-\tfrac14\mathfrak{N}[\mathsf{k}]+\sum_{v=1}^5\mathfrak{J}_{0,v}[\mathsf{k}]-\tfrac14 c_{\mathsf{k}},\qquad \mathfrak{K}[\eta]=\mathcal{S}[b\eta]-\mathfrak{J}^{\mathrm{II}}[\mathsf{k}_\eta]=\mathcal{N}_\eta-\mathsf{St}[\eta]-\tfrac32 a_K\mathcal{O}(w_\eta);$$

so

$$\mathsf{St}[\eta]=\mathcal{N}_\eta-\tfrac14\mathfrak{N}[\mathsf{k}_\eta]-\mathsf{Rm}[\eta]-\tfrac14 c_{\mathsf{k}_\eta},\qquad \mathfrak{K}[\eta]=\mathsf{Rm}[\eta]-\tfrac32 a_K\mathcal{O}(w_\eta)+\tfrac14\mathfrak{N}[\mathsf{k}_\eta]+\tfrac14 c_{\mathsf{k}_\eta}.$$

If $\|\eta\| \le 1$, the weights of $\mathfrak{J}_{0,v}[\mathsf{k}_\eta]$ are at most $3+5b$ for $v \le 3$ and at most $L^K b$ for $v = 4, 5$, and those of $\frac{3}{2} a_K \mathcal{O}(w_\eta)$ are at most 3. The field of directions of $\mathcal{N}_\eta$ is $a_K^{-1} \sum_\rho \eta^\rho(x_\mathfrak{b}) \mathbf{u}_{\mathfrak{b},\rho}$ and that of $\mathfrak{N}[\mathsf{k}_\eta]$ is $\sum_\rho \mathsf{k}_\eta^\rho(x_\mathfrak{b}) \mathbf{y}_{\mathfrak{b},\rho}$; both vanish off the bonds with $\operatorname{dist}(x_\mathfrak{b}, \operatorname{supp}\eta) \le a_K$. All these functions depend only on the bond variables within $4a_K$ of $\operatorname{supp}\eta$.

(b) Let $\mathsf{N}_\mathbf{X}$ be a null term, ν a Gibbs state at (a_K, β) or a torus measure, and Y a bounded Borel function that does not depend on the bonds of Λ. Then $\nu(\mathsf{N}_\mathbf{X} Y) = 0$. Hence every joint cumulant of $\mathsf{N}_\mathbf{X}$ with functions that do not depend on these bonds vanishes; so does every joint cumulant of order ≥ 2 with a constant entry.

(c) If $Y_1, \dots, Y_r$ do not depend on the bonds within $2a_K$ of $\operatorname{supp}\eta$, the joint cumulants under ν of $\mathsf{St}[\eta]$ and of $-\mathsf{Rm}[\eta]$ with $Y_1, \dots, Y_r$ coincide, and $\nu(A^\nu[\mathsf{St}[\eta]] \prod_i A^\nu[Y_i]) = -\nu(A^\nu[\mathsf{Rm}[\eta]] \prod_i A^\nu[Y_i])$. The same holds, without the sign, for $\mathfrak{K}[\eta]$ and $\mathsf{Rm}[\eta] - \frac{3}{2} a_K \mathcal{O}(w_\eta)$. ■

Proof sketch. (a) The general-field formula (301) at the constant weight β gives $\mathsf{St}[\eta] = \mathfrak{v}_\eta(\beta \sum_p a_p) - \mathfrak{K}[\eta]$; the divergence formula (302) gives $\operatorname{div} \mathfrak{v}_\eta = -\frac{3}{2} \sum_p a_p w_\eta(p) = -\frac{3}{2} a_K \mathcal{O}(w_\eta)$, so $\mathfrak{v}_\eta(\beta \sum_p a_p) = \mathcal{N}_\eta - \frac{3}{2} a_K \mathcal{O}(w_\eta)$; and the summation by parts in the orbital remainder Proposition H.1(c) at the vector weight $\beta\eta$ gives $\mathfrak{K}[\eta] = \mathcal{S}[b\eta] - \mathfrak{J}^{\mathrm{II}}[\mathsf{k}_\eta]$, as $a_K^{-1}\beta = L^{2K} b$. The first identity is obtained by computing $\mathfrak{N}[\mathsf{k}]$ from its definition with the calculus of the derivations J.1 and ordering the result by densities; it is an identity between polynomials in finitely many bond variables, and inserting it gives the last two.

On $\mathbb{L}_K$ the finitely many bonds on which these functions depend may be realised on a torus so large that nothing wraps. The weights: $\mathsf{k}_\eta^\rho(y) = \int_0^1 \partial_\rho \eta^\rho(y + s a_K e_\rho)\, ds$, so $|\mathsf{k}_\eta| \le \sup|\nabla\eta|$, $\operatorname{Lip} \mathsf{k}_\eta \le 3 \sup|\nabla^2 \eta|$, $|w_\eta| \le 2 \sup|\nabla\eta|$; $|\mathsf{e}_\mathsf{P}^\mathsf{k}| \le 4 \sup|\mathsf{k}|$ and $a_K |\nabla_\rho^- \nabla_\rho^+ \mathsf{k}^\rho| \le 2 \operatorname{Lip} \mathsf{k}$ give $3 + \frac{9}{2} b$ for $v = 1$, the half lattice spacing between $x_\mathfrak{b}$ and $x(p)$ gives $\frac{b}{8} \operatorname{Lip} \mathsf{k}$ for $v = 2$, and $\frac{b}{2} \operatorname{Lip} \mathsf{k}$, $\frac{\beta}{4} \sup|\mathsf{k}|$, $\beta \sup|\mathsf{k}|$ for $v = 3, 4, 5$, with $\beta = L^K b$.

The field of directions of $\mathfrak{v}_\eta$ is given in YMM1:(2103); $\mathsf{k}_\eta^\rho(x_\mathfrak{b}) \ne 0$ only if $x_\mathfrak{b}$ or $x_\mathfrak{b} + a_K e_\rho$ lies in $\operatorname{supp}\eta$; a weight at an index that belongs to p depends on the values of k within a_K of $x(p)$, and the sites of its box lie within $\frac{3}{2} a_K$ of $x(p)$ (Lemma 3.10). (b) Haar measure is invariant under left translations, so $\int \partial_\mathfrak{b}^\mathsf{a} \Phi \, dU(\mathfrak{b}) = 0$ for every Φ smooth in $U(\mathfrak{b})$. Take $\Phi = \mathbf{X}_\mathfrak{b}^\mathsf{a} e^{H_\Lambda}$, $H_\Lambda = -\beta \sum a_p$ over the plaquettes that contain a bond of Λ, and sum over $\mathfrak{b} \in \Lambda$ and a:

$$\int \Big(\operatorname{div} \mathfrak{v}_\mathbf{X} - \beta\, \mathfrak{v}_\mathbf{X} \sum_p a_p \Big) e^{H_\Lambda} \prod_{\mathfrak{b} \in \Lambda} dU(\mathfrak{b}) = 0$$

at every value of the other bonds, and Y is constant under this integral. So the Gibbs kernel of Λ annihilates $\mathsf{N}_\mathbf{X} Y$, and the equations of Dobrushin, Lanford and Ruelle (YMM1:(1819)) give $\nu(\mathsf{N}_\mathbf{X} Y) = 0$; on a torus the same holds with the Wilson weight. A joint cumulant is a sum over partitions of products of means, and the block that contains $\mathsf{N}_\mathbf{X}$ contributes 0; of the other entries nothing is used but that they do not depend on the bonds of Λ, so tensor entries are admitted like scalar ones. (c) follows from (a) and (b), constants dropping out of A^ν and of cumulants of order ≥ 2. □

Lemma 3.10 (The densities; the cubic density)**.** (a) A polynomial in the entries of finitely many $SU(2)$ matrices and their inverses has exactly one polynomial continuation to $SL(2, \mathbb{C})$, and gauge invariance passes to it. The functions a_p, $\langle \mathbf{y}_{\mathfrak{b},\rho}, \mathbf{w}(W_{\mathfrak{b},p}) \rangle$ ($\mathfrak{b} \subset \partial p$, $\rho \ne \mu_\mathfrak{b}$) and $\Psi_\rho(p)$ are densities of order 2; $\mathfrak{e}_{\rho(p)}(p)$ is one of order 3; a_p^2 is one of order 4; each on the smallest box that holds the bonds on which it depends, all of whose sites lie within $\frac{3}{2} a_K$ of $x(p)$, with constants and heights that are pure numbers. All are real on $SU(2)$ configurations, and every insertion built from them has a counting number that is a pure number.

(b) $\mathfrak{r}_\rho^\sharp(p) = 0$ for ρ in the plane of p. For $\rho = \rho(p)$ it is a gauge invariant polynomial in the twenty bond variables of the two cubes with common face p, on the box $Q(p)$ of their twelve

sites. Proposition H.1 proves the real bound $|\mathfrak{r}^\sharp_\rho(p)| \le c_{\rm orb}\mu^3$ when their eleven plaquette variables are within μ of $\mathbf{1}$, with a fixed $c_{\rm orb}$, and the complex bound of order 3 with a pure constant $c_\sharp$ and height $\hat c_\sharp$. A site is the lowest site of three boxes $Q(p)$, so $\mathcal{S}_\varkappa$ is an insertion of type $(3, c_\sharp, \hat c_\sharp, 3)$ with $|\varkappa|_\infty = \max|\varkappa|$.

(c) For a diagonal isometry $\mathsf{r} : x \mapsto \mathrm{diag}(s_1,s_2,s_3)x + v$ of the lattice, $\mathfrak{r}^\sharp_\rho(\mathsf{r}p)(U) = s_\rho\, \mathfrak{r}^\sharp_\rho(p)(\mathsf{r}^{-1}U)$; so $\mathcal{S}_\varkappa \circ \mathsf{r}^{-1} = \mathcal{S}_{\varkappa'}$, $\varkappa'(q) = s_{\rho(q)}\varkappa(\mathsf{r}^{-1}q)$, and $\mathcal{S}[\Xi]\circ\mathsf{r}^{-1} = \mathcal{S}[\Xi^{\mathsf{r}}]$ with $\Xi^{\mathsf{r}}_\rho(y) = s_\rho \Xi_\rho(\mathsf{r}^{-1}y)$, $\mathsf{H}(\Xi^{\mathsf{r}}) = \mathsf{H}(\Xi)$. In particular $\mathfrak{r}^\sharp$ is odd under inversions, and the torus mean of $\mathcal{S}[\Xi]$ vanishes. ■

Proof sketch. (a) A polynomial that vanishes on $SU(2)^n$ vanishes on $SL(2,\mathbb{C})^n$ ($SU(2)$ is a real form). The densities (293), (298) are polynomials in the vector parts and the traces of plaquette holonomies at a corner ($\langle \mathbf{w}(V), \mathbf{w}(V)\rangle = a(2-a)$, $a = 1 - \frac12 \mathrm{tr}\, V$, and $|a_p| \le \frac12 r^2$ as in Lemma 3.11); they vanish to the second order at the trivial configuration for a_p, $\langle \mathbf{y}, \mathbf{w}(W)\rangle$, $\Psi_\rho(p)$, to the third order for $\mathfrak{e}_\rho(p)$, whose terms of second order cancel, and to the fourth for a_p^2. A petal holonomy is conjugate, by a product of at most three bond matrices of norm ≤ 2, to a plaquette variable or its inverse, so it is within $2^6 r$ of $\mathbf{1}$ when the plaquette variables are within r; the orders follow, and the heights at $|U(\mathfrak{b})| \le 2$ in the same way. (b) The local polynomial, the real cubic estimate and its complex version follow from Proposition H.1. Its proof uses a tree on the two cubes and cancellation of the quadratic Taylor polynomial. (c) The covariance in that proposition gives the stated transformation of the weights. The isometry preserves plaquette centres and sup distances, hence also H. Reflection through the plane of p reverses its normal component and fixes p, so invariance of the torus measure gives the zero mean. □

Lemma 3.11 (The defect is a null petal form)**.** Let $K \in \mathbb{N}$, $\beta > 0$, $\eta \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and $H : \mathbb{R}^3 \to V$ bounded.

(a) $\Delta[\eta] = F(k^0,v^0) + F(k^1,v^1)$, where (k^0,v^0) is null, $|k^0|_1 + |v^0|_\infty \le 22\, b \sup|\nabla\eta|$, $|k^1|_1 + |v^1|_\infty \le 60\, b\, a_K \sup|\nabla^2\eta|$, and the weights vanish at the sites farther than $2a_K$ from $\mathrm{supp}\,\eta$. Moreover $\mathcal{T}_K(H) = F(k,v)$ with $|k|_1 \le 3|H|_\infty$, $|v|_\infty \le |H|_\infty$.

(b) A rough insertion $F(k,v)$ is an insertion of order 2 on the boxes $x + a_K\{-1,0,1\}^3$, with pure numbers as constant and height, counting number ≤ 600, and $|\varkappa|_\infty \le L^K \max\{|k|_1, |v|_\infty\}$. ■

Proof sketch. (a) Each bond $\mathfrak{b} = \langle x, x + a_K e_\mu\rangle$ lies in four plaquettes whose loops are petals at x, $W_{\mathfrak{b},p(\mathfrak{b},\alpha')} = W_x(\mu,\alpha')$, and $\mathbf{u}_{\mathfrak{b},\rho} = -\frac12 \sum_{\epsilon=\pm} \epsilon\, \mathbf{w}(W_x(\mu,\epsilon\rho))$; so $\Theta_\beta[\eta]$, Y and $\mathcal{O}$ are petal forms: $\Theta_\beta[\eta] = a_K^{-1}\sum_x \sum_\mu \sum_{\alpha'} \sum_{\rho\ne\mu} \sum_{\epsilon=\pm} k^\Theta q_x((\mu,\epsilon\rho),(\mu,\alpha'))$ with $k^\Theta = -\frac{\epsilon}{2} b a_K^{-1}[\eta^\rho(x_\mathfrak{b}) - \eta^\rho(x_\mathfrak{b} + \frac12 a_K e_{\alpha'})]$, 48 terms at a site. Expanding the values of η about the site x splits the weights into a part linear in $\nabla\eta(x)$, which is (k^0,v^0), and a remainder of size $a_K \sup|\nabla^2\eta|$; counting the terms gives $|k^0|_1 \le 18 b \sup|\nabla\eta|$, $|v^0|_\infty \le 4b\sup|\nabla\eta|$ and the bound for (k^1,v^1). With $G = \nabla\eta(x)$, $T_{\lambda\lambda'} = \langle B_\lambda, B_{\lambda'}\rangle$, $H = (\mathrm{tr}\, G)\mathbf{1} - G - G^{\mathrm T}$ and $\sum_\mu \langle F_{\mu\rho}, F_{\mu\nu}\rangle = \delta_{\rho\nu}\mathrm{tr}\, T - T_{\rho\nu}$, which follows from $\sum_\mu \varepsilon_{\mu\rho\lambda}\varepsilon_{\mu\nu\lambda'} = \delta_{\rho\nu}\delta_{\lambda\lambda'} - \delta_{\rho\lambda'}\delta_{\lambda\nu}$, the symbol of (k^0,v^0) at x is

$$b\,[(\mathrm{tr}\, G)\,\mathrm{tr}\, T - \mathrm{Tr}(GT)] - \tfrac{b}{2}(\mathrm{tr}\, G)\,\mathrm{tr}\, T - \tfrac{b}{2}\mathrm{Tr}(HT) = 0,$$

the three members coming from Θ_β, from $-b\,\mathcal{O}(\nabla\cdot\eta)$ and from $-b\,\mathcal{T}_K(H^{\rm cons}[\eta])$, because $\frac12\mathrm{Tr}(HT) = \frac12(\mathrm{tr}\, G)\,\mathrm{tr}\, T - \mathrm{Tr}(GT)$ for symmetric T. This is the one place where it is used that the six fields are petal forms of the gauge field itself. (b) All the densities at the site x are densities on the one box $x + a_K\{-1,0,1\}^3$: 576 forms $q_x(\pi,\pi')$ and three $a_{p_m(x)}$; they are gauge invariant since both loops are based at x. A petal holonomy is conjugate, by a product of at most three bond matrices of norm ≤ 2, to a plaquette variable or its inverse; so $|\mathbf{w}(W_x(\pi))| \le 2^6 r$, $|q_x(\pi,\pi')| \le 2^{12} r^2$ and $|a_p| \le \frac12 r^2$ (as $\mathrm{tr}(V-\mathbf{1}) = -\det(V-\mathbf{1})$ on $SL(2,\mathbb{C})$) when $|U(\mathfrak{b})| \le 2$ and $|\partial U(q) - \mathbf{1}| \le r \le 1$; the heights follow in the same way. □

Lemma 3.12 (The frame)**.** Let $0 < g \le \gamma$.

(a) Every $(K,\beta) \in \mathfrak{d}(g)$ has $g^{-2} + B_\sharp - \bar{B}/L < b \le \mathsf{b}_+$; so $b \in [\gamma^{-2}, \mathsf{b}_+]$ and $b \ge 4$. For every side $2L^m \in \mathfrak{L}(g)$ and every $1 < \mathsf{b}' \le \mathsf{b}_+$, $MR(\mathsf{b}') \le L^m$, with the non-decreasing cube-size function R of YMM1:74.

(b) Let $0 < \phi < 1$, and let K_ϕ be the least integer $K \ge 2$ with $(1-\phi)K \ge 2$, $L^{\phi K}\gamma^{-2} \ge \mathsf{t}_\natural$ and $\phi K > 16\mathfrak{p}_0^2 c_{\log}/(\log L)^2$, where $\mathsf{t}_\natural$, $c_{\log}$ are numbers of the setting (B.13, Section B.13). For $K \ge K_\phi$, every $\mathsf{b}' \ge \gamma^{-2}$ and every m with $MR(\mathsf{b}') \le L^m$, the level $t = K - \lceil \phi K \rceil$ is an admissible top level: (Th) holds on T_{2L^m} with (K, b', m, t), and the numbers θ_k of the chain satisfy

$$L\theta_k \le \Theta_K L^{-(K-k)/2} \quad (0 \le k \le t), \qquad \Theta_K = \max\{1, \tfrac{13}{72}(L-1)(1+Kc_{\log})^{\mathfrak{p}_0}\} \le CK^{\mathfrak{p}_0},$$

so that $\sum_{k<n} L\theta_k \le \Theta_K L^{-(K-n)/2}$ for $1 \le n \le t$.

(c) If $0 < \phi \le \frac{1}{84}$ and $K \ge \max\{K_\phi, 5\}$, then $u = \lceil \phi K \rceil \le \lceil \frac{K}{84} \rceil \le \lceil \frac{K}{14} \rceil$, $u \le \frac{K}{84} + 1$, $4u \le \frac{K}{21} + 4 \le K$ and $t \ge \frac{3}{4}K$.

■

Proof sketch. (a) By YMM1:(1535) and Corollary YMM1:74.2, applied at the common constants of Section YMM1:82 and at $g \le \gamma$, the label lies in $(g^{-2} + B_\sharp - L^{-1}\bar{B}, L(g^{-2} + \bar{B})]$; by YMM1:74, with $\bar{B} = B_\sharp L/(L-1)$, $B_\sharp - L^{-1}\bar{B} = B_\sharp \frac{L-2}{L-1} \ge 0$, and $\gamma \le \frac{1}{2}$. The bound $MR(\mathsf{b}') \le L^m$ is YMM1:(1528) with R non-decreasing. (b) Of a top level (Th) asks only $1 \le t \le K-1$ and $L^{K-t}\mathsf{b}' \ge \mathsf{t}_\natural$ (B.13), besides $K \ge 2$, $\mathsf{b}' \ge \gamma^{-2}$ and $MR(\mathsf{b}') \le L^m$; the first two conditions on K_ϕ give these. By YMM1:(2176), $\mathsf{s}^{\mathrm{abs}}_{K-y} \le \mathsf{s}_\gamma L^{-y/2}(1+yc_{\log})^{\mathfrak{p}_0}$; with $\log(1+a) \le 2\sqrt{a}$ and the third condition the logarithm of the factor is negative for $y \ge \phi K$, so the runs of the chain are admissible at all levels $k \le t$, and $L\theta_k \le \frac{13}{72}(L-1)L^{-(K-k)/2}(1+(K-k)c_{\log})^{\mathfrak{p}_0}$; summing the geometric series ($L \ge 13$) gives the last bound. (c) $\phi K \le \frac{K}{84}$, and the ceiling is non-decreasing: this gives the first two bounds. $\lceil x \rceil < x+1$ gives $u \le \frac{K}{84} + 1$, so $4u \le \frac{K}{21} + 4$ and $t = K - u \ge \frac{83}{84}K - 1$; for $K \ge 5$, $\frac{K}{21} + 4 \le K$ and $\frac{83}{84}K - 1 \ge \frac{3}{4}K$, both being $K \ge \frac{21}{5}$. □

Proposition 3.13 (The chain with one insertion, on the whole cut set)**.** Let the constants satisfy (Th1), (Th2), and let (Th) hold on T_ℓ, $\ell = 2L^m$, with (K, b', m, t_*); the line is $x_j = L^{K-j}\mathsf{b}'$, $x_0 = \beta$. Let $\mathfrak{J}$ be an insertion of type $(m_\mathfrak{J}, c, \hat{c}, N)$, $m_\mathfrak{J} \ge 2$, $\varsigma = 2m_\mathfrak{J} - 3$, and put

$$\mathsf{m}_j = 8NM^3 c\,\alpha_0^{m_\mathfrak{J}}|\varkappa|_\infty L^{-\varsigma j}, \quad \mathsf{n}^{\mathrm{f}} = 16NM^3\hat{c}\,\tfrac{\mathsf{C}_\mathcal{A}}{r_P^\circ}\,\delta(x_0)|\varkappa|_\infty, \quad \mathsf{d}_1 = K^{\mathrm{d}}\mathsf{n}^{\mathrm{f}}, \quad \mathsf{n}_j = \sum_{i \le j} L^{i-j}\mathsf{d}_i,$$
$$\mathsf{d}_{j+1} = \theta_j(\mathsf{n}_j + \mathsf{m}_j),$$

$$\mathsf{o}_k = N_k\big[Nc\,(\mathsf{e}_k^{\mathrm{c}})^{m_\mathfrak{J}}|\varkappa|_\infty L^{-\varsigma k} + C_{\mathrm{old}}\mathsf{n}_k\big], \qquad r_\mathfrak{J} = \min\Big\{\frac{w_\star}{32\,\mathsf{n}^{\mathrm{f}}}, \frac{E_0}{16(\mathsf{d}_1 + \mathsf{m}_1)}\Big\},$$

with the numbers α_0, $\mathsf{C}_\mathcal{A}$, r_P°, $\delta(\cdot)$, K^{d}, θ_j, $\mathsf{e}_k^{\mathrm{c}}$, $N_k = (\ell L^{K-k})^3$, C_{old}, $w_\star$, E_0 of the chain (YMM1:114, YMM1:(2163)). For complex $|s|, |s'| < r_\mathfrak{J}$ there are pointed families $E^{(i)}[s]$ of level i, $1 \le i \le t_*$, with $E^{(i)}[0] = E^{(i)}$ the families of the chain, and numbers $\mathsf{c}_i(s)$, such that:

(i) $\|E^{(i)}[s]\| < \frac{15}{16}E_0 + \mathbf{1}_{\{i=1\}}|s|\mathsf{d}_1$ and $\|E^{(i)}[s] - E^{(i)}[s']\| \le |s-s'|\mathsf{d}_i$; the members are holomorphic in s;

(ii) (locality) if $\mathfrak{J}_0, \dots, \mathfrak{J}_r$ have pairwise disjoint carriers and $\mathfrak{J}_\sigma = \sum_a \sigma_a \mathfrak{J}_a$, $\sigma \in \{0,1\}^{r+1}$, then for $|s|$ below a common radius the member at a polymer X of the families of $\mathfrak{J}_\sigma$ depends only on the σ_a for which $\mathfrak{J}_a$ meets X;

(iii) for $1 \le k \le t_*$,

$$(\mathcal{M}^k)_*(\mathsf{p}_k\, e^{s\mathfrak{J}}\rho_0\, dU) = \exp\Big[\sum_{i \le k} \mathsf{c}_i(s)\Big]\mathbf{1}_{\mathsf{Cut}_k} e^{\Phi_k^s}\, dV,$$

a bounded complex Borel density, where $\Phi_k^s(V) = \Phi_k(V) + \sum_{i\le k}\sum_{X,z}[\delta E_s^{(i)}(X,U,z) - \delta E_s^{(i)}(X,\mathbf{1},z)] + s\mathfrak{J}(U)$, $\delta E_s^{(i)} = E^{(i)}[s] - E^{(i)}$, Φ_k is the exponent of the chain (the definition of Φ_k^w in Proposition YMM1:114.2 at zero source) and U is any element of the minimal orbit over V, that is, any configuration over V (Definition 3.2 (3)), on which Φ_k^s does not depend: Φ_k is a function of V (Proposition YMM1:114.2); the double sum is the difference of the actions at U of the two bare arrays formed by the families $E^{(i)}[s]$, resp. $E^{(i)}$, $i \le k$, and the action of a bare array is defined at every element of the minimal orbit over V and takes one value there (Propositions YMM1:114.2 and YMM1:113.13); and $\mathfrak{J}$ is gauge invariant, while the minimal orbit is one orbit of gauge transformations of the bare lattice. The numbers are $\mathsf{c}_i(s) = \mathsf{c}_i(0) + \sum_{X,z}\delta E_s^{(i)}(X,\mathbf{1},z)$, with $\mathsf{c}_i(0)$ the constants of the chain (from the constant YMM1:(2173) of a step). At the level $k = t$ the display gives $\Lambda^{\mathrm{sf}}(e^{s\mathfrak{J}}) = \exp[\sum_{i\le t}\mathsf{c}_i(s)]\int \mathbf{1}_{\mathsf{In}_t} e^{\Phi_t^s}\,dV$;

(iv) $|\Phi_k^s - \Phi_k^{s'}| \le |s - s'|\,\mathsf{o}_k$ on Cut_k;

(v) (several insertions; a source) for finitely many insertions $\mathfrak{J}_a$ of orders ≥ 2, with their numbers $\mathsf{d}_{i,a}$, $\mathsf{m}_{j,a}$, $\mathsf{o}_{k,a}$, $r_a = r_{\mathfrak{J}_a}$, and strengths $\mathbf{s} = (s_a)$ in the parameter domain $\{\sum_a |s_a|/r_a < 1\}$, the same construction with $\sum_a s_a\mathfrak{J}_a$ gives families $E^{(i)}[\mathbf{s}]$ with $\|E^{(i)}[\mathbf{s}]\| < \frac{15}{16}E_0 + \mathbf{1}_{\{i=1\}}\sum_a |s_a|\mathsf{d}_{1,a}$, $\|E^{(i)}[\mathbf{s}] - E^{(i)}[\mathbf{s}']\| \le \sum_a |s_a - s'_a|\mathsf{d}_{i,a}$, $|\Phi_k^{\mathbf{s}} - \Phi_k^{\mathbf{s}'}| \le \sum_a |s_a - s'_a|\mathsf{o}_{k,a}$ on Cut_k, members at X that depend only on the s_a with $\mathfrak{J}_a$ meeting X and are jointly holomorphic, and (iii) for $\sum_a s_a\mathfrak{J}_a$; the same holds with a complex source w of the action density in the class, $\rho_0 e^{\mathcal{O}(w)}$ taking the place of ρ_0.

No largeness of K enters: (i)–(v) hold at every admissible top level. ■

Proof. The one-step estimates used here are Lemma YMM1:77.1 and Proposition YMM1:77.2, together with the density identity in Theorem YMM1:W. They are applied on the full analytic background cores, with reference coupling $\mathsf{t} = x_j$ and $\tau = 1$; the source and insertion parameters do not change this Gaussian reference. In their fourth-family norm the fluctuation variable is B, the physical field is $g_j B$, and the quadratic weight is $1 + M^{-3}\sum_b |B(b)|^2$. The sum runs over the fluctuation bonds in the polymer. The source class and the array ceiling are those of Proposition YMM1:114.2, with $E_0^{\mathrm{s}} = E_0$ and $K^{\mathrm{d}} = (351/2)L^3K_\Pi$. Its hypotheses include the fixed smallness budgets and the whole-chart conditions needed for the pushed-forward density. Its proof gives the output bound $15E_0/16$ from every admissible array; Proposition YMM1:114.3 gives the weighted difference estimate used below.

The families are defined by recursion on the height, as for the chain, with two additions. At height 0 the first step receives, besides its families, the family $s\mathbb{W}_{\mathfrak{J}}$ in the fourth place, $\mathbb{W}_{\mathfrak{J}}(Y;\cdot) = \sum_{\iota:X_0(Q_\iota)=Y}\varkappa_\iota[\mathsf{j}_\iota(e^{iB'}U) - \mathsf{j}_\iota(U)]$ ($X_0(Q)$ the union of the cubes of level 0 that hold a site of Q), of norm $\le |s|\mathsf{n}^{\mathrm{f}} < w_\star/32$; the source-inclusive unperturbed fourth family has norm at most $7w_\star/32$, so the one-step hypotheses of Lemma YMM1:77.1 hold, and its output $E^{(1)}[s]$ is a pointed family. At height $j \ge 1$ the early member of level j is replaced by $E^{(j)}[s] + sH_{\mathfrak{J}}^{(j)}$, where $H_{\mathfrak{J}}^{(j)}(X,\cdot,z)$ distributes over the sites of X the boxes Q_ι with $X_j(Q_\iota) = X$; it has norm $\le \mathsf{m}_j$, it vanishes at the trivial configuration, and it sums to $\mathfrak{J}$ at every background over a field cut, that is, at every element U of the minimal orbit $\mathcal{C}(\mathbf{B}_j, V)$ over a block field $V \in \mathsf{Cut}_j$. (Here and below the minimal orbit $\mathcal{C}(\mathbf{B}_k, V)$ over a block field V of level k and its elements, the *backgrounds* over V, are those of Section P; a gauge invariant function, such as $\mathfrak{J}$ or the sum $\mathsf{Sum}[\mathsf{f}]$ of the members of a pointed family, takes one value on the orbit; a configuration *over* Cut_k is a background over some $V \in \mathsf{Cut}_k$.) For every run whose early members have norms $\le E_0$, Proposition YMM1:114.2 gives an output family of norm $< 15E_0/16$. The three contributions to this bound are at most $E_0/2$, $E_0/4$ and $3E_0/16$; the next run admits every early member of norm at most E_0.

With $|s|(\mathsf{d}_1+\mathsf{m}_1)<\frac{1}{16}E_0$ the perturbed early members, of norms $<\frac{15}{16}E_0+|s|(\mathsf{d}_1+\mathsf{m}_1)$ (as $\mathsf{m}_j\le\mathsf{m}_1$), are admissible, and the recursion of Proposition YMM1:114.2 gives $E^{(j+1)}[s]$, of norm $<\frac{15}{16}E_0$: this is the first half of (i) at $i\ge 2$. At $i=1$ the Lipschitz bound of one step in its family in the fourth place (Proposition YMM1:77.2, whose coefficient is at most $54(3L^3-3)K_\Pi<K^{\mathrm{d}}$ in these size budgets) gives $\|E^{(1)}[s]-E^{(1)}[s']\|\le K^{\mathrm{d}}|s-s'|\mathsf{n}^{\mathrm{f}}=|s-s'|\mathsf{d}_1$, and with $s'=0$ the first half of (i) at $i=1$.

For $j\ge 1$ the second half of (i) at $i=j+1$ follows from the Lipschitz bound of a run in its early members, the loss of memory of Proposition YMM1:114.3: for two runs from the level j whose early members of the levels $i\le j$ differ in norm by at most Δ_i, the families they produce differ by $\Delta_{j+1}\le\theta_j\sum_{i\le j}L^{-(j-i)}\Delta_i$, $\theta_j=K^{\mathrm{d}}K_\Lambda\mathsf{s}_j^{\mathrm{abs}}$. The runs at s and at s' have $\Delta_i\le|s-s'|\mathsf{d}_i$ for $i<j$ and $\Delta_j\le|s-s'|(\mathsf{d}_j+\mathsf{m}_j)$, so $\Delta_{j+1}\le\theta_j|s-s'|(\mathsf{n}_j+\mathsf{m}_j)=|s-s'|\mathsf{d}_{j+1}$. Holomorphy is that of one step in its data. (ii) follows from the locality clauses of Lemma YMM1:77.1 and Proposition YMM1:114.2 (two families in the fourth place, or two bare arrays, that agree near X give the same output at X), by induction on the level.

For (iii), the chart identity is Theorem YMM1:W on the same whole-chart domain; $\mu_k=(\mathcal{M}^k)_*(\mathsf{p}_k e^{s\mathfrak{J}}\rho_0 dU)$ satisfies $\mu_{k+1}=\mathbf{1}_{\mathsf{Cut}_{k+1}}\mathbf{T}(\mathfrak{G}_k\chi^{\mathrm{sf}}\mu_k)$ by the rules of images of complex measures ($\mathbf{T}$ the image under one block averaging, $\mathfrak{G}_k$ the gauge factor, χ^{sf} the small-field indicator); the chart integral of the first step is $\exp[\mathsf{c}_1(s)+\Phi_1^s]$, and by induction $e^{\Phi_k^s}$ is on Cut_k the integrand of the run started at level k. The numbers of (iii) are the constants of these steps (Proposition YMM1:114.2): in the normalizing constant of a step only the values at the trivial configuration of the family that the step produces depend on its data, so that

$$\mathsf{c}_i(s)=\mathsf{c}_i(0)+\sum_{X,z}\delta E_s^{(i)}(X,\mathbf{1},z),\qquad \delta E_s^{(i)}=E^{(i)}[s]-E^{(i)},$$

with $\mathsf{c}_i(0)$ the constants of the chain. The sums are continuous on the open set Cut_k, hence Borel, and gauge invariant. (iv): at a background U over $V\in\mathsf{Cut}_k$,

$$\Phi_k^s(V)-\Phi_k^{s'}(V)=(s-s')\,\mathfrak{J}(U)+S[\mathfrak{g}](U),\qquad S[\mathfrak{g}](U)=\sum_{i\le k}\sum_{X,z}[\mathsf{g}_i(X,U,z)-\mathsf{g}_i(X,\mathbf{1},z)],$$

the action of the bare array $\mathfrak{g}$ with the families $\mathsf{g}_i=E^{(i)}[s]-E^{(i)}[s']$, of norms $\le|s-s'|\mathsf{d}_i$ by (i), with vanishing counterterms and empty slot. The bound of the action of a bare array at a background field, Proposition YMM1:113.13, states: for $1\le k\le t_*$, $V\in\mathsf{Cut}_k$, $U\in\mathcal{C}(\mathbf{B}_k,V)$ and pointed families g_i of the levels $i\le k$,

$$|S[\mathfrak{g}](U)|\le C_{\mathrm{old}}\,N_k\sum_{i\le k}L^{-(k-i)}\|\mathsf{g}_i\|,$$

with the number C_{old} of equation YMM1:(2163), a function of the constants, at every admissible top level; no largeness of K enters. Here it gives $|S[\mathfrak{g}](U)|\le C_{\mathrm{old}}N_k\mathsf{n}_k|s-s'|$. The idea of that bound: U is regular of level k at the radius α_0 (YMM1:113.10), hence regular of level i at the radius $\alpha_0L^{-2(k-i)}$, and a member at a polymer X of level i minus its value at $\mathbf{1}$ is of second order in this radius as long as X is not too large (the local estimate in the proof of Lemma YMM1:113.12); so the polymers of moderate size through the $N_i=L^{3(k-i)}N_k$ sites of level i contribute $N_iL^{-4(k-i)}=N_kL^{-(k-i)}$ times the norm, and the larger polymers, and all polymers at the few levels i next to k, are paid for by the decay $e^{-(\kappa+1)d_i(X)}$ of the members and the sums of (320), the numbers $L^{4l}e^{-c_{\mathrm{A}}L^l}$, $l\ge 0$, being bounded (c_{A} the number of equation YMM1:(2163)).

Besides, $|\mathfrak{J}(U)|\le N_kNc(\mathsf{e}_k^{\mathrm{c}})^{m_{\mathfrak{J}}}|\varkappa|_\infty L^{-\varsigma k}$: the plaquette variables of U are within $\mathsf{m}_k(U)L^{-2k}<\mathsf{e}_k^{\mathrm{c}}L^{-2k}\le 1$ of $\mathbf{1}$ ($\mathsf{Cut}_k=\mathcal{C}_k^{\flat}(\mathsf{e}_k^{\mathrm{c}})$, YMM1:113.10, with the regularity number $\mathsf{m}_k(U)=L^{2k}\max_p|\partial U(p)-\mathbf{1}|$ of Definition B.2), so that a density of order $m_{\mathfrak{J}}$ is at most $c(\mathsf{e}_k^{\mathrm{c}}L^{-2k})^{m_{\mathfrak{J}}}$ there, and $\mathfrak{J}$ has at most $N(\ell L^K)^3=NN_kL^{3k}$ indices. The two bounds add up to $|s-s'|\,\mathsf{o}_k$. (v): the statements of one step are worded for parameters in a point or an open subset of some $\mathbb{C}^p$; every estimate above is

linear in the insertion; so the proof goes through with $\mathbf{s} \in \mathbb{C}^{\#a}$, and with the source among the parameters. □

Lemma 3.14 (Conditional means; the numbers of one insertion)**.** In the setting of Proposition 3.13:

(a) $(\mathcal{M}^k)_*(\mathsf{p}_k Y \rho_0 dU) = (\mathsf{Q}_{k\leftarrow 0} Y)\,\nu_k$ for bounded Borel Y, with $\mathsf{Q}_{k\leftarrow 0} = \mathsf{Q}_{k-1}\cdots\mathsf{Q}_0$ and $\mathsf{Q}_k h = \mathsf{I}[hF_k]/\mathsf{I}[F_k]$ on Cut_{k+1}, 0 off it (I the chart integral, F_k the integrand of the step). $\mathsf{Q}_k h$ is a bounded Borel function, linear in h, that depends on h on Cut_k alone; $\mathsf{Q}_k 1 = \mathbf{1}_{\mathsf{Cut}_{k+1}}$; $\nu_k \ge 0$ and $\|\mathsf{Q}_k h - a_0\|_{L^\infty(\nu_{k+1})} \le \|h - a_0\|_{L^\infty(\nu_k)}$ for $a_0 \in \mathbb{C}$. For $k \ge 1$ and a pointed family g of level $i' \le k$ (or a formal sum of such), $\mathsf{Q}_k \Sigma_k[\mathsf{g}] = \Sigma_{k+1}[\mathsf{g} + \mathsf{S}_k \mathsf{g}]$ at every point, with a linear map S_k, $\|\mathsf{S}_k \mathsf{g}\| \le \theta_k L^{-(k-i')}\|\mathsf{g}\|$, whose member at X depends on the members of g at the polymers inside X alone.

(b) There is a number $\dot{c}_k$ with $\mathsf{Q}_{k\leftarrow 0}\mathfrak{J} = \dot{c}_k + \partial_s A_k(0,\cdot)$ ν_k-almost everywhere on Cut_k, $A_k(s,\cdot) = \Phi_k^s - \Phi_k$; $|\partial_s A_k(0,\cdot)| \le \mathsf{o}_k$, and $|A_k(s,V)/s - \partial_s A_k(0,V)| \le 2|s|\mathsf{o}_k/r_{\mathfrak{J}}$ for $0 < |s| \le \frac{1}{2} r_{\mathfrak{J}}$. Hence $\omega_t(\mathfrak{J}) \le \mathsf{o}_t$; ω_t is a seminorm.

(c) Let $m \in \mathbb{N}$, $\ell = 2L^m$, $\gamma^{-2} \le \mathsf{b}_- \le \mathsf{b}_+$ with $MR(\mathsf{b}_+) \le L^m$, $0 < \phi \le \frac{1}{4}$, and fix a type. Let $K \ge K_\phi$, $u = \lceil \phi K \rceil$, $t = K - u$, $\mathsf{b}' \in [\mathsf{b}_-, \mathsf{b}_+]$ and $\beta = L^K \mathsf{b}'$, so that (Th) holds on T_ℓ with (K, b', m, t) (Lemma 3.12 (b)). With C a function of m, b_+, ϕ and the type: $\mathsf{o}_t \le C K^{2\mathfrak{p}_0} L^{4u-K} |\varkappa|_\infty$ at order 2, $\mathsf{o}_t \le C K^{3\mathfrak{p}_0} L^{4u-\frac{3}{2}K} |\varkappa|_\infty$ at orders ≥ 3, and $1/r_{\mathfrak{J}} \le C|\varkappa|_\infty$. If $0 < \phi \le \frac{1}{84}$ and $K \ge \max\{K_\phi, 5\}$, these bounds hold with C a function of m, b_+ and the type alone, not of ϕ, and with such a C also $\max_i \mathsf{d}_i \le C|\varkappa|_\infty$ and, at order 2, $\sum_{i \le n_0} L^i \mathsf{d}_i \le C K^{\mathfrak{p}_0} L^{-(K-n_0)/2} |\varkappa|_\infty$ for $1 \le n_0 \le t$. First-passage data $(K, \beta) \in \mathfrak{d}(g)$ on a side $\ell \in \mathfrak{L}(g)$ are the case $\mathsf{b}_- = \gamma^{-2}$, $\mathsf{b}_+ = X_g + \bar{B}$, $\mathsf{b}' = b$ (Lemma 3.12 (a)).

(d) For the data of (c), now with any $0 < \phi < 1$, $\sup|\mathfrak{J}| \le N\hat{c}\,\ell^3 L^{3K} |\varkappa|_\infty$ at real configurations, and, with the numbers c', A_0, $\mathsf{C}^\Sigma_{\mathrm{maj}}$, $C_{\mathrm{low}}(x) = c_{\mathrm{low}} + \frac{9}{2}\log x$ of the definition YMM1:115.2 of R_t,

$$\mathsf{R}_t \le C_{\mathrm{R}} L^{3u} \exp\bigl[-c' A_0^2 (\phi K \log L)^{2\mathfrak{p}_0}\bigr], \qquad C_{\mathrm{R}} = 2M^{-3}\ell^3 \exp\bigl[(\mathsf{C}^\Sigma_{\mathrm{maj}} + 2 + C_{\mathrm{low}}(\mathsf{b}_+))\ell^3\bigr],$$

uniformly in $\mathsf{b}' \in [\gamma^{-2}, \mathsf{b}_+]$; for $\phi K \log L \ge 1$ the exponent is $\le -c' A_0^2 (\phi \log L)^2 K^2$, so R_t lies below every power of L^{-K} for large K.

■

Proof sketch. (a) If $\mu_k = h\nu_k$, then $\mu_{k+1} = (\mathsf{Q}_k h)\nu_{k+1}$, by the expression of the step through the chart integral (which depends on its function at the points of Cut_k alone, and is a positive kernel at zero source); induction on k. At zero source Q_k averages against a finite positive measure, whence the contraction ($|\int_E (\mathsf{Q}_k h - a_0)\, d\nu_{k+1}| \le \|h - a_0\|_\infty \nu_{k+1}(E)$ for Borel E). For the last identity, perturb the early member of level i' by $\mu\mathsf{g}$, admissible for $|\mu|\|\mathsf{g}\| < \frac{1}{16}E_0$ by the room between $\frac{15}{16}E_0$ and E_0, and take the derivative in μ at 0 of the identity of the step for the run with this early member: $\mathsf{S}_k\mathsf{g}$ is the derivative of the next family, bounded by the Lipschitz bound of a run (the one-step estimate in the proof of Proposition YMM1:114.3, with $\Delta_{i'} = |\mu|\|\mathsf{g}\|$ and $\Delta_i = 0$ at the other levels $i \le k$), and local by the locality of one step. (b) Integrate the display of Proposition 3.13 (iii) against a bounded Borel h: both sides are holomorphic in s; by (iv), $|A_k| \le |s|\mathsf{o}_k$, so Cauchy's estimates give $|\partial_s A_k(0)| \le \mathsf{o}_k$ and $|A_k/s - \partial_s A_k(0)| \le 2|s|\mathsf{o}_k/r_{\mathfrak{J}}$; differentiate at $s = 0$ under the integrals (dominated convergence) and compare with (a). (c) Insert $x_t = L^u \mathsf{b}'$, $(\mathsf{e}^{\mathrm{c}}_t)^2 = c_\rho^2 A_0^2 (\log x_t)^{2\mathfrak{p}_0}/x_t \le C K^{2\mathfrak{p}_0} L^{-u}$ (as $\log x_t \le K\log L + \log \mathsf{b}_+$ and $x_t \ge \gamma^{-2} L^u$), $N_t = \ell^3 L^{3u}$, $\delta(x_0) \le C K^{\mathfrak{p}_0} L^{-K/2}$ into the definitions; the recursion gives $L^t \mathsf{n}_t \le C(\mathsf{d}_1 + \sum_j \theta_j L^j \mathsf{m}_j)$ and $L^{j+1}\mathsf{d}_{j+1} = L\theta_j(L^j \mathsf{n}_j + L^j \mathsf{m}_j)$, and Lemma 3.12 (b) sums the $L\theta_j$.

At orders ≥ 3, $\mathsf{e}^{\mathrm{c}}_t \le 1$ and $L^{-3t} \le L^{-t-K/2}$ because $t \ge (1-\phi)K - 1 \ge \frac{K}{4}$, as $\phi \le \frac{1}{4}$ and $K \ge 2$. (d) The height at $|U(\mathfrak{b})| = 1$ and at most $N(\ell L^K)^3$ indices; for R_t insert $N_t = \ell^3 L^{3u}$, $\log x_t \ge u \log L \ge \phi K \log L$ ($\mathsf{b}' > 1$), $C_{\mathrm{low}}(\mathsf{b}') \le C_{\mathrm{low}}(\mathsf{b}_+)$ and $\mathfrak{p}_0 \ge 1$ into YMM1:115.2. □

Proposition 3.15 (Cumulants of distant insertions on one torus)**.** (a) Let (Th) hold on T_ℓ with top level t, let $\mathsf{R}_t \le \frac12$, and let $\mathfrak{J}_0,\dots,\mathfrak{J}_r$, $r\ge 1$, be insertions of orders ≥ 2 whose carriers are pairwise at sup distance $\ge \mathsf{d}_\times > 0$ on T_ℓ. Let r_* and $\bar{\mathsf{d}}$ be the numbers $r_{\mathfrak{J}}$ and $\max_i \mathsf{d}_i$ of Proposition 3.13 formed at order 2 with the largest constants and the largest weight among the $\mathfrak{J}_a$, $r_1 = \min\{\frac12 r_*, (16\sum_a \mathsf{o}_t(\mathfrak{J}_a))^{-1}\}$ and $\mathsf{t}_\times = e^2 C_{\mathrm{E},0}\sum_{i\le t} N_i \exp[-\mathsf{d}_\times L^{K-i}/M]$, $C_{\mathrm{E},0}$ the number of (320). If $32(r+2)r_1\bar{\mathsf{d}}\,\mathsf{t}_\times \le 1$, then

$$|\langle \mathfrak{J}_0;\dots;\mathfrak{J}_r\rangle_{K,\ell,\beta}| \le \mathsf{op}_{r+1}\prod_a \omega_t(\mathfrak{J}_a) + 9\cdot 2^{r+1}(r+2)\,\bar{\mathsf{d}}\,\mathsf{t}_\times r_1^{-r} + 4\,\mathsf{op}'_{r+1}\mathsf{R}_t\prod_a \sup|\mathfrak{J}_a|.$$

(b) (A form with any bounds of the conditional means.) In (Th), $1\le t\le t_*$, $\mathsf{R}_t\le\frac12$, let $\mathfrak{J}_a$, $a\in\mathsf{E}$, $\mathsf{r}=\#\mathsf{E}\ge 2$, be insertions of orders ≥ 2 with carriers pairwise at sup distance $\ge \mathsf{d}_\times$ on T_ℓ, $\mathsf{y} = (\mathsf{d}_\times - a_K)L^{K-t}/M \ge 4$, $\mathsf{t}'_\times = 4e^2 C_{\mathrm{E},0}N_t e^{-\mathsf{y}}$, and let $\epsilon_a>0$, $\mathsf{a}_a\in\mathbb{C}$ satisfy $|\mathsf{Q}_{t\leftarrow 0}\mathfrak{J}_a - \mathsf{a}_a| \le \epsilon_a$ almost everywhere for $\mathbf{1}_{\mathsf{In}_t}\nu_t$, and $2E_0\mathsf{t}'_\times\prod_{a\in I}(\mathsf{r}/r_{\mathfrak{J}_a}) \le \prod_{a\in I}\epsilon_a$ for all $I\subset\mathsf{E}$ with $\#I\ge 2$. Then the joint cumulant of the $\mathfrak{J}_a$ under the small-field functional (Definition 3.2 (3)) is at most $(\frac12 + \mathsf{op}'_{\mathsf{r}}\mathsf{B}\mathsf{I}_{\mathsf{r}})\prod_a\epsilon_a$ in modulus, and the joint cumulant under $\langle\cdot\rangle_{K,\ell,\beta}$ differs from it by at most $4\,\mathsf{op}'_{\mathsf{r}}\mathsf{R}_t\prod_a\sup|\mathfrak{J}_a|$.

■

Proof sketch. (a) Let $Z_\sigma(s)$ be the small-field functional at the top level t applied to $e^{s\mathfrak{J}_\sigma}$. Since $\sum_\sigma(-1)^{r+1-|\sigma|}\prod_{a\in B}\sigma_a$ is 1 for $B=\{0,\dots,r\}$ and 0 otherwise,

$$(r+1)!\,\mathrm{cum}^{\mathrm{sf}}(\mathfrak{J}_0,\dots,\mathfrak{J}_r) = \sum_{\sigma\in\{0,1\}^{r+1}}(-1)^{r+1-|\sigma|}\,\partial_s^{r+1}\log Z_\sigma(0).$$

By Proposition 3.13 (ii), $\Phi_\sigma - \Phi_0 - \sum_a \sigma_a A_a$, where A_a is the change of the exponent for $\mathfrak{J}_a$ alone, is a sum over polymers that contain boxes of two insertions, and so is the same combination of the constants $\sum_{i\le t}(\mathsf{c}_i(s)-\mathsf{c}_i(0)) = \sum_{i\le t}\sum_{X,z}\delta E_s^{(i)}(X,\mathbf{1},z)$ (proof of Proposition 3.13 (iii)); by (321) such a polymer of level i has linear size $\ge \mathsf{d}_\times L^{K-i}/M - 2$, and by (i) and (320) the sum is at most $2(r+2)|s|\bar{\mathsf{d}}\,\mathsf{t}_\times$. With $\lambda\propto \mathbf{1}_{\mathsf{In}_t}e^{\Phi_0}dV$ a probability measure, Proposition 3.13 (iii) gives, on $|s|\le r_1$, $\log(Z_\sigma/Z_0) = (\text{linear in }\sigma) + \log\lambda(\exp\sum_a\sigma_a A_a) + O(\bar{\mathsf{d}}\mathsf{t}_\times)$.

The alternating sum annihilates the linear part and leaves $s^{r+1}\mathrm{cum}_\lambda(\dot A_0,\dots,\dot A_r) + O(s^{r+2})$; Cauchy's estimate on $|s| = r_1$ bounds the rest by the second member. By Lemma 3.14 (b), $\dot A_a = \mathsf{Q}_{t\leftarrow 0}\mathfrak{J}_a - \text{const}$ λ-almost everywhere, and a cumulant of $r+1$ bounded functions, from which constants drop out, is at most op_{r+1} times the product of their sup norms. The discarding statement among the construction results (YMM1:115.2: the small-field functional lies between the term without large fields and the bare density, for all bounded Borel gauge invariant functions) gives $|Z\langle F\rangle - \Lambda^{\mathrm{sf}}(F)| \le \sup|F|\,\mathsf{R}_t Z$ for real gauge invariant F, and the expression of a cumulant through means gives the last member. (b) The generating function $T(\mathbf{s}) = \Lambda^{\mathrm{sf}}(e^{\sum_a s_a\mathfrak{J}_a})$ is entire, and the cumulant is $\partial_{\mathbf{s}}^{\mathsf{E}}\log T(0)$, $\partial_{\mathbf{s}}^{\mathsf{E}} = \prod_{a\in\mathsf{E}}\partial_{s_a}$.

Let $E^{(i)}[\mathbf{s}]$ be the families of Proposition 3.13 (v) for the $\mathfrak{J}_a$, $\delta E_{\mathbf{s}}^{(i)} = E^{(i)}[\mathbf{s}] - E^{(i)}$, and put

$$\mathsf{C}(\mathbf{s}) = \sum_{i\le t}(\mathsf{c}_i(\mathbf{s})-\mathsf{c}_i(0)) = \sum_{i\le t}\sum_{X,z}\delta E_{\mathbf{s}}^{(i)}(X,\mathbf{1},z), \qquad \mathsf{D}_{\mathbf{s}}(V) = \Phi_t^{\mathbf{s}}(V) - \Phi_t(V)$$
$$= \sum_a s_a\mathfrak{J}_a(U) + \sum_{i\le t}\sum_{X,z}\big[\delta E_{\mathbf{s}}^{(i)}(X,U,z) - \delta E_{\mathbf{s}}^{(i)}(X,\mathbf{1},z)\big]$$

for $V\in\mathsf{In}_t$ and a background U over V, the first identity by the formula for the numbers $\mathsf{c}_i(\mathbf{s})$ in the proof of Proposition 3.13 (iii). Multiplied by $\mathbf{1}_{\mathsf{In}_t}$, the display of Proposition 3.13 (iii), which holds for $\sum_a s_a\mathfrak{J}_a$ by (v), gives, on the parameter domain $\{\sum_a|s_a|/r_{\mathfrak{J}_a}<1\}$,

$$T(\mathbf{s}) = T(0)\,e^{\mathsf{C}(\mathbf{s})}\,\langle e^{\mathsf{D}_{\mathbf{s}}}\rangle,$$

where $\langle\cdot\rangle$ is the mean under the probability measure $\mathbf{1}_{\mathsf{In}_t}\nu_t/\nu_t(\mathsf{In}_t)$, proportional to $\mathbf{1}_{\mathsf{In}_t}e^{\Phi_t}dV$, and $T(0)=\nu_t(\mathsf{In}_t)\ge(1-\mathsf{R}_t)Z_{K,\ell,\beta}\ge\frac12 Z_{K,\ell,\beta}>0$ by the discarding statement (YMM1:115.2) and $\mathsf{R}_t\le\frac12$. Hence the cumulant is $\partial_{\mathbf{s}}^{\mathsf{E}}\mathsf{C}(0)+\partial_{\mathbf{s}}^{\mathsf{E}}\mathrm{Log}\langle e^{\mathsf{D}_{\mathbf{s}}}\rangle|_{\mathbf{s}=0}$. The term of (i,X,z) in C and in $\mathsf{D}_{\mathbf{s}}$ depends on the s_a with $\mathfrak{J}_a$ meeting X alone (locality, Proposition 3.13 (v)), and $\sum_a s_a\mathfrak{J}_a$ is linear in $\mathbf{s}$; so a jet $\partial_{\mathbf{s}}^I$, $\#I\ge2$, receives contributions only from polymers X that meet the carriers of two insertions. Such a polymer of level i holds two points at sup distance $\ge\mathsf{d}_\times$, so $d_i(X)\ge\mathsf{d}_\times L^{K-i}/M-2\ge\mathsf{y}L^{t-i}-2$ ((321)), and by (320), over the $N_i=L^{3(t-i)}N_t$ sites of level i,

$$\sum_{i\le t}\sum_{z}\sum_{X\ni z\ \text{meeting two carriers}} e^{-(\kappa+1)d_i(X)}\le e^2C_{\mathrm{E},0}N_t\sum_{l\ge0}L^{3l}e^{-\mathsf{y}L^l}\le 2e^2C_{\mathrm{E},0}N_te^{-\mathsf{y}}=\tfrac12\mathsf{t}'_\times,$$

the quotient of two successive terms being at most $L^3e^{-4(L-1)}\le\frac12$ as $\mathsf{y}\ge4$. On this parameter domain $\|E^{(i)}[\mathbf{s}]\|<E_0$ by (v) and the choice of the $r_{\mathfrak{J}_a}$, so $|\delta E_{\mathbf{s}}^{(i)}(X,\cdot,z)|\le 2E_0e^{-(\kappa+1)d_i(X)}$ at the background and at $\mathbf{1}$. $\mathsf{D}_{\mathbf{s}}$ holds two values of each such term (at U and at $\mathbf{1}$), C one; so the parts of $\mathsf{D}_{\mathbf{s}}(V)$ and of C that $\partial_{\mathbf{s}}^I$ sees are holomorphic and of moduli at most $2E_0\mathsf{t}'_\times$ and $E_0\mathsf{t}'_\times$. This domain contains the polydisc of radii $r_{\mathfrak{J}_a}/\mathsf{r}$, and Cauchy's estimate for one derivative in each variable of I gives

$$|\partial_{\mathbf{s}}^I\mathsf{D}_{\mathbf{s}}(V)|_{\mathbf{s}=0}|\le 2E_0\mathsf{t}'_\times\prod_{a\in I}\frac{\mathsf{r}}{r_{\mathfrak{J}_a}}\le\prod_{a\in I}\epsilon_a,\qquad |\partial_{\mathbf{s}}^{\mathsf{E}}\mathsf{C}(0)|\le E_0\mathsf{t}'_\times\prod_{a\in\mathsf{E}}\frac{\mathsf{r}}{r_{\mathfrak{J}_a}}\le\tfrac12\prod_{a\in\mathsf{E}}\epsilon_a;$$

the second is the term $\frac12$ of the bound. The first jets are $\partial_{s_a}\mathsf{D}_{\mathbf{s}}|_{\mathbf{s}=0}=\mathsf{Q}_{t\leftarrow0}\mathfrak{J}_a-\partial_{s_a}\mathsf{C}(0)$ almost everywhere for $\mathbf{1}_{\mathsf{In}_t}\nu_t$ (Lemma 3.14 (b) for $\mathfrak{J}_a$, with $\dot c_t=\partial_{s_a}\mathsf{C}(0)$), so within ϵ_a of the constant $\mathsf{a}'_a=\mathsf{a}_a-\partial_{s_a}\mathsf{C}(0)$. With $\tilde{\mathsf{D}}_{\mathbf{s}}=\mathsf{D}_{\mathbf{s}}-\sum_a s_a\mathsf{a}'_a$, $\mathrm{Log}\langle e^{\mathsf{D}_{\mathbf{s}}}\rangle=\mathrm{Log}\langle e^{\tilde{\mathsf{D}}_{\mathbf{s}}}\rangle+\sum_a s_a\mathsf{a}'_a$ near 0, and the linear function is killed by $\partial_{\mathbf{s}}^{\mathsf{E}}$ as $\mathsf{r}\ge2$. Moments by partitions, $\partial_{\mathbf{s}}^I e^{\tilde{\mathsf{D}}_{\mathbf{s}}}|_{\mathbf{s}=0}=\sum_\pi\prod_{I'\in\pi}\partial_{\mathbf{s}}^{I'}\tilde{\mathsf{D}}_{\mathbf{s}}|_{\mathbf{s}=0}$ over the partitions π of I, bounded by $\mathsf{Bl}_{\#I}\prod_{a\in I}\epsilon_a$ almost everywhere, and logarithms by partitions give $|\partial_{\mathbf{s}}^{\mathsf{E}}\mathrm{Log}\langle e^{\tilde{\mathsf{D}}_{\mathbf{s}}}\rangle|_{\mathbf{s}=0}|\le\mathsf{op}_{\mathsf{r}}\mathsf{Bl}_{\mathsf{r}}\prod_a\epsilon_a\le\mathsf{op}'_{\mathsf{r}}\mathsf{Bl}_{\mathsf{r}}\prod_a\epsilon_a$. The discarding is as in (a). □

Lemma 3.16 (Regular configurations; a family at a background)**.** Let (Th) hold on T_ℓ, $\ell=2L^m$, with (K,b',m,t_*) and $\gamma^{-2}\le\mathsf{b}'\le\mathsf{b}_+$.

(a) For $1\le j\le n\le t_*$, $V\in\mathsf{Cut}_n$ and $U\in\mathcal{C}(\mathbf{B}_n,V)$: $\varepsilon_n:=2\mathsf{e}_n^{\mathrm{c}}/\varepsilon_{\mathcal{W}}\le\alpha_0$ ($\varepsilon_{\mathcal{W}}$ the number of Proposition YMM1:52.3, which enters the field cuts YMM1:113.10, YMM1:113.10), and U is regular of level n at the radius ε_n on T_ℓ in the sense of Definition P.3: $|\partial U(p)-\mathbf{1}|<\varepsilon_nL^{-2n}$ at every bare plaquette and $|J^{(n)}(U)(\mathfrak{b})|<\varepsilon_n$ at every positively oriented bare bond, $J^{(n)}$ the current of level n (Definition P.3). Moreover $U\in\mathcal{C}(\mathbf{B}_j,\mathcal{M}^jU)$ and $\mathcal{M}^jU\in\mathsf{Cut}_j$; the same holds for $\mathsf{r}U$, r any isometry of the block lattice of level j, which is again regular of level n at the radius ε_n; every member of every pointed family of level j is formed at U, at $\mathsf{r}U$ and at $\mathbf{1}$. Finally $\varepsilon_n^2\le\bar{\mathsf{c}}_\varepsilon(K\log L+\log\mathsf{b}_+)^{2\mathfrak{p}_0}L^{-(K-n)}$, $\bar{\mathsf{c}}_\varepsilon=4c_\rho^2A_0^2\gamma^2/\varepsilon_{\mathcal{W}}^2$.

(b) Let f be a pointed family of level j, $1\le j\le n\le t_*$, $V\in\mathsf{Cut}_n$, $U\in\mathcal{C}(\mathbf{B}_n,V)$. Then

$$|\mathsf{Sum}[\mathsf{f}](U)-\mathsf{Sum}[\mathsf{f}](\mathbf{1})|\le\|\mathsf{f}\|\Big\{32B_*^2M^2C_{\mathrm{E},2}r_\alpha^{-2}\,\varepsilon_n^2\,N_nL^{-(n-j)}+2C_{\mathrm{E},0}N_je^{-[D_*-1]_+}\Big\},$$

where $B_*\ge1$ and $c_{*,\mathrm{rg}}\in(0,1]$ are the constants of Theorem YMM1:F, with $c_{*,\mathrm{rg}}=c_*$ as in Section P.1, $r_\alpha=a^{\mathrm{us}}(\alpha_0,\alpha_1)$ is the usable radius YMM1:(933), $C_{\mathrm{E},p}$ are the numbers of Proposition YMM1:45.1 and Lemma O.1, and, with $\alpha=\varepsilon_nL^{-2(n-j)}$,

$$D_*=D_*(j,n)=\min\Big\{\frac{c_{*,\mathrm{rg}}}{4M\alpha},\ \frac{r_\alpha}{8B_*M\alpha},\ \frac{L^{m+K-j}-5}{2M}\Big\}:$$

for a polymer X of level j with $d_j(X)+1\le D_*$, Lemma P.4, on a cube of side $2(d_j(X)+1)M$ of level j that holds X, gives a gauge in which $U=e^{iL^{-j}A}$ on X with $|A|,|\nabla A|<4B_*(d_j(X)+1)M\alpha\le\frac12 r_\alpha$. If $t_*\le K-\phi K$, then $K-j\ge K-n\ge\phi K$ and $\alpha\le\varepsilon_n$, so by (a) the first two members of D_* are at least $cL^{\phi K/2}(K\log L+\log\mathsf{b}_+)^{-\mathfrak{p}_0}$, c a function of the constants,

and the third is at least $(L^{\phi K}-5)/(2M)$; hence $D_*>7K\log L+1$ for K large in terms of b_+ and ϕ. So for $0<\phi<1$, $t_*\le K-\phi K$ and $K\ge K_2$, a function of b_+ and ϕ,

$$|\mathsf{Sum}[\mathsf{f}](U)-\mathsf{Sum}[\mathsf{f}](\mathbf{1})|\le \mathsf{B}_nL^j\|\mathsf{f}\|,\qquad \mathsf{B}_n=\mathsf{B}_0'L^{3(K-n)-K},\quad \mathsf{B}_0'$$
$$=\ell^3\big[32B_*^2M^2C_{\mathrm{E},2}r_\alpha^{-2}\bar{\mathsf{c}}_\varepsilon(K\log L+\log\mathsf{b}_+)^{2\mathfrak{p}_0}+2C_{\mathrm{E},0}\big]\le CK^{2\mathfrak{p}_0}.$$

(c) (Petals in a Hölder gauge.) Let $0<\kappa_{\mathrm{H}}<1$, $h=L^{-n}$, and let U be regular of level n at a radius $\varepsilon\le 1$ with $6\rho_{\mathrm{H}}<L^{m+K-n}$, $\rho_{\mathrm{H}}\varepsilon\le a_{\mathrm{g}}$, $h\,\mathsf{c}_{\mathrm{g}}\rho_{\mathrm{H}}\varepsilon\le\frac14$, where ρ_{H}, a_{g}, c_{g}, $\mathsf{c}_{\mathrm{g}}(\kappa_{\mathrm{H}})$ are the numbers of Theorem BT; put $e_1=\mathsf{c}_{\mathrm{g}}\rho_{\mathrm{H}}\varepsilon$, $e_2=\mathsf{c}_{\mathrm{g}}(\kappa_{\mathrm{H}})\rho_{\mathrm{H}}\varepsilon$. At every site x there are $F_{12}(x),F_{13}(x),F_{23}(x)\in\mathfrak{g}$ with, for all petals π,π' at x,

$$|q_x(\pi,\pi')-\mathsf{s}(\pi)\mathsf{s}(\pi')h^4\langle F_{m(\pi)},F_{m(\pi')}\rangle|\le D(2\varepsilon h^2+D),\qquad |a_{p_m(x)}-\tfrac12h^4|F_m|^2|$$
$$\le\tfrac12D(2\varepsilon h^2+D)+\tfrac18\varepsilon^4h^8,$$

$D=4e_2h^{2+\kappa_{\mathrm{H}}}+(21+29e_1)e_1^2h^3$; and if moreover $\mathsf{c}_{\mathrm{g}}\rho_{\mathrm{H}}\varepsilon\le1$, then

$$|\mathbf{y}_{\mathfrak{b},\rho}(U)|\le 48\,\mathsf{c}_{\mathrm{g}}(\kappa_{\mathrm{H}})\rho_{\mathrm{H}}\,\varepsilon\,h^{2+\kappa_{\mathrm{H}}}$$

at every pair $(\mathfrak{b},\rho)$.

■

Proof sketch. (a) For a block field V of level n the largest plaquette defect is $\max_p|\partial V(p)-\mathbf{1}|$, the maximum over the plaquettes p of the block lattice of level n (the plaquette size $\varpi(V)$). On Cut_n it is $<2\mathsf{e}_n^{\mathrm{c}}$ (YMM1:113.10), and $2\mathsf{e}_n^{\mathrm{c}}\le\varepsilon_{\mathcal{W}}\alpha_0$, $\mathsf{e}_n^{\mathrm{c}}\le\frac12c_2^{\mathrm{SO}}$ (YMM1:(2134)); so $\varepsilon_n\le\alpha_0\le1$, and $2\mathsf{e}_n^{\mathrm{c}}=\varepsilon_{\mathcal{W}}\varepsilon_n$. The field cut is $\mathsf{Cut}_n=\mathcal{C}_n^\flat(\mathsf{e}_n^{\mathrm{c}})$ (YMM1:113.10), and the window of the classes of covariance, Lemma B.4(1) at the radii $(b_0,b_1)=(\varepsilon_n,1)$ and $\mathsf{e}=\mathsf{e}_n^{\mathrm{c}}$ (as $2\mathsf{e}=\varepsilon_{\mathcal{W}}b_0$), gives $\mathsf{Cut}_n=\mathcal{C}_n(\varepsilon_n,1;\mathsf{e}_n^{\mathrm{c}})$: the pairs of every $U\in\mathcal{C}(\mathbf{B}_n,V)$ lie in the cores at the radii $(\varepsilon_n,1)$, so that $\mathsf{m}_n(U)<\varepsilon_n$ and $|J^{(n)}(U)(\mathfrak{b})|<\varepsilon_n$ at every positively oriented bare bond (Lemma B.4(1)): U is regular of level n at the radius ε_n, current included.

Heredity, Lemma B.4(2): as $x_n=L^{-(n-j)}x_j$ gives $\mathsf{e}_n^{\mathrm{c}}\le L^{(n-j)/2}\mathsf{e}_j^{\mathrm{c}}$, hence $L^{-2(n-j)}\mathsf{e}_n^{\mathrm{c}}\le\mathsf{e}_j^{\mathrm{c}}$, the background over $\mathcal{M}^jU$ exists, $U\in\mathcal{C}(\mathbf{B}_j,\mathcal{M}^jU)$, and $\mathcal{M}^jU\in\mathcal{C}_j^\flat(\mathsf{e}_j^{\mathrm{c}})=\mathsf{Cut}_j$. An isometry r of the block lattice of level j commutes with block averaging up to the level j, $\mathcal{M}^j(\mathsf{r}U)=\mathsf{r}\mathcal{M}^jU$, and carries the minimal orbits of the level j and the sets $\mathcal{C}_j^\flat(\mathsf{e})$ into themselves (Lemma G.1, Proposition YMM1:52.3, and Lemma B.4(3)); so $\mathcal{M}^j(\mathsf{r}U)\in\mathsf{Cut}_j$ and $\mathsf{r}U\in\mathcal{C}(\mathbf{B}_j,\mathcal{M}^j(\mathsf{r}U))$; it keeps plaquette defects and currents bond by bond (Lemma G.1), so $\mathsf{r}U$ is regular of level n at the radius ε_n.

As $2\mathsf{e}_j^{\mathrm{c}}\le\varepsilon_{\mathcal{W}}\alpha_0$, the window at the radii (α_0,α_1) gives $\mathsf{Cut}_j=\mathcal{C}_j(\alpha_0,\alpha_1;\mathsf{e}_j^{\mathrm{c}})$: the pairs of U and of $\mathsf{r}U$ at every polymer X of level j lie in the cores $\mathcal{U}_j^\circ(X;\alpha_0,\alpha_1)$ on which the members of the pointed families of level j are local terms, and so does the trivial pair (the usable-ball inclusion in Section P); so every such member is formed at U, at $\mathsf{r}U$ and at $\mathbf{1}$. Finally $x_n=L^{K-n}\mathsf{b}'\ge\gamma^{-2}L^{K-n}$, $\log x_n\le K\log L+\log\mathsf{b}_+$, and $\varepsilon_n^2=4c_\rho^2A_0^2\varepsilon_{\mathcal{W}}^{-2}(\log x_n)^{2\mathfrak{p}_0}/x_n$ (the definitions preceding Lemma YMM1:113.10).
(b) Fix a polymer X of level j, $d=d_j(X)$, and a member E, $\|\mathsf{E}\|_X\le\|\mathsf{f}\|e^{-(\kappa+1)d}$.

If $d+1\le D_*$, the gauge of Lemma P.4 on X gives $U^u=e^{iL^{-j}A}$ and $v=(A,\mathrm{Ad}(u)J^{(j)}(U))$ of size $\le4B_*(d+1)M\varepsilon_n\vartheta^2\le\frac12r_\alpha$, $\vartheta=L^{-(n-j)}$, and the local term is formed at U with $\mathsf{E}(U)=\mathsf{E}(v)$, $\mathsf{E}(\mathbf{1})=\mathsf{E}(0)$, by pair dependence and gauge invariance (Definition YMM1:49.4; Section P.1). $v\mapsto\mathsf{E}(v)$ is holomorphic on the ball of radius r_α and its differential at 0 vanishes: it is invariant under the constant gauge transformations $g\in\{\mathbf{1},i\sigma_1,i\sigma_2,i\sigma_3\}$, and $\sum_g gYg^{-1}=0$ for Y of trace 0; by the maximum principle $|\mathsf{E}(v)-\mathsf{E}(0)|\le2\|\mathsf{E}\|_X(\|v\|/r_\alpha)^2$. If $d+1>D_*$ the difference is $\le2\|\mathsf{E}\|_X$.

Sum with (320) over the N_j sites; $N_j\vartheta^4=N_nL^{-(n-j)}$. The second form follows from (a), $N_n=\ell^3L^{3(K-n)}$ and $N_je^{-[D_*-1]_+}\le\ell^3L^{-4K}$. (c) Theorem BT gives, on a cube of side $2\rho_{\mathrm{H}}$ about x in the units of level n, a gauge in which $U=e^{ihA}$, A a 1-form with values in $\mathfrak{g}$, with $|A|,|\nabla A|<e_1$

and ∇A Hölder continuous of exponent κ_{H} with constant e_2 (forward differences of spacing h). In this gauge put, for a plane $m=\{\mu<\nu\}$ and a site x'' of the cube,

$$F_m(x'') := (\nabla_\mu A_\nu - \nabla_\nu A_\mu)(x'') + i[A_\mu(x''), A_\nu(x'')],$$

the curvature in the gauge: it is Hermitian and of trace 0, so $F_m(x'')\in\mathfrak{g}$, and the $F_m(x)$ of the statement are these at $x''=x$, in the gauge about x. Expanding the four exponentials of the plaquette variable $P_m(x'')=P_{\mu\nu}(x'')=W_{x''}(\mu,\nu)$ of $p_m(x'')$, with $\mathbf{a}=ihA_\mu(x'')$ and $\mathbf{b}=ihA_\nu(x''+he_\mu)$,

$$P_{\mu\nu}(x'')-\mathbf{1} = ih^2(\nabla_\mu A_\nu-\nabla_\nu A_\mu)(x'')+[\mathbf{a},\mathbf{b}]+R, \qquad |R|\le (5+29e_1)e_1^2h^3,$$

and $[\mathbf{a},\mathbf{b}]=-h^2[A_\mu(x''),A_\nu(x'')]+R'$, $|R'|\le 2e_1^2h^3$; the commutator, of size up to $2e_1^2h^2$, is the part $ih^2\cdot i[A_\mu,A_\nu]$ of ih^2F_m. So $|P_{\mu\nu}(x'')-\mathbf{1}-ih^2F_m(x'')|\le(7+29e_1)e_1^2h^3$, and, taking the Hermitian part of $(P_{\mu\nu}(x'')-\mathbf{1})/i$, $|\mathbf{w}(P_{\mu\nu}(x''))-h^2F_m(x'')|\le(7+29e_1)e_1^2h^3$. The holonomy of a petal π at x is $W_x(\pi)=T\,P_{m(\pi)}(x'')^{\mathsf{s}(\pi)}\,T^{-1}$ for a plaquette $p_{m(\pi)}(x'')$ with $|x''-x|_1\le 2h$, T a product of at most three bond variables; so $|\mathbf{w}(W_x(\pi))-\mathsf{s}(\pi)\mathbf{w}(P_{m(\pi)}(x''))|\le 2|T-\mathbf{1}|\,\varepsilon h^2\le 6e_1^2h^3$, as $\varepsilon\le e_1$. The Hölder bound of ∇A and $|A(x'')-A(x)|\le 2he_1$ give $|F_m(x'')-F_m(x)|\le 2e_2(2h)^{\kappa_{\mathrm{H}}}+8e_1^2h$. Together

$$|\mathbf{w}(W_x(\pi))-\mathsf{s}(\pi)h^2F_{m(\pi)}(x)|\le 4e_2h^{2+\kappa_{\mathrm{H}}}+(21+29e_1)e_1^2h^3=D,$$

and $|\mathbf{w}(W_x(\pi))|<\varepsilon h^2$, a petal holonomy being, at a real configuration, a unitary conjugate of a plaquette variable or of its inverse. Both bounds follow by $|\langle\mathbf{w},\mathbf{w}'\rangle-\langle\mathbf{v},\mathbf{v}'\rangle|\le|\mathbf{w}-\mathbf{v}||\mathbf{w}'|+|\mathbf{v}||\mathbf{w}'-\mathbf{v}'|$, and by $a_p=\frac12|\mathbf{w}(\partial U(p))|^2+\frac12 a_p^2$ with $0\le a_p<\frac12\varepsilon^2h^4$. $\mathbf{y}_{\mathfrak{b},\rho}$ is the covariant difference of the curvatures of the two neighbouring plaquettes of one plane at $\mathfrak{b}$; in the gauge it is at most $2e_2h^{2+\kappa_{\mathrm{H}}}+46e_1^2h^3$. □

Lemma 3.17 (A regular configuration against its mirror image)**.** Let $0\le\kappa_\star<1$, $r_1=(6e^3)^{-1}$, and in the notation of Lemma 3.16 (c), with $\kappa_\star$ for κ_{H}, let $e_3=12e_2+2304e_1^2r_1^{-3}$.

(a) Let $1\le j\le n\le K$, $\vartheta=L^{-(n-j)}$, $6\rho_{\mathrm{H}}<L^{m+K-n}$, U regular of level n at the radius ε on T_ℓ with $\rho_{\mathrm{H}}\varepsilon\le a_{\mathrm{g}}$, $e_1\le r_1^2$, z a site, r_z the inversion through z, and $1\le R_\circ\le\vartheta^{-1}$. In the units of level j, on the cube Q of radius $R_\circ$ about z, there are a gauge transformation u and a real 1-form a' with $U^u=e^{iL^{-j}a'}$ on the bonds of Q and $(\mathsf{r}_zU)^{\mathsf{r}_zu}=e^{iL^{-j}\mathsf{r}_z^*a'}$, $(\mathsf{r}_z^*a')_\mu(x)=-a'_\mu(2z-x-L^{-j}e_\mu)$; and with $\bar a=\frac12(a'+\mathsf{r}_z^*a')$, $w=\frac12(a'-\mathsf{r}_z^*a')$,

$$|\bar a|,\ |\nabla\bar a|\le 45R_\circ\vartheta^2e_1, \qquad |w|,\ |\nabla w|\le R_\circ^2\vartheta^{2+\kappa_\star}e_3, \qquad |J^{(j)}(U)|,\ |J^{(j)}(\mathsf{r}_zU)|<\vartheta^3\varepsilon.$$

(b) Let (Th) hold, $1\le j<n_0<t_*$, $K-j+1\ge y_{\mathrm{par}}$ (the number of Lemma 3.19 (e)), $\vartheta=L^{-(n_0-j)}$, $\varepsilon=\varepsilon_{n_0}$, with $6\rho_{\mathrm{H}}<L^{m+K-n_0}$, $\rho_{\mathrm{H}}\varepsilon\le a_{\mathrm{g}}$, $e_1\le r_1^2$, $180e_1\le r_\alpha$, $4e_3\le r_\alpha$. For a site z of level j let $\theta_z(p)=\prod_\lambda\vartheta_0((x(p)-z)_\lambda/(L^ja_K))$, $\vartheta_0=1$ on $(-\frac12,\frac12)$, $\frac12$ at $\pm\frac12$, 0 elsewhere, so that $\theta_z\ge0$, $\sum_z\theta_z=1$ and $\theta_z\circ\mathsf{r}_z=\theta_z$; for a weight $\varkappa$ of the plaquettes put $\Sigma_z[\varkappa]=\mathsf{Sum}[\mathsf{D}^{(j)}[\theta_z\varkappa]]$ with the births of Lemma 3.19. Then for $V\in\mathsf{Cut}_{n_0}$ and $U\in\mathcal{C}(\mathbf{B}_{n_0},V)$

$$\sum_z|\Sigma_z[\varkappa](U)-\Sigma_z[\varkappa](\mathsf{r}_zU)|\le C\,N_j\bar{\mathsf{p}}_j\max|\varkappa|\Big\{\frac{e_3(720e_1+11e_3)}{r_\alpha^2}\vartheta^{4+\kappa_\star}+\frac{\varepsilon^2}{r_\alpha^2}\vartheta^5+e^{-[D_*-1]_+}\Big\},$$

C a function of the constants, $D_*=D_*(j,n_0)$ the number of Lemma 3.16 (b), $\bar{\mathsf{p}}_j$ that of Lemma 3.19 (e).

■

Proof sketch. (a) Theorem BT gives the Hölder gauge on the cube of side $2\rho_{\mathrm{H}}$ about z in the units of level n; in the units of level j, $a=\vartheta A$ has $|a|<\vartheta e_1$, $|\nabla a|<\vartheta^2e_1$, and ∇a has the Hölder constant $\vartheta^{2+\kappa_\star}e_2$. A second gauge $e^{i\lambda}$, $\lambda(x)=\sum_\nu(x-z)_\nu c_\nu$ with c_μ the mean of a_μ at z and $z-L^{-j}e_\mu$, is odd under r_z; the new 1-form is $a'_\mu(x)=L^j\Psi(\lambda(x);L^{-j}a_\mu(x),L^{-j}c_\mu)$, where $e^{i\Psi(X;Y,Z)}=e^{iX}e^{iY}e^{-i(X+Z)}$

defines a holomorphic Ψ with $|\Psi-(Y-Z)|$ of second order and with the parity $G(-X,Y_o,-Y_e,-Z)=-G(X,Y_o,Y_e,Z)$ for $G(X,Y_o,Y_e,Z)=\Psi(X;Y_e+Y_o,Z)-\Psi(-X;-Y_e+Y_o,-Z)$.

The bound for $\bar a$ follows from $|\nabla a|$ and the Taylor estimate for Ψ. To see the extra gain for w, put $h=L^{-j}$, $x^*=2z-x-he_\mu$, $X=\lambda(x)$, $Y=ha_\mu(x)$, $Y^*=ha_\mu(x^*)$, $Z=hc_\mu$, $Y_o=(Y-Y^*)/2$ and $Y_e=(Y+Y^*)/2$. Since $\lambda(x^*)=-X-Z$, the inverse identity gives $2hw_\mu(x)=G(X,Y_o,Y_e,Z)$. The Taylor expansion of this function is $G=2(Y_e-Z)+i[2X+Z,Y_o]+R_{\ge3}$, where $R_{\ge3}$ starts at degree three and each of its monomials contains Y, Y^* or Z, because $\Psi(X;0,0)=0$. The paired paths from z to x and from $z-he_\mu$ to x^* cancel the constant gradient. The Hölder estimate therefore bounds $h^{-1}(Y_e-Z)$ and its forward gradient by $12R_\circ^2\vartheta^{2+\kappa_\star}e_2$. Moreover $|X|\le 5R_\circ\vartheta e_1$, $|Y_o|\le 4hR_\circ\vartheta^2e_1$ and $|Y|,|Y^*|,|Z|\le h\vartheta e_1$. Thus the quadratic term contains the smaller variable Y_o, and every higher term contains a bond variable. Cauchy's estimate in scalar directions at the radius r_1, with split radii for the first derivatives, using $e_1\le r_1^2$ and $R_\circ\vartheta\le1$, bounds their contributions to w and ∇w by $800r_1^{-3}R_\circ^2\vartheta^3e_1^2$. Finally $\vartheta^3\le\vartheta^{2+\kappa_\star}$, which gives the claimed bound with e_3. The currents scale as $J^{(j)}=\vartheta^3J^{(n)}$. (b) Fix z, a polymer X of level j whose plaquettes meet the support of θ_z, and a member $\mathsf E$ of $\mathsf D^{(j)}[\theta_z\varkappa]$ at X, $\|\mathsf E\|_X\le\bar{\mathsf p}_j\max|\varkappa|e^{-(\kappa+1)d}$. With $R_d=M(d+2)+3$: if $R_d\le\vartheta^{-1}$, by (a) the configurations U and $\mathsf r_zU$, written in the gauge of (a), are $v=\bar v+w$ and $v^*=\bar v-w$ with $\|\bar v\|\le45R_d\vartheta^2e_1$, $\|w\|\le R_d^2\vartheta^{2+\kappa_\star}e_3$, and a local term with vanishing differential at 0 (as in Lemma 3.16 (b)) changes by at most $\|\mathsf E\|_X\|w\|(16\|\bar v\|+11\|w\|)/r_\alpha^2$ between them; if $R_d>\vartheta^{-1}$ but $d+1\le D_*$, both values are within $2\|\mathsf E\|_X(\cdot/r_\alpha)^2$ of $\mathsf E(0)$ as in Lemma 3.16 (b), and $e^{-d}\le C\vartheta$ there; if $d+1>D_*$, the difference is $\le2\|\mathsf E\|_X$.

At most R_d^3 sites z meet a polymer; sum with (320). □

Lemma 3.18 (A cut at a level; the null part of the defect)**.** Let $\ell=2L^m\in\mathfrak L(g)$, $(K,\beta)\in\mathfrak d(g)$, $0<\phi\le\frac1{84}$, $u=\lceil\phi K\rceil$, $t=K-u$, and let $K\ge\max\{K_\phi,K_2,K_\Theta\}$, K_2 the number of Lemma 3.16 (b) and K_Θ the least integer from which on $\Theta_KL^{-\phi K/2}\le1$.

(a) Let $1\le n_0\le t$, $\mathfrak J$ an insertion of order 2, and $\epsilon_X=\sup|\mathfrak J(U)|$ over the $U\in\mathcal C(\mathbf B_{n_0},V)$, $V\in\mathsf{Cut}_{n_0}$. Then

$$\omega_t(\mathfrak J)\le\epsilon_X+e\,\mathsf B_0'L^{3u-K}\sum_{i\le n_0}L^i\mathsf d_i\le\epsilon_X+CK^{3\mathfrak p_0}L^{3u-K-(K-n_0)/2}|\varkappa|_\infty.$$

(b) Let η be a C^2 vector field on T_ℓ (or $\eta\in C_c^2(\mathbb R^3;\mathbb R^3)$ carried by the interior of a cell of side $\frac12\ell$ and regarded on T_ℓ), $0<\kappa_{\mathrm H}<1$, $1\le n\le t$, $y=K-n$, $\mathsf r$ an isometry of the block lattice of level n, and let K be so large that the data of Lemma 3.16 (c) hold at $\varepsilon=\varepsilon_n$. Then, the supremum being over the $U\in\mathcal C(\mathbf B_n,V)$, $V\in\mathsf{Cut}_n$,

$$\sup|F(k^0,v^0)(\mathsf r^{-1}U)|\le CK^{2\mathfrak p_0}L^{(3+\kappa_{\mathrm H})y-\kappa_{\mathrm H}K}\,b\sup|\nabla\eta|.$$

■

Proof sketch. (a) Let $0<s\le\frac12r_{\mathfrak J}$ be real. On Cut_{n_0}, by Proposition 3.13 (iii), $s^{-1}(\Phi^s_{n_0}-\Phi_{n_0})=\mathfrak J\circ U_{n_0}+\sum_{i\le n_0}(\Sigma_{n_0}[\mathsf f_s^{(i)}]-a[\mathsf f_s^{(i)}])$, with $\mathsf f_s^{(i)}=s^{-1}(E^{(i)}[s]-E^{(i)})$ of norm $\le\mathsf d_i$ and $a[\cdot]$ the value at the trivial configuration. Apply $\mathsf Q_{t\leftarrow n_0}$. A conditional mean is not larger than a supremum, so the first term stays $\le\epsilon_X$. By Lemma 3.14 (a) a family of level i is carried to level t as $\Sigma_t[\mathsf T_{n_0}\mathsf f]$, $\mathsf T_{n_0}\mathsf f=\sum S_{k_m}\cdots S_{k_1}\mathsf f$ over the chains $n_0\le k_1<\cdots<k_m<t$, at the price $\prod_k(1+L\theta_k)\le\exp[\Theta_KL^{-u/2}]\le e$; and at level t a pointed family of level $\le t$ differs at a background from its value at the trivial configuration by at most $\mathsf B_tL^i\|\mathsf f\|$, $\mathsf B_t=\mathsf B_0'L^{3u-K}$ (Lemma 3.16 (b)).

Constants are carried to constants. Let $s\to0$ with Lemma 3.14 (b) at $k=n_0$, and use (c) of that Lemma. What is born below n_0 is born at a small coupling; above n_0 nothing is born. (b) By Lemma 3.16 (a) the configuration $\mathsf r^{-1}U$ is regular of level n at ε_n, with $\varepsilon_n^2\le CK^{2\mathfrak p_0}L^{-y}$. The main terms of Lemma 3.16 (c) add up at each site to h^4 times the symbol of (k^0,v^0) at $(F_m(x))_m$, which vanishes: the symbol of the null pair (k^0,v^0) is zero at every triple $(F_{12},F_{13},F_{23})\in\mathfrak g^3$

(Lemma 3.11 (a), Definition 3.2 (2)), whatever the curvatures $F_m(x)$ of Lemma 3.16 (c) are; what is left is at most $L^K(\ell L^K)^3(|k^0|_1+3|v^0|_\infty)\,C\varepsilon_n^2 h^{4+\kappa_{\rm H}}$, $h=L^{-n}$, and $4K-y-(4+\kappa_{\rm H})(K-y)=(3+\kappa_{\rm H})y-\kappa_{\rm H}K$. □

Lemma 3.19 (Births of the cubic half)**.** Let (Th) hold on T_ℓ, at zero source, let $0\le k<t_*$, and let $\varkappa$ be a complex weight of the plaquettes.

(o) At the height k there is a family $\mathbb{V}^\sharp_\varkappa$ in the fourth place, the *cubic potential*: for $k=0$ the family $\mathbb{W}$ of the insertion $\mathcal{S}_\varkappa$ of the proof of Proposition 3.13, for $k\ge1$ the sum over the polymers X_1 of level k of the potentials $\mathbb{V}[f_{X_1}]$ (equation YMM1:(870)) of the local functions $f_{X_1}=\sum_{p:X_k(Q(p))=X_1}\varkappa(p)\mathfrak{r}^\sharp_{\rho(p)}(p)$. It is linear in $\varkappa$, and its member at Y depends on $\varkappa$ on the plaquettes of Y alone. It is formed and holomorphic on the sets $\mathfrak{D}^{\rm src}(Y)$ of (274), on which the fluctuation field $\mathcal{A}=g_kB$ of the step is bounded, bond by bond, by the radius $\varepsilon_{\rm src}$ of (274), a number that does not depend on x_k ($\varepsilon_{\rm src}=r_P^\circ$ at $k=0$); it vanishes at $\mathcal{A}=0$; and there

$$|\mathbb{V}^\sharp_\varkappa(Y;P,\mathcal{A})|\le CL^{-3k}\max|\varkappa|\,e^{-\lambda_V d_k(Y)},$$

λ_V the rate of the size $\mathsf{n}^{\rm f}$ of the families in the fourth place (272). Its size is at most $C\delta(x_k)L^{-3k}\max|\varkappa|$, and its sum is the variation of $\mathcal{S}_\varkappa$ from the zero-fluctuation background to the configuration of the chart integral. For $k\ge1$ this is $\mathcal{S}_\varkappa(U_k(V_W[\mathcal{A}]))-\mathcal{S}_\varkappa(U_{k+1}(W))$ in the chart over W; for $k=0$ it is the shifted value minus the background value in the definition of $\mathbb{W}$.

Let E_μ be the output of the step of height k with the family $\mathbb{V}'_k+\mu\mathbb{V}^\sharp_\varkappa$ in the fourth place, $\mathbb{V}'_k$ that of the chain and $|\mu|\,\mathsf{n}^{\rm f}(\mathbb{V}^\sharp_\varkappa)\le\frac{1}{32}w_\star$, and let $\mathsf{D}^{(k+1)}[\varkappa]=\partial_\mu E_\mu|_{\mu=0}$, value by value (the *births*). Put $\mathsf{s}_0=\mathcal{S}_\varkappa$, and $\mathsf{s}_j=\mathcal{S}_\varkappa\circ U_j$ on Cut_j, 0 off it.

(a) $\mathsf{D}^{(k+1)}[\varkappa]$ is a pointed family of level $k+1$, complex linear in $\varkappa$, with $\|\mathsf{D}^{(k+1)}[\varkappa]\|\le K^{\rm d}\mathsf{n}^{\rm f}(\mathbb{V}^\sharp_\varkappa)$.
(b) Its member at (X,z) depends on $\varkappa$ on the plaquettes of X alone, and vanishes if $\varkappa=0$ there.
(c) For $k+1<t_*$: $\mathsf{Q}_k\mathsf{s}_k=\mathsf{s}_{k+1}+\Sigma_{k+1}[\mathsf{D}^{(k+1)}[\varkappa]]$ at every point of $\mathcal{V}_{k+1}$.
(d) $\sup_{\mathsf{Cut}_n}|\mathsf{s}_n|\le 3c_{\rm orb}\,\ell^3L^{3K-6n}(\mathsf{e}_n^{\rm c})^3\max|\varkappa|$ for $1\le n\le t_*$.
(e) (Parity.) There are $y_{\rm par}$ and $\mathsf{C}'_{\rm par}$, functions of the constants, such that for $K-k\ge y_{\rm par}$

$$\|\mathsf{D}^{(k+1)}[\varkappa]\|\le\bar{\mathsf{p}}_{k+1}\max|\varkappa|,\qquad \bar{\mathsf{p}}_{k+1}=\mathsf{C}'_{\rm par}(\log x_k)^{\mathfrak{p}_0}\,g_k^2\,L^{-3k},\quad g_k^2=x_k^{-1}.$$

(f) (Covariance.) Let $k+1<t_*$, $\mathsf{r}:x\mapsto\mathrm{diag}(s_1,s_2,s_3)x+v$ an isometry of the block lattice of level $k+1$, and $(\mathsf{r}^\sharp\varkappa)(p)=s_{\rho(p)}\varkappa(\mathsf{r}p)$ (for an inversion, $-\varkappa(\mathsf{r}p)$). For $W\in\mathsf{Cut}_{k+1}$ and $U\in\mathcal{C}(\mathbf{B}_{k+1},W)$: $\mathsf{r}W\in\mathsf{Cut}_{k+1}$, $\mathsf{r}U\in\mathcal{C}(\mathbf{B}_{k+1},\mathsf{r}W)$, and $\mathsf{Sum}[\mathsf{D}^{(k+1)}[\varkappa]](\mathsf{r}U)=\mathsf{Sum}[\mathsf{D}^{(k+1)}[\mathsf{r}^\sharp\varkappa]](U)$.

■

Proof sketch. (o) For $k\ge1$ each f_{X_1} is a local term of level k: by Lemma 3.10 (b) a summand is $\le C\alpha_0^3L^{-6k}|\varkappa(p)|$ on the domain of the local terms, and at most $24M^3L^{3k}$ plaquettes have one region $X_k(Q(p))$. The potential of a term on its region is formed and holomorphic on the sets $\mathfrak{D}(Y)$ of Section YMM1:51.8, which at the radius $\varepsilon=\varepsilon_{\rm src}$ are the sets $\mathfrak{D}^{\rm src}(Y)$ ((274)), and it vanishes at $\mathcal{A}=0$, by Proposition YMM1:51.15; it sums to the variation of the term by equation YMM1:(872), at the admitted chart and background points of that proposition, and it decays in the size of the polymer by equation YMM1:(871), as $e^{-(\bar\kappa-1)\mathfrak{m}_k(X_1,Y)}$ in the number $\mathfrak{m}_k(X_1,Y)$ of the cubes of Y outside X_1.

A region $X_1=X_k(Q(p))$ has linear size 0, so $d_k(Y)\le\mathfrak{m}_k(X_1,Y)$ ((322)); with $0<\lambda_V\le\bar\kappa-2$ (the rate condition following (274), at the places of the chain) the remaining decay $e^{-\mathfrak{m}_k(X_1,Y)}$ pays for the at most 8 regions per cube of Y. Summing over the regions gives the family, linear in $\varkappa$, local, formed and holomorphic on $\mathfrak{D}^{\rm src}(Y)$, zero at $\mathcal{A}=0$, with $|\mathbb{V}^\sharp_\varkappa(Y;P,\mathcal{A})|\le\mathsf{h}_\varkappa e^{-\lambda_V d_k(Y)}$ there,

$\mathsf{h}_\varkappa = CL^{-3k}\max|\varkappa|$. For $k=0$ the same holds for $\mathbb{W}$, at the radius r_P° and with $\mathsf{h}_\varkappa = C\max|\varkappa|$: by its definition in the proof of Proposition 3.13 it is a sum, over the at most $8NM^3$ boxes of one region, of differences $\mathsf{j}_\iota(e^{iB'}U)-\mathsf{j}_\iota(U)$, which vanish at $\mathcal{A}=0$, where $B'=0$; at fluctuation fields below the radius r_P° the bond variables of $e^{iB'}U$ and of U have norms <2, so each value is at most the height of the density; and the member at Y vanishes unless $d_0(Y)=0$.

The sizes follow by Schwarz's lemma. On the field polydisc of the step $|\mathcal{A}(b)| = g_k|B(b)| < \mathsf{C}_\mathcal{A}\delta(x_k) \le \frac12\varepsilon_{\mathrm{src}}$ (condition (Sr), the half-radius condition following (274)). Fix Y, P and $B\neq 0$, and put $\beta = \sup_b|B(b)|$: the function $\zeta\mapsto \mathbb{V}^\sharp_\varkappa(Y;P,\zeta g_kB)$ is holomorphic on the disc $|\zeta|<\varepsilon_{\mathrm{src}}/(g_k\beta)$, of radius >2, bounded there by $\mathsf{h}_\varkappa e^{-\lambda_V d_k(Y)}$ and zero at 0, and its even part is even. Schwarz's lemma at $\zeta=1$ bounds the family and its part odd under $B\mapsto -B$ by $\mathsf{h}_\varkappa e^{-\lambda_V d_k(Y)}g_k\beta/\varepsilon_{\mathrm{src}}$, and its even part by $\mathsf{h}_\varkappa e^{-\lambda_V d_k(Y)}(g_k\beta/\varepsilon_{\mathrm{src}})^2$.

With $g_k\beta<\mathsf{C}_\mathcal{A}\delta(x_k)$, $\beta\le\frac12 M^{3/2}(1+\mathsf{q})$ and $\beta^2\le M^3(1+\mathsf{q})$, $\mathsf{q}=M^{-3}\sum_b|B(b)|^2$ the weight in the size (272), the sizes are at most $\mathsf{C}_\mathcal{A}\varepsilon_{\mathrm{src}}^{-1}\delta(x_k)\mathsf{h}_\varkappa$ for the family, $\frac12 M^{3/2}\varepsilon_{\mathrm{src}}^{-1}g_k\mathsf{h}_\varkappa$ for its odd part and $M^3\varepsilon_{\mathrm{src}}^{-2}g_k^2\mathsf{h}_\varkappa$ for its even part. (a)–(c) The step of height k with the further family $\mu\mathbb{V}^\sharp_\varkappa$, which sums to μ times the variation of $\mathcal{S}_\varkappa$ from its background value, gives, at every $W\in\mathsf{Cut}_{k+1}$ and $U\in\mathcal{C}(\mathbf{B}_{k+1},W)$, the chart integral of $F_ke^{\mu\mathsf{s}_k}$ as $\mathsf{I}[F_k](W)\exp[\sum_{X,z}(E_\mu-E_0)(X,U,z)+\mu\mathcal{S}_\varkappa(U)]$ (Proposition E.7); differentiating at $\mu=0$ gives $\mathsf{I}[\mathsf{s}_kF_k](W)=\mathsf{I}[F_k](W)\{\mathsf{Sum}[\mathsf{D}^{(k+1)}[\varkappa]](U)+\mathcal{S}_\varkappa(U)\}$, which is (c).

The derivative of a family that is holomorphic in μ is a pointed family, with the Lipschitz bound of the step in its family in the fourth place; linearity follows over a bidisc and by the chain rule; locality from the locality clauses of the two Theorems. (d) On Cut_n the plaquette variables are within $\mathsf{e}_n^{\mathrm{c}}L^{-2n}\le 1$ of $\mathbf{1}$; Lemma 3.10 (b) at $\mu=\mathsf{e}_n^{\mathrm{c}}L^{-2n}$, $3\ell^3L^{3K}$ plaquettes, the fixed factor $3c_{\mathrm{orb}}$. (e) Split $\mathbb{V}^\sharp_\varkappa=\mathbb{V}^{\mathrm{ev}}+\mathbb{V}^{\mathrm{od}}$ into its parts even and odd under the reflection $B\mapsto -B$ of the fluctuation field; both are families in the fourth place, and $\mathsf{D}^{(k+1)}=\mathsf{D}^{\mathrm{ev}}+\mathsf{D}^{\mathrm{od}}$, the derivatives of the output in the two directions.

The even part vanishes to the second order at $B=0$: by Schwarz's lemma on the disc of radius $\varepsilon_{\mathrm{src}}/(g_k\sup|B|)>2$, as in (o), $\varepsilon_{\mathrm{src}}$ the radius of the sources (274), its size is at most $CM^3\varepsilon_{\mathrm{src}}^{-2}g_k^2L^{-3k}\max|\varkappa|$, and by (a) the norm of D^{ev} is at most K^{d} times this. The odd part has, by (o), the size $\mathsf{n}^{\mathrm{f}}(\mathbb{V}^{\mathrm{od}})\le CM^{3/2}\varepsilon_{\mathrm{src}}^{-1}g_kL^{-3k}\max|\varkappa|$ only, and its contribution is bounded by a parity argument in two parameters, in which the odd parts of the step's own families enter; these are small: the base family $\mathbb{V}'_k$ in the fourth place has even and odd parts of size at most a number ν_k of the chain, and the three interaction families have even and odd parts of size at most $K_P\delta(x_k)$ ((273)); both numbers are proportional to $\delta(x_k)$ and at most $\frac18 w_\star$.

Put

$$\rho=\min\Big\{\frac{w_\star}{8K_P\delta(x_k)}-1,\ \frac{w_\star}{64\nu_k}\Big\},\qquad \varpi_0=\frac{w_\star}{64\rho\,\mathsf{n}^{\mathrm{f}}(\mathbb{V}^{\mathrm{od}})},$$

and for $|\mu|<\rho$, $|\varpi|<\varpi_0$ give the step, in the fourth place, the family $(\mathbb{V}'_k)^{\mathrm{ev}}+\mu(\mathbb{V}'_k)^{\mathrm{od}}+\varpi\mu\mathbb{V}^{\mathrm{od}}$, and, for each of the three interaction families, its even part plus μ times its odd part. These data are admissible: the interaction families have sizes at most $(1+\rho)K_P\delta(x_k)\le\frac18 w_\star$, and the family in the fourth place has size at most $(1+\rho)\nu_k+\varpi_0\rho\,\mathsf{n}^{\mathrm{f}}(\mathbb{V}^{\mathrm{od}})\le\frac14 w_\star$. Keep the Gaussian structure, cutoff and quadratic data fixed, and set

$$\Phi(\mu,\varpi)=\sum_b h_z(b)E^\bullet(X,b;\mathfrak{E}_{\mu,\varpi}),$$

the interaction-dependent pointed term at (X,z). The normalizer and the fixed cutoff term are independent of μ,ϖ, so their ϖ derivatives vanish. The change of variables $B\mapsto -B$ preserves the Gaussian, the cutoff, the field polydiscs and the quadratic pairing, and carries all four families at μ to those at $-\mu$. The orthogonal covariance in Proposition YMM1:48.4 and Lemma YMM1:77.1 therefore gives $\Phi(-\mu,\varpi)=\Phi(\mu,\varpi)$. Those same localized-term estimates give holomorphy on the

parameter bidisc and

$$|\Phi(\mu,\varpi)| \le 3L^3 K_\Pi(32\nu_{\mathrm{int}} + 9\nu')e^{-(\kappa+1)d_{k+1}(X)} \le Cw_\star e^{-(\kappa+1)d_{k+1}(X)},$$

where $\nu_{\mathrm{int}} \le w_\star/8$ bounds each internal family and $\nu' \le w_\star/4$ bounds the fourth family. The tent weights are fixed throughout.

Hence $\psi(\mu) = \partial_\varpi \Phi(\mu, 0)$ is even, and Cauchy's estimate gives $|\psi| \le Cw_\star e^{-(\kappa+1)d_{k+1}(X)}/\varpi_0 = C\rho\,\mathsf{n}^{\mathrm{f}}(\mathbb{V}^{\mathrm{od}})e^{-(\kappa+1)d_{k+1}(X)}$ on $|\mu| < \rho$. At $\mu = 0$ none of the four families reads ϖ, so $\psi(0) = 0$, and ψ, being even, vanishes to the second order at 0; the maximum principle for $\psi(\mu)/\mu^2$ on $|\mu| < \rho$ gives $|\psi(1)| \le C\rho^{-1}\mathsf{n}^{\mathrm{f}}(\mathbb{V}^{\mathrm{od}})e^{-(\kappa+1)d_{k+1}(X)}$. At $\mu = 1$ the data are those of the step with $\mathbb{V}'_k + \varpi\mathbb{V}^{\mathrm{od}}$ in the fourth place, so the member of D^{od} at X is $\psi(1)$. For $K - k \ge y_{\mathrm{par}}$, $\rho > 2$ and $\rho^{-1} \le \mathsf{c}'_\rho \delta(x_k) = \mathsf{c}'_\rho A_1 g_k (\log x_k)^{\mathfrak{p}_0}$, c'_ρ a function of the constants; so the norm of D^{od} is at most $CM^{3/2}\varepsilon_{\mathrm{src}}^{-1}(\log x_k)^{\mathfrak{p}_0} g_k^2 L^{-3k} \max|\varkappa|$, the factor ρ^{-1} supplying the second power of g_k.

Together: $\bar{\mathsf{p}}_{k+1}$; the factor g_k^2, not g_k, is what makes the label disappear in $g_k^2\mathsf{b}' = L^{-(K-k)}$. (f) Let $0 \le i \le k$. An isometry r of the block lattice of level $k+1$ is one of every block lattice of a level $i+1 \le k+1$ (Lemma G.1). The chart of the step of height i is covariant under r (the chart calculation in the proof of Proposition YMM1:52.4): the push-forward operator $\mathsf{O} = \mathsf{O}_{\mathsf{r},W}$ of the isometry (defined on the positive nonpivot bonds at the beginning of that proof) is a linear bijection of the fluctuation fields that keeps dB, the quadratic form $(\cdot,\cdot)_1$ and the range Rg_{x_i}; $V_i^{\mathrm{bf}}(\mathsf{r}W) = \mathsf{r}V_i^{\mathrm{bf}}(W)$ and $V_{\mathsf{r}W}(\mathsf{O}B) = \mathsf{r}V_W(B)$; the exponent and the Jacobian are unchanged, $G_{\mathsf{r}W}(\mathsf{O}B) = G_W(B)$, $\mathsf{J}_{\mathsf{r}W}(\mathsf{O}B) = \mathsf{J}_W(B)$; and the elimination factor $z^{(i)}_{V_i^{\mathrm{bf}}(W)}(\Gamma)$ of the chart integral (191) is unchanged, as the Gaussian normaliser $Z^{(i)}(W;\mathsf{A}^\circ)$ of Section B.2, which is this factor times a Gaussian integral that $B \mapsto \mathsf{O}B$ carries into itself, is unchanged.

The substitution $B \mapsto \mathsf{O}B$ in (191) gives

$$\mathsf{I}[F](\mathsf{r}W) = \mathsf{I}[F \circ \mathsf{r}](W)$$

for bounded Borel F on $\mathcal{V}_i$ and $W \in \mathsf{Cut}_{i+1}$; and $\mathsf{r}W \in \mathsf{Cut}_{i+1}$, the minimal orbits being carried along (Lemma B.4(3); Lemma 3.16 (a)). The integrands of the chain are invariant, by induction on i: $F_0 = \rho_0$ on Cut_0 (the definition preceding Proposition YMM1:114.2), and the lattice isometries keep ρ_0 and Cut_0; if $F_i \circ \mathsf{r} = F_i$ on Cut_i, then for $W \in \mathsf{Cut}_{i+1}$ the points $V_W(B)$ and $\mathsf{r}V_W(B) = V_{\mathsf{r}W}(\mathsf{O}B)$ lie in Cut_i (the downward stability YMM1:113.10), and the step identity $\mathsf{I}[F_i] = e^{\mathsf{c}_{i+1}}F_{i+1}$ on Cut_{i+1}, with a number c_{i+1} (Proposition YMM1:114.2, equation YMM1:(2174)), gives $e^{\mathsf{c}_{i+1}}F_{i+1}(\mathsf{r}W) = \mathsf{I}[F_i \circ \mathsf{r}](W) = \mathsf{I}[F_i](W) = e^{\mathsf{c}_{i+1}}F_{i+1}(W)$. So, for $W \in \mathsf{Cut}_{k+1}$,

$$(\mathsf{Q}_k h)(\mathsf{r}W) = \frac{\mathsf{I}[(h\circ\mathsf{r})(F_k\circ\mathsf{r})](W)}{\mathsf{I}[F_k\circ\mathsf{r}](W)} = \frac{\mathsf{I}[(h\circ\mathsf{r})F_k](W)}{\mathsf{I}[F_k](W)} = (\mathsf{Q}_k(h\circ\mathsf{r}))(W).$$

By Lemma 3.10 (c), $\mathcal{S}_\varkappa(\mathsf{r}U) = \mathcal{S}_{\mathsf{r}^\sharp\varkappa}(U)$, and the minimal orbits are carried along, so $\mathsf{s}_n^\varkappa \circ \mathsf{r} = \mathsf{s}_n^{\mathsf{r}^\sharp\varkappa}$ on Cut_n ($n = k+1$, and $n = k$ at the points $V_W(B)$); inserted in (c) at $\mathsf{r}W$ and at W this gives $\mathsf{Sum}[\mathsf{D}^{(k+1)}[\varkappa]](\mathsf{r}U) = (\mathsf{Q}_k\mathsf{s}_k^\varkappa)(\mathsf{r}W) - \mathsf{s}_{k+1}^\varkappa(\mathsf{r}W) = (\mathsf{Q}_k\mathsf{s}_k^{\mathsf{r}^\sharp\varkappa})(W) - \mathsf{s}_{k+1}^{\mathsf{r}^\sharp\varkappa}(W) = \mathsf{Sum}[\mathsf{D}^{(k+1)}[\mathsf{r}^\sharp\varkappa]](U)$. □

Lemma 3.20 (Carrying families up; stopping)**.** Let $t \ge 1$ and $L \ge 2$. For $1 \le j \le t$ let $\mathfrak{F}_j$ be complex vector spaces with seminorms $\|\cdot\|_j$, $\mathsf{c}(\mathsf{f}) = L^j\|\mathsf{f}\|_j$ for $\mathsf{f} \in \mathfrak{F}_j$, $\mathfrak{F}_{\le n} = \bigoplus_{j\le n}\mathfrak{F}_j$; for $1 \le n \le t$ let $\mathscr{B}_n$ be complex vector spaces with seminorms $|\cdot|_n$ and elements $\mathbf{1}_n$; let $\Sigma_n : \mathfrak{F}_{\le n} \to \mathscr{B}_n$ be linear, a a linear form on $\mathfrak{F}_{\le t}$, $S_i : \mathfrak{F}_{\le i} \to \mathfrak{F}_{i+1}$ and $\mathsf{Q}_i : \mathscr{B}_i \to \mathscr{B}_{i+1}$ linear ($1 \le i < t$), and $\theta_i, \mathsf{B}_n \ge 0$, with

(N) $\|S_i\mathsf{f}\|_{i+1} \le \theta_i L^{-(i-i')}\|\mathsf{f}\|_{i'}$ for $\mathsf{f} \in \mathfrak{F}_{i'}$, $i' \le i$ (so $\mathsf{c}(S_i\mathsf{f}) \le L\theta_i\mathsf{c}(\mathsf{f})$);
(A) $\mathsf{Q}_i\mathbf{1}_i = \mathbf{1}_{i+1}$, $|\mathsf{Q}_i h|_{i+1} \le |h|_i$, $\mathsf{Q}_i\Sigma_i[\mathsf{g}] = \Sigma_{i+1}[\mathsf{g} + S_i\mathsf{g}]$;
(B) $|\Sigma_n[\mathsf{f}] - a[\mathsf{f}]\mathbf{1}_n|_n \le \mathsf{B}_n\mathsf{c}(\mathsf{f})$ for $\mathsf{f} \in \mathfrak{F}_j$, $j \le n$.

Put $\mathsf{T}_t = \mathrm{id}$ and $\mathsf{T}_n\mathsf{g} = \mathsf{T}_{n+1}(\mathsf{g} + S_n\mathsf{g})$.

(a) $\Sigma_t[\mathsf{T}_n\mathsf{g}] = \mathsf{Q}_{t-1}\cdots\mathsf{Q}_n\Sigma_n[\mathsf{g}]$; $|\Sigma_t[\mathsf{T}_n\mathsf{g}] - a_0\mathbf{1}_t|_t \le |\Sigma_n[\mathsf{g}] - a_0\mathbf{1}_n|_n$ for every $a_0 \in \mathbb{C}$; and $\mathsf{T}_n\mathsf{g} = \mathsf{T}_{n'}\mathsf{g} + \sum_{k=n}^{n'-1}\mathsf{T}_{k+1}S_k\mathsf{g}$ for $n \le n' \le t$.

(b) Let $1 \le j \le n_0 \le t$ and $\mathsf{D} \in \mathfrak{F}_j$. A *chain* is $\underline{k} = (k_1 < \cdots < k_m)$, $m \ge 1$, $j \le k_1$, $k_m < t$, and $\mathsf{f}_{\underline{k}} = S_{k_m} \cdots S_{k_1} \mathsf{D}$. Let n map the chains to integers with $k_m < \mathsf{n}(\underline{k}) \le t$; a chain is *live* if $k_1 < n_0$ and $k_{l+1} < \mathsf{n}(k_1, \dots, k_l)$ for $1 \le l < m$. Then $\mathsf{T}_j \mathsf{D} = \mathsf{T}_{n_0} \mathsf{D} + \sum_{\text{live}} \mathsf{T}_{\mathsf{n}(\underline{k})} \mathsf{f}_{\underline{k}}$, and for every $a_0 \in \mathbb{C}$

$$\Big| \Sigma_t[\mathsf{T}_j \mathsf{D}] - \Big(a_0 + \sum_{\text{live}} a[\mathsf{f}_{\underline{k}}] \Big) \mathbf{1}_t \Big|_t \le |\Sigma_{n_0}[\mathsf{D}] - a_0 \mathbf{1}_{n_0}|_{n_0} + \mathsf{c}(\mathsf{D}) \sum_{\underline{k} \text{ live}} \mathsf{B}_{\mathsf{n}(\underline{k})} \prod_l L\theta_{k_l}.$$

(c) Let $K' \ge t$, $q \ge 1$, $0 < \tau < \frac{1}{2}$, $\Theta_0 \ge 1$, $\mathsf{B}_0 > 0$ with $L\theta_k \le \Theta_0 L^{-(K'-k)/2}$ $(1 \le k < t)$ and $\mathsf{B}_n \le \mathsf{B}_0 L^{q(K'-n)-K'}$ $(1 \le n \le t)$; let $u = K' - t$, $y_* = K' - n_0$, $m_{q,\tau} = 2 + \lfloor \log(q/\tau)/\log(1+\tau/q) \rfloor$, $Y(\underline{k}) = \sum_l (K' - k_l)$ and $\mathsf{n}(\underline{k}) = \max\{k_m + 1, \min\{t, \lceil K' - \tau Y(\underline{k})/q \rceil\}\}$. Then every live chain has at most $m_{q,\tau}$ members, and

$$\sum_{\underline{k} \text{ live}} \mathsf{B}_{\mathsf{n}(\underline{k})} \prod_l L\theta_{k_l} \le \mathsf{B}_0 L^{-K'} m_{q,\tau} (t\Theta_0)^{m_{q,\tau}} \max\{ L^{-(\frac{1}{2}-\tau)y_*}, L^{qu - y_*/2} \}.$$

■

Proof sketch. (a) Downward induction on n with the third member of (A); $a_0 \mathbf{1}_t = \mathsf{Q}_{t-1} \cdots \mathsf{Q}_n (a_0 \mathbf{1}_n)$ and the second member of (A); $\mathsf{T}_n \mathsf{g} = \mathsf{T}_{n+1} \mathsf{g} + \mathsf{T}_{n+1} S_n \mathsf{g}$ and induction on $n' - n$. (b) (a) at (j, n_0) gives $\mathsf{T}_{n_0} \mathsf{D}$ and the live chains of length 1; for a live chain of length m, (a) at $(k_m + 1, \mathsf{n}(\underline{k}))$ splits $\mathsf{T}_{k_m+1} \mathsf{f}_{\underline{k}}$ into $\mathsf{T}_{\mathsf{n}(\underline{k})} \mathsf{f}_{\underline{k}}$ and the live chains of length $m+1$ that prolong it; a chain has at most $t-1$ members. The bound: (a) for each summand, (B) at the level $\mathsf{n}(\underline{k})$, and (N). (c) The price of a chain is $\le \mathsf{B}_0 L^{-K'} \Theta_0^m L^{q(K'-\mathsf{n})-Y/2}$, $\mathsf{n} = \mathsf{n}(\underline{k})$, a bound that does not increase with n.

Put $\mathsf{n}^\circ = \min\{t, \lceil K' - \tau Y/q \rceil\}$, so that $\mathsf{n} = \max\{k_m + 1, \mathsf{n}^\circ\} \ge \mathsf{n}^\circ$ and $\mathsf{n} \le t$. If n° is the ceiling, then $K' - \mathsf{n} \le K' - \mathsf{n}^\circ \le \tau Y/q$ and the exponent is $\le -(\frac{1}{2} - \tau) Y$; otherwise $\mathsf{n}^\circ = t$, so $\mathsf{n} = t$, and the exponent is $qu - Y/2$. (When $\mathsf{n} = k_m + 1 > \mathsf{n}^\circ$, then $\mathsf{n}^\circ < t$ is the ceiling, and the first case applies.) For a live chain $Y > y_*$. If $(k_1, \dots, k_{m+1})$ is live, then $k_{m+1} < K' - \tau Y_m/q$, so $y_{m+1} > \tau Y_m/q$ with $y_l = K' - k_l$; hence $Y_{l+1} > (1 + \tau/q) Y_l$, and $y_{m+1} < y_1$ gives $(1+\tau/q)^{m-1} y_1 \le Y_m < (q/\tau) y_1$. There are at most t^m chains of length m. □

Proposition 3.21 (The conditional mean of the cubic half)**.** Let $\ell = 2L^m$, $\gamma^{-2} \le \mathsf{b}_- \le \mathsf{b}_+$ with $MR(\mathsf{b}_+) \le L^m$, and let parameters $0 < \psi < \frac{2}{9}$, $0 \le \kappa_\star < 1$, $0 < \tau < \frac{1}{2}$, $0 < \phi < \frac{1}{6}\psi$ be given; put

$$c'' = \min\{1 - \tfrac{9}{2}\psi,\ \kappa_\star - (3 + \kappa_\star)\psi,\ (\tfrac{1}{2} - \tau)\psi,\ \tfrac{1}{2}\psi - 3\phi\}, \qquad \bar{m} = 2 + \lfloor \log(3/\tau)/\log(1 + \tau/3) \rfloor.$$

There are K_3, a function of b_+ and the parameters, and C_3, p_3, functions of m, b_+ and the parameters, such that for all $K \ge K_3$, $\mathsf{b}' \in [\mathsf{b}_-, \mathsf{b}_+]$, $\beta = L^K \mathsf{b}'$ and $t = K - \lceil \phi K \rceil$:

(a) (Th) holds on T_ℓ with (K, b', m, t), so that Proposition 3.13 and Lemma 3.14 hold with $t_* = t$;

(b) for every real field $\eta = (\eta^\rho)_\rho$ on T_ℓ, with $\mathsf{H}(\eta) = \max_\rho \sup |\eta^\rho| + \max_\rho \operatorname{Lip} \eta^\rho$, there is a number $\mathsf{a}[\eta]$, real linear in η and a sum of values at the trivial configuration, with

$$|(\mathsf{Q}_{t \leftarrow 0} \mathcal{S}[\mathsf{b}' \eta])(V) - \mathsf{a}[\eta]| \le C_3\, \mathsf{H}(\eta)\, K^{p_3} L^{-c'' K} \qquad \text{for } \nu_t\text{-almost all } V \in \mathsf{Cut}_t.$$

At $\psi = \frac{1}{7}$, $\kappa_\star = \frac{3}{4}$, $0 < \tau \le \frac{1}{4}$, $0 < \phi < \frac{1}{42}$:

$$c'' = c_0' := \min\{\tfrac{1}{14} - \tfrac{\tau}{7},\ \tfrac{1}{14} - 3\phi\}, \qquad p_3 = 3\mathfrak{p}_0 + 1 + \bar{m}(1 + \mathfrak{p}_0),$$

K_3 a function of b_+ and ϕ, C_3 a function of m, b_+ and τ; $c_0' \ge \frac{1}{28}$ for $\tau = \frac{1}{4}$, $\phi \le \frac{1}{84}$, and c_0' does not fall as $\phi \to 0$. At $\psi = \frac{1}{5}$, $\kappa_\star = \frac{9}{10}$: $c'' = \frac{1}{10} - \max\{\frac{1}{5}\tau, 3\phi\}$. ■

Proof sketch. Put $\varkappa(p) = L^{2K} \mathsf{b}' \eta^{\rho(p)}(x(p))$, so that $\mathcal{S}[\mathsf{b}'\eta] = \mathcal{S}_\varkappa$ is an insertion of order 3 (Lemma 3.10 (b)); power counting alone (Lemma 3.14 (c)) gives it only $L^{4u+K/2}$, and the gain comes from parity and covariance. Let $u = \lceil \phi K \rceil$, $t = K - u$, $y_* = \lceil \psi K \rceil$, $n_0 = K - y_*$. K_3 is so large that: Lemma 3.12 (b) applies; $1 \le n_0 < t$; $\psi K \ge y_{\text{par}}$; $K \ge K_2$ (Lemma 3.16 (b)); and the data of

Lemmas 3.16 (c) and 3.17 hold at ε_{n_0}, with $D_* \geq 7K\log L + 1$. Each of these holds from a K on, a power of L^K against a power of K; this is (a).

1. The births. By Lemma 3.19 (c), $\mathsf{Q}_{j-1}\mathsf{s}_{j-1} = \mathsf{s}_j + \Sigma_j[\mathsf{D}^{(j)}]$, $\mathsf{D}^{(j)} = \mathsf{D}^{(j)}[\varkappa]$, for $1 \leq j \leq n_0$; by induction and linearity

$$\mathsf{Q}_{t\leftarrow 0}\mathcal{S}_\varkappa = \mathsf{Q}_{t\leftarrow n_0}\mathsf{s}_{n_0} + \sum_{j=1}^{n_0} \mathsf{Q}_{t\leftarrow j}\Sigma_j[\mathsf{D}^{(j)}].$$

2. The scheme. The pointed families of level j with their norms, the bounded functions on $\mathcal{V}_n$ vanishing off Cut_n with the essential supremum for ν_n, $\mathbf{1}_n = \mathbf{1}_{\mathsf{Cut}_n}$, the maps Σ_n, the value $a[\mathsf{f}] = \mathsf{Sum}[\mathsf{f}](\mathbf{1})$ at the trivial configuration, the maps S_i and Q_i of Lemma 3.14 (a), the numbers θ_i and B_n of Lemma 3.16 (b) satisfy (N), (A), (B) of Lemma 3.20, and its hypotheses (c) hold with $K' = K$, $q = 3$, $\Theta_0 = \Theta_K$ (Lemma 3.12 (b)) and $\mathsf{B}_0 = \mathsf{B}'_0$; $m_{3,\tau} = \bar{m}$. So $\mathsf{Q}_{t\leftarrow j}\Sigma_j[\mathsf{D}^{(j)}] = \Sigma_t[\mathsf{T}_j\mathsf{D}^{(j)}]$.

3. The entry. A conditional mean does not exceed a supremum:

$$|\mathsf{Q}_{t\leftarrow n_0}\mathsf{s}_{n_0}| \leq 3c_{\mathrm{orb}}\ell^3 L^{3K-6n_0}(\mathsf{e}^{\mathrm{c}}_{n_0})^3 \max|\varkappa|$$

(Lemma 3.19 (d)), with $(\mathsf{e}^{\mathrm{c}}_{n_0})^3\mathsf{b}' \leq CK^{3\mathfrak{p}_0}L^{-\frac{3}{2}y_*}$ and $\max|\varkappa| \leq L^{2K}\mathsf{b}'\mathsf{H}(\eta)$: the exponent of L is $\frac{9}{2}y_* - K$.

4. The norms. By Lemma 3.19 (e), with $g_k^2\mathsf{b}' = L^{-(K-k)}$: $\mathsf{c}_j := L^j\|\mathsf{D}^{(j)}\| \leq CK^{\mathfrak{p}_0}L^{K-j}\mathsf{H}(\eta)$; the label has disappeared.

5. Covariance at the levels $j < n_0$. With the partition of unity θ_z of Lemma 3.17 (b) and $\Sigma_z[\varkappa] = \mathsf{Sum}[\mathsf{D}^{(j)}[\theta_z\varkappa]]$, linearity gives $\mathsf{Sum}[\mathsf{D}^{(j)}[\varkappa]] = \sum_z \Sigma_z[\varkappa]$, and Lemma 3.19 (f) for the inversion r_z, with $\theta_z \circ \mathsf{r}_z = \theta_z$, gives $\Sigma_z[\varkappa](\mathsf{r}_z U) = -\Sigma_z[\varkappa\circ\mathsf{r}_z](U)$. So

$$\Sigma_z[\varkappa](U) = \tfrac{1}{2}(\Sigma_z[\varkappa](U) - \Sigma_z[\varkappa](\mathsf{r}_z U)) + \tfrac{1}{2}\Sigma_z[\varkappa - \varkappa\circ\mathsf{r}_z](U).$$

The first parts are bounded by Lemma 3.17 (b): with $N_j\vartheta^4 = N_{n_0}\vartheta$, $\varepsilon^2_{n_0} \leq CK^{2\mathfrak{p}_0}L^{-y_*}$ and $\bar{\mathsf{p}}_j L^{2K}\mathsf{b}' \leq CK^{\mathfrak{p}_0}L^{K-2j+2}$, their sum over z is at most $CK^{3\mathfrak{p}_0}\mathsf{H}(\eta)L^{3y_*}L^{-j}\vartheta^{\kappa_\star}$, a gain $\vartheta^{\kappa_\star}$ over the size of one family at a background: the even part of the gauge potential of a regular configuration costs ϑ^2, its odd part $\vartheta^{2+\kappa_\star}$, and a local term vanishes quadratically, so the difference is of order $\varepsilon^2_{n_0}\vartheta^{4+\kappa_\star}$. The second parts are $\frac{1}{2}\mathsf{Sum}[\mathsf{D}^{(j)}[\tilde{\varkappa}_j]]$, $\tilde{\varkappa}_j = \sum_z \theta_z(\varkappa - \varkappa\circ\mathsf{r}_z)$, a weight with $\max|\tilde{\varkappa}_j| \leq L^{2K}\mathsf{b}'\mathsf{H}(\eta)L^{j-K}$ (an inversion keeps $\rho(p)$ and moves $x(p)$ by at most L^{j-K} where $\theta_z(p) \neq 0$); by Lemma 3.16 (b) at $n = n_0$ they differ from their values at $\mathbf{1}$ by $CK^{3\mathfrak{p}_0}\mathsf{H}(\eta)L^{3y_*}L^{-j}L^{-(K-j)}$. Together, for $1 \leq j < n_0$,

$$\varsigma'_j := \sup_{V\in\mathsf{Cut}_{n_0}} |\mathsf{Sum}[\mathsf{D}^{(j)}](U_{n_0}(V)) - \tfrac{1}{2}\mathsf{Sum}[\mathsf{D}^{(j)}[\tilde{\varkappa}_j]](\mathbf{1})| \leq C\mathsf{H}(\eta)K^{3\mathfrak{p}_0}L^{3y_*}L^{-j-\kappa_\star(n_0-j)}.$$

6. Stopping. Lemma 3.20 (b) with $a_0 = \frac{1}{2}\mathsf{Sum}[\mathsf{D}^{(j)}[\tilde{\varkappa}_j]](\mathbf{1})$ for $j < n_0$ (where $|\Sigma_{n_0}[\mathsf{D}^{(j)}] - a_0\mathbf{1}_{n_0}| \leq \varsigma'_j$), and (B) at $n = j = n_0$, with the stopping rule of Lemma 3.20 (c); a chain of the maps S_k costs a factor $L\theta_k$ at each step, a chain is stopped at the level $\mathsf{n}(\underline{k})$, where its value at the background is compared with its value at the trivial configuration at the price $\mathsf{B}_{\mathsf{n}} = \mathsf{B}'_0 L^{3(K-\mathsf{n})-K}$, and the live chains have at most $\bar{m}$ members. With

$$\mathsf{a}[\eta] = \sum_{j<n_0}\Big(\tfrac{1}{2}\mathsf{Sum}[\mathsf{D}^{(j)}[\tilde{\varkappa}_j]](\mathbf{1}) + \sum_{\underline{k}\ \text{live}} \mathsf{Sum}[\mathsf{S}_{k_m}\cdots\mathsf{S}_{k_1}\mathsf{D}^{(j)}](\mathbf{1})\Big) + \mathsf{Sum}[\mathsf{D}^{(n_0)}](\mathbf{1}),$$

real linear in η (the live chains depend on K, t, n_0, j, τ alone), for ν_t-almost all $V \in \mathsf{Cut}_t$

$$\begin{aligned}|(\mathsf{Q}_{t\leftarrow 0}\mathcal{S}_\varkappa)(V) - \mathsf{a}[\eta]| \leq{}& \sup_{\mathsf{Cut}_{n_0}}|\mathsf{s}_{n_0}| + \sum_{j<n_0}\varsigma'_j + \mathsf{B}_{n_0}\mathsf{c}_{n_0}\\ &+ \sum_{j<n_0}\mathsf{B}'_0\mathsf{c}_j L^{-K}\bar{m}(t\Theta_K)^{\bar{m}}\max\big[L^{-(\frac{1}{2}-\tau)y_*}, L^{3u-y_*/2}\big].\end{aligned}$$

7. The exponents. With $\psi K \leq y_* \leq \psi K + 1$ and $u \leq \phi K + 1$, the four groups give the exponents $1 - \frac{9}{2}\psi$ (the entry), $1 - 4\psi$ (the births at the level n_0, $\mathsf{B}_{n_0}\mathsf{c}_{n_0} \leq CK^pL^{4y_*-K}\mathsf{H}(\eta)$),

$\kappa_\star - (3+\kappa_\star)\psi$ (covariance, as $j + \kappa_\star(n_0 - j) \geq \kappa_\star n_0$) together with $1 - 3\psi$ (the part in $\operatorname{Lip}\eta$ and the tails), and $(\frac{1}{2} - \tau)\psi$, $\frac{1}{2}\psi - 3\phi$ (the families carried up from the levels $j < n_0$ and stopped, as $\sum_j L^{-j} \leq 1$). As $1 - 4\psi$ and $1 - 3\psi$ exceed $1 - \frac{9}{2}\psi$, the least is c''; all powers of K are at most K^{p_3}. At $\psi = \frac{1}{7}$, $\kappa_\star = \frac{3}{4}$ the six numbers are $\frac{5}{14}$, $\frac{3}{7}$, $\frac{3}{14}$, $\frac{4}{7}$, $\frac{1}{14} - \frac{1}{7}\tau$, $\frac{1}{14} - 3\phi$. The label b' has entered only through $x_i \in [\gamma^{-2}L^{K-i}, \mathsf{b}_+ L^{K-i}]$, $g_k^2 \mathsf{b}' = L^{-(K-k)}$ and $\mathsf{b}'^{-1/2} \leq \gamma$, so the bound is uniform in $\mathsf{b}' \in [\mathsf{b}_-, \mathsf{b}_+]$. □

Boards. A board of $\mathbb{L}_K$ with cells of side l and offset o has the wall planes $x_\mu = o_\mu + \mathsf{l}(t' + \frac{1}{2})$, $t' \in \mathbb{Z}$; on $T_{\ell'}$ it has eight cells, exchanged by the mirror maps r_κ, $\kappa \in (\mathbb{Z}/2)^3$. A function of a cell is a bounded Borel function of the bonds with both end points in it, and its chessboard seminorm is given by $\|F\|^8_{\mathrm{ch},\ell'} = \langle \prod_\kappa F \circ \mathsf{r}_\kappa^{-1} \rangle_{K,\ell',\beta}$, after periodisation (Section B.1); it is subadditive and homogeneous (B.1).

Lemma 3.22 (Boards for small sets)**.** (a) (Two sets.) Let $0 < \delta_0 \leq \mathsf{l}$, $0 < h \leq \frac{1}{64}\delta_0$ with $\mathsf{l} \in h\mathbb{Z}$, and let $S_1, S_2 \subset \mathbb{R}^3$ have sup diameters $\leq \frac{1}{8}\delta_0$, with $\sup_{S_1} x_{\mu_0} + \delta_0 \leq \inf_{S_2} x_{\mu_0}$ for one direction μ_0. There is $o \in h\mathbb{Z}^3$ such that S_1, S_2 lie in two different cells of the board with offset o, each at sup distance $\geq \frac{1}{16}\delta_0$ from the walls of its cell.

(b) (n sets.) Let $n \geq 1$, $0 < h < \mathsf{l}/(2n)$ with $\mathsf{l} \in h\mathbb{Z}$, and let $S_1, \dots, S_n \subset \mathbb{R}^3$ be non-empty sets of sup diameter $\leq \mathsf{l}/(4n)$. There is $o \in h\mathbb{Z}^3$ such that every point of every S_a is farther than $\mathsf{l}/(8n)$ from every wall plane of the board with offset o; so each S_a lies in one cell. Different S_a may lie in the same cell.

■

Proof sketch. (a) For a direction μ let I_1, I_2 be the closed $\frac{1}{16}\delta_0$-neighbourhoods of the convex hulls of the projections of S_1, S_2 (the projections themselves need not be intervals): intervals of length $\leq \frac{1}{4}\delta_0$. Wanted is $c_\mu \in \frac{\mathsf{l}}{2} + h\mathbb{Z}$ with $(c_\mu + \mathsf{l}\mathbb{Z}) \cap (I_1 \cup I_2) = \emptyset$, and for $\mu = \mu_0$ besides $\sup I_1 < c_{\mu_0} < \inf I_2$. The bad set $(I_1 \cup I_2) + \mathsf{l}\mathbb{Z}$ has measure $\leq \frac{1}{2}\delta_0$ in a period, in at most two intervals. For μ_0 the gap $(\sup I_1, \sup I_1 + \frac{7}{8}\delta_0)$ lies between I_1 and I_2; minus the bad set it has measure $\geq \frac{3}{8}\delta_0$ in at most four intervals, one of length $\geq \frac{3}{32}\delta_0 > h$, which holds a point of $\frac{\mathsf{l}}{2} + h\mathbb{Z}$.

For $\mu \neq \mu_0$ a period minus the bad set has measure $\geq \mathsf{l} - \frac{1}{2}\delta_0 \geq \frac{1}{2}\delta_0$ in at most three intervals. A connected set that meets no wall plane lies in one cell, and a wall plane of the direction μ_0 parts S_1 from S_2. (b) Fix a direction. The closed $\frac{\mathsf{l}}{8n}$-neighbourhoods of the convex hulls of the projections of the S_a are intervals of length $\leq \frac{\mathsf{l}}{2n}$; on the circle $\mathbb{R}/\mathsf{l}\mathbb{Z}$ they form n arcs of total length $\leq \frac{\mathsf{l}}{2}$. The complement has measure $\geq \frac{\mathsf{l}}{2}$ and at most n components, so one of them is an open arc of length at least $\frac{\mathsf{l}}{2n} > h$, which contains a point of $\frac{\mathsf{l}}{2} + h\mathbb{Z}$; take it as a wall position.

A box that meets no wall plane lies in one cell. □

Lemma 3.23 (Families, mirror copies, oscillations)**.** Fix $c_* \in \{\frac{1}{28}, \frac{1}{14}\}$ and $0 < \phi \leq \frac{1}{84}$, put $u = \lceil \phi K \rceil$, $t = K - u$, and let $(\tau, y_{\mathrm{c}}, \kappa_{\mathrm{H}}) = (\frac{1}{4}, \lceil \frac{K}{14} \rceil, \frac{1}{2})$ if $c_* = \frac{1}{28}$, $(\tau, y_{\mathrm{c}}, \kappa_{\mathrm{H}}) = (21\phi, \lceil \frac{K}{6} \rceil, \frac{3}{4})$ if $c_* = \frac{1}{14}$. To each of the functions $\mathsf{X} = \mathcal{T}_K(H)$, $a_K\mathcal{O}(w_\eta)$, $\mathsf{Rm}[\eta]$, $\Delta[\eta]$, $\mathsf{St}[\eta]$, $\mathfrak{K}[\eta]$, $\mathcal{T}^{\mathrm{c}}[\eta]$ we attach the following family of at most nine insertions, whose sum differs from X by null terms and a constant (Lemmas 3.9, 3.11):

- $\mathcal{T}_K(H)$ itself (a rough insertion) for $\mathcal{T}_K(H)$, and $a_K\mathcal{O}(w_\eta)$ itself for $a_K\mathcal{O}(w_\eta)$; difference 0;
- $\mathcal{S}[b\eta]$, $-\mathfrak{J}_{0,v}[\mathsf{k}_\eta]$ ($v \leq 5$), $\frac{3}{2}a_K\mathcal{O}(w_\eta)$ for $\mathsf{Rm}[\eta]$; difference 0;
- $F(k^0, v^0)$, $F(k^1, v^1)$ for $\Delta[\eta]$; difference 0;
- the negatives of the seven insertions of $\mathsf{Rm}[\eta]$ for $\mathsf{St}[\eta]$; difference $\mathcal{N}_\eta - \frac{1}{4}\mathfrak{N}[\mathsf{k}_\eta] - \frac{1}{4}c_{\mathsf{k}_\eta}$;
- $\mathcal{S}[b\eta]$, $-\mathfrak{J}_{0,v}[\mathsf{k}_\eta]$ for $\mathfrak{K}[\eta]$; difference $\frac{1}{4}\mathfrak{N}[\mathsf{k}_\eta] + \frac{1}{4}c_{\mathsf{k}_\eta}$;
- $-b^{-1}$ times the seven insertions of $\mathsf{Rm}[\eta]$ and the two of $\Delta[\eta]$ for $\mathcal{T}^{\mathrm{c}}[\eta]$; difference $b^{-1}(\mathcal{N}_\eta - \frac{1}{4}\mathfrak{N}[\mathsf{k}_\eta] - \frac{1}{4}c_{\mathsf{k}_\eta})$.

The support of X is that of H, resp. η; $\mathsf{n}(\mathsf{X}) = |H|_\infty$, resp. $\|\eta\|$; X is *small* unless $\mathsf{X} = \mathcal{T}_K(H)$. Let $0 < \delta \le \frac{1}{8}\mathsf{l}$. There are C_ω, p_ω, functions of g, ℓ', c_*, ϕ, and K_{B}, a function of these and δ, such that for all $(K,\beta) \in \mathfrak{d}(g)$ with $K \ge K_{\mathrm{B}}$, every board with offset in $a_{K-t}\mathbb{Z}^3$, every such X with support in a cell at distance $\ge \delta$ from its walls, and every κ:

(a) r_κ maps the block lattices of all levels $\le t$ onto themselves. The mirror copy $\mathfrak{J} \circ \mathsf{r}_\kappa^{-1}$ of an insertion of type $(m, c, \hat{c}, N)$ is an insertion of order m with constant $2^{6m}\max\{c, \hat{c}\}$, height $\hat{c}$, the same weights, carrier the image of the carrier, and counting number $\le 20N$; for rough insertions the constants are unchanged; and $\mathcal{S}[b\eta] \circ \mathsf{r}_\kappa^{-1} = \mathcal{S}[b\eta^{\mathsf{r}}]$ with $(\eta^{\mathsf{r}})^{\rho'}(\mathsf{r}_\kappa y) = \pm\eta^\rho(y)$, $\mathsf{H}(\eta^{\mathsf{r}}) = \mathsf{H}(\eta)$.

(b) X and the members of its family are real functions of the cell that depend only on the bond variables within $4a_K$ of the support, with weights $\le (3 + 60\mathsf{b}_+)L^{2K}\mathsf{n}(\mathsf{X})$; the members are insertions whose orders, constants, heights and counting numbers are pure numbers.

(c) The oscillations of the copies of the family add up to $\sum_e \omega_t(\mathfrak{J}_e \circ \mathsf{r}_\kappa^{-1}) \le \varpi(\mathsf{X})\,\mathsf{n}(\mathsf{X})$, with $\varpi = \varpi_{\mathrm{T}} = C_\omega K^{p_\omega} L^{4u}$ if $\mathsf{X} = \mathcal{T}_K(H)$ and $\varpi = \varpi_{\mathrm{s}} = C_\omega K^{p_\omega} L^{3u - c_* K}$ if X is small; and $L^{-K} \le \varpi_{\mathrm{s}} \le \varpi_{\mathrm{T}} \le L^K$.

■

Proof sketch. (a) Twice a wall coordinate lies in $a_{K-t}\mathbb{Z}$, as $o \in a_{K-t}\mathbb{Z}^3$ and $\mathsf{l} \in a_{K-t}\mathbb{Z}$, so the reflections preserve $a_{K-n}\mathbb{Z}^3$ for $n \le t$. The plaquette variables of the reflected configuration, from the standard corner and sense, are $g\,\partial U(\mathsf{r}q)^{\pm 1} g^{-1}$ with $|g^{\pm 1}| \le 2^3$, hence within $2^6 r$ of $\mathbf{1}$ if those of U are within r; the density is then $\le c(2^6 r)^m$ if $2^6 r \le 1$, and $\le \hat{c} \le \hat{c}(2^6 r)^m$ otherwise. A reflected box has the same shape; for a given lowest site there is one possible original lowest site for each of the 20 admissible shapes, whence $20N$. For petal forms the bound $|q_x| \le 2^{12} r^2$ holds for all petals at once.

The identity for the cubic half is Lemma 3.10 (c). (b) Lemmas 3.9 and 3.11; the weights of the members are those listed there, and for $\mathcal{T}^{\mathrm{c}}$ they carry the factor $b^{-1} \le \gamma^2$; the types are those of Lemmas 3.10 (a), (b) and 3.11 (b). (c) Let $\mathsf{n}(\mathsf{X}) = 1$, so $\mathsf{H}(\eta) \le 3$. For every copy: $\mathcal{S}[b\eta]$, by (a) and Proposition 3.21 applied to η^{r} at (τ, ϕ) and $\psi = \frac{1}{7}$, $\kappa_\star = \frac{3}{4}$: $\omega_t \le 3C_3 K^{p_3} L^{-c_0' K}$, and $c_0' \ge c_* - 3\phi$; the four insertions of order 2 of Rm, of weight $\le 3 + 5\mathsf{b}_+$, $F(k^1, v^1)$, of weight $\le 60\mathsf{b}_+$, and $a_K \mathcal{O}(w_\eta)$: by Lemmas 3.11 (b) and 3.14 (b), (c), $\le CK^{2\mathsf{p}_0} L^{4u-K}$; $\mathfrak{J}_{0,4}, \mathfrak{J}_{0,5}$, of orders $3, 4$ and weight $\le L^K \mathsf{b}_+$: $\le CK^{3\mathsf{p}_0} L^{4u - K/2}$; $F(k^0, v^0) \circ \mathsf{r}_\kappa^{-1}$, of weight $\le 22\mathsf{b}_+ L^K$: Lemma 3.18 (a) at $n_0 = K - y_{\mathrm{c}} \le t$ with (b) at κ_{H}, $\le CK^{2\mathsf{p}_0} L^{(3+\kappa_{\mathrm{H}})y_{\mathrm{c}} - \kappa_{\mathrm{H}} K} + CK^{3\mathsf{p}_0} L^{3u - y_{\mathrm{c}}/2}$, the two exponents being $\le -\frac{K}{4} + \frac{7}{2}$ and $3u - \frac{K}{28}$ for $c_* = \frac{1}{28}$, and $\le -\frac{K}{8} + \frac{15}{4}$ and $3u - \frac{K}{12}$ for $c_* = \frac{1}{14}$; $\mathcal{T}_K(H) = F(k, v)$, of weight $\le 3L^K |H|_\infty$: $\le CK^{2\mathsf{p}_0} L^{4u}$.

These bounds depend on the type and the weight alone, so they hold for every copy. Since $u \le \frac{K}{84} + 1$, every exponent of a small kind is $\le 3u - c_* K + 4$ for $K \ge 5$, and a family has at most nine members. Finally $3u - c_* K \ge -K$ and $4u \le K/21 + 4$. □

Proposition 3.24 (One torus, one cell: products)**.** In the situation of Lemma 3.23, let $m \ge 1$. There is K_{P}, a function of $g, \ell', c_*, \phi, m, \delta$, such that for all $(K,\beta) \in \mathfrak{d}(g)$ with $K \ge K_{\mathrm{P}}$, every $\mathsf{d} > 0$ with $\mathsf{d}L^u \ge K^2$, every board with offset in $a_{K-t}\mathbb{Z}^3$, and all $\mathsf{X}_1, \dots, \mathsf{X}_m$ with supports in one cell, at distance $\ge \delta$ from its walls and pairwise at sup distance $\ge \mathsf{d}$,

$$\Big\| \prod_{a=1}^m (\mathsf{X}_a - \langle \mathsf{X}_a \rangle_{K,\ell',\beta}) \Big\|_{\mathrm{ch},\ell'} \le \mathsf{C}_m \prod_{a=1}^m \varpi(\mathsf{X}_a)\,\mathsf{n}(\mathsf{X}_a), \qquad \mathsf{C}_m = \max_{m' \le m} (\mathsf{Op}_{8m'} + 1)^{1/8},$$

where $\mathsf{Op}_N = \sum_\pi \prod_{I \in \pi} \mathsf{op}_{\#I}$ over the partitions π of $\{1, \dots, N\}$ without blocks of one element. ■

Proof sketch. Both sides are homogeneous in each datum; let $\mathsf{n}(\mathsf{X}_a) = 1$. The eighth power of the left side is the mean of the $8m$ functions $Y_{(a,\kappa)} = \mathsf{X}_a \circ \mathsf{r}_\kappa^{-1} - \langle \mathsf{X}_a \rangle$, which are centred by the invariance of the torus measure under lattice isometries; so it equals $\sum_\pi \prod_{I \in \pi} \langle Y_i; i \in I \rangle$ over the partitions without

singletons. Two copies of one datum are $\geq 2\delta$ apart, two data of one cell are $\geq \mathsf{d}$ apart in every copy, and by Lemma 3.23 (b) the carriers of different entries are $\geq \mathsf{d}_\times = \min\{\mathsf{d}, 2\delta\} - 8a_K \geq \frac{1}{2}\min\{\mathsf{d}, 2\delta\}$ apart. In a cumulant each X_a may be replaced by its family: its difference with the family consists of null terms, on whose bonds the other entries do not depend, so that their joint cumulants with the other entries vanish, and of a constant, which drops out of joint cumulants of order ≥ 2 (Lemma 3.9 (b), after moving the copy back by an isometry).

So $\langle Y_i; i \in I\rangle$ is a sum of at most $9^{\#I}$ cumulants of insertions, each at most $\mathsf{op}_{\#I}\prod\omega_t + \epsilon_\circ$ by Proposition 3.15 (a), $\epsilon_\circ$ a bound of its last two members. By Lemma 3.14 (c), (d), the weights $\leq (3 + 60\mathsf{b}_+)L^{2K}$, $\mathsf{d}L^u \geq K^2$ and $\mathfrak{p}_0 \geq 1$,

$$\mathsf{t}_\times \leq e^2 C_{\mathrm{E},0} K\ell'^3 L^{3u} e^{-K^2/2M}, \qquad \mathsf{R}_t \leq C_{\mathrm{R}} L^{3u}\exp[-c' A_0^2(\phi\log L)^2 K^2]$$

for $\phi K\log L \geq 1$; both members of $\epsilon_\circ$ are $\exp[-\mathrm{const}\, K^2 + O(K\log K)]$, so $9^{8m}\epsilon_\circ \leq L^{-16mK}$ times a pure number for $K \geq K_{\mathrm{P}}$, and the condition of Proposition 3.15 (a) holds. Each i lies in exactly one block; summing, $\|\cdot\|^8 \leq \mathsf{Op}_{8m}\prod_a \varpi_a^8 + L^{-8mK} \leq (\mathsf{Op}_{8m}+1)\prod_a \varpi_a^8$, because $\varpi_a \geq L^{-K}$. □

Corollary 3.25 (Seminorms of single functions)**.** Let $0 < \delta \leq \frac{1}{8}\mathsf{l}$, and for a cutoff K put $u = \lceil K/400\rceil$, $t = K - u$. There are C, p, K_0, functions of g, ℓ', δ, such that for all $(K,\beta) \in \mathfrak{d}(g)$ with $K \geq K_0$, every board of eight cells of side l on $T_{\ell'}$ with an offset in $a_{K-t}\mathbb{Z}^3$, and all data with support in one cell at distance $\geq \delta$ from its walls, with $\langle\cdot\rangle = \langle\cdot\rangle_{K,\ell',\beta}$:

(a) let $m^\circ, c^\circ, N^\circ$ be numbers; there is K_0°, a function of $g, \ell', \delta, m^\circ, c^\circ, N^\circ$, such that for $K \geq K_0^\circ$: if F is a real function of the cell that is a sum of at most seven insertions of orders ≥ 2, of types $(m, c, \hat{c}, N)$ with $m \leq m^\circ$, $c \leq c^\circ$, $\hat{c} \leq c^\circ$ and $N \leq N^\circ$, with weights $\leq L^{2K}\mathsf{b}_+$ and carriers within $4a_K$ of the support, and if for every mirror copy the oscillations of the copies of these insertions add up to at most $\omega \leq 1$, then $\|F - \langle F\rangle\|_{\mathrm{ch},\ell'} \leq C_8(\omega + L^{-K})$, with a pure number C_8. In (b)–(d), (a) is applied to insertions whose orders, constants, heights and counting numbers are pure numbers (Lemma 3.23 (b)), and K_0 is taken not smaller than K_0° at these numbers;

(b) $\|\mathsf{St}[\eta] - \langle\mathsf{St}[\eta]\rangle\|_{\mathrm{ch},\ell'} = \|\mathsf{Rm}[\eta] - \langle\mathsf{Rm}[\eta]\rangle\|_{\mathrm{ch},\ell'} \leq CK^p L^{-K/28}\|\eta\|$, and the same bound holds for $\mathfrak{K}[\eta] - \frac{1}{4}\mathfrak{N}[\mathsf{k}_\eta]$, whose torus mean is 0;

(c) $\|\Delta[\eta] - \langle\Delta[\eta]\rangle\|_{\mathrm{ch},\ell'} \leq CK^p L^{-K/36}\|\eta\|$, and the same holds for $\mathcal{T}^{\mathrm{c}}[\eta]$;

(d) $\|\mathcal{T}_K(H') - \langle\mathcal{T}_K(H')\rangle\|_{\mathrm{ch},\ell'} \leq CK^{2\mathfrak{p}_0} L^{K/100}|H'|_\infty$.

■□

Proof sketch. (a) The eighth power of the left side is the mean of the eight centred copies, which is the sum, over the partitions of the eight copies without blocks of one element, of products of their joint cumulants. Copies in different cells have carriers at sup distance $\geq 2\delta - 8a_K \geq \delta$. The copies of the insertions are insertions with the same weights, of orders $\leq m^\circ$, constants $\leq 2^{6m^\circ}c^\circ$, heights $\leq c^\circ$ and counting numbers $\leq 20N^\circ$ (Lemma 3.23 (a)). A joint cumulant of $r+1 \geq 2$ copies is a sum of at most 7^{r+1} joint cumulants of insertions, constants dropping out, each bounded by Proposition 3.15 (a); its condition holds for large K, as $r_1\bar{\mathsf{d}} \leq \frac{1}{2}r_*\bar{\mathsf{d}}$ is at most a number of the constants and $\mathsf{t}_\times \to 0$.

In its last two members $\bar{\mathsf{d}} \leq CL^{2K}$, $1/r_1 \leq CK^{3\mathfrak{p}_0}L^{3K}$, $\mathsf{t}_\times \leq e^2 C_{\mathrm{E},0}K\ell'^3 L^{3u}e^{-\delta L^u/M}$, $\sup|\mathfrak{J}| \leq CL^{5K}$, with C a function of ℓ', b_+, m°, c°, N° (Lemma 3.14 (c), (d), at these types: the numbers d_i, o_k and $1/r_{\mathfrak{J}}$ of Proposition 3.13 increase with the constant, the height and the counting number, and the orders are finitely many), and R_t lies below every power of L^{-K} (Lemma 3.14 (d)); so these members are $\leq 7^{-8}L^{-8K}$ for $K \geq K_0^\circ$, a function of g, ℓ', δ, m°, c°, N°.

Summing over the choices of the insertions, the products of their oscillations add up to at most $\mathsf{op}_{r+1}\omega^{r+1}$; so a block I of a partition contributes at most $\mathsf{op}_{\#I}\omega^{\#I} + L^{-8K} \leq (\mathsf{op}_{\#I}+1)(\omega+L^{-K})^{\#I}$, and summing over the partitions gives the bound with $C_8^8 = \sum_\pi\prod_{I\in\pi}(\mathsf{op}_{\#I}+1)$, the sum over the partitions π of eight elements without blocks of one element. (b) The mirror copy of a null term

is a null term, and the torus measure is invariant under lattice isometries; so Lemma 3.9 (a), (b), applied to one copy at a time, show that a joint cumulant of $r+1$ copies of $\mathsf{St}[\eta]$ is $(-1)^{r+1}$ times the joint cumulant of the corresponding copies of $\mathsf{Rm}[\eta]$; over a partition of the eight copies the signs multiply to $+1$, and the two eighth moments agree.

The family of $\mathsf{Rm}[\eta]$ has seven members (Lemma 3.23), whose copies have oscillations $\le CK^pL^{-K/28}\|\eta\|$ by Proposition 3.21 at $\tau=\frac14$, $\phi=\frac{1}{400}$, where $c_0'=\frac{1}{28}$, and by Lemma 3.14 (c); (a) applies after division by a multiple of $\|\eta\|$. By Lemma 3.9 (a), $\mathfrak{K}[\eta]-\frac14\mathfrak{N}[\mathsf{k}_\eta]=\mathsf{Rm}[\eta]-\frac32 a_K\mathcal{O}(w_\eta)+\frac14 c_{\mathsf{k}_\eta}$ is a constant plus six of these members; its torus mean vanishes by 8.10(b) and by Lemma 3.9 (b) at $Y=1$. (c) The two members of the family of $\Delta[\eta]$ have oscillations $\le CK^pL^{3u-K/28}\|\eta\|\le CK^pL^{-K/36}\|\eta\|$ (Lemma 3.23 (c) at $c_*=\frac{1}{28}$, as $\frac{3}{400}+\frac{1}{36}<\frac{1}{28}$); and $b\,\mathcal{T}^{\mathrm{c}}[\eta]=\mathsf{St}[\eta]-\Delta[\eta]$ with $b\ge\gamma^{-2}\ge4$, the seminorm being subadditive and homogeneous (B.1). (d) $\mathcal{T}_K(H')$ is one rough insertion, with oscillation $\le CK^{2\mathfrak{p}_0}L^{4u}|H'|_\infty$ (Lemma 3.23 (c)), and $4u\le\frac{K}{100}+4$. □

Lemma 3.26 (From one torus to every periodic Gibbs state)**.** There is $\mathsf{Q}=\mathsf{Q}(g,\ell')\ge1$ such that for all $(K,\beta)\in\mathfrak{d}(g)$:

(a) for every $\nu\in\mathcal{G}^{\mathrm{per}}_{K,\beta}$, every board with cells of side l (any offset), every finite set $\mathcal{K}_0$ of cells and all real functions $F_{\mathbf{k}}$ of the cells $\mathbf{k}\in\mathcal{K}_0$,

$$\Big|\nu\Big(\prod_{\mathbf{k}\in\mathcal{K}_0}F_{\mathbf{k}}\Big)\Big|\le\prod_{\mathbf{k}\in\mathcal{K}_0}\mathsf{Q}\,\|F_{\mathbf{k}}\|_{\mathrm{ch},\ell'};$$

in particular $|\nu(F)-c|\le\mathsf{Q}\|F-c\|_{\mathrm{ch},\ell'}$, and $|\langle F_1;F_2\rangle_\nu|\le2\mathsf{Q}^2\|F_1-c_1\|_{\mathrm{ch},\ell'}\|F_2-c_2\|_{\mathrm{ch},\ell'}$ for functions of two different cells and real c,c_1,c_2;

(b) the same bound holds for the torus measure $\langle\cdot\rangle_{K,\ell,\beta}$ of every side $\ell\in\mathfrak{L}(g)$, $\ell\ge\ell'$, in the place of ν, if the cells of $\mathcal{K}_0$ lie in one period box of T_ℓ.

■

Proof sketch. (a) Let $\ell_k=2L^{m_1+k}\in\mathfrak{L}(g)$. The domination of periodic Gibbs states (Proposition YMM1:91.9) gives $|\nu(\prod F_{\mathbf{k}})|\le\liminf_k\prod\|F_{\mathbf{k}}\|_{\mathrm{ch},\ell_k}$; the comparison of two sides (B.1 (e)) gives $\|F\|_{\mathrm{ch},\ell_k}\le\|F\|_{\mathrm{ch},\ell'}e^{|3(p_{\ell'}-p_{\ell_k})}$, $p_\ell=\ell^{-3}\log Z_{K,\ell,\beta}$; and the transfer statement N.1, with (319), taken at zero source, bounds the factor $e^{|3(p_{\ell'}-p_{\ell_k})}=Z^{1/8}_{K,\ell',\beta}Z^{-(\mathsf{l}/\ell_k)^3}_{K,\ell_k,\beta}$ by a number Q that depends on none of K,β,ℓ_k. Here Theorems YMM1:AJ and YMM1:AD enter, as a bound of stability; no reflection positivity of ν, and nothing of ν beyond periodicity, is used. The two-cell forms follow from $\langle F_1;F_2\rangle_\nu=\nu((F_1-c_1)(F_2-c_2))-\nu(F_1-c_1)\nu(F_2-c_2)$. (b) The chessboard estimate on T_ℓ for cells of one period box (B.1 (b)), the comparison of the two sides ℓ, ℓ', and the same bound of the pressures. □

Lemma 3.27 (A change of scale)**.** Let $z\ge1$ be an integer, $\Lambda=L^z$, $D^z:\mathbb{L}_K\to\mathbb{L}_{K-z}$, $x\mapsto\Lambda x$, $(D^zU)(D^z\mathfrak{b})=U(\mathfrak{b})$, $H^{(z)}(x)=H(\Lambda^{-1}x)$ and $\eta^{[z]}(x)=\Lambda\eta(\Lambda^{-1}x)$.

(a) $\mathcal{T}_K(H)=\Lambda\,\mathcal{T}_{K-z}(H^{(z)})\circ D^z$; $(H^{\mathrm{cons}}[\eta])^{(z)}=H^{\mathrm{cons}}[\eta^{[z]}]$; $\|\eta^{[z]}\|\le\Lambda\|\eta\|$ for $\Lambda\ge1$, $|H^{(z)}|_\infty=|H|_\infty$, and supports are multiplied by Λ.

(b) D^z_* maps $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ onto $\mathcal{G}^{\mathrm{per}}_{K-z,\beta}$, and the torus measure of T_ℓ at (K,β) to that of $T_{\Lambda\ell}$ at $(K-z,\beta)$.

(c) Let $0<g\le\gamma$, and let g_1',g_2' be the reference couplings with $g_1'^{-2}=\Lambda g^{-2}/2$, $g_2'^{-2}=L\Lambda g^{-2}/4$. For every $(K,\beta)\in\mathfrak{d}(g)$ with $K>z$ there is $\iota\in\{1,2\}$ with $(K-z,\beta)\in\mathfrak{d}(g_\iota')$.

(d) If $2\mathsf{l}_\iota$ is the least side at g_ι', then $\mathsf{l}_\iota/\Lambda\to0$ and $g_\iota'\to0$ as $z\to\infty$; so $g_\iota'\le\gamma^{\mathrm{sd}}_W\le\gamma^{\mathrm{ref}}_W$ for large z.

■

Proof sketch. (a) $x(D^zp)=\Lambda x(p)$, $x_{D^z\mathfrak{b}}=\Lambda x_{\mathfrak{b}}$, plaquette and bond variables are carried, and $a^{-1}_{K-z}=\Lambda^{-1}a_K^{-1}$; insert in Definition 3.1 (1). The derivatives of orders $0,1,2$ of $\eta^{[z]}$ get the factors $\Lambda,1,\Lambda^{-1}$, and $\partial\eta^{[z]}=(\partial\eta)^{(z)}$. (b) D^z is a bijection of the bonds and plaquettes that keeps incidence;

the Gibbs kernel of a finite set of bonds depends on β and the plaquettes alone, not on the spacing; $D^z\tau_v = \tau_{\Lambda v}D^z$ carries periodicity to periodicity. (c) By Lemma 3.12 (a), $g^{-2} < b \le L(g^{-2}+\bar B)$. As $g_2'^{-2} > g_1'^{-2} \ge \frac{13}{2}g^{-2}$, $g_2' < g_1' < g \le \gamma$ are reference couplings.

With $LB_\sharp = (L-1)\bar B$: $I(g_1') = (\Lambda g^{-2}/2 + \bar B, L\Lambda g^{-2}/2 + (L-2)\bar B]$ and $I(g_2') = (L\Lambda g^{-2}/4 + \bar B, L^2\Lambda g^{-2}/4 + (L-2)\bar B]$; since $\bar B < \gamma^{-2}$ (equation YMM1:(1523)), $\gamma^{-2} \le g^{-2}$ and $L \ge 13$, these two intervals overlap and cover $(\Lambda g^{-2}, L\Lambda(g^{-2}+\bar B)] \ni \Lambda b$. For $b' \in I(g')$ and every K' the pair $(K', L^{K'}b')$ is a first-passage datum at g' with label b' (Corollary YMM1:74.2, at the reference coupling $g' \le \gamma$); take $K' = K - z$, $b' = \Lambda b$: $L^{K-z}\Lambda b = \beta$. (d) By the definition of the sides (YMM1:(1528)) through the cube-size function R of YMM1:74, which grows like a power of $\log x$, the least side at g_ι' grows like a power of $z\log L + \log(g^{-2}+\bar B)$, while $\Lambda = L^z$; and $g_\iota'^{-2} \ge \Lambda g^{-2}/2 \to \infty$. □

Lemma 3.28 (Schwarz at a lattice mirror; uniform boundedness)**.** (a) Let $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, μ_0 a direction, $c \in a_K(\mathbb{Z} + \frac12)$, θ_c the reflection in $\{x_{\mu_0} = c\}$, and F, G real bounded Borel local functions of the bonds in $\{x_{\mu_0} > c\}$, resp. in $\{x_{\mu_0} < c\}$. Then $\langle \theta_c F; F\rangle_\nu \ge 0$, $\langle \theta_c G; G\rangle_\nu \ge 0$ and $|\langle F; G\rangle_\nu| \le \|F\|_{\nu,c}\|G\|_{\nu,c}$, where $\|F\|_{\nu,c} = \langle \theta_c F; F\rangle_\nu^{1/2}$.

(b) Let ρ_j be probability measures on the configurations of $\mathbb{L}_{K_j}$ such that

$$\lim_j \langle \mathcal{T}_{K_j}(H); \mathcal{T}_{K_j}(H')\rangle_{\rho_j}$$

exists for all $H, H' \in C_c(\mathbb{R}^3; V)$ with disjoint supports. For disjoint compact sets A, A' there is $C_2(A, A') < \infty$ with

$$|\langle \mathcal{T}_{K_j}(H); \mathcal{T}_{K_j}(H')\rangle_{\rho_j}| \le C_2(A, A')|H|_\infty |H'|_\infty$$

for all j and all continuous H, H' that vanish off A, A'.

■

Proof sketch. (a) ν is invariant under θ_c and reflection positive at the bond mirror $\{x_{\mu_0} = c\}$ (YMM1:103.4); so $(A, B) = \nu(\overline{\theta_c A}\, B)$ is a positive semidefinite Hermitian form on the bounded local functions of the closed upper side. With $F_0 = F - \nu(F)$ and $G_0 = G - \nu(G)$: $\langle F; G\rangle_\nu = (\theta_c G_0, F_0)$, $(F_0, F_0) = \langle \theta_c F; F\rangle_\nu$, $(\theta_c G_0, \theta_c G_0) = \langle \theta_c G; G\rangle_\nu$; Schwarz's inequality. (b) On the Banach spaces E_A, $E_{A'}$ of continuous V-valued functions vanishing off A, A' with the sup norm, the bilinear forms $B_j(H, H') = \langle \mathcal{T}_{K_j}(H); \mathcal{T}_{K_j}(H')\rangle_{\rho_j}$ are bounded ($|\mathcal{T}_K(H)| \le a_K^{-1}(2\#\{p : x(p) \in A\} + \#\{\mathfrak{b} : x_{\mathfrak{b}} \in A\})|H|_\infty$) and converge at every point, so they are bounded at every point; the principle of uniform boundedness, applied twice, gives $\sup_j \|B_j\| < \infty$. □

3.5. **Proofs of the results.**

Proof of Theorem H. Step 1: parameters. For (i), (ii) take $c_* = \frac{1}{14}$, for (iii) $c_* = \frac{1}{28}$, and $\phi = (c_* - c)/(4n-1) \le \frac{1}{84}$, with u, t and the other parameters of Lemma 3.23.

Step 2: pieces. Let $\chi_i(x) = \prod_\mu \psi(x_\mu/r_0 - i_\mu)$, $i \in \mathbb{Z}^3$, $r_0 = \mathsf{l}/(8n)$, with $0 \le \psi \in C^\infty(\mathbb{R})$, $\operatorname{supp}\psi \subset (-1, 1)$, $\sum_{j\in\mathbb{Z}} \psi(\cdot - j) = 1$: a smooth partition of unity with $\operatorname{supp}\chi_i$ of sup diameter $\le 2r_0$. All the functions X_a are linear in their data, A^ν is linear and cumulants are multilinear; so each left side is a sum of at most $(2R/r_0 + 3)^{3n}$ terms in which each datum is replaced by a piece $\chi_i\eta_a$ or $\chi_i H_a$, with $\|\chi_i\eta\| \le C_\chi\|\eta\|$ and $|\chi_i H|_\infty \le |H|_\infty$. The pieces are pieces of the data: $H^{\mathrm{cons}}[\chi_i\eta]$, not $\chi_i H^{\mathrm{cons}}[\eta]$. In one term the supports have sup diameter $\le \mathsf{l}/(4n)$ and are pairwise $\ge \mathsf{d}$ apart; no relation between the size of the pieces and d is asked.

Step 3: board. Lemma 3.22 (b) with $h = a_{K-t} = L^{-u} < \mathsf{l}/(2n)$ gives an offset in $a_{K-t}\mathbb{Z}^3$ for which every X_a has its support in one cell, at distance $\ge \delta = \mathsf{l}/(8n)$ from its walls; no wall needs to separate two supports.

Step 4: subsets. Let $c_a = \langle \mathsf{X}_a \rangle_{K,\ell',\beta}$ and $\mathsf{e}_a = \mathsf{Q}\,\mathsf{C}_n \varpi(\mathsf{X}_a)\mathsf{n}(\mathsf{X}_a)$. Grouping the factors by cells, Lemma 3.26 (a) and Proposition 3.24 in each cell give, for every $B \subset \{1,\dots,n\}$,

$$\Big|\nu\Big(\prod_{a\in B}(\mathsf{X}_a - c_a)\Big)\Big| \le \prod_{a\in B} \mathsf{e}_a.$$

Step 5: centring. $A^\nu[\mathsf{X}_a] = (\mathsf{X}_a - c_a) - \delta_a$, $\delta_a = \nu(\mathsf{X}_a) - c_a$, and $|\delta_a| \le \mathsf{e}_a$ by Step 4 at $B = \{a\}$. Expanding the product gives 2^n terms, each of modulus $\le \prod_{a=1}^n \mathsf{e}_a$: every term carries the factor of every entry, the small ones among them.

Step 6: cumulants. A joint cumulant of order $n \ge 2$ is unchanged when constants are subtracted from its entries, and it is a sum over partitions of products of moments; so $|\langle \mathsf{X}_1;\dots;\mathsf{X}_n\rangle_\nu| \le \mathsf{op}_n \prod_a \mathsf{e}_a$.

Step 7: exponent. By Lemma 3.23 (c), $\prod_a \varpi(\mathsf{X}_a) = C_\omega^n K^{np_\omega} L^E$, and since $u \le \phi K + 1$ and $n - n_1 \le n_1(n-1)$,

$$E = n_1(3u - c_* K) + 4u(n-n_1) \le -n_1 K(c_* - (4n-1)\phi) + 4n = -cn_1 K + 4n.$$

Step 8: constants. Both bounds hold with $p = np_\omega$ and

$$C = (2R/r_0 + 3)^{3n} \max\{2^n, \mathsf{op}_n\}(\mathsf{Q}\mathsf{C}_n C_\omega C_\chi)^n L^{4n}$$

, for $K \ge K_0 = \max_{m\le n} K_{\mathrm{P}}(m, \mathsf{l}/(8n))$, enlarged so that $L^{-u} < \mathsf{l}/(2n)$, whenever $\mathsf{d}L^u \ge K^2$. The distance has entered only through this condition. For (iii) this is the assertion; for (i), (ii), K_0 is enlarged so that $\mathsf{d}L^{\lceil \phi K\rceil} \ge K^2$ for all $K \ge K_0$. The cases of (ii) follow also from (i): $\Delta = \mathsf{St} - b\,\mathcal{T}^{\mathrm{c}}$ with $b \le \mathsf{b}_+$ in a multilinear product; $\mathsf{St}[\eta]$ and $-\mathsf{Rm}[\eta]$ have equal centred products and cumulants with distant entries (Lemma 3.9 (c)); and a joint cumulant is a sum over partitions of products of the moments of Step 4. (iv) is Step 4 for $\mathsf{X}_a = \mathfrak{K}[\eta_a]$, $B = \{1\},\{1,2\}$, $c_a = \langle \mathfrak{K}[\eta_a]\rangle_{K,\ell',\beta} = 0$ (8.10(b)). □

Proof of Corollary 3.4. The bounds in (b), (c), (d) and the first bound in (a) are Theorem H (i), (ii) at $n = 2$: with $n_1 = 2$ for (a), (b) and for (c) with $Z = \mathsf{St}[\eta'], \Delta[\eta']$; with $n_1 = 1$ for (c) with $Z = \mathcal{T}_K(H')$ and for (d). The equality in (a) is Lemma 3.9 (c), applied twice in ν, first with $Y = A^\nu[\mathsf{St}[\eta']]$ and then with $Y = A^\nu[\mathsf{Rm}[\eta]]$ ($\mathsf{d} > 8a_K$ for large K). For the mean and the products in (a), Step 4 of the proof above is applied to $\mathsf{X}_a = \mathfrak{K}[\cdot]$ with $c_a = \langle \mathfrak{K}[\cdot]\rangle_{K,\ell',\beta} = 0$, the orbital remainder having mean zero under every torus measure (8.10(b)): at $B = \{1\}$ it bounds $|\nu(\mathfrak{K}[\eta'])|$, at $B = \{1,2\}$ it bounds $|\nu(\mathfrak{K}[\eta']\mathfrak{K}[\eta])|$, and the product of the means is bounded by the product of the two bounds at $B = \{1\}$. □

Proof of Theorem I. Step 0: the number z. With the notation of Lemma 3.27, let $z \ge 1$ be the least integer such that $g'_\iota \le \gamma_W^{\mathrm{ref}}$ for $\iota = 1,2$ and $\mathsf{l}_2 \le \Lambda\mathsf{d}/2$, $2\mathsf{l}_\iota$ the least side at g'_ι; it exists by Lemma 3.27 (d), and $\mathsf{l}_1 \le \mathsf{l}_2$. It is a function of g and d.

Step 1: the labels. Let $(K,\beta) \in \mathfrak{d}(g)$, $K > z$. By Lemma 3.27 (c) there is ι with $(K',\beta) \in \mathfrak{d}(g')$, $K' = K - z$, $g' = g'_\iota \le \gamma_W^{\mathrm{ref}}$. Put $\mathsf{l} = \mathsf{l}_\iota$, $\ell_0 = 2\mathsf{l}$, $\delta' = \mathsf{l}/(8q)$.

Step 2: the change of scale. By Lemma 3.27 (a), (b), the left members of (S), (T) are Λ^q times the same expressions at (K',β), for the state $\mathfrak{s} = D_*^z \nu \in \mathcal{G}^{\mathrm{per}}_{K',\beta}$, resp. the torus measure of $T_{\Lambda\ell}$, the field $\eta' = \eta^{[z]}$ and the weights $H'_a = H_a^{(z)}$; $\|\eta'\| \le \Lambda\|\eta\|$, $|H'_a|_\infty = |H_a|_\infty$, and the supports are pairwise at sup distance $\ge \Lambda\mathsf{d} \ge 2\mathsf{l}$. In (T), two points of T_ℓ have sup distance $\le \ell/2$, so $\mathsf{d} \le \ell/2$, $\mathsf{l} \le \Lambda\ell/4$, and $\Lambda\ell = 2L^{m+z}$ is a side at g'.

Step 3: pieces. A partition of unity of mesh $\mathsf{l}/(8q)$ for η' and a partition into boxes of the same size for the H'_a cut each datum into at most $P = (2\Lambda R/\delta' + 3)^3$, resp. $(\Lambda\ell/\delta')^3$, pieces; by multilinearity it is enough to bound one choice of pieces, η'_1 and H''_a, of sup diameters $\le \mathsf{l}/(4q)$ and pairwise at sup distance $\ge 2\mathsf{l}$, and to multiply by P^q.

Step 4: a board. Lemma 3.22 (b) with $h = a_{K'-t'}$, $t' = K' - \lceil K'/400\rceil$, gives a board of side l with an offset in $a_{K'-t'}\mathbb{Z}^3$ in which every piece lies in one cell at distance $\ge \delta'$ from its walls; a cell has diameter $\mathsf{l} < 2\mathsf{l}$, so the cells of different pieces are different, in (T) also modulo the period of $T_{\Lambda\ell}$.

Step 5: the seminorms on the least torus at g'. Let $\langle\cdot\rangle_0 = \langle\cdot\rangle_{K',\ell_0,\beta}$, $\Phi_1 = \mathcal{T}_{K'}(H^{\mathrm{cons}}[\eta'_1]) - \langle\cdot\rangle_0$ and $\Phi_a = \mathcal{T}_{K'}(H''_a) - \langle\cdot\rangle_0$, $a \geq 2$. At the coupling g', with the fixed side ℓ_0, Corollary 3.25 (c) (that is, Lemma 3.23 (c) at $c_* = \frac{1}{28}$, $\phi = \frac{1}{400}$, $u' = \lceil K'/400 \rceil$, and Proposition 3.24 at $m = 1$) gives $\|\Phi_1\|_{\mathrm{ch},\ell_0} \leq CK'^p L^{3u'-K'/28}\|\eta'_1\| \leq CK'^p L^{-K'/36}\|\eta'_1\|$, since $\frac{3}{400} + \frac{1}{36} < \frac{1}{28}$. For a spectator, $\|\Phi_a\|^8_{\mathrm{ch},\ell_0}$ is the mean of the eight centred copies of $\mathcal{T}_{K'}(H''_a)$ in the eight cells, carried by closed sets pairwise at sup distance $\geq 2\delta'$ on T_{ℓ_0}; the mean of a product of centred functions is the sum, over the partitions without singletons, of products of joint cumulants, and the uniform bound of joint cumulants on a torus (item (i) of the subsection on the input, Lemma C.5 (b)), at the coupling $g' \leq \gamma^{\mathrm{ref}}_W$, the side $\ell_0 \in \mathfrak{L}(g')$ and δ', bounds every joint cumulant of $2 \leq r \leq 8$ of these copies by $\mathsf{K}^{\mathrm{ub}}_r(g', \ell_0, \delta') \prod 60|H''_a|_\infty$ for $K' \geq s_r(\delta') + 2$ and $3a_{K'} \leq \delta'$, a number that depends neither on K' nor on β.

So $\|\Phi_a\|_{\mathrm{ch},\ell_0} \leq 60\mathsf{M}_8^{1/8}|H_a|_\infty$ with a number M_8 that does not depend on K'.

Step 6: from T_{ℓ_0} to $\mathfrak{s}$. Lemma 3.26, at the coupling g', (a) for $\mathfrak{s} = D^z_*\nu$ and (b) for the torus measure of $T_{\Lambda\ell}$, gives for every non-empty $B \subset \{1, \dots, q\}$: $|\mathfrak{s}(\prod_{a\in B} \Phi_a)| \leq \prod_{a\in B} \mathsf{Q}'\|\Phi_a\|_{\mathrm{ch},\ell_0}$.

Step 7: the two polynomials. The joint cumulant of the q functions is a sum over the partitions of $\{1, \dots, q\}$ of products of the moments of Step 6, and the centred product is a sum of 2^q products of such moments; in each term the index 1 stands in exactly one factor. So both are at most $\max\{2^q, \mathsf{op}_q\}\, \epsilon \prod_{a\geq 2} \mathsf{m}_a$, with $\epsilon = \mathsf{Q}'CK'^p L^{-K'/36}\|\eta'_1\|$ and $\mathsf{m}_a = 60\mathsf{Q}'\mathsf{M}_8^{1/8}|H_a|_\infty$.

Step 8: back to (K, β). The left members of (S), (T) are at most

$$\Lambda^q P^q \max\{2^q, \mathsf{op}_q\}\mathsf{Q}'C\Lambda C_\chi K^p L^{z/36} L^{-K/36}\|\eta\| \prod_{a\geq 2} 60\mathsf{Q}'\mathsf{M}_8^{1/8}|H_a|_\infty$$

; the numbers depend on g'_ι, I_ι, q, z and R, resp. ℓ, hence on g, q, d and R, resp. ℓ; take the larger over $\iota = 1, 2$. In (T), $\mathcal{T}_K$ of a weight on T_ℓ carried by one cell is $\mathcal{T}_K$ of its lift, taken through the periodisation. A spectator costs here a number independent of the cutoff, and every piece has a cell of its own: these are the two points of the change of scale. □

Proof of Proposition 3.5. (a) By Lemmas 3.9 (a) and 3.10, $\mathsf{Rm}[\eta]$ is a sum of seven insertions: $\mathcal{S}[b\eta]$, of order 3 and weight $\leq L^{2K} b \sup|\eta|$; four of order 2 with weights $\leq (3 + 5b)\|\eta\|$; two of orders 3 and 4 with weights $\leq L^K b\|\eta\|$; their sites lie within $\frac{7}{2}a_K$ of $\operatorname{supp}\eta$. The mirror copies are insertions of the same orders and weights (Lemma 3.23 (a), whose part on insertions holds for every diagonal isometry of the lattice), and $\mathcal{S}[b\eta] \circ \mathsf{r}_\kappa^{-1} = \mathcal{S}[b\eta^{\mathsf{r}}]$. In the frame of Proposition 3.21 (a) at the given parameters, the oscillation of every copy of $\mathcal{S}[b\eta]$ is $\leq C\mathsf{b}_+\mathsf{H}(\eta)K^p L^{-c''K}$ (Proposition 3.21 (b) for the field η^{r}), and those of the other six are $\leq CK^{2\mathfrak{p}_0}L^{4u-K}$ and $\leq CK^{3\mathfrak{p}_0}L^{4u-K/2}$ times $\|\eta\|$ (Lemma 3.14 (b), (c), at a depth $\phi \leq \frac{1}{4}$); as $\phi < \frac{1}{6}\psi$ and $\psi < \frac{2}{9}$, $\frac{1}{2} - 4\phi > c''$.

These bounds depend on the type, the weight and H alone, not on the cell or the offset. The carriers of copies in different cells are $\geq 2r - 8a_K$ apart; Proposition 3.15 (b), whose conditions hold for large K, since $\mathsf{t}'_\times \leq CL^{3u}e^{-rL^u/M}$ lies below every power of L^{-K} and $\mathsf{R}_t \leq \frac{1}{2}$ from a cutoff on that depends on m_1, b_+ and ϕ (Lemma 3.14 (d)), bounds every joint cumulant of q such copies, $2 \leq q \leq 8$, by $(\frac{1}{2} + \mathsf{op}'_q\mathsf{Bl}_q)\prod_a \epsilon_a$ plus the discarding term, which is smaller for large K (Lemma 3.14 (d)). Indeed, every number ϵ of the statement is at least L^{-K} times $\mathsf{b}_+\mathsf{H}(\eta)$, resp. $\|\eta\|$, as $C \geq 1$, the powers of K there are ≥ 1 and every exponent of L there is $\geq -K$, while every copy $\mathfrak{J}$ has $1/r_{\mathfrak{J}} \leq CL^{2K}$ and $\sup|\mathfrak{J}| \leq CL^{5K}$ times the same norm (Lemma 3.14 (c), (d), with the weights above), and $\mathsf{t}'_\times$ and R_t lie below every power of L^{-K}; so for large K, $2E_0\mathsf{t}'_\times \prod_{a\in I}(q/r_{\mathfrak{J}_a}) \leq \prod_{a\in I}\epsilon_a$ for every set I of at least two of the q copies, which is the last condition of Proposition 3.15 (b), and $4\,\mathsf{op}'_q\mathsf{R}_t\prod_a \sup|\mathfrak{J}_a| \leq \frac{1}{2}\prod_a \epsilon_a$, which absorbs the discarding term; as op'_q and Bl_q increase with q, the bound $(\frac{1}{2} + \mathsf{op}'_q\mathsf{Bl}_q)\prod_a \epsilon_a + \frac{1}{2}\prod_a \epsilon_a$ gives the factor $1 + \mathsf{op}'_8\mathsf{Bl}_8$ of the statement.

The eighth moment of the centred copies is the sum, over the 715 partitions of eight elements without singletons (each with at most four blocks), of products of joint cumulants of copies, each a

sum of at most $7^{\#I}$ cumulants of insertions; this gives the bound. It is ≥ 0 by reflection positivity of the torus measure at a wall (Section B.1). (b) The same without the cubic member, at any $0 < \phi < \frac{1}{8}$: the six exponents are $4\phi - 1$ and $4\phi - \frac{1}{2}$. For $\mathcal{S}[\Xi]$: the copies $\mathcal{S}[\Xi^{\mathsf{r}}]$, Proposition 3.21 (b), Proposition 3.15 (b) and the moments as in (a); its mean is 0 by Lemma 3.10 (c). (c) For first-passage data the labels lie in $[\gamma^{-2}, X_g + \bar{B}]$ and $MR(\mathsf{b}_+) \leq L^{m_1}$ for every side (Lemma 3.12 (a)). At $\psi = \frac{1}{5}$, $\kappa_\star = \frac{9}{10}$ the four numbers are $\frac{1}{10}$, $\frac{3}{25}$, $\frac{1}{10} - \frac{1}{5}\tau$, $\frac{1}{10} - 3\phi$. For the mirrored pair let $c < c'' < \frac{1}{10}$, $\delta_0 = \min\{\frac{1}{2}\mathsf{d}, \mathsf{l}\}$, and cut η into at most $C(R/\delta_0)^3$ pieces of sup diameter $\leq \frac{1}{8}\delta_0$, and $\theta\eta$ into their mirror images. A piece of $\theta\eta$ and a piece of η are $\geq \mathsf{d} \geq 2\delta_0$ apart, so in one direction their projections are $\geq \delta_0$ apart, and Lemma 3.22 (a) with $h = a_K$ puts them in two different cells of a board with an offset in $a_K\mathbb{Z}^3$, at distance $\geq \frac{1}{16}\delta_0$ from the walls.

By (a), the chessboard seminorm of the centred remainder of each piece is $\leq CK^pL^{-c''K}\|\eta\|$, and Lemma 3.26 (a) for two cells bounds the covariance of the two pieces by $2\mathsf{Q}^2$ times the product. The equality with the stress insertions is Lemma 3.9 (c), used twice. For $\mathfrak{K}$: $\mathfrak{K}[\eta] = \mathsf{Rm}[\eta] - \frac{3}{2}a_K\mathcal{O}(w_\eta) + \frac{1}{4}\mathfrak{N}[\mathsf{k}_\eta] + \frac{1}{4}c_{\mathsf{k}_\eta}$; the null terms and the constant drop out of the covariance (Lemma 3.9 (b)), and the seminorm of the centred $a_K\mathcal{O}(w_\eta)$ of a piece is $\leq CK^{2\mathfrak{p}_0}L^{4u-K}\|\eta\|$ as in (b); the seminorm is subadditive. □

Proof of Theorem J. (i) The supports are compact and pairwise disjoint, hence pairwise at a positive sup distance d, and they lie in a ball of radius R. By Definition 3.3 and Theorem H (i) with $n_1 = 1$, $\mathsf{X}_1 = \mathcal{T}^{\mathrm{c}}[\eta]$,

$$\begin{aligned}|\sigma(H^{\mathrm{cons}}[\eta], H_2, \dots, H_n)| &= \lim_j \Big|\rho_j\Big(A^{\rho_j}[\mathcal{T}^{\mathrm{c}}[\eta]] \prod_{a\geq 2} A^{\rho_j}[\mathcal{T}_{K_j}(H_a)]\Big)\Big| \\ &\leq \lim_j CK_j^pL^{-cK_j}\|\eta\| \prod_{a\geq 2}|H_a|_\infty = 0.\end{aligned}$$

(ii) Take $n = 2$; and $\partial_i(\theta\eta)^j(x) = \Theta_{ii}\Theta_{jj}(\partial_i\eta^j)(\Theta x)$ gives $H^{\mathrm{cons}}[\theta\eta] = \theta H^{\mathrm{cons}}[\eta]$, with support in $\{x_3 < 0\}$. (iii) By Lemma 3.9 (a) and $\mathsf{St}[\eta] = b\,\mathcal{T}^{\mathrm{c}}[\eta] + \Delta[\eta]$, identically in the configuration, $\mathfrak{K}[\eta] = \mathcal{N}_\eta - b\,\mathcal{T}^{\mathrm{c}}[\eta] - \Delta[\eta] - \frac{3}{2}a_K\mathcal{O}(w_\eta)$, and likewise for $\theta\eta$; the only null term is $\mathcal{N}_\eta$, there is no constant, and the null terms drop out of the covariance by Lemma 3.9 (b). Hence $\langle\mathfrak{K}[\theta\eta];\mathfrak{K}[\eta]\rangle_{\rho_j} - b_j^2\langle\mathcal{T}^{\mathrm{c}}[\theta\eta];\mathcal{T}^{\mathrm{c}}[\eta]\rangle_{\rho_j}$ is a sum of covariances each of which has a factor Δ or $a_K\mathcal{O}(w)$. The family of such a factor has oscillations $\leq CK^pL^{3u-c_*K}$ by Lemmas 3.11, 3.14 and 3.18 alone; the other factor is either of the same kind or $b\,\mathcal{T}^{\mathrm{c}}[\cdot] = \mathcal{T}_K(bH^{\mathrm{cons}}[\cdot])$, treated as a tensor field at the price CK^pL^{4u}.

Steps 2–7 of the proof of Theorem H at $n = 2$, $n_1 = 1$, with $\phi < c_*/7$, bound each covariance by $CK_j^pL^{(7\phi-c_*)K_j} \to 0$. With $\gamma^{-2} \leq b_j \leq \mathsf{b}_+$ (Lemma 3.12 (a)): if $\langle\mathfrak{K}[\theta\eta];\mathfrak{K}[\eta]\rangle_{\rho_j} \to 0$, then $\langle\mathcal{T}^{\mathrm{c}}[\theta\eta];\mathcal{T}^{\mathrm{c}}[\eta]\rangle_{\rho_j} \to 0$, which by Definition 3.3 is (N); conversely, (N) gives $\langle\mathfrak{K}[\theta\eta];\mathfrak{K}[\eta]\rangle_{\rho_j} \to 0$, and $\langle\mathsf{St}[\theta\eta];\mathsf{St}[\eta]\rangle_{\rho_j} \to 0$ because $\mathsf{St}[\eta] = \mathcal{N}_\eta - \mathfrak{K}[\eta] - \frac{3}{2}a_K\mathcal{O}(w_\eta)$ identically (Lemma 3.9 (a)), the null term dropping out and the cross terms with $a_K\mathcal{O}(w)$ tending to 0 by the same count. □

Proof of Theorem K. (i) Any side of $\mathfrak{L}(g)$ may serve as the fixed side: take $\ell' = \ell$, $c_* = \frac{1}{28}$, $\phi = (\frac{1}{28} - c)/(4q - 1) \leq \frac{1}{196}$; Lemmas 3.12, 3.14, 3.18 and Proposition 3.21 hold on every side at g. A partition of unity of T_ℓ into pieces of sup diameter $\leq \ell/8$ and multilinearity leave a bounded number of cumulants of pieces of η; each piece lifts to a datum on $\mathbb{R}^3$ in a cell of side $\ell/2$, at distance $\geq \ell/16$ from its walls, and, the formulas being local, its lattice functions on T_ℓ are the periodised ones, so that Lemmas 3.9, 3.11 and 3.23 (c), without mirror copies, hold on T_ℓ. By Lemma 3.9 (b) under $\langle\cdot\rangle_{K,\ell,\beta}$, the entry $\mathcal{T}_K(H^{\mathrm{cons}}[\eta])$ of the cumulant may be replaced by its family of nine insertions, the difference being null terms whose bonds the other entries do not depend on and a constant; a spectator $\mathcal{T}_K(H_a)$ is one rough insertion, of weight $\leq 3L^K|H_a|_\infty$, whose oscillation bound $CK^{2\mathfrak{p}_0}L^{4u}|H_a|_\infty$ depends on the weight and the type alone. The cumulant becomes a sum of at most nine cumulants of q insertions with carriers pairwise $\geq \mathsf{d} - 8a_K$ apart,

and Proposition 3.15 (a) on T_ℓ bounds each by

$$(\mathsf{op}_q C_\omega^q K^{qp_\omega} L^{3u-K/28+4u(q-1)} + L^{-qK}) \|\eta\| \prod_{a\geq 2} |H_a|_\infty, \qquad 3u - \tfrac{K}{28} + 4u(q-1) \leq -cK + 4q.$$

No board is needed. (ii) For $b \in I(g)$, Corollary YMM1:74.2 gives $(K, L^K b) \in \mathfrak{d}(g)$, with the label b, for every K. So (i) holds along $\beta = L^K b$, and the cumulants tend to 0; for Lipschitz weights with pairwise disjoint supports these are the joint cumulants $\langle \mathcal{T}_K(H_1); \dots; \mathcal{T}_K(H_q)\rangle_{K,\ell,L^K b}$ at $H_1 = H^{\mathrm{cons}}[\eta]$, whose limit as $K \to \infty$ is the torus limit functional $\mathcal{S}_q^{\ell,b}$ (item (iii) of the subsection on the input, Theorem BU (a), for $0 < g \leq \gamma_W^{\mathrm{ref}}$), and $H_\eta^{\mathrm{c}} = -H^{\mathrm{cons}}[\eta]$. At $H_a = h_a \mathbf{1}$, $\mathcal{T}_K(h_a \mathbf{1}) = \mathcal{O}(w_{h_a \mathbf{1}})$. □

Proof of Corollary 3.6. (i) Let $O_1, \dots, O_n$ be bounded open sets with pairwise disjoint closures; the closures are compact, of bounded sup diameters and pairwise at a positive sup distance. So the uniform bound of centred products in periodic Gibbs states (item (ii) of the subsection on the input, Theorem BV (a), at $\nu' = \nu$: beyond a threshold in the cutoff, for real bounded weights vanishing off closed sets of sup diameter $\leq \varrho_0$ that are pairwise at sup distance $\geq 2\delta_0$, the bound $C_n^{\mathrm{lc}}(g, \delta_0, \varrho_0) \prod_a |H_a|_\infty$, uniform in the states and the positions) gives $|\sigma_j(H_1, \dots, H_n)| \leq C_n \prod_a |H_a|_\infty$ uniformly in j, for K_j beyond the threshold of that statement, for all real bounded weights H_a vanishing off O_a, where $\sigma_j(H_1, \dots, H_n) = \nu_j(\prod_a A^{\nu_j}[\mathcal{T}_{K_j}(H_a)])$.

A diagonal argument over a countable family of tuples of C_c^1 fields, dense in the sup norm, and the compactness of the range of the labels (Lemma 3.12 (a)) give a subsequence along which $a_{K_j}\beta_j \to b_*$ and σ_j converges at all tuples of C_c^1 fields with disjoint supports; σ_j is n-linear, and C_c^1 is sup-norm dense in the continuous functions vanishing off such a set, so (σ_j) is a Cauchy sequence at every C_c tuple. A subsequence of a defining sequence defines the same σ, and its labels converge along a further subsequence. The bound passes to σ; as the number of item (ii) depends on the sup diameters of the single supports and on a lower bound of their distances, not on their positions, the same statement gives the second form, for tuples of any extent, and this form passes to σ in the same way.

A lattice isometry r carries $\mathcal{T}_K(H)$ to $\mathcal{T}_K(\mathsf{r}H)$: it permutes the plaquettes and the bonds, and $q_{\mathfrak{b}}$ changes by the signs that R gives to the two directions normal to $\mathfrak{b}$. The ν_j are invariant under the reflections in the lattice mirrors of the nine families; products of two of them give translations of the lattice, and those through a site generate the cubic group. For $v \in \mathbb{R}^3$ take lattice vectors $v_j \to v$ and use the uniform bound and the uniform continuity of the weights; this gives the covariance. The single entry gives $\nu_j(A^{\nu_j}[\,\cdot\,]) = 0$, and the trace part is the definition, $\mathcal{T}_K(f\mathbf{1}) = \mathcal{O}(w_{f\mathbf{1}})$.

The limits at g of item (iv) of the subsection on the input are tensor limits in the sense of Definition 3.3: the lattice field $O_K^T(H)$ displayed in the subsection on the input, which weights the action density a_p of each plaquette with $H_{\rho(p)\rho(p)}$ at its centre and the bond form $q_{\mathfrak{b}}$ with $H_{\lambda_{\mathfrak{b}}\lambda'_{\mathfrak{b}}}$ at the midpoint of the bond, is $\mathcal{O}(w_H) + Y[\mathsf{w}_H] = \mathcal{T}_K(H)$, with the weights read at the same points and the normalisations of Definition 3.1 (1), those limits are limits of products of centred entries along first-passage data at g with $K_j \to \infty$, and the states are periodic Gibbs states. (ii) Reflection positivity at the nine families of mirrors is in item (iv) of the subsection on the input (Theorem BV (c)), and the Hilbert space with $H \geq 0$ and the cone $\mathcal{P}(\{E < |q|\}) = 0$ of the joint spectral measure $\mathcal{P}$ of (H, P_1, P_2), which contains $H \geq |P_1|$ and $H \geq |P_2|$, in item (v) there (Theorem BW (a)); we recall the argument. Reflection positivity of the ν_j at the nine families of lattice mirrors and their invariance under the reflections in these mirrors (YMM1:103.4) give positivity at lattice mirrors $\{\mathsf{n} \cdot x = c_j\}$, $c_j \to c$; a lattice reflection acts on $\mathcal{T}_K(H)$ as on its weight; the uniform bound of (i) and the uniform continuity of C_c^1 weights pass this to the limit; the covariance of σ under all translations is that of (i).

The Hilbert space is obtained by quotient and completion. For a lattice translation by k steps normal to the mirror, iterated Schwarz inequalities in the positive form, $|u(k)| \leq u(0)^{1-2^{-n}} |u(2^n k)|^{2^{-n}}$

for $u(k)=\langle A,\tau_{ka_Ke_3}A\rangle$, give $|\sigma(\theta\bar F'\cdot\tau_{te_3}F)|\le\|[F']\|\,\|[F]\|$; so e^{-tH} is well defined, a semigroup of self-adjoint contractions, weakly continuous by the uniform bound, hence e^{-tH} with $H\ge0$, $H\Omega=0$; the translations parallel to the mirror act unitarily and commute with it, and a countable dense family gives separability. The square cone, $k\in\{1,2\}$, comes from the five-point inequality of periodic Gibbs states (Lemma F.5, at the directions 3, k and the lattice mirror $\{x_3=0\}$): for $\nu\in\mathcal G^{\mathrm{per}}_{K,\beta}$, every bounded Borel local function A of the bonds in $\{x_3\ge0\}$, θ_0 the reflection in $\{x_3=0\}$, $u_\nu(w)=\nu(\overline{\theta_0A}\,\tau_wA)$ for $w\in a_K\mathbb Z^3$, and every $\mathtt t\in a_K\mathbb N$,

$$u_\nu(0)-4u_\nu(\mathtt te_3)+u_\nu(2\mathtt te_3)+u_\nu(\mathtt te_3+\mathtt te_k)+u_\nu(\mathtt te_3-\mathtt te_k)\ge0;$$

it rests on the reflection positivity of ν at $\{x_3=0\}$, at $\{x_3=\frac12a_K\}$ and at the diagonal mirror $\{x_3+x_k=0\}$ and on its invariance under $a_K\mathbb Z^3$ (the lattice energy–momentum inequality, Proposition YMM1:99.3 and Lemma F.5). Let $F=\sum_ic_iX_i$ be a finite complex combination of tuples $X_i=(H_{i,a})_a$ of C^1_c fields with pairwise disjoint supports in $\{x_3>0\}$, and take $\nu=\nu_j$, $A=A_j=\sum_ic_i\prod_aA^{\nu_j}[\mathcal T_{K_j}(H_{i,a})]$, for large j a local function of the bonds in $\{x_3>0\}$, and $\mathtt t=\mathtt t_j\in a_{K_j}\mathbb N$ with $\mathtt t_j\to t>0$. As ν_j is invariant under the lattice reflections and translations, which act on $\mathcal T_K(H)$ as on its weight, $u_{\nu_j}(w)=\sum_{i,l}\bar c_ic_l\,\sigma_j(\theta X_i\cdot\tau_wX_l)$, with σ_j as in (i); by the uniform bound of (i) and the uniform continuity of the weights, $u_{\nu_j}(w_j)\to u(w)=\sigma(\theta\bar F\cdot\tau_wF)$ for $w_j\to w$. So $u(0)-4u(te_3)+u(2te_3)+u(te_3+te_k)+u(te_3-te_k)\ge0$ for every $t>0$; with $\psi=[F]$, $e^{-tH}[F]=[\tau_{te_3}F]$ and $e^{itP_k}[F]=[\tau_{te_k}F]$ this reads

$$\langle\psi,\{1-4e^{-tH}+e^{-2tH}+e^{-tH}(e^{itP_k}+e^{-itP_k})\}\psi\rangle=\int4e^{-tE}\Big(\sinh^2\frac{tE}{2}-\sin^2\frac{tq_k}{2}\Big)\,d\langle\psi,\mathcal P\psi\rangle\ge0,$$

$\mathcal P$ the joint spectral measure of (H,P_1,P_2). The classes $[F]$ are dense in $\mathcal H(\sigma)$; so the lemma of slope one at small steps (Lemma F.5), applied to the image of $\mathcal P$ under $(E,q_1,q_2)\mapsto(E,q_k)$, gives $\mathcal P(\{E<|q_k|\})=0$: $E\ge|q_k|$ on the support of $\mathcal P$, that is $H\ge|P_k|$. (iii) $\|[(H^{\mathrm{cons}}[\eta])\cdot F]\|^2$ is a sum of values $\bar c_kc_l\,\sigma(\theta\bar X_k\cdot\theta H^{\mathrm{cons}}[\eta]\cdot H^{\mathrm{cons}}[\eta]\cdot X_l)$ at tuples with pairwise disjoint supports in which $H^{\mathrm{cons}}[\eta]$ stands beside the other entries ($\theta H^{\mathrm{cons}}[\eta]=H^{\mathrm{cons}}[\theta\eta]$ has its support in $\{x_3<0\}$); each vanishes by Theorem J (i). The last assertion is $\langle[F'],[(H^{\mathrm{cons}}[\eta])\cdot F]\rangle=0$. □

Proof of Proposition 3.7. (a) Order the sum that defines $\Theta_\beta[\eta]$ by the bonds. The four plaquettes that contain $\mathfrak b$ are $p(\mathfrak b,\pm\tau)$, $x(p(\mathfrak b,\pm\tau))=x_{\mathfrak b}\pm\frac12a_Ke_\tau$, and $\mathbf w(W_{\mathfrak b,p(\mathfrak b,\pm\tau)})=\frac12\mathbf y_{\mathfrak b,\tau}\mp\mathbf u_{\mathfrak b,\tau}$. For $f=\eta^\rho$ and $D_\pm=f(x_{\mathfrak b})-f(x_{\mathfrak b}\pm\frac12a_Ke_\tau)$: $D_++D_-=-\frac{a_K^2}{4}(\Delta_\tau f)(x_{\mathfrak b})$ and $D_--D_+=a_K(\nabla^{\mathrm c}_\tau f)(x_{\mathfrak b})$, so that, with $\beta=ba_K^{-1}$,

$$\Theta_\beta[\eta]=b\,a_K^{-1}\sum_{\mathfrak b}\sum_{\rho,\tau}(\nabla^{\mathrm c}_\tau\eta^\rho)(x_{\mathfrak b})\langle\mathbf u_{\mathfrak b,\rho},\mathbf u_{\mathfrak b,\tau}\rangle-b\,\mathcal R[z^\eta].$$

For $\rho\ne\tau$ the two terms give $-H^{\mathrm{cons}}_K[\eta]_{\lambda_{\mathfrak b}\lambda'_{\mathfrak b}}(x_{\mathfrak b})q_{\mathfrak b}$, which sum to $b\,Y[\mathtt w_{H^{\mathrm{cons}}_K[\eta]}]$ exactly. For $\rho=\tau$, $|\mathbf w(W_x(\mu,\pm\rho))|^2=a_\pm(2-a_\pm)$ gives $|\mathbf u_{\mathfrak b,\rho}|^2=(a_++a_-)-\frac12(a_+^2+a_-^2)-\frac14|\mathbf y_{\mathfrak b,\rho}|^2$; the parts with $a_+^2+a_-^2$ and $|\mathbf y|^2$ are $-b\{\frac12\mathcal A[v^\eta]+\frac14\mathcal Y[v^\eta]\}$, and the part with a_++a_-, ordered by the plaquettes with $(\nabla^{\mathrm c}_\tau f)(y+\frac12a_Ke_\tau)+(\nabla^{\mathrm c}_\tau f)(y-\frac12a_Ke_\tau)=2(\nabla^{\mathrm s}_\tau f)(y)$, has at $a_K^{-1}a_p$ the weight $2(\nabla^{\mathrm s}\cdot\eta-\nabla^{\mathrm s}_\lambda\eta^\lambda)(x(p))$, $\lambda=\rho(p)$; taking off $b\,\mathcal O(\nabla^{\mathrm s}\cdot\eta)$ leaves $b\,\mathcal O(w_{H^{\mathrm{cons}}_K[\eta]})$. (b) With $\partial^{\mathfrak a}_{\mathfrak b}$ the derivative along $e^{is\sigma_{\mathfrak a}}U(\mathfrak b)$ and $J_{\mathfrak b}=\sum_{p\ni\mathfrak b}\mathbf w(W_{\mathfrak b,p})=\mathbf y_{\mathfrak b,\rho}+\mathbf y_{\mathfrak b,\rho'}$, the calculus of the derivations (J.1) gives $\partial^{\mathfrak a}_{\mathfrak b}\sum_{p\ni\mathfrak b}a_p=\langle\sigma_{\mathfrak a},J_{\mathfrak b}\rangle$ and $\sum_{\mathfrak a}\partial^{\mathfrak a}_{\mathfrak b}\langle\sigma_{\mathfrak a},\mathbf u_{\mathfrak b,\rho}\rangle=\frac32(a_+-a_-)$. Invariance of Haar measure and the equation of the Gibbs state for the single bond $\mathfrak b$ (YMM1:(1819)) give $\beta\langle\langle\mathbf u_{\mathfrak b,\rho},J_{\mathfrak b}\rangle;Y\rangle_\nu=\frac32\langle a_+-a_-;Y\rangle_\nu$. Write $\sum_\tau z_{\rho\tau}\langle\mathbf u_{\mathfrak b,\rho},\mathbf y_{\mathfrak b,\tau}\rangle=(z_{\rho\rho}-z_{\rho\rho'})\langle\mathbf u_{\mathfrak b,\rho},\mathbf y_{\mathfrak b,\rho}\rangle+z_{\rho\rho'}\langle\mathbf u_{\mathfrak b,\rho},J_{\mathfrak b}\rangle$, use $\langle\mathbf u_{\mathfrak b,\rho},\mathbf y_{\mathfrak b,\rho}\rangle=-(a_+-a_-)+\frac12(a_+^2-a_-^2)$, and sum by parts over the plaquettes, which defines δ. (c) $|\mathbf y_{\mathfrak b,\rho}|^2=4(a_++a_-)-(a_++a_-)^2-2a_{R(\mathfrak b,\rho)}$, a_R the action of the holonomy around the 1×2 rectangle $R(\mathfrak b,\rho)=p(\mathfrak b,\rho)\cup p(\mathfrak b,-\rho)$, is a density of order 2 on that rectangle, and a_p^2 one of order 4; so $\mathcal P_K[v,w]$ is an insertion with weights $L^K|(v,w)|_\infty$ whose carrier lies within a_K of the carrier of the weights; a mirror copy of a planar null form is a

planar null form with the same sup norm of the weights (the trace of a holonomy around a box depends neither on the corner nor on the sense). Let $u = \lceil \phi K \rceil$, $t = K - u$, $n_0 = K - \lceil \psi K \rceil$. At a background U over $V \in \mathsf{Cut}_{n_0}$, $U \in \mathcal{C}(\mathbf{B}_{n_0}, V)$, regular of level n_0 at ε_{n_0} (Lemma 3.16 (a)), Lemma 3.16 (c) gives $|\mathbf{y}_{\mathfrak{b},\rho}| \le C\varepsilon_{n_0} L^{-(2+\kappa_\star)n_0}$ and $a_p \le \frac{1}{2}\varepsilon_{n_0}^2 L^{-4n_0}$; with at most $9\ell^3 L^{3K}$ boxes, $\epsilon_X \le C\ell^3 L^{4K}\varepsilon_{n_0}^2 L^{-(4+2\kappa_\star)n_0}|(v,w)|_\infty \le CK^{2\mathfrak{p}_0} L^{-[2\kappa_\star-(3+2\kappa_\star)\psi]K}|(v,w)|_\infty$.

Lemma 3.18 (a) at n_0 adds $CK^{3\mathfrak{p}_0}L^{3u-\psi K/2}|(v,w)|_\infty$, which is $\le CK^{2\mathfrak{p}_0}L^{4u-\psi K/2}|(v,w)|_\infty$ for large K, as $K^{\mathfrak{p}_0} \le L^{\phi K}$; so every copy has oscillation $\le CK^{2\mathfrak{p}_0}L^{-c_{\mathrm{Y}}K}|(v,w)|_\infty$. Proposition 3.15 (b) bounds the joint cumulants of $2 \le q \le 8$ copies in different cells, whose carriers are $\ge r$ apart, and the eighth moment of the centred copies is the sum over the 715 partitions without singletons; it is ≥ 0 by Section B.1. The supremum of c_{Y} is approached at $\kappa_\star \uparrow 1$, $\phi \downarrow 0$, $\psi = \frac{4}{11}$. (d) Take the board of the least torus whose walls normal to e_{μ_0} stand at $c+\mathsf{l}\mathbb{Z}$, the other walls chosen so that the cube lies in one cell at distance $\ge r$ from its walls ($\mathsf{l} \ge 16r$); $F = \mathcal{P}_K[v,w]$ and $\theta_c F$ are functions of two neighbouring cells, and the eight copies of $\theta_c(F-c_0)$ are those of $F-c_0$, c_0 the torus mean. With $\nu(\theta_c F) = \nu(F)$ and Lemma 3.26 (a) for two cells, $\|F\|_{\nu,c}^2 = \nu(\theta_c(F-c_0)(F-c_0)) - (\nu(F)-c_0)^2 \le \mathsf{Q}^2\|F-c_0\|_{\mathrm{ch},\ell'}^2$, and (c) at the parameters $(\kappa_\star,\psi,\phi) = (\frac{1}{2},\frac{1}{8},\frac{1}{256})$ gives the first assertion. For the limit let d_0 be the distance of the supports, $r \le \frac{1}{24}d_0$, and cut η and H' into pieces of sup diameter $< \frac{1}{2}r$.

By (a), $\mathsf{St}[\eta] = b\,\mathcal{T}_K(H^{\mathrm{cons}}[\eta]) + b\,\mathcal{T}_K(H_K''[\eta]) - b\mathcal{N}_K$, $\mathcal{N}_K = \frac{1}{4}\mathcal{Y}[v^\eta] + \frac{1}{2}\mathcal{A}[v^\eta] + \mathcal{R}[z^\eta]$. By Definition 3.3 and $b_j \to b_*$, $\langle b_j\mathcal{T}_{K_j}(H^{\mathrm{cons}}[\eta]); \mathcal{T}_{K_j}(H')\rangle_{\rho_j} \to b_*\sigma(H^{\mathrm{cons}}[\eta], H')$; the term with H_K'', of size $\frac{3}{2}a_K \sup|\nabla^2\eta|$ and carried by a fixed compact set disjoint from $\operatorname{supp} H'$, tends to 0 by Lemma 3.28 (b). By (b), $\langle \mathcal{N}_K; \mathcal{T}_K(H')\rangle_{\rho_j} = \langle F; \mathcal{T}_K(H')\rangle_{\rho_j} + \langle \mathcal{T}_K(H_K^\natural); \mathcal{T}_K(H')\rangle_{\rho_j}$ with the planar null form $F = \mathcal{P}_K[\frac{1}{4}v^\eta, \frac{1}{2}\sigma v^\eta + \frac{1}{2}\delta\zeta^\eta]$ (σv the sum of the weights of a plaquette over its four bonds) and a diagonal weight $H_K^\natural$ of size $\le Ca_K(1+\beta^{-1})\sup|\nabla^2\eta|$, whose term tends to 0 by Lemma 3.28 (b).

A lattice mirror $c_j \in a_{K_j}(\mathbb{Z}+\frac{1}{2})$ at distance about $2r$ from $\operatorname{supp}\eta$ parts the carrier of F, which lies in a cube of side r as in the first assertion, from the bonds on which $\mathcal{T}_K(H')$ depends; Lemma 3.28 (a) gives $|\langle F; \mathcal{T}_K(H')\rangle_{\rho_j}| \le \|F\|_{\rho_j,c_j}\|\mathcal{T}_K(H')\|_{\rho_j,c_j}$; the second factor is $\langle \mathcal{T}_K(\theta_{c_j}H'); \mathcal{T}_K(H')\rangle_{\rho_j}^{1/2}$, bounded uniformly in j by Lemma 3.28 (b), and the first tends to 0 by the first assertion. (e) By reflection positivity at the bond mirror, $\langle F,G\rangle_\rho = \langle \theta_K F; G\rangle_\rho$ is a positive semidefinite form on the bounded functions of the bonds in $\{x_3 > \frac{1}{2}a_K\}$, with seminorm $\|F\|_\rho$, and $\langle \theta_K\mathcal{T}_K(H_K^{\mathrm{cons}}[\eta]); \mathcal{T}_K(H_K^{\mathrm{cons}}[\eta])\rangle_\rho = \|\mathcal{T}_K(H_K^{\mathrm{cons}}[\eta])\|_\rho^2 \ge 0$. By (a) and Lemma 3.9 (a), $b\,\mathcal{T}_K(H_K^{\mathrm{cons}}[\eta]) - \mathfrak{Y}[\eta] = \mathcal{Z} - \frac{1}{4}c_{\mathsf{k}_\eta} + X''[\eta]$, $\mathcal{Z} = \mathcal{N}_\eta - \frac{1}{4}\mathfrak{N}[\mathsf{k}_\eta]$, $X''[\eta] = -\mathsf{Rm}[\eta] + b(\frac{1}{2}\mathcal{A}[v^\eta] + \mathcal{R}[z^\eta])$, since $\mathfrak{Y}[\eta] = \frac{b}{4}\mathcal{Y}[v^\eta]$. $\rho(\mathcal{Z}Y) = 0$ for every bounded function Y of the lower side (Lemma 3.9 (b)), and $\theta_K\mathcal{Z}$ is a null term of the lower side; so the null terms drop out of the form, and $\|b\,\mathcal{T}_K(H_K^{\mathrm{cons}}[\eta]) - \mathfrak{Y}[\eta]\|_\rho = \|X''[\eta]\|_\rho$.

Cut η by a partition of unity into pieces of sup diameter $\le \frac{1}{8}\mathsf{l}$, $\ell' = 2\mathsf{l}$ the least side at g. For a function F_1 of the upper side carried by one piece, a board B of the least torus with an offset in $a_K\mathbb{Z}^3$ puts the piece and its mirror image in two cells, both at sup distance $\ge r = \min\{\frac{1}{4}h_0, \frac{1}{32}\mathsf{l}\}$ from the walls (either the bond mirror is a wall of the board, or a wall stands between the piece and its image). Let $F_2 = \theta_K F_1$ and c_1 the torus mean of F_1. As ρ is invariant under θ_K (YMM1:103.4), $\rho(F_2) = \rho(F_1)$, so $\|F_1\|_\rho^2 = \rho((F_2-c_1)(F_1-c_1)) - (\rho(F_1)-c_1)^2$, and Lemma 3.26 (a) for two cells gives $\|F_1\|_\rho^2 \le \mathsf{Q}^2\|F_2-c_1\|_{\mathrm{ch},\ell'}\|F_1-c_1\|_{\mathrm{ch},\ell'}$, both seminorms formed on B.

The reflection θ_K induces an isometry of the lattice of the least torus; it carries B to a board $\theta_K\mathsf{B}$ with an offset in $a_K\mathbb{Z}^3$ (if the walls of B normal to e_3 stand at $W+\mathsf{l}\mathbb{Z}$, those of $\theta_K\mathsf{B}$ stand at $a_K - W + \mathsf{l}\mathbb{Z}$), conjugates the mirror maps of B to those of $\theta_K\mathsf{B}$ and keeps the torus measure. So F_2 has the torus mean c_1, and the seminorm of $F_2 - c_1$ formed on B is the seminorm of $F_1 - c_1$ formed on $\theta_K\mathsf{B}$, in which the piece lies in one cell at sup distance $\ge r$ from the walls. The bounds used next hold for every board with an offset in $a_K\mathbb{Z}^3$ and every cell, the function being carried at sup distance $\ge r$ from its walls; so both factors fall under one bound.

The seminorm $\|\cdot\|_\rho$ is subadditive, and the pieces add up. The chessboard seminorms are bounded by Proposition 3.5 (a) for Rm with a rate $c'' > c$, by power counting for $b(\frac{1}{2}\mathcal{A}[v^\eta]+\mathcal{R}[z^\eta])$ (orders 4 and 2, weights $\le CL^K\|\eta\|$ and $\le C\|\eta\|$, rates $\frac{1}{2}-4\phi$ and $1-4\phi$), and by (c) for $\mathfrak{Y}[\eta]$ with parameters such that $c_{\mathrm{Y}} > c$ (possible as $c < \frac{1}{10} < \frac{2}{11}$). So $\|b\,\mathcal{T}_K(H_K^{\mathrm{cons}}[\eta])\|_\rho \le \|X''[\eta]\|_\rho + \|\mathfrak{Y}[\eta]\|_\rho \le CK^pL^{-cK}\|\eta\|$. For (N): $\mathcal{T}_K(H_K^{\mathrm{cons}}[\eta]) - \mathcal{T}_K(H^{\mathrm{cons}}[\eta]) = \mathcal{T}_K(H_K''[\eta])$ with $|H_K''[\eta]|_\infty \le \frac{3}{2}a_K\|\eta\|$, and the bound of item (ii) of the subsection on the input (Theorem BV (a)) at $n=2$ on the covariance of two tensor entries with disjoint supports, by a number times the product of the sup norms of the weights, uniformly in the cutoff and in the periodic Gibbs state, gives $\|\mathcal{T}_K(H_K^{\mathrm{cons}}[\eta])\|_\rho^2 - \|\mathcal{T}_K(H^{\mathrm{cons}}[\eta])\|_\rho^2 \to 0$; $\theta_K\mathcal{T}_K(H) = \mathcal{T}_K(\theta_K H)$ with $\theta_K H$ the translate by $a_K e_3$ of θH, which tends to θH uniformly; so along the defining sequence of a tensor limit $\sigma(\theta H^{\mathrm{cons}}[\eta], H^{\mathrm{cons}}[\eta]) = \lim_j \|\mathcal{T}_{K_j}(H^{\mathrm{cons}}[\eta])\|_{\rho_j}^2 = 0$ (with $b_j^{-1} \le \gamma^2$). □

Proof of Proposition 3.8. (a) $K_3 = \nabla\nabla\varphi$, $\varphi(u) = \frac{1}{4\pi|u|}$ harmonic off 0, is symmetric, $\sum_\nu \partial_\nu (K_3)_{\nu\rho} = \partial_\rho \Delta\varphi = 0$, and $\partial_\nu (K_3)_{\beta\rho} = \partial_\rho (K_3)_{\beta\nu}$. With $K^i = K_3(\cdot - y_i)$: $\sum_\nu \partial_\nu M_{\nu\rho} = K^1_{\nu\alpha} B_{\alpha\beta} \partial_\rho K^2_{\beta\nu}$ and $\sum_\nu \partial_\nu M_{\rho\nu} = (\partial_\rho K^1_{\nu\alpha}) B_{\alpha\beta} K^2_{\beta\nu}$, summed over the repeated indices; the sum is $\partial_\rho(K^1_{\nu\alpha}B_{\alpha\beta}K^2_{\beta\nu}) = \partial_\rho \mathrm{tr}\, M$. Integrating by parts, $\int \mathrm{tr}[H^{\mathrm{cons}}[\eta]M] = \sum_\rho \int \eta^\rho [-\partial_\rho \mathrm{tr}\, M + \sum_\nu \partial_\nu (M_{\nu\rho} + M_{\rho\nu})] = 0$.

The joint cumulant of the quadratic forms $\frac{1}{2}\int \mathrm{Tr}(H_a T)$ of Gaussian fields is $\frac{1}{2}$ times the sum over the cyclic orders of the traces of the products of weights and covariances, times 3 for the three fields; as the supports are compact and pairwise disjoint, consecutive points of a term lie in different supports, at sup distances bounded below, so every integrand is bounded and compactly supported. In each term the integral over x_1 is $\int \mathrm{tr}[H_1(x_1)M(x_1)]\,dx_1$ with $y_1 = x_{\pi 2}$, $y_2 = x_{\pi q}$ and B the product of the other factors (K_3 being even); for $x_2, \dots, x_q$ in the supports of $H_2, \dots, H_q$ the points y_1, y_2 lie off $\mathrm{supp}\,\eta$, so $\eta \in C_c^2(\mathbb{R}^3 \setminus \{y_1, y_2\}; \mathbb{R}^3)$, and at $H_1 = H^{\mathrm{cons}}[\eta]$ the integral over x_1 vanishes term by term. (b) Under $\nu \otimes \gamma_K$ the functions of U alone have the laws they have under ν, and X_K is linear in χ_K with $\gamma_K(\mathsf{X}_K) = 0$; so the mirrored covariance of $\mathcal{T}_K^{\mathrm{X}}(H^{\mathrm{cons}}[\cdot])$ at $\theta\eta$ and η is that of $\mathcal{T}^{\mathrm{c}}$ under ν, which tends to 0 by Corollary 3.4 (b), plus $\epsilon^2 \gamma_K(\mathsf{X}_K[H^{\mathrm{cons}}[\theta\eta]]\mathsf{X}_K[H^{\mathrm{cons}}[\eta]])$. At $\eta = he_3$ the diagonal entries of $H^{\mathrm{cons}}[\eta]$ are $\partial_3 h\,(1,1,-1)$; its off-diagonal entries, $-\partial_1 h$ at $(1,3)$, $(3,1)$ and $-\partial_2 h$ at $(2,3)$, $(3,2)$, do not enter X_K, which reads the entries $H_{\lambda\lambda}$ alone.

So in the limit $K \to \infty$, in which the free lattice field of mass 1 gives the continuum one, $\mathsf{X}_K[H^{\mathrm{cons}}[\eta]] \to \int \partial_3 h\,(\partial_1^2 + \partial_2^2 - \partial_3^2)\chi = \int h\,(2\partial_3^3 - \partial_3\Delta)\chi$. For f supported in $\{x_3 > 0\}$ the free covariance gives $\iint f(\Theta x) G(x-y) f(y)\,dx\,dy = \int |\hat f(p)|^2 d\rho(p)$, $\hat f(p) = \int e^{-E(p)x_3 + ip\cdot(x_1,x_2)} f(x)\,dx$; with $\partial_3 \mapsto -E$ and $\Delta \mapsto E^2 - |p|^2 = 1$ on the mass shell this is the integral of $|\hat h|^2 E^2 (2E^2-1)^2$. For $0 \le h \ne 0$, $\hat h(0) = \int h e^{-x_3} dx > 0$ and $\hat h$ is continuous, so the integral is positive. The added member is no function of the gauge field, and no null term takes its divergence away: the collapse of Lemma 3.11 fails for the dressed field, and with it (N). □

3.6. **Scope of the conclusions.** The bounds are bounds in the cutoff at a fixed distance of the supports, or, in Theorem H (iii), at distances that may shrink like $K^2 L^{-\lceil \phi K \rceil}$; no mass gap, uniqueness of the vacuum or clustering is used. In every statement the supports of the entries are pairwise disjoint, and a tensor limit is defined only on such tuples. Theorem J (iii) concerns covariances: (N) for one tensor limit gives the vanishing of the mirrored two-point functions of $\mathfrak{K}$ and St along its own defining sequence, and nothing on the means $\nu(\mathfrak{K})$ apart. The bounds for St, Rm and $\mathfrak{K}$ contain no tensor field and give (N) only through the collapse (Lemma 3.11), as the instance of Proposition 3.8 (b) shows.

For $\gamma_W^{\mathrm{ref}} < g \le \gamma$ tensor limits at g exist along subsequences as well, by the following route. Let $z \ge 1$ be the least integer for which the reference couplings g_1', g_2' of Lemma 3.27 (c), $g_1'^{-2} = \Lambda g^{-2}/2$, $g_2'^{-2} = L\Lambda g^{-2}/4$, $\Lambda = L^z$, satisfy $g_1', g_2' \le \gamma_W^{\mathrm{ref}}$; it exists by Lemma 3.27 (d) and is a function of g, and D^z is the dilation $x \mapsto \Lambda x$ of $\mathbb{L}_K$ onto $\mathbb{L}_{K-z}$, $(D^z U)(D^z \mathfrak{b}) = U(\mathfrak{b})$. By Lemma 3.27 (a)–(c),

$\mathcal{T}_K(H) = L^z \mathcal{T}_{K-z}(H^{(z)}) \circ D^z$, D^z_* carries periodic Gibbs states to periodic Gibbs states, and every $(K,\beta) \in \mathfrak{d}(g)$ with $K > z$ has $(K-z,\beta) \in \mathfrak{d}(g'_1) \cup \mathfrak{d}(g'_2)$.

So item (ii) of the subsection on the input (Theorem BV (a)), read at g'_1 and at g'_2 for the dilated weights, bounds $\nu(\prod_a A^\nu[\mathcal{T}_K(H_a)])$ by $C \prod_a |H_a|_\infty$ for real bounded weights H_a vanishing off fixed bounded open sets with pairwise disjoint closures, uniformly in $(K,\beta) \in \mathfrak{d}(g)$ with large K and in $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, the number C containing the factor L^{nz}. The labels lie in the compact interval $[\gamma^{-2}, \mathsf{b}_+]$ (Lemma 3.12 (a)), and the diagonal extraction of the proof of Corollary 3.6 (i) gives a subsequence along which the labels converge and which defines a tensor limit at g.

Conservation is an input of the covariance of tensor limits under all of $O(3)$. For $0 < g \le \gamma^{\mathrm{sd}}_W$, and by the change of scale of Lemma 3.27 for $0 < g \le \gamma^{\mathrm{ref}}_W$, every tensor limit σ at g has $\sigma(\mathsf{R}H_1, \mathsf{R}H_2) = \sigma(H_1, H_2)$ for every $\mathsf{R} \in O(3)$, with $(\mathsf{R}H)(x) = \mathsf{R}H(\mathsf{R}^{-1}x)\mathsf{R}^{\mathrm{T}}$, and all $H_1, H_2 \in C^1_c(\mathbb{R}^3; V)$ with disjoint supports (the theorem on the tensor limits of Section 6 on reflection positivity at every plane, the forward light cone and Wightman fields for the tensor $\mathrm{tr}\, F_{ij}F_{kl}$, part (3), at two entries; the seven conditions (h1)–(h7) below are derived for tensor limits in Step 3 of its proof).

The argument is that of Proposition 6.20 of that section, a statement on a real symmetric bilinear functional σ_2 on the pairs of continuous weights with disjoint supports under seven conditions (h1)–(h7). Let first $0 < g \le \gamma^{\mathrm{sd}}_W$, and $\sigma_2 = \sigma$. (h1) σ is invariant under the translations and the cubic group, and (h2) $|\sigma(\theta\bar{h}, h')| \le c(\mathcal{K})|h|_\infty |h'|_\infty$ for h, h' supported in a compact set $\mathcal{K} \subset \{x_3 > 0\}$ (Corollary 3.6 (i)). (h3) In the Hilbert space of Corollary 3.6 (ii), with $v(h) = [(h)]$, the joint spectral measure $\mathcal{P}$ of (H, P_1, P_2) is carried by the square cone $\{E \ge \max(|q_1|, |q_2|)\}$, and $e^{-a_3 H} e^{i(a_1 P_1 + a_2 P_2)} v(h) = v(\tau_a h)$ for $a_3 \ge 0$; so the mirrored two-point function is the Laplace transform of a matrix of measures carried by this cone. (h4) σ is positive at the diagonal mirror $\{x_1 + x_3 = 0\}$ (Corollary 3.6 (ii)). (h5) is (C) of Theorem J (ii); in the helicity basis of the rotations about one axis it gives three linear relations between these measures.

The last two conditions are inputs that rest, like the scalar theory, on Theorems YMM1:D, YMM1:AJ and YMM1:AD. (h6) The scalar two-point function is invariant under the rotations: by Corollary 3.6 (i) the trace part $\sigma(f_1\mathbf{1}, f_2\mathbf{1})$ is the limit, along the defining sequence of σ, of the centred products of the action density fields, that is the scalar limit of this sequence, and a scalar limit is invariant under all isometries of $\mathbb{R}^3$ (Theorem YMM1:AP). (h7) A bound $\sigma(\theta h, h) \le C d^{-a} |h|^2_\infty$ with $a < 4$ at the off-diagonal bumps h of size d near the mirror; here it holds with $a = 0$: there is $C_\infty(g)$, a function of g, such that $\sigma(\theta h, h) \le C_\infty(g)\, b_*^{-2} |h|^2_\infty$, b_* the limit of the labels along a defining sequence of σ with convergent labels (Corollary 3.6 (i)), for $0 < d < 1$ and every real $h = h_0(E_{\mu\nu} + E_{\nu\mu})$, $E_{\mu\nu}$ the matrix units, $\mu \ne \nu$, with h_0 supported in the ball of radius d about a point x_0 with $x_{0,3} \in [\frac{3}{2}d, 2d]$ (Proposition 6.15 (e), stated for $0 < g \le \gamma^{\mathrm{sd}}_W$ alone, and recalled in the subsection on the input).

It is the bound at short distance of the covariance of two off-diagonal bond fields, whose means vanish, in the periodic Gibbs states at the first-passage data at g, with a number that depends neither on the scale d nor on the cutoff, carried to the limit: on the least torus at g the renormalisation group of Theorem YMM1:D gives it at the scale d, and the chessboard estimate with the bound of Theorems YMM1:AJ and YMM1:AD on differences of pressures carries it to every periodic Gibbs state. It is had for $0 < g \le \gamma^{\mathrm{sd}}_W$, and this sets the first range. With (h1)–(h7) only the harmonics of a covariant kernel remain: the imaginary rotations about e_2 act on the measures of (h3) as the boosts of (E, q_1); by (h7) and conservation the boosted measures have finitely many harmonics, of orders at most $6 + a < 10$; (h6) makes the measure of the trace invariant under the boosts; a wrong harmonic of odd order is positive and negative by (h4), so it vanishes, and one of even order is emptied by (h5) and by its scaling under the boosts; so the kernel is covariant under the rotations about e_2, which generate $O(3)$ with the cubic group.

For $\gamma^{\mathrm{sd}}_W < g \le \gamma^{\mathrm{ref}}_W$ take z with $g'_1, g'_2 \le \gamma^{\mathrm{sd}}_W$ (Lemma 3.27 (d)), and pass to a subsequence of the defining sequence (K_j, β_j, ρ_j) of σ along which the index ι of Lemma 3.27 (c) is one and the same;

a subsequence defines the same σ. By Lemma 3.27 (a)–(c), $(K_j - z, \beta_j, D^z_* \rho_j)$ defines the tensor limit $\sigma_z(H'_1, \dots, H'_n) = \Lambda^{-n} \sigma(H'_1(\Lambda\,\cdot), \dots, H'_n(\Lambda\,\cdot))$ at $g'_\iota \le \gamma^{\mathrm{sd}}_W$, so $\sigma(H_1, H_2) = \Lambda^2 \sigma_z(H_1^{(z)}, H_2^{(z)})$; as $(\mathsf{R}H)^{(z)} = \mathsf{R}H^{(z)}$, the covariance of σ_z gives that of σ.

4. Point plates and holomorphic kernels

We construct bounded point-plate operators from reflection-positive functionals with a finite slab-insertion bound. The construction first permits an arbitrary bound as a function of the slab width. A power bound gives quantitative growth of the holomorphic kernels and point fields.

The tensor indices are part of the reflection and covariance conventions. We give the operator construction, the gluing of quarter-turned tubes and the converses on the closed spans of the resulting vectors. Gaussian examples show why a finite insertion bound alone need not be a power bound. The final application identifies the precise lattice estimates required for curvature bilinears.

4.1. **Notation and hypotheses.** We work in $\mathbb{R}^3 \ni x = (x_1, x_2, x_3)$ with the standard basis e_1, e_2, e_3; the coordinate x_3 is Euclidean time, and all distances are Euclidean. Scalar products are antilinear in the left argument, and products of operators are taken in the order of their indices. $M \ge 1$ is the constant in the norm $\|\cdot\|_\sharp$ of Definition 4.1(2); only $M \ge 1$ is used here. The reference coupling g, its two ceilings $\gamma^{\mathrm{sd}}_W \le \gamma^{\mathrm{ref}}_W$, first-passage data, periodic Gibbs states, the spacing a_K of the lattice at the cutoff K and the constants L and $\bar B$ are the construction data fixed in Section 2; they enter Theorem Q alone.

Definition 4.1 (Values, functions, isometries)**.** (1) $V = \mathrm{Sym}_3(\mathbb{R})$ and $V_{\mathbb{C}} = \mathrm{Sym}_3(\mathbb{C})$ carry the norm $|E|_2 = (\operatorname{tr} E^* E)^{1/2}$; besides, $|E|_\infty := \max_{\lambda,\lambda'} |E_{\lambda\lambda'}| \le |E|_2$. Every $E \in V_{\mathbb{C}}$ is $E = E^0 + iE^1$ with $E^0 = \frac12(E + \bar E)$ and $E^1 = \frac{1}{2i}(E - \bar E)$ in V, and $|E|_2^2 = |E^0|_2^2 + |E^1|_2^2$. For $r \in \mathrm{O}(3)$ we put $\varrho(r)E := rEr^{\mathsf T}$; then $|\varrho(r)E|_2 = |E|_2$ and $\overline{\varrho(r)E} = \varrho(r)\bar E$.

(2) For $O \subset \mathbb{R}^N$ open and $\mathbb{K} \in \{V, V_{\mathbb{C}}, \mathbb{C}\}$, $C^1_c(O;\mathbb{K})$ is the space of the C^1 maps $\mathbb{R}^N \to \mathbb{K}$ whose support is compact and contained in O, and $C_c(O;\mathbb{K})$ the same with continuous maps. With $|\cdot|_2$ on the values, $\|f\|_\infty = \sup |f(x)|_2$, $\operatorname{Lip} f = \sup_{x \ne x'} |f(x) - f(x')|_2 / |x - x'|$, $|\nabla f|^2 = \sum_\mu |\partial_\mu f|_2^2$, $\|f\|_{C^1} = \max\{\|f\|_\infty, \sup |\nabla f|\}$ and $\|f\|_{L^1} = \int |f(x)|_2 \, dx$; at $N = 3$, $\|f\|_\sharp = \max\{\|f\|_\infty, 40M \operatorname{Lip} f\}$. The functions f^0, f^1, $\bar f$ are taken pointwise, and f is real if its values lie in V (or in $\mathbb{R}$).

(3) An isometry $r\colon x \mapsto r^\circ x + v$ of $\mathbb{R}^3$ acts on functions by the tensor action $(rf)(x) = \varrho(r^\circ) f(r^{-1}x)$. We denote by τ_v the translation by v, by θ_c the reflection $x \mapsto x - 2(x_3 - c)e_3$, by $\theta = \theta_0$ both this reflection and the matrix $\operatorname{diag}(1, 1, -1)$, so that $(\theta_c f)(x) = \varrho(\theta) f(\theta_c x)$; $E_+ = \{x_3 > 0\}$; W_3 is the group of the 48 signed permutation matrices, $\mathbb{R}^3 \rtimes W_3$ the group of the isometries $x \mapsto wx + v$, $w \in W_3$, and $B(y, r)$ the open ball of radius r about y.

■

Definition 4.2 (Tuples, complex members, tensor functionals)**.** (1) For $O \subset \mathbb{R}^3$ open, $\mathfrak{S}^V(O)$ consists of $\emptyset$ and of the tuples $X = (H_1, \dots, H_n)$ of functions $H_a \in C^1_c(O; V)$ with pairwise disjoint supports; the function 0 is admitted as a member. X is of type $(\mathsf{d}; R)$ if each support lies in a closed ball of radius R and any two supports are at a distance $\ge \mathsf{d}$. Isometries act member by member; $X \cdot Y$ is the concatenation, formed when no support of a member of X meets one of Y. $\mathbb{C}\mathfrak{S}^V(O)$ is the free complex vector space over $\mathfrak{S}^V(O)$; for $F = \sum \zeta_i X_i$ we put $\bar F = \sum \bar\zeta_i X_i$, and isometries and concatenation are extended linearly and bilinearly.

(2) For $H_1, \dots, H_n \in C^1_c(\mathbb{R}^3; V_{\mathbb{C}})$ with pairwise disjoint supports,

$$(H_1, \dots, H_n)_{\mathbb{C}} := \sum_\varepsilon i^{|\varepsilon|} (H_1^{\varepsilon_1}, \dots, H_n^{\varepsilon_n}) \in \mathbb{C}\mathfrak{S}^V(\mathbb{R}^3), \qquad |\varepsilon| = \varepsilon_1 + \dots + \varepsilon_n,$$

the sum running over the $\varepsilon \in \{0,1\}^n$ with $H_a^1 \ne 0$ wherever $\varepsilon_a = 1$; thus $(H)_{\mathbb{C}} = (H)$ for real H.

(3) A tensor functional is a map $\sigma\colon \mathfrak{S}^V(\mathbb{R}^3) \to \mathbb{R}$ with $\sigma(\emptyset) = 1$ which is n-linear on $\prod_a C^1_c(O_a; V)$ whenever $O_1, \dots, O_n \subset \mathbb{R}^3$ are open sets with pairwise disjoint closures; it is extended linearly to $\mathbb{C}\mathfrak{S}^V(\mathbb{R}^3)$. It is centred if $\sigma((H)) = 0$ for every $H \in C^1_c(\mathbb{R}^3; V)$.

■

Definition 4.3 (The class)**.** Let σ be a tensor functional.

(T1°) σ is symmetric and $\sigma(\tau_v X) = \sigma(X)$ for all $v \in \mathbb{R}^3$ and X.
(T1) σ is symmetric and $\sigma(rX) = \sigma(X)$ for all $r \in \mathbb{R}^3 \rtimes W_3$ and X.
(T2) There are numbers $C^\sigma_n(\mathsf{d}; R) \in [0, \infty)$, one for each $n \geq 1$, $\mathsf{d} > 0$, $R > 0$, with $|\sigma(H_1, \dots, H_n)| \leq C^\sigma_n(\mathsf{d}; R) \prod_a \|H_a\|_\sharp$ at all tuples of type $(\mathsf{d}; R)$.
(T3) $\sigma(\theta\bar{F} \cdot F) \geq 0$ for all $F \in \mathbb{C}\mathfrak{S}^V(E_+)$.

For σ with (T3), $\langle F, G\rangle_\sigma := \sigma(\theta\bar{F} \cdot G)$ is a positive semi-definite Hermitian form on $\mathbb{C}\mathfrak{S}^V(E_+)$ (Lemma 4.13); $\mathcal{H}(\sigma)$ is the completion of the quotient by its null space, $[F]$ is the class of F, and $\Omega := [\emptyset]$. For σ with (T1°), (T2) and (T3), Lemma 4.13 provides the operators $\mathcal{T}_t[F] = [\tau_{te_3}F]$, $t \geq 0$, and $\mathcal{U}(v)[F] = [\tau_v F]$, $v \in e_3^\perp$, and their joint spectral measure $\mathcal{P}$ on $[0, \infty) \times e_3^\perp \ni (E, q)$. In these terms:

(T4) $\mathcal{P}(\{(E, q) : E < |q_1|\}) = 0$.
($\mathrm{T5}_N$) For a number $c_I \in (0, \frac{1}{16}]$ and a function $N\colon (0, 1] \to (0, \infty)$, which may be any function: for all $\eta \in (0, 1]$, all real $H \in C^1_c(\mathbb{R}^3; V)$ with $\operatorname{supp} H \subset B(y, c_I\eta)$ for some y with $|y_3| \leq \eta/8$, and all $F, G \in \mathbb{C}\mathfrak{S}^V(\{x_3 > \eta/4\})$,

$$|\sigma(\theta\bar{F} \cdot (H) \cdot G)| \leq N(\eta)\, \|H\|_\sharp\, \|[\tau_{-(\eta/4)e_3}F]\|\, \|[\tau_{-(\eta/4)e_3}G]\|.$$

(T5) The insertion bound: ($\mathrm{T5}_N$) holds with $N(\eta) = C_I\eta^{-\mathsf{p}_I}$ for numbers $C_I > 0$ and $\mathsf{p}_I \geq 0$.

The class is the set of the tensor functionals with (T1), (T2), (T3), (T4) and ($\mathrm{T5}_N$), for some $c_I \in (0, \frac{1}{16}]$ and some function N as in ($\mathrm{T5}_N$); a member of the class has the insertion bound with a power if it has (T5) besides. (T1°), which follows from (T1), takes the place of (T1) in (A)–(C) of Theorem L and in Theorem M. We say that σ has ($\mathrm{T5}_N$), or (T5), in the sup norm if the bound holds with $\|H\|_\infty$ in place of $\|H\|_\sharp$; as $\|H\|_\infty \leq \|H\|_\sharp$, it then has ($\mathrm{T5}_N$), or (T5), with the same numbers. In (T2) the numbers $C^*_n(\mathsf{d}; R) := \sup |\sigma(H_1, \dots, H_n)| / \prod_a \|H_a\|_\sharp$, the supremum over the tuples of type $(\mathsf{d}; R)$ without a member 0, serve as well, and they do not increase with d; so the class does not change if one asks in (T2) for numbers that do not increase with d. ■

Definition 4.4 (The plane, the tubes, labels, profiles)**.** (1) We put $x = (y, x_2)$ with $y = (y^0, y^1) = (x_3, x_1)$, $n_0 = (1, 0)$, $\tau_y := \tau_{y^0e_3 + y^1e_1}$, $\theta y = (-y^0, y^1)$ and $\mathbb{R}^2_+ = \{y^0 > 0\}$. A point $\xi = (\xi^0, \xi^1) \in \mathbb{C}^2$ is identified with $(\xi^1, 0, \xi^0) \in \mathbb{C}^3$.

(2) $d_{\mathrm{Tb}}(\xi) = \operatorname{Re}\xi^0 - |\operatorname{Im}\xi^1|$, $\mathrm{Tb} = \{d_{\mathrm{Tb}} > 0\}$, $\xi^* = (\overline{\xi^0}, -\overline{\xi^1})$, $\xi^\pm = \xi^0 \pm i\xi^1$, and $\mathrm{Tb}^{(n)} = \{x \in (\mathbb{C}^2)^n : x_1 \in \mathrm{Tb},\ x_{k+1} - x_k \in \mathrm{Tb}\}$.

(3) $d_3(\mathfrak{z}) = \operatorname{Re}\mathfrak{z}_3 - |\operatorname{Im}\mathfrak{z}_1| - |\operatorname{Im}\mathfrak{z}_2|$, $\mathrm{Tb}_3 = \{d_3 > 0\}$, $\mathfrak{z}^* = (-\bar{\mathfrak{z}}_1, -\bar{\mathfrak{z}}_2, \bar{\mathfrak{z}}_3)$, and $\mathrm{Tb}_3^{(n)}$ is formed as in (2).

(4) R_t, $t \in \mathbb{R}$, is the rotation about e_2 with $R_te_3 = \cos t\, e_3 + \sin t\, e_1$ and $R_te_1 = -\sin t\, e_3 + \cos t\, e_1$. On $\mathbb{C}^2$ and for $\zeta \in \mathbb{C}$, R_ζ is the linear map with $(R_\zeta\xi)^\pm = e^{\pm i\zeta}\xi^\pm$; for real ζ it is the rotation R_ζ acting on y. We put $n_\upsilon := R_\upsilon n_0 = (\cos\upsilon, \sin\upsilon)$.

(5) A label is an $\mathfrak{a} \in \mathcal{L}_\mathbb{C} := C^1_c(\mathbb{R}; V_\mathbb{C})$; it is real if it is V-valued. We put $\mathfrak{a}^\theta := \varrho(\theta)\bar{\mathfrak{a}}$; $\lambda_\mathfrak{a}$ is the length of the smallest closed interval that contains $\operatorname{supp}\mathfrak{a}$ ($\lambda_0 = 0$); $\nu(\mathfrak{a}) := (\lambda_\mathfrak{a} + 1)\|\mathfrak{a}\|_{C^1}$ and $\nu_\infty(\mathfrak{a}) := (\lambda_\mathfrak{a} + 1)\|\mathfrak{a}\|_\infty$. For $r \in \mathrm{O}(3)$, $\varrho(r)\mathfrak{a}$ is taken pointwise; for a tuple $\mathbf{a} = (\mathfrak{a}_1, \dots, \mathfrak{a}_n)$ of labels, $\bar{\mathbf{a}}$ and $\varrho(r)\mathbf{a}$ are taken label by label.

(6) A profile is an $\alpha \in C^1_c(\mathbb{R}^2; \mathbb{C})$, and $(\alpha \otimes \mathfrak{a})(x) := \alpha(y)\mathfrak{a}(x_2)$. Profiles $\alpha_1, \dots, \alpha_n$ have time-ordered supports if $\operatorname{supp}\alpha_k \subset \{g_{k-1} < y^0 < g_k\}$ for real numbers $g_0 < \dots < g_n$, and are time-ordered in $\mathbb{R}^2_+$ if moreover $g_0 \geq 0$; then $\sigma(\alpha_1 \otimes \mathfrak{a}_1, \dots, \alpha_n \otimes \mathfrak{a}_n) := \sigma((\alpha_1 \otimes \mathfrak{a}_1, \dots, \alpha_n \otimes \mathfrak{a}_n)_\mathbb{C})$. We put $Y = (y_1, \dots, y_n)$ and $dY = dy_1 \cdots dy_n$.

(7) Helicity. $\epsilon_\pm := e_3 \pm i e_1$; $E_{\pm 2} := \epsilon_\pm \epsilon_\pm^{\mathsf T}$, $E_{\pm 1} := \frac12(e_2\epsilon_\pm^{\mathsf T} + \epsilon_\pm e_2^{\mathsf T})$, $E_0 := e_2 e_2^{\mathsf T}$ and $E_{0'} := \frac12(\epsilon_+\epsilon_-^{\mathsf T} + \epsilon_-\epsilon_+^{\mathsf T}) = e_3 e_3^{\mathsf T} + e_1 e_1^{\mathsf T}$ form a basis of $V_{\mathbb C}$; $\mathrm{hel}(\pm 2) = \pm 2$, $\mathrm{hel}(\pm 1) = \pm 1$, $\mathrm{hel}(0) = \mathrm{hel}(0') = 0$. A helicity label is a label φE_s with a real $\varphi \in C^1_c(\mathbb R)$; for a tuple $\mathbf a$ of helicity labels $\varphi_k E_{s_k}$ we put $S(\mathbf a) := \sum_k \mathrm{hel}(s_k)$.

■

Definition 4.5 (Operators and numbers)**.** Let σ have (T1°), (T2) and (T3).

(1) Under (T4): $T(\xi) := \int_{\{E \ge |q_1|\}} e^{-\xi^0 E + i\xi^1 q_1}\, d\mathcal P(E,q)$ for $\xi \in \overline{\mathrm{Tb}}$.

(2) Under (T1) and (T4): $T_3(\mathfrak z) := \int_{\{E\ge|q_1|,\ E\ge|q_2|\}} e^{-\mathfrak z_3 E + i\mathfrak z_1 q_1 + i\mathfrak z_2 q_2}\, d\mathcal P(E,q)$ for $\mathfrak z \in \overline{\mathrm{Tb}_3}$.

(3) Under (T5$_N$): for $d>0$ and $f \in C^1_c(\{|x_3|<d\}; V_{\mathbb C})$, the centred slab operator $B^c_d(f)$ is the bounded operator with $B^c_d(f)[F] = [(\tau_{de_3} f)_{\mathbb C} \cdot \tau_{2de_3} F]$ for $F \in \mathbb C\mathfrak S^V(E_+)$ (Lemmas 4.15 and 4.16); then $\langle [\tau_{-de_3}F], B^c_d(f)[\tau_{-de_3}F']\rangle = \sigma(\theta\bar F \cdot (f)_{\mathbb C} \cdot F')$ for $F, F' \in \mathbb C\mathfrak S^V(\{x_3 > d\})$.

(4) $\mathrm{mv}_0 = 9\pi/(5\pi^2-8)$, $\mathrm{mv}_1 = \frac{3\pi}{4}\mathrm{mv}_0$, $\mathrm{mv}_2 = \sqrt2\,\mathrm{mv}_0\mathrm{mv}_1 + 2\mathrm{mv}_0^2$ and $\mathrm{mv}_3 = \mathrm{mv}_0^3 + \sqrt3\,\mathrm{mv}_0^2\mathrm{mv}_1$ are the construction constants; $c_{\mathrm{plt}} := 480\cdot 8^3 \mathrm{mv}_2 c_I^{-4} M$ and $c_{\mathrm{pt}} := 320 \cdot 8^4 \mathrm{mv}_3 c_I^{-4} M$; under (T5), $\wp := \mathsf p_I + 4$, $\wp' := \mathsf p_I + 3$, $C_{\mathrm{plt}} := c_{\mathrm{plt}} C_I$, $C_{\mathrm{pt}} := c_{\mathrm{pt}} C_I$, $C_\flat := 2^{\wp+1} C_{\mathrm{plt}}$ and $C'_\flat := 2^{\wp'+1}\cdot 12 \cdot 8^2 \mathrm{mv}_0^2 c_I^{-3} C_I$.

■

4.2. **Principal results.**

Theorem L (Point plates, kernels and vectors with matrix labels; point fields with a matrix index)**.** Let σ be a tensor functional. The numbers of Definition 4.5 are formed with the constants c_I and N, or c_I, C_I and $\mathsf p_I$, with which σ has (T5$_N$), or (T5); none of them depends on n, on the labels or on the numbers of (T2).

(A) *Point plates.* Suppose that σ has (T1°), (T2), (T3), (T4) and (T5$_N$), with N arbitrary. Then there are bounded operators $B_{\mathfrak a}(\xi,\xi')$ on $\mathcal H(\sigma)$, for $\mathfrak a \in \mathcal L_{\mathbb C}$ and $\xi, \xi' \in \mathrm{Tb}$, holomorphic in norm in (ξ,ξ') and complex linear in $\mathfrak a$, such that:

(i) $\|B_{\mathfrak a}(\xi,\xi')\| \le 2c_{\mathrm{plt}}\,\nu(\mathfrak a)\,N(\eta)\eta^{-4}$ for every $\eta \in (0, \min\{1, d_{\mathrm{Tb}}(\xi), d_{\mathrm{Tb}}(\xi')\}]$, and the factor 2 may be omitted for real $\mathfrak a$;

(ii) $T(\kappa)B_{\mathfrak a}(\xi,\xi')T(\kappa') = B_{\mathfrak a}(\kappa+\xi, \xi'+\kappa')$ for $\kappa,\kappa' \in \overline{\mathrm{Tb}}$, and $B_{\mathfrak a}(\xi,\xi')^* = B_{\mathfrak a^\theta}(\xi'^*, \xi^*)$;

(iii) $B^c_d(\alpha\otimes\mathfrak a) = \int \alpha(y)\, B_{\mathfrak a}(dn_0+y, dn_0-y)\, dy$ for $d>0$ and profiles α with support in $\{|y^0|<d\}$; if $\operatorname{supp}\alpha \subset \{|y^0| \le d'\}$ with $0 \le d' < d$, then $\|B^c_d(\alpha\otimes\mathfrak a)\| \le 2c_{\mathrm{plt}}\,\nu(\mathfrak a)\,N(\eta)\eta^{-4}\|\alpha\|_{L^1}$ for every $\eta \in (0, \min\{1, d-d'\}]$;

(iv) a weakly continuous family of bounded operators on $\mathrm{Tb}\times\mathrm{Tb}$ that has the shift rule of (ii) and satisfies the identity of (iii) in matrix elements, for all $d>0$ and all real profiles with support in $\{|y^0|<d\}$, is the family $B_{\mathfrak a}$; in particular $B_{\mathfrak a}$ depends on σ and $\mathfrak a$ alone, not on c_I or N;

(v) for $\xi,\xi',\kappa_1,\kappa_2 \in \mathrm{Tb}$, $\kappa_0 \in \overline{\mathrm{Tb}}$ and $\mathfrak a' \in \mathcal L_{\mathbb C}$, the operator $B_{\mathfrak a}(\xi,\kappa_1)T(\kappa_0)B_{\mathfrak a'}(\kappa_2,\xi')$ depends on $(\kappa_1,\kappa_0,\kappa_2)$ only through $\varkappa = \kappa_1+\kappa_0+\kappa_2$ and equals $B_{\mathfrak a}(\xi, \frac{\varkappa}{2})B_{\mathfrak a'}(\frac{\varkappa}{2},\xi')$; the vector $B_{\mathfrak a}(\xi,\kappa)\Omega$ and the numbers $\langle\Omega, B_{\mathfrak a}(\kappa,\xi)\psi\rangle$, $\psi \in \mathcal H(\sigma)$, do not depend on $\kappa \in \mathrm{Tb}$.

(B) *Kernels and vectors.* Let σ be as in (A), $n \ge 1$, $\mathbf a = (\mathfrak a_1,\dots,\mathfrak a_n) \in \mathcal L^n_{\mathbb C}$ and $\kappa \in \mathrm{Tb}$. Put

$$K_n(\xi;\mathbf a) := \langle \Omega, B_{\mathfrak a_1}(\kappa, \tfrac{\xi_1}{2}) B_{\mathfrak a_2}(\tfrac{\xi_1}{2}, \tfrac{\xi_2}{2}) \cdots B_{\mathfrak a_n}(\tfrac{\xi_{n-1}}{2}, \kappa)\Omega\rangle, \qquad \xi \in \mathrm{Tb}^{n-1},$$

$$\Psi(x;\mathbf a) := B_{\mathfrak a_1}(x_1, \tfrac{x_2-x_1}{2}) B_{\mathfrak a_2}(\tfrac{x_2-x_1}{2}, \tfrac{x_3-x_2}{2}) \cdots B_{\mathfrak a_n}(\tfrac{x_n-x_{n-1}}{2}, \kappa)\Omega, \qquad x \in \mathrm{Tb}^{(n)},$$

with $K_1(\mathfrak a_1) = \langle\Omega, B_{\mathfrak a_1}(\kappa,\kappa)\Omega\rangle$ and $\Psi(x_1;\mathfrak a_1) = B_{\mathfrak a_1}(x_1,\kappa)\Omega$; we call the $\Psi(x;\mathbf a)$ plate vectors. They do not depend on κ, they are complex linear in each label, and:

(KV1$_N$) $K_n(\cdot;\mathbf a)$ is holomorphic on Tb^{n-1}, and $|K_n(\xi;\mathbf a)| \le \prod_k (2c_{\mathrm{plt}}\,\nu(\mathfrak a_k)) \cdot (N(\eta)\eta^{-4})^n$ for every $\eta \in (0, \min\{1, \frac12 \min_k d_{\mathrm{Tb}}(\xi_k)\}]$; for $n=1$, for every $\eta \in (0,1]$;

(KV2) if the profiles $\alpha_1,\dots,\alpha_n$ have time-ordered supports, then

$$\sigma(\alpha_1\otimes\mathfrak{a}_1,\dots,\alpha_n\otimes\mathfrak{a}_n)=\int\prod_k\alpha_k(y_k)\,K_n(y_2-y_1,\dots,y_n-y_{n-1};\mathbf{a})\,dY,$$

and if they are time-ordered in $\mathbb{R}^2_+$, then

$$[(\alpha_1\otimes\mathfrak{a}_1,\dots,\alpha_n\otimes\mathfrak{a}_n)_{\mathbb{C}}]=\int\prod_k\alpha_k(y_k)\,\Psi(Y;\mathbf{a})\,dY;$$

(KV3) $\Psi(\cdot;\mathbf{a})$ is holomorphic in norm on $\mathrm{Tb}^{(n)}$; $T(\kappa')\Psi(x;\mathbf{a})=\Psi(x+(\kappa',\dots,\kappa');\mathbf{a})$ for $\kappa'\in\overline{\mathrm{Tb}}$;

$$\langle\Omega,\Psi(z;\mathbf{a}')\rangle=K_{n'}(z_2-z_1,\dots,z_{n'}-z_{n'-1};\mathbf{a}')$$

and

$$\langle\Psi(x;\mathbf{a}),\Omega\rangle=K_n((x_n-x_{n-1})^*,\dots,(x_2-x_1)^*;\mathfrak{a}_n^\theta,\dots,\mathfrak{a}_1^\theta);$$

and, for $\mathbf{a}'\in\mathcal{L}^{n'}_{\mathbb{C}}$ and $z\in\mathrm{Tb}^{(n')}$,

$$\langle\Psi(x;\mathbf{a}),\Psi(z;\mathbf{a}')\rangle=K_{n+n'}\big((x_n-x_{n-1})^*,\dots,(x_2-x_1)^*,x_1^*+z_1,z_2-z_1,\dots,z_{n'}-z_{n'-1};\mathfrak{a}_n^\theta,\dots,\mathfrak{a}_1^\theta,\mathfrak{a}_1',\dots,\mathfrak{a}_{n'}'\big);$$

(KV4) $\overline{K_n(\xi;\mathbf{a})}=K_n(\bar\xi;\bar{\mathbf{a}})$, the bars taken coordinate by coordinate and label by label; if σ is centred, then $K_1=0$;

(KV5) a continuous function on $(\mathbb{R}^2_+)^{n-1}$ that satisfies the first formula of (KV2) for all real profiles with time-ordered supports is $K_n(\cdot;\mathbf{a})$ there; hence $K_n(\cdot;\mathbf{a})$ is the only holomorphic function on Tb^{n-1} with that formula, $\Psi(\cdot;\mathbf{a})$ is the only map on $\mathrm{Tb}^{(n)}$, holomorphic in norm, with the second formula, and both depend on σ and $\mathbf{a}$ alone.

(C) *The power.* Suppose that σ has (T1°), (T2), (T3), (T4) and (T5). Then, besides (B), for all $n\ge1$, $\mathbf{a}\in\mathcal{L}^n_{\mathbb{C}}$ and $\xi\in\mathrm{Tb}^{n-1}$,

$$\text{(KV1)}\qquad |K_n(\xi;\mathbf{a})|\le\prod_k\big(C_\flat\,\nu(\mathfrak{a}_k)\big)\cdot\min\{1,\min_k d_{\mathrm{Tb}}(\xi_k)\}^{-\wp n},$$

the right side being $C_\flat\nu(\mathfrak{a}_1)$ for $n=1$, and with $2^\wp C_{\mathrm{plt}}$ in place of $C_\flat$ if all labels are real. More precisely, $|K_n(\xi;\mathbf{a})|\le\prod_{k=1}^n\big(2C_{\mathrm{plt}}\,\nu(\mathfrak{a}_k)\min\{1,\frac12 d_{\mathrm{Tb}}(\xi_{k-1}),\frac12 d_{\mathrm{Tb}}(\xi_k)\}^{-\wp}\big)$, the terms with ξ_0 and ξ_n left out, and $\|B_{\mathfrak{a}}(\xi,\xi')\|\le 2C_{\mathrm{plt}}\,\nu(\mathfrak{a})\min\{1,d_{\mathrm{Tb}}(\xi),d_{\mathrm{Tb}}(\xi')\}^{-\wp}$. If σ has (T5) in the sup norm, then (KV1) holds also with $\wp'$, $\nu_\infty(\mathfrak{a}_k)$ and $C_\flat'$ in place of $\wp$, $\nu(\mathfrak{a}_k)$ and $C_\flat$.

(D) *Point fields.* Suppose that σ has (T1), (T2), (T3), (T4) and (T5$_N$). Then σ is reflection positive at each of the mirrors $\{x_\mu=0\}$, $\mu=1,2,3$; $\mathcal{P}$ is carried by $\{E\ge|q_1|,\ E\ge|q_2|\}$; and T_3 is a strongly continuous family of contractions on $\overline{\mathrm{Tb}_3}$, holomorphic in norm on Tb_3, with $T_3(\mathfrak{z})T_3(\mathfrak{z}')=T_3(\mathfrak{z}+\mathfrak{z}')$, $T_3(\mathfrak{z})^*=T_3(\mathfrak{z}^*)$, $T_3(\mathfrak{z})\Omega=\Omega$, $T_3(x)[F]=[\tau_xF]$ for real x with $x_3\ge0$, and $T(\xi)=T_3(\xi^1,0,\xi^0)$. There are bounded operators $B_E(\mathfrak{z},\mathfrak{z}')$ on $\mathcal{H}(\sigma)$, for $E\in V_{\mathbb{C}}$ and $\mathfrak{z},\mathfrak{z}'\in\mathrm{Tb}_3$, holomorphic in norm in $(\mathfrak{z},\mathfrak{z}')$ and complex linear in E, such that:

(i) $\|B_E(\mathfrak{z},\mathfrak{z}')\|\le 2c_{\mathrm{pt}}|E|_2N(\eta)\eta^{-4}$ for every $\eta\in(0,\min\{1,d_3(\mathfrak{z}),d_3(\mathfrak{z}')\}]$, and the factor 2 may be omitted for $E\in V$;

(ii) $T_3(\kappa)B_E(\mathfrak{z},\mathfrak{z}')T_3(\kappa')=B_E(\kappa+\mathfrak{z},\mathfrak{z}'+\kappa')$ for $\kappa,\kappa'\in\overline{\mathrm{Tb}_3}$, and $B_E(\mathfrak{z},\mathfrak{z}')^*=B_{\varrho(\theta)\bar E}(\mathfrak{z}'^*,\mathfrak{z}^*)$;

(iii) $B_d^c(H)=\int B_{H(x)}(de_3+x,de_3-x)\,dx$ for $d>0$ and $H\in C^1_c(\{|x_3|<d\};V_{\mathbb{C}})$;

(iv) for each E, a weakly continuous family of bounded operators on $\mathrm{Tb}_3\times\mathrm{Tb}_3$ that has the shift rule of (ii) and satisfies (iii) in matrix elements at $H=hE$, for all $d>0$ and all real $h\in C^1_c(\{|x_3|<d\};\mathbb{R})$, is the family B_E; for $\kappa_1,\kappa_2\in\mathrm{Tb}_3$ and $\kappa_0\in\overline{\mathrm{Tb}_3}$ the operator $B_E(\mathfrak{z},\kappa_1)T_3(\kappa_0)B_{E'}(\kappa_2,\mathfrak{z}')$ depends on $(\kappa_1,\kappa_0,\kappa_2)$ only through $\varkappa=\kappa_1+\kappa_0+\kappa_2$ and equals $B_E(\mathfrak{z},\frac{\varkappa}{2})B_{E'}(\frac{\varkappa}{2},\mathfrak{z}')$; and $B_E(\mathfrak{z},\kappa)\Omega$ and $\langle\Omega,B_E(\kappa,\mathfrak{z})\psi\rangle$ do not depend on $\kappa\in\mathrm{Tb}_3$.

(E) *Plates from point fields; point bound and insertion bound.* Let σ be as in (D).

(i) $B_{\mathfrak a}(\xi,\xi') = \int B_{\mathfrak a(s)}(\xi + se_2, \xi' - se_2)\,ds$ for $\mathfrak a \in \mathcal L_{\mathbb C}$ and $\xi,\xi' \in \mathrm{Tb}$; hence $\|B_{\mathfrak a}(\xi,\xi')\| \le 2c_{\mathrm{pt}}\|\mathfrak a\|_{L^1}N(\eta)\eta^{-4}$ for η as in (A)(i). For $H \in C^1_c(\{|x_3| < d\}; V_{\mathbb C})$ with support in $\{|x_3| \le d'\}$, $0 \le d' < d$, and for $\eta \in (0, \min\{1, d-d'\}]$, $\|B^c_d(H)\| \le 2c_{\mathrm{pt}}N(\eta)\eta^{-4}\|H\|_{L^1}$ and $\|B^c_d(H)\| \le c_{\mathrm{pt}}N(\eta)\eta^{-4}\sum_c \|\operatorname{tr}(b_cH)\|_{L^1}$ for every basis (b_c) of V orthonormal for $(E,E') \mapsto \operatorname{tr} EE'$. If σ has (T5), then (KV1) holds also with $2^{\wp+1}C_{\mathrm{pt}}\|\mathfrak a_k\|_{L^1}$ in place of $C_\flat\nu(\mathfrak a_k)$.

(ii) Let $\mathsf C_{\mathrm{pt}}(\eta) := \sup\{\|B_E(\mathfrak z,\mathfrak z')\| : E \in V,\ |E|_2 = 1,\ d_3(\mathfrak z), d_3(\mathfrak z') \ge \eta\}$ for $\eta \in (0,1]$. Then $\mathsf C_{\mathrm{pt}}(\eta) \le c_{\mathrm{pt}}N(\eta)\eta^{-4}$, and $\mathsf C_{\mathrm{pt}}(\eta) \le 8^4 \mathrm{mv}_0^3 c_I^{-3} N(\eta)\eta^{-3}$ if σ has ($\mathrm{T5}_N$) in the sup norm. For η, H, F, G as in ($\mathrm{T5}_N$),

$$|\sigma(\theta\bar F\cdot(H)\cdot G)| \le \mathsf C_{\mathrm{pt}}(\tfrac{\eta}{16})\,\|H\|_{L^1}\,\|[\tau_{-(\eta/4)e_3}F]\|\,\|[\tau_{-(\eta/4)e_3}G]\|, \qquad \|H\|_{L^1} \le \tfrac{4\pi}{3}(c_I\eta)^3\|H\|_\infty.$$

Consequently, if σ has (T5) in the sup norm with C_I and $\mathsf p_I$, then $\mathsf C_{\mathrm{pt}}(\eta) \le 8^4\mathrm{mv}_0^3c_I^{-3}C_I\eta^{-\mathsf p_I-3}$; if $\mathsf C_{\mathrm{pt}}(\eta) \le C\eta^{-\mathsf p}$ for $\eta \in (0,1]$, then σ has (T5) in the sup norm with the same c_I, with $\max\{\mathsf p-3, 0\}$ for $\mathsf p_I$ and $\frac{4\pi}{3}\,16^{\mathsf p}c_I^3C$ for C_I; in particular (T5) with $\mathsf p_I$ gives (T5) in the sup norm with $\mathsf p_I+1$.

(F) *Reflections; other spaces of values.* (a) If σ has ($\mathrm{T1}^\circ$) and (T3), then $\sigma(\theta_cX) = \sigma(X)$ for every $X \in \mathfrak S^V(\mathbb R^3)$ none of whose supports meets $\{x_3 = c\}$. (b) Let V' be a real Euclidean space of finite dimension and ϑ an orthogonal involution of V'; define tuples, tensor functionals and the conditions ($\mathrm{T1}^\circ$), (T2), (T3), (T4), ($\mathrm{T5}_N$), (T5) as above, with V' in place of V, its Euclidean norm in place of $|\cdot|_2$, translations acting on the argument alone, $(\theta_cf)(x) := \vartheta f(\theta_cx)$, and $\mathfrak a^\theta := \vartheta\bar{\mathfrak a}$. Then (A), (B) and, under (T5), (KV1) hold for V' and ϑ, with the same constants.

■□

Theorem M (A converse on the closed span of the plate vectors)**.** Let σ have ($\mathrm{T1}^\circ$), (T2), (T3), (T4) and ($\mathrm{T5}_N$), with N arbitrary, and let $\mathcal H_{\mathrm{pl}} \subset \mathcal H(\sigma)$ be the closed span of Ω and of all plate vectors $\Psi(x;\mathbf a)$, $n \ge 1$, $\mathbf a \in \mathcal L^n_{\mathbb C}$, $x \in \mathrm{Tb}^{(n)}$. Suppose that there are numbers $C' > 0$ and $\varpi \ge 0$ with $|K_n(\xi;\mathbf a)| \le \prod_k(C'\nu(\mathfrak a_k))\cdot\min\{1, \min_k d_{\mathrm{Tb}}(\xi_k)\}^{-\varpi n}$ for all $n \ge 1$, $\xi \in \mathrm{Tb}^{n-1}$ and $\mathbf a \in \mathcal L^n_{\mathbb C}$. Then $B_{\mathfrak b}(\xi,\xi')\mathcal H_{\mathrm{pl}} \subset \mathcal H_{\mathrm{pl}}$ and

$$\|B_{\mathfrak b}(\xi,\xi')\Phi\| \le C'\nu(\mathfrak b)\min\{1, 2d_{\mathrm{Tb}}(\xi), d_{\mathrm{Tb}}(\xi')\}^{-\varpi}\|\Phi\| \qquad (\Phi \in \mathcal H_{\mathrm{pl}},\ \mathfrak b \in \mathcal L_{\mathbb C},\ \xi,\xi' \in \mathrm{Tb}).$$

Conversely, if $\|B_{\mathfrak b}(\xi,\xi')\Phi\| \le C''\nu(\mathfrak b)\min\{1, d_{\mathrm{Tb}}(\xi), d_{\mathrm{Tb}}(\xi')\}^{-\varpi}\|\Phi\|$ for all such Φ, $\mathfrak b$, ξ, ξ', then the bound on the K_n holds with $C' = 2^\varpi C''$. ■□

Corollary 4.6 (The density formula with a matrix)**.** Let σ have (T1), (T2), (T3), (T4) and ($\mathrm{T5}_N$), let $d > 0$ and $F, F' \in \mathbb C\mathfrak S^V(\{x_3 > d\})$, and put, for $|x_3| < d$ and $E \in V_{\mathbb C}$,

$$\mathsf v_d(x;E) := \langle [\tau_{-de_3}F], B_E(de_3 + x, de_3 - x)[\tau_{-de_3}F']\rangle.$$

Then $\mathsf v_d(x;E)$ is complex linear in E; $\mathsf v_d(\cdot;E)$ is the restriction to the real points of a holomorphic function on $\{w \in \mathbb C^3 : |\operatorname{Re} w_3| + |\operatorname{Im} w_1| + |\operatorname{Im} w_2| < d\}$; $\sigma(\theta\bar F\cdot(H)_{\mathbb C}\cdot F') = \int \mathsf v_d(x;H(x))\,dx$ for every $H \in C^1_c(\{|x_3| < d\}; V_{\mathbb C})$; and $|\mathsf v_d(x;E)| \le 2c_{\mathrm{pt}}|E|_2N(\eta)\eta^{-4}\|[\tau_{-de_3}F]\|\,\|[\tau_{-de_3}F']\|$ for every $\eta \in (0, \min\{1, d-|x_3|\}]$, the factor 2 omitted for $E \in V$. ■□

Theorem N (One holomorphic function on all quarter-turned tubes)**.** Let $n \ge 2$, and let σ have (T1), (T2), (T3), (T4) and ($\mathrm{T5}_N$). For a permutation $\mathfrak s$ of $\{1,\dots,n\}$, $Z = (z_1,\dots,z_n) \in (\mathbb C^2)^n$ and $\mathbf a \in \mathcal L^n_{\mathbb C}$ put $\mathfrak sZ := (z_{\mathfrak s(1)},\dots,z_{\mathfrak s(n)})$, $\mathfrak s\mathbf a := (\mathfrak a_{\mathfrak s(1)},\dots,\mathfrak a_{\mathfrak s(n)})$ and $\partial Z := (z_2 - z_1,\dots,z_n - z_{n-1})$; for $\upsilon \in \frac{\pi}{2}\mathbb Z$ let $\mathcal Z(\mathfrak s,\upsilon) := \{Z : \partial(\mathfrak sZ) \in (R_\upsilon\mathrm{Tb})^{n-1}\}$, $\mathcal Z_n := \bigcup_{\mathfrak s,\upsilon}\mathcal Z(\mathfrak s,\upsilon)$, and on $\mathcal Z(\mathfrak s,\upsilon)$

$$K^{\mathfrak s}_\upsilon(Z;\mathbf a) := K_n\big(R_{-\upsilon}\partial(\mathfrak sZ); \mathfrak s\,\varrho(R_{-\upsilon})\mathbf a\big),$$

$R_{-\upsilon}$ acting on each difference. Then:

(a) $K^{\mathfrak s}_\upsilon$ depends on υ modulo 2π only and is holomorphic on $\mathcal Z(\mathfrak s,\upsilon)$;

(b) for non-zero profiles $\alpha_1,\dots,\alpha_n$ with $\operatorname{supp}\alpha_1\times\cdots\times\operatorname{supp}\alpha_n\subset\mathcal{Z}(\mathfrak{s},\upsilon)$, $\sigma(\alpha_1\otimes\mathfrak{a}_1,\dots,\alpha_n\otimes\mathfrak{a}_n)=\int\prod_k\alpha_k(y_k)\,K^{\mathfrak{s}}_{\upsilon}(Y;\mathbf{a})\,dY$;

(c) $K^{\mathfrak{s}}_{\upsilon}=K^{\mathfrak{s}'}_{\upsilon'}$ on $\mathcal{Z}(\mathfrak{s},\upsilon)\cap\mathcal{Z}(\mathfrak{s}',\upsilon')$; so there is exactly one holomorphic function $\mathcal{K}_n(\cdot;\mathbf{a})$ on $\mathcal{Z}_n$ that equals $K^{\mathfrak{s}}_{\upsilon}$ on every $\mathcal{Z}(\mathfrak{s},\upsilon)$, and it is complex linear in each label;

(d) $\mathcal{K}_n(\mathfrak{s}'Z;\mathfrak{s}'\mathbf{a})=\mathcal{K}_n(Z;\mathbf{a})=\mathcal{K}_n(Z+(v,\dots,v);\mathbf{a})$ for every permutation $\mathfrak{s}'$ and $v\in\mathbb{C}^2$; $\mathcal{K}_n(R_{\pi/2}Z;\mathbf{a})=\mathcal{K}_n(Z;\varrho(R_{-\pi/2})\mathbf{a})$; and $\overline{\mathcal{K}_n(Z;\mathbf{a})}=\mathcal{K}_n(\bar Z;\bar{\mathbf{a}})$;

(e) if σ has (T5), then $|\mathcal{K}_n(Z;\mathbf{a})|\le\prod_k(C_\flat\nu(\mathfrak{a}_k))\cdot\min\{1,\min_k d_{\mathrm{Tb}}((R_{-\upsilon}\partial(\mathfrak{s}Z))_k)\}^{-\wp n}$ on $\mathcal{Z}(\mathfrak{s},\upsilon)$;

(f) for real $x\in\mathrm{Tb}^{(n_1)}$ and $z\in\mathrm{Tb}^{(n_2)}$, real s, labels $\mathbf{a}\in\mathcal{L}^{n_1}_{\mathbb{C}}$, $\mathbf{a}'\in\mathcal{L}^{n_2}_{\mathbb{C}}$ and $X:=(\theta x_{n_1},\dots,\theta x_1,z_1,\dots,z_{n_2})$,

$$\langle\Psi(R_{is}x;\mathbf{a}),\Psi(R_{is}z;\mathbf{a}')\rangle=\mathcal{K}_{n_1+n_2}(R_{is}X;\mathfrak{a}^\theta_{n_1},\dots,\mathfrak{a}^\theta_1,\mathfrak{a}'_1,\dots,\mathfrak{a}'_{n_2});$$

(g) for helicity labels, $\varrho(R_t)E_s=e^{-i\,\mathrm{hel}(s)t}E_s$ and $(\varphi E_s)^\theta=(-1)^{\mathrm{hel}(s)}\varphi E_s$; hence, for a tuple $\mathbf{a}$ of helicity labels, $K^{\mathfrak{s}}_{\upsilon}(Z;\mathbf{a})=e^{iS(\mathbf{a})\upsilon}K_n(R_{-\upsilon}\partial(\mathfrak{s}Z);\mathfrak{s}\mathbf{a})$, $\mathcal{K}_n(R_{\pi/2}Z;\mathbf{a})=e^{iS(\mathbf{a})\pi/2}\mathcal{K}_n(Z;\mathbf{a})$, and the Gram formula of Theorem L (KV3) takes the form

$$\langle\Psi(x;\mathbf{a}),\Psi(z;\mathbf{a}')\rangle=(-1)^{S(\mathbf{a})}K_{n+n'}(\dots;\mathfrak{a}_n,\dots,\mathfrak{a}_1,\mathfrak{a}'_1,\dots,\mathfrak{a}'_{n'}),$$

with the same arguments;

(h) let $\mathbf{a}$ be a tuple of helicity labels, $S=S(\mathbf{a})$, and X a configuration of n pairwise different points of $\mathbb{R}^2$ on one line. Then $R_\zeta X\in\mathcal{Z}_n$ for every $\zeta\in\mathbb{C}$, and $\zeta\mapsto e^{-iS\zeta}\mathcal{K}_n(R_\zeta X;\mathbf{a})$ is entire and of period $\frac{\pi}{2}$; so

$$\mathcal{K}_n(R_\zeta X;\mathbf{a})=\sum_{m\in\mathbb{Z}}c_m(X;\mathbf{a})\,e^{i(S+4m)\zeta},\qquad c_m(R_tX;\mathbf{a})=e^{i(S+4m)t}c_m(X;\mathbf{a})\ (t\in\mathbb{R}),$$

the series converging locally uniformly. With the weight $k(E)$ of an $E\in V_{\mathbb{C}}$ defined by $\varrho(R_t)E=e^{ik(E)t}E$ one has $k(E_s)=-\mathrm{hel}(s)$, so the frequencies are the multiples of 4 diminished by $\kappa=\sum_k k(E_{s_k})=-S$. If σ has (T5), then $c_m(X;\mathbf{a})=0$ unless $4|m|\le\wp n+|S|$, in particular unless $4|m|\le(\wp+2)n$.

■□

Theorem O (A converse on the closed span of the point vectors)**.** Let σ have (T1), (T2), (T3), (T4) and ($\mathrm{T5}_N$). For $n\ge1$, $\mathbf{E}=(E_1,\dots,E_n)\in V^n_{\mathbb{C}}$, $\kappa\in\mathrm{Tb}_3$, $\mathfrak{z}\in\mathrm{Tb}_3^{n-1}$ and $\mathfrak{x}\in\mathrm{Tb}_3^{(n)}$ put

$$W_n(\mathfrak{z};\mathbf{E}):=\langle\Omega,B_{E_1}(\kappa,\tfrac{\mathfrak{z}_1}{2})B_{E_2}(\tfrac{\mathfrak{z}_1}{2},\tfrac{\mathfrak{z}_2}{2})\cdots B_{E_n}(\tfrac{\mathfrak{z}_{n-1}}{2},\kappa)\Omega\rangle,\qquad \Psi_3(\mathfrak{x};\mathbf{E}):=B_{E_1}(\mathfrak{x}_1,\tfrac{\mathfrak{x}_2-\mathfrak{x}_1}{2})\cdots B_{E_n}(\tfrac{\mathfrak{x}_n-\mathfrak{x}_{n-1}}{2},\kappa)\Omega,$$

which do not depend on κ by Theorem L (D)(iv), and let $\mathcal{H}_{\mathrm{pt}}$ be the closed span of Ω and of all point vectors $\Psi_3(\mathfrak{x};\mathbf{E})$. Suppose that there are $C'>0$ and $\varpi\ge0$ with $|W_n(\mathfrak{z};\mathbf{E})|\le\prod_k(C'|E_k|_2)\cdot\min\{1,\min_k d_3(\mathfrak{z}_k)\}^{-\varpi n}$ for all n, $\mathfrak{z}$, $\mathbf{E}$. Then $B_E(\mathfrak{z},\mathfrak{z}')\mathcal{H}_{\mathrm{pt}}\subset\mathcal{H}_{\mathrm{pt}}$,

$$\|B_E(\mathfrak{z},\mathfrak{z}')\Phi\|\le C'|E|_2\min\{1,2d_3(\mathfrak{z}),d_3(\mathfrak{z}')\}^{-\varpi}\|\Phi\|\qquad(\Phi\in\mathcal{H}_{\mathrm{pt}}),$$

and for $\eta\in(0,1]$, real $H\in C^1_c(\mathbb{R}^3;V)$ with support in $B(y,c_I\eta)$, $|y_3|\le\eta/8$, $F\in\mathbb{C}\mathfrak{S}^V(\{x_3>\eta/4\})$ and $G\in\mathbb{C}\mathfrak{S}^V(\{x_3>\eta/4\})$ with $[\tau_{-(\eta/4)e_3}G]\in\mathcal{H}_{\mathrm{pt}}$,

$$|\sigma(\theta\bar F\cdot(H)\cdot G)|\le\tfrac{4\pi}{3}\,c_I^3\,16^{\varpi}C'\,\eta^{3-\varpi}\,\|H\|_\infty\,\|[\tau_{-(\eta/4)e_3}F]\|\,\|[\tau_{-(\eta/4)e_3}G]\|:$$

on $\mathcal{H}_{\mathrm{pt}}$, the insertion bound in the sup norm holds with the power $\max\{\varpi-3,0\}$. ■□

Theorem P (Three Gaussian examples)**.** (a) Let σ_0 be a scalar functional, that is, a functional on the tuples of real scalar C^1_c functions on $\mathbb{R}^3$ with pairwise disjoint supports, with $\sigma_0(\emptyset)=1$ and multilinear in the same sense, and suppose that σ_0 has conditions (R1)–(R5) of Definition YMM1:95.1 (symmetry and invariance under $\mathbb{R}^3\rtimes W_3$, regularity, reflection positivity, the condition $E\ge|q_1|$, and the insertion bound with numbers c_I, C_I, p_I). Then $\sigma(H_1,\dots,H_n):=\sigma_0(\operatorname{tr}H_1,\dots,\operatorname{tr}H_n)$ is a tensor functional with (T1)–(T5), with the

numbers c_I, $\sqrt{3}\,C_I$ and p_I. If σ_0 has (R1)–(R4) and the insertion bound with a function N_0 in place of $C_I\eta^{-\mathsf{p}_I}$, then σ has (T1)–(T4) and (T5$_N$) with $N=\sqrt{3}\,N_0$.

(b) Let ϕ^1,ϕ^2,ϕ^3 be independent Gaussian free fields of mass zero on $\mathbb{R}^3$, with covariance $G(x)=(4\pi|x|)^{-1}$, let $\phi^c_\varepsilon := j^{(3)}_\varepsilon * \phi^c$, and for $H\in C^1_c(\mathbb{R}^3;V)$ put $T_\varepsilon(H):=\sum_{c=1}^3\sum_{a,b=1}^3\int H_{ab}(x)\mathbin{:}\partial_a\phi^c_\varepsilon(x)\,\partial_b\phi^c_\varepsilon(x)\mathbin{:}dx$, the colons denoting the Wick order. For $(H_1,\dots,H_n)\in\mathfrak{S}^V(\mathbb{R}^3)$ the limit $\sigma(H_1,\dots,H_n):=\lim_{\varepsilon\to0}\mathbb{E}[T_\varepsilon(H_1)\cdots T_\varepsilon(H_n)]$ exists, and with $\sigma(\emptyset)=1$ it is a centred tensor functional, invariant under all isometries of $\mathbb{R}^3$ in the tensor action, with (T1)–(T4) and with (T5) in the sup norm with $c_I=\frac{1}{16}$, $\mathsf{p}_I=0$ and some C_I. The same holds when $\nabla\phi^c$ is replaced by the Hodge duals of the field strengths of three independent free photon fields with the action $\frac14\int F_{ij}F_{ij}$: at disjoint supports this multiplies $\sigma(H_1,\dots,H_n)$ by $(-1)^n$.

(c) Let $S(x):=\int_0^\infty e^{\sqrt{m}}e^{-m|x|}(4\pi|x|)^{-1}\,dm$ for $x\neq0$, and

$$\sigma(H_1,\dots,H_n):=\sum_{\pi}\prod_{\{k,l\}\in\pi}\iint \operatorname{tr}H_k(x)\,S(x-y)\,\operatorname{tr}H_l(y)\,dx\,dy,$$

the sum over the partitions π of $\{1,\dots,n\}$ into pairs (it is empty for odd n), and $\sigma(\emptyset)=1$. Then σ is a centred tensor functional with (T1)–(T4) and with (T5$_N$) for $c_I=\frac{1}{16}$ and a finite function N, so that (A), (B) and (D) of Theorem L, and (E)(i) but for its last sentence, hold for it. But for every real $\varphi\in C^1_c(\mathbb{R})$ with $\varphi\geq0$, $\varphi\neq0$, and the unit matrix $\mathbf{1}$, $t^qK_2((t,0);\varphi\mathbf{1},\varphi\mathbf{1})\to\infty$ as $t\downarrow0$ for every $q\geq0$; hence (KV1) holds for no $C_\flat$ and no $\wp$, and σ has (T5) for no C_I and no p_I.

■□

Remark 4.7 (A fixed matrix does not reduce the theorem to the scalar case). For $E\in V$ with $\varrho(\theta)E=E$ and σ as in Theorem L (C), the scalar functional $\sigma_E(h_1,\dots,h_n):=\sigma(h_1E,\dots,h_nE)$ is reflection positive, since $\theta(hE)=(h\circ\theta)E$; the map $[F]_{\sigma_E}\mapsto[FE]_\sigma$, every member h replaced by hE, is then an isometry that intertwines the translations, so that σ_E has the regularity bound with $|E|_2^nC^\sigma_n$, the cone condition and the insertion bound with $|E|_2C_I$, because $\|hE\|_\sharp=|E|_2\|h\|_\sharp$. The scalar reconstruction hypotheses in Definition YMM1:95.1 include invariance under $\mathbb{R}^3\rtimes W_3$, whereas (T1°) gives σ_E invariance under translations. If σ has (T1), then $\sigma_E(wX)=\sigma_{\varrho(w)^{-1}E}(X)$ for $w\in W_3$, w acting on the scalar tuple X by $h\mapsto h\circ w^{-1}$, since $(h\circ w^{-1})E=w\big(h\,\varrho(w)^{-1}E\big)$ in the tensor action and (T1) holds at w; and $\varrho(w)E=E$ for all $w\in W_3$ only for $E\in\mathbb{R}\mathbf{1}$.

Moreover, polarisation in E of the scalar kernels of the σ_E yields only the sums

$$\sum_\pi K_n(\xi;\varphi_1E_{\pi(1)},\dots,\varphi_nE_{\pi(n)})$$

over the permutations π, not the single kernels. Thus applying scalar reconstruction separately to the σ_E does not prove Theorem L. Its proof below retains a matrix in every tuple member and every label.

Theorem Q (The limits of the fields $\operatorname{tr}F_{ij}F_{kl}$)**.** Let g be a reference coupling with $0<g\leq\gamma_W^{\mathrm{ref}}$. A Gibbs sequence at g is a sequence $(K_j,\beta_j,\nu_j)_{j\geq1}$ in which (K_j,β_j) are first-passage data at g, $K_j\to\infty$, and ν_j is a periodic Gibbs state at (K_j,β_j). For a bounded V-valued function H on $\mathbb{R}^3$ with bounded support put

$$\mathcal{O}^{\mathsf{T}}_K(H):=a_K^{-1}\sum_p H_{\lambda(p)\lambda(p)}(x(p))\,a_p-a_K^{-1}\sum_b H_{\lambda_b\lambda'_b}(x_b)\,q_b,$$

the sums running over the plaquettes p and the positively oriented bonds b of $a_K\mathbb{Z}^3$. Here $a_p:=1-\frac12\operatorname{tr}U(\partial p)$, with $U(\partial p)$ the product of the values of the configuration U around p, $x(p)$ is the centre of p and $\lambda(p)$ the direction normal to p; for $b=\langle x,x+a_Ke_\mu\rangle$, x_b is the midpoint of b,

$\lambda_b < \lambda_b'$ are the two directions other than μ, and

$$q_b := \tfrac{1}{4} \sum_{\varepsilon,\varepsilon'=\pm1} \varepsilon\varepsilon' \, \langle w(W_x(\mu, \varepsilon\lambda_b)), w(W_x(\mu, \varepsilon'\lambda_b'))\rangle,$$

where, for $\alpha, \alpha' \in \{\pm1, \pm2, \pm3\}$ with $|\alpha| \neq |\alpha'|$ and $e_{-\mu} := -e_\mu$, $W_x(\alpha, \alpha')$ is the product, in the order of the path $x \to x + a_K e_\alpha \to x + a_K e_\alpha + a_K e_{\alpha'} \to x + a_K e_{\alpha'} \to x$, of the values of U on its four bonds, a bond run against its orientation carrying the inverse value; $w(V) := (V - V^{-1})/2i$ and $\langle X, Y\rangle := \frac{1}{2} \operatorname{tr} XY$. This is the lattice field $\operatorname{tr} F_{ij} F_{kl}$ at the cutoff K smeared with H, as in Section C on the six fields $\operatorname{tr} F_{ij} F_{kl}$. It is real and linear in H, and $\mathcal{O}^{\mathsf{T}}_K(f\mathbf{1})$ is the action-density field smeared with f. The sequence converges if

$$\sigma(H_1, \dots, H_n) := \lim_{j\to\infty} \nu_j\Big(\prod_{a=1}^{n} (\mathcal{O}^{\mathsf{T}}_{K_j}(H_a) - \nu_j(\mathcal{O}^{\mathsf{T}}_{K_j}(H_a)))\Big)$$

exists for every $(H_1, \dots, H_n) \in \mathfrak{S}^V(\mathbb{R}^3)$; with $\sigma(\emptyset) := 1$, σ is its limit. A tensor limit at g is the limit, in the same sense but at every tuple of continuous V-valued functions with compact, pairwise disjoint supports, of a Gibbs sequence at g along which $a_{K_j}\beta_j$ converges to a number b_*.

(a) Every Gibbs sequence at g has a subsequence that converges at every tuple of continuous V-valued functions with compact, pairwise disjoint supports and along which $a_{K_j}\beta_j$ converges to a number $b_* \in [g^{-2}, L(g^{-2} + \bar{B})]$; its limit is a tensor limit at g with the number b_*. In particular every Gibbs sequence at g has a convergent subsequence, and tensor limits at g exist.

(b) Let σ be the limit of a convergent Gibbs sequence at g. Then:
  (i) σ is a centred tensor functional with (T1), (T2), (T3) and (T4), and $\mathcal{P}$ is carried by $\{E \geq \max(|q_1|, |q_2|)\}$;
  (ii) for every $\eta \in (0, 1]$ the least number $\mathsf{c}^\circ_\sigma(\eta)$ with

$$|\sigma(\theta\bar{F} \cdot (h) \cdot F')| \leq \mathsf{c}^\circ_\sigma(\eta) \|h\|_{L^1} \|[\tau_{-\eta e_3} F]\| \, \|[\tau_{-\eta e_3} F']\|$$

  for all $F, F' \in \mathbb{C}\mathfrak{S}^V(\{x_3 > \eta\})$ and all real $h \in C^1_c(\{|x_3| < \eta/2\}; V)$ is finite, and σ has $(\mathrm{T5}_N)$ with $c_I = \frac{1}{16}$ and $N(\eta) = \frac{4\pi}{3}\, 16^{-3} \eta^3 \, \mathsf{c}^\circ_\sigma(\eta/8)$;
  (iii) the trace part $\sigma_0(f_1, \dots, f_n) := \sigma(f_1\mathbf{1}, \dots, f_n\mathbf{1})$ is the centred-moment limit of the same Gibbs sequence for the action-density field, and $[F]_{\sigma_0} \mapsto [F\mathbf{1}]_\sigma$, every member f replaced by $f\mathbf{1}$, is an isometry of $\mathcal{H}(\sigma_0)$ onto a closed subspace of $\mathcal{H}(\sigma)$ that reduces $\mathcal{T}_t$, $\mathcal{U}(v)$ and $\mathcal{P}$;
  (iv) consequently (A), (B) and (D) of Theorem L, (E)(i) but for its last sentence, Corollary 4.6, and Theorem N but for (e) and the last assertion of (h), hold for σ.

(c) Let $0 < g \leq \gamma^{\mathrm{sd}}_W$, let σ be a tensor limit at g with the number b_*, and let σ^1 be its restriction to $\mathfrak{S}^V(\mathbb{R}^3)$. Then σ^1 is the limit of a convergent Gibbs sequence at g, so that (b) applies to it, and for every $\mathsf{p} > \frac{17}{2}$ there is a number C_p, depending only on g, p and the fixed construction constants, such that:
  (i) $|\sigma^1(\theta\bar{F} \cdot (h) \cdot G)| \leq C_\mathsf{p} \min\{1, d - d'\}^{-\mathsf{p}} b_*^{-1} \|h\|_{L^1} \|[\tau_{-de_3} F]\| \, \|[\tau_{-de_3} G]\|$ for $0 \leq d' < d$, real $h \in C^1_c(\mathbb{R}^3; V)$ with support in $\{|x_3| \leq d'\}$, and $F, G \in \mathbb{C}\mathfrak{S}^V(\{x_3 > d\})$;
  (ii) σ^1 has (T5) in the sup norm with $c_I = \frac{1}{16}$, $\mathsf{p}_I = \mathsf{p} - 3$ and $C_I = \frac{4\pi}{3}\, 16^{\mathsf{p}-3} C_\mathsf{p}/b_*$; so all of Theorem L, Corollary 4.6 and Theorem N apply to σ^1, and (KV1) holds in the form for the sup norm with $\wp' = \mathsf{p}$;
  (iii) $\|B_\mathfrak{a}(\xi, \xi')\| \leq \sqrt{2}\, C_\mathsf{p} b_*^{-1} \|\mathfrak{a}\|_{L^1} \min\{1, d_{\mathrm{Tb}}(\xi), d_{\mathrm{Tb}}(\xi')\}^{-\mathsf{p}}$ for $\mathfrak{a} \in \mathcal{L}_\mathbb{C}$, without the factor $\sqrt{2}$ for real $\mathfrak{a}$, and $|K_n(\xi; \mathbf{a})| \leq \prod_k (\sqrt{2} \cdot 2^\mathsf{p} C_\mathsf{p} b_*^{-1} \|\mathfrak{a}_k\|_{L^1}) \cdot \min\{1, \min_k d_{\mathrm{Tb}}(\xi_k)\}^{-\mathsf{p}n}$;
  (iv) $\|B_E(\mathfrak{z}, \mathfrak{z}')\| \leq \sqrt{2}\, C_\mathsf{p} b_*^{-1} |E|_2 \min\{1, d_3(\mathfrak{z}), d_3(\mathfrak{z}')\}^{-\mathsf{p}}$ for $E \in V_\mathbb{C}$, without the factor $\sqrt{2}$ for $E \in V$; $\mathcal{U}_w B_E(\mathfrak{z}, \mathfrak{z}') \mathcal{U}_w^{-1} = B_{\varrho(w)E}(w\mathfrak{z}, w\mathfrak{z}')$ for the eight $w \in W_3$ with $we_3 = e_3$,

where $\mathcal{U}_w[F] := [wF]$; the functions W_n of Theorem O are holomorphic on Tb_3^{n-1}, n-linear in $\mathbf{E}$, and $|W_n(\mathfrak{z};\mathbf{E})| \le \prod_k (\sqrt{2}\cdot 2^{\mathsf{p}} C_{\mathsf{p}} b_*^{-1} |E_k|_2)\cdot \min\{1, \min_k d_3(\mathfrak{z}_k)\}^{-\mathsf{p}n}$; and

$$\sigma^1(h_1,\dots,h_n) = \int W_n(x_2-x_1,\dots,x_n-x_{n-1}; h_1(x_1),\dots,h_n(x_n))\,dx_1\cdots dx_n$$

whenever $\sup_{\mathrm{supp}\, h_k} x_3 < \inf_{\mathrm{supp}\, h_{k+1}} x_3$ for all k; for $w \in W_3$, the same holds with $W_n(w^{-1}(x_2-x_1),\dots;\varrho(w^{-1})h_1(x_1),\dots)$ whenever $w^{-1}(h_1,\dots,h_n)$ is so ordered, that is, whenever the supports are ordered in the coordinate direction we_3;

(v) for a compact set $\mathcal{C}$ of real points of $\mathrm{Tb}^{(j)}$ and $c_{\mathcal{C}} := \min\{1, \min_{z\in\mathcal{C}} \min_i \min\{z_1^0, \tfrac12 (z_{i+1}-z_i)^0\}\}$: $\|\Psi(R_{is}z;\mathbf{a})\| \le \prod_i (\sqrt{2}\, C_{\mathsf{p}} b_*^{-1} \|\mathfrak{a}_i\|_{L^1}) \cdot c_{\mathcal{C}}^{-\mathsf{p}j} e^{\mathsf{p}j|s|}$ for $z\in\mathcal{C}$, $s\in\mathbb{R}$ and $\mathbf{a}\in\mathcal{L}^j_{\mathbb{C}}$.

4.3. **Construction estimates.** Theorems L–P use neither Theorem YMM1:D nor Theorems YMM1:AJ and YMM1:AD among the construction results, nor the continuum-limit and reconstruction conclusions of Theorems YMM1:A and YMM1:AP; no lattice, coupling, cutoff or volume enters them. They rest on the following statements among the construction results.

- The abstract reconstruction theorem: a vector space with a positive semi-definite Hermitian form and a distinguished vector, a semigroup of maps symmetric for the form with a bound of $\langle F, \mathcal{T}_t^\circ F\rangle$ uniform in t, and commuting maps that preserve the form, all weakly continuous, give a strongly continuous semigroup of self-adjoint contractions and a strongly continuous unitary group, commuting and fixing the vector.
- The statement on the joint spectral measure of such a pair, on $[0,\infty)\times\mathbb{R}^2$, with $\mathcal{P}(\{0\})$ fixing an invariant vector; the rule $\int \mathbf{1}_B\, d\mathcal{P} = \mathcal{P}(B)$ and the spectral integrals $g(\mathcal{P})$ with the complex measures $\langle\psi, \mathcal{P}(\cdot)\psi'\rangle$.
- The facts of analysis (the identity theorem from real points; the fundamental lemma; for scalar C_c^1 functions $\mathrm{Lip} \le \sup|\nabla\cdot|$, the continuity of translations in $\|\cdot\|_{C^1}$, the convergence in $\|\cdot\|_{C^1}$ of the Riemann sums $\sum_k \varepsilon^N \alpha(\varepsilon k)\tau_{\varepsilon k} j$ to $\alpha * j$ with supports in $\mathrm{supp}\,\alpha + \mathrm{supp}\, j$, and $\alpha * j_\delta \to \alpha$ in $\|\cdot\|_{C^1}$; a weakly holomorphic, locally bounded operator function is holomorphic in norm; a $\frac{\pi}{2}$-periodic entire function f with $|f(t+i\tau)| \le Ce^{A|\tau|}$ equals $\sum_{4|m|\le A} c_m e^{4im\zeta}$).
- The scalar partitions of unity (a function $\chi \in C_c^1(\mathbb{R})$ with $0\le\chi\le 1$, $\mathrm{supp}\,\chi = [-1,1]$, $\mathrm{Lip}\,\chi = \frac{\pi}{2}$, $\sum_k \chi(s-k) = 1$, and the products $\chi_{\mathsf{h},k}(x) = \prod_i \chi(x_i/\mathsf{h} - k_i)$, $k\in\mathbb{Z}^3$, with $\sum_k \chi_{\mathsf{h},k} = 1$, $\mathrm{supp}\,\chi_{\mathsf{h},k} \subset \{|x-\mathsf{h}k|_\infty \le \mathsf{h}\}$ and $\mathrm{Lip}\,\chi_{\mathsf{h},k} \le \sqrt{3}\pi/2\mathsf{h}$).
- The calculus of operator functions (products and compositions with affine maps of functions holomorphic in norm are holomorphic in norm; the Cauchy estimate, by which a function holomorphic in norm and bounded by b on a polydisc of radius ρ in $\mathbb{C}^m$ has a Lipschitz constant at most $c_m b/\rho$ on the concentric polydisc of radius $\rho/2$; integrals of norm-continuous operator functions of compact support, with matrix elements, the norm bound by the integral of the norm, linearity, and passage to uniform limits).
- The mean-value formula with its numbers and mollifiers (for $N\in\{2,3\}$ and $r>0$ there are real functions $\alpha_{r,t}^{(N)} \in C_c^1(\mathbb{R}^N)$, $t\in(-r,r)^N$, supported in $[-r,r]^N$, with $\sup|\alpha_{r,t}^{(N)}| \le \mathrm{mv}_0^N r^{-2N}$ and $\sup|\partial_j \alpha_{r,t}^{(N)}| \le \mathrm{mv}_0^{N-1}\mathrm{mv}_1 r^{-2N-1}$, such that $u(0) = \int_{(-r,r)^N} dt \int u(y+it)\alpha_{r,t}^{(N)}(y)\,dy$ for every u holomorphic near the closed polydisc of radius r about 0; and mollifiers $j_\delta^{(N)} \ge 0$, real, with integral 1, supported in $\{|y|\le\delta/2\}$ and even under the reflection of each coordinate).

For Theorem P we use, in addition, Wick's theorem, the reflection positivity of Gaussian free fields and of the Gaussian fields with the covariances $S_\Lambda(x) = \int_0^\Lambda e^{\sqrt{m}} e^{-m|x|}(4\pi|x|)^{-1} dm$, $\Lambda<\infty$, and the description of the reconstructed spaces of these fields as Fock spaces on which the time and space translations act by $e^{-t\mathbf{H}_0}$ and $e^{iv\cdot\mathbf{P}_0}$, with the fields in Fock-space form. Each S_Λ is a superposition

with positive weights of the covariances of free fields of masses $m < \Lambda$; the proof of Theorem P (c) uses these fields at $\Lambda < \infty$, the functional of (c) being defined by the pairing formula of S.

For the free field ϕ of mass $m \geq 0$ on $\mathbb{R}^3$ (and in the same way for superpositions of such fields over m with a positive weight, such as the fields with the covariances S_Λ, the one-particle space carrying the weight in m): the covariance $\mathbb{E}[\phi(x)\phi(y)] = \int e^{ip\cdot(\vec{x}-\vec{y})-|x_3-y_3|\omega_m(p)}\, d\mu_m(p)$, with $\vec{x} = (x_1, x_2)$, $\omega_m(p) = (|p|^2 + m^2)^{1/2}$ and $d\mu_m(p) = (2\pi)^{-2}(2\omega_m(p))^{-1}d^2p$ on $\mathbb{R}^2$; the identity $\mathbb{E}[\prod_i :e^{\phi(f_i)}:] = \exp\sum_{i<k}\mathbb{E}[\phi(f_i)\phi(f_k)]$ for the Wick exponentials of finitely many smeared fields; the class of $:e^{\phi(g)}:$, for real $g \in C^1_c(E_+;\mathbb{C})$, which is the coherent vector $e^{a^*(u_g)}\Omega$ of the Fock space over $L^2(\mathbb{R}^2, \mu_m)$, $u_g(p) = \int g(x)e^{-x_3\omega_m(p)+ip\cdot\vec{x}}\, dx$; and the matrix elements $\langle e^{a^*(u)}\Omega, :O(a^*, a): e^{a^*(v)}\Omega\rangle = O(\bar{u}, v)\, e^{\langle u,v\rangle}$ of a normal-ordered polynomial in the creation and annihilation operators between coherent vectors.

Theorem Q rests in addition on three statements among the construction results, which give Gibbs sequences at g: the choice preceding equation YMM1:(2326), by which $\gamma^{\mathrm{ref}}_W \leq \gamma$ for the constant γ among the construction results; Corollary YMM1:74.2, by which, for $0 < g \leq \gamma$, the interval $I(g)$ among the construction results, defined in (YMM1:(1527)), is not empty and the pairs $(K, L^K\mathsf{b})$, $\mathsf{b} \in I(g)$, $K \in \mathbb{N}$, are first-passage data at g; and Proposition YMM1:91.2, by which at each first-passage datum at g the states of the tori form a non-empty set of periodic Gibbs states. It rests further on three results of two other sections, which in turn rest on Theorems YMM1:D, YMM1:AJ and YMM1:AD among the construction results.

(I) (Section C on the six fields $\operatorname{tr} F_{ij}F_{kl}$ on the tori and on $\mathbb{R}^3$.) Let $0 < g \leq \gamma^{\mathrm{ref}}_W$. Every Gibbs sequence (K_j, β_j, ν_j) at g has a subsequence that converges at every tuple of $\mathfrak{S}^V(\mathbb{R}^3)$, and along a further subsequence $a_{K_j}\beta_j$ converges to a number in $[g^{-2}, L(g^{-2} + \bar{B})]$. Moreover, for open sets $O_1, \dots, O_n$ that lie in a bounded set and are at pairwise positive distances there are a number C, depending on g, n and the sets, and an index j_0 such that for $j \geq j_0$ the centred moments $\nu_j(\prod_a(\mathcal{O}^{\mathsf{T}}_{K_j}(H_a) - \nu_j(\mathcal{O}^{\mathsf{T}}_{K_j}(H_a))))$ are bounded by $C\prod_a \sup_x |H_a(x)|_\infty$ for all bounded Borel functions $H_a\colon \mathbb{R}^3 \to V$ that vanish off O_a, $a = 1, \dots, n$; they are n-linear in such functions.

(II) (The same section.) Let σ be the limit of a convergent Gibbs sequence at $0 < g \leq \gamma^{\mathrm{ref}}_W$. Then σ is symmetric and centred; for every $n \geq 1$, $\delta > 0$ and $R > 0$ there is a number $C_n(\delta, R)$ with $|\sigma(H_1, \dots, H_n)| \leq C_n(\delta, R)\prod_a \sup_x |H_a(x)|_\infty$ at all tuples of type $(\delta; R)$; $\sigma(rX) = \sigma(X)$ for $r \in \mathbb{R}^3 \rtimes W_3$, acting on arguments and indices; $\sigma(\theta_{n,c}\bar{F}\cdot F) \geq 0$ for every $n \in \{e_\mu,\ e_\mu \pm e_\lambda\}$, every real c, the reflection $\theta_{n,c}$ in $\{n\cdot x = c\}$ acting on indices too, and every $F \in \mathbb{C}\mathfrak{S}^V(\{n\cdot x > c\})$; the joint spectral measure of the reconstructed translations is carried by $\{E \geq \max(|q_1|, |q_2|)\}$; for every $\eta \in (0, 1]$ there is a finite number bounding $|\sigma(\theta\bar{F}\cdot(h)\cdot F')|$ by itself times $\int |h(x)|_\infty dx\, \|[\tau_{-\eta e_3}F]\|\, \|[\tau_{-\eta e_3}F']\|$, for $F, F' \in \mathbb{C}\mathfrak{S}^V(\{x_3 > \eta\})$ and real $h \in C^1_c(\{|x_3| < \eta/2\}; V)$; and the statement on the trace part in Theorem Q (b)(iii) holds.

(III) (Section 2 on the point bound for the fields $\operatorname{tr} F_{ij}F_{kl}$.) Let $0 < g \leq \gamma^{\mathrm{sd}}_W$ and let σ be a tensor limit at g with the number b_*. For every $\mathsf{p} > \frac{17}{2}$ there is a number C_{p}, depending only on g, p and the fixed construction constants, such that the centred slab operators of σ, formed on the space reconstructed from tuples of continuous members, satisfy $\|B^c_d(h)\| \leq C_{\mathsf{p}} \min\{1, d - d'\}^{-\mathsf{p}} b_*^{-1} \int |h(x)|_\infty\, dx$ for $0 \leq d' < d$ and every real $h \in C_c(\mathbb{R}^3; V)$ with support in $\{|x_3| \leq d'\}$.

The passage from (I) to the tuples of continuous members, on the whole range $0 < g \leq \gamma^{\mathrm{ref}}_W$, is a step of this section, made in item (d) of the remark below from the convergence and the bound of (I); Theorem Q (a) rests on (I) and on this step. Accordingly the tensor limits at g of Theorem Q are defined in this section for every $0 < g \leq \gamma^{\mathrm{ref}}_W$; for $0 < g \leq \gamma^{\mathrm{sd}}_W$ they are the tensor limits that Section 2 on the point bound treats and that (III) reads.

Remark 4.8 (How (I) and (II) are obtained). In Section C on the six fields, (I) and (II) come from bounds for products of centred fields that read only the number of the fields, the sup norms of their weights, the least distance of the supports and the diameters of the supports, together with the passage of the lattice symmetries and of reflection positivity to the limit; item (d) ends with the step of this section that passes the convergence of (I) to the tuples of continuous members. For a Gibbs sequence (K_j, β_j, ν_j) at g we write $\sigma_j(H_1, \dots, H_n) := \nu_j(\prod_a(\mathcal{O}^{\mathsf{T}}_{K_j}(H_a) - \nu_j(\mathcal{O}^{\mathsf{T}}_{K_j}(H_a))))$, so that the limit of a convergent Gibbs sequence is $\sigma = \lim_j \sigma_j$.

(a) *One torus.* At a first-passage datum (K, β) at g and a side ℓ among the construction results at g, the joint cumulants of q fields $\mathcal{O}^{\mathsf{T}}_K(H_a)$ whose weights vanish off closed sets at pairwise sup distances $\geq 2\delta$ are bounded by a number of g, q, ℓ and δ times $\prod_a \sup_x |H_a(x)|_\infty$, as soon as $3a_K \leq \delta$ and K exceeds a threshold that reads g, q and δ. Here Theorem YMM1:D enters.

(b) *One cell.* Let $\mathsf{l} = L^{-i}$, $0 < \delta \leq \mathsf{l}/4$, and let ℓ' be a side at g with $\ell' \geq 2\mathsf{l}$. Let $H_1, \dots, H_n$ vanish off closed subsets of one cell, of side l, of a board of the lattice $a_K\mathbb{Z}^3$, at sup distances $\geq \delta$ from the walls of the cell and $\geq 2\delta$ from one another, and let $\mathsf{D} := \prod_a(\mathcal{O}^{\mathsf{T}}_K(H_a) - c_a)$, with c_a the mean of $\mathcal{O}^{\mathsf{T}}_K(H_a)$ in the torus measure of side ℓ'. The N-th power of the chessboard seminorm of D on the torus of side ℓ', $N = (\ell'/\mathsf{l})^3$, is the mean of the product of the N mirror copies of D. The mirror maps have diagonal linear parts, and a lattice symmetry r carries $\mathcal{O}^{\mathsf{T}}_K(H)$ to $\mathcal{O}^{\mathsf{T}}_K(rH)$; so the copies are products of nN centred fields of the same kind, with weights of the same sup norms at pairwise sup distances $\geq 2\delta$. The mean of a product of centred fields is the sum, over the partitions without blocks of one element, of the products of the joint cumulants of the blocks, and (a) bounds each of them. So the chessboard seminorm of D is at most a number of g, n, l, ℓ' and δ times $\prod_a \sup_x |H_a(x)|_\infty$.

(c) *All volumes and all periodic Gibbs states.* By the chessboard estimate among the construction results, the modulus of the mean of D in the torus measure of every side $\ell \geq \ell'$ at g is at most $e^{\mathsf{l}^3(p_{\ell'} - p_\ell)}$ times this seminorm, p_ℓ being the pressure on the torus of side ℓ; by the domination among the construction results along a sequence of sides tending to infinity, the same holds in every periodic Gibbs state. The pressure gap $0 \leq p_{\ell'} - p_\ell \leq G_g$, with a number G_g of g and the constants among the construction results, rests on Theorems YMM1:AJ and YMM1:AD and turns the factor into $e^{G_g\mathsf{l}^3}$.

For weights in several cells of one board, the mean of the product of the cell products is at most the product of the cell bounds, and no number reads the positions of the cells. Cutting the weights into cubes of side $\mathsf{l}/4n$ of one grid and choosing, for each product of pieces, a board whose walls keep a distance from all the pieces, one obtains a bound by a number times $\prod_a \sup_x |H_a(x)|_\infty$ for weights that vanish off closed sets of given diameters at a given least distance, the number reading g, n, the least distance and the diameters alone; the expansion of $\prod_a(\mathcal{O}^{\mathsf{T}}_K(H_a) - \nu(\mathcal{O}^{\mathsf{T}}_K(H_a)))$ into the products $\prod_{a\in J}(\mathcal{O}^{\mathsf{T}}_K(H_a) - c_a)$, $J \subset \{1, \dots, n\}$, whose coefficients $\prod_{a\notin J}(c_a - \nu(\mathcal{O}^{\mathsf{T}}_K(H_a)))$ are bounded by the case of one weight, passes it to the σ_j.

The bound holds uniformly in the cutoff from a threshold on, in the first-passage datum and in the periodic Gibbs state. These are the bounds of (II) and, at the σ_j, the bound of (I).

(d) *Extraction.* The bounds of (c) hold for bounded weights, and the σ_j are multilinear. For each finite union O of open cubes with rational corners choose a countable subset of $C^1_c(O; V)$, dense in $C^1_c(O; V)$ for the sup norm; the tuples of such members, for sets O with pairwise disjoint closures, form a countable family, and a diagonal subsequence converges at each of its tuples. For a tuple $X \in \mathfrak{S}^V(\mathbb{R}^3)$, and a tuple X' of the family whose members are ε-close to those of X in the sup norm and lie in the same sets O, the bound (c) and multilinearity give $|\sigma_j(X) - \sigma_j(X')| \leq C\varepsilon$ for all large j, with C independent of j and $\varepsilon \leq 1$; so the

subsequence converges at X. The numbers $a_{K_j}\beta_j$ lie in $(g^{-2}, L(g^{-2}+\bar{B})]$, and a further subsequence makes them converge. This is (I).

The step of this section: continuous members. Let $0 < g \le \gamma_W^{\mathrm{ref}}$, take the subsequence of (I) along which $a_{K_j}\beta_j$ converges to a number b_*, and let $X = (H_1, \dots, H_n)$ be a tuple of continuous V-valued functions with compact, pairwise disjoint supports. Choose open sets $O_a \supset \operatorname{supp} H_a$ in a bounded set with pairwise disjoint closures. As $C_c^1(O_a; V)$ is dense in $C_c(O_a; V)$ for the sup norm (by mollification), there are $H_a' \in C_c^1(O_a; V)$ with $\sup_x |H_a(x) - H_a'(x)|_\infty \le \varepsilon \le 1$, and $X' = (H_1', \dots, H_n') \in \mathfrak{S}^V(\mathbb{R}^3)$. By multilinearity,

$$\sigma_j(X) - \sigma_j(X') = \sum_{a=1}^{n} \sigma_j(H_1', \dots, H_{a-1}', H_a - H_a', H_{a+1}, \dots, H_n),$$

each term having weights that vanish off $O_1, \dots, O_n$; so the bound of (I) gives $|\sigma_j(X) - \sigma_j(X')| \le nC\varepsilon \prod_a (\sup_x |H_a(x)|_\infty + 1)$ for $j \ge j_0$, a bound free of j. As $(\sigma_j(X'))_j$ converges along the subsequence, $(\sigma_j(X))_j$ is a Cauchy sequence along it. So the subsequence converges at every tuple of continuous members, its limit is a tensor limit at g with the number b_*, and together with (I) this is Theorem Q (a).

(e) *Symmetry, covariance, positivity.* Symmetry and centring pass to the limit. The periodic Gibbs states are invariant under the symmetries $a_K\mathbb{Z}^3 \rtimes W_3$ of the lattice, and such a symmetry r carries $\mathcal{O}_K^{\mathsf{T}}(H)$ to $\mathcal{O}_K^{\mathsf{T}}(rH)$, r acting on the argument and on the indices of H; so $\sigma_j(rX) = \sigma_j(X)$. A real translation is the limit of lattice translations, with an error that the bounds of (c) and the Lipschitz constants of the members control. The periodic Gibbs states are reflection positive at the lattice mirrors $\{n \cdot x = c\}$, $c \in a_K\mathbb{Z}$, of the nine families $n \in \{e_\mu,\ e_\mu \pm e_\lambda\}$; the reflection acts on the field as on the weight, on the argument and on the indices, and a real c is the limit of such lattice values.

(f) *The cone.* Reflection positivity at the mirrors of the families e_3 and $e_3 \pm e_k$, $k = 1, 2$, gives, by Lemma F.5, for $u(w) := \sigma_j(\theta\bar{F} \cdot \tau_w F)$, $F \in \mathbb{C}\mathfrak{S}^V(E_+)$, and every $t \in a_{K_j}\mathbb{N}$,

$$u(0) - 4u(te_3) + u(2te_3) + u(te_3 + te_k) + u(te_3 - te_k) \ge 0.$$

In the limit, with lattice points $t_j \to t$, and by density, for every $\psi \in \mathcal{H}(\sigma)$ and every $t > 0$, $\int f_t \, d\langle\psi, \mathcal{P}\psi\rangle \ge 0$ with

$$f_t(E, q) = (1 - e^{-tE})^2 - e^{-tE}|1 - e^{itq_k}|^2 = 4e^{-tE}(\sinh^2 \tfrac{tE}{2} - \sin^2 \tfrac{tq_k}{2}).$$

At $\psi = \mathcal{P}(\Delta)\psi'$, for all Borel sets Δ, this gives $f_t \ge 0$ $\mathcal{P}$-almost everywhere, for all rational $t > 0$ at once; there $\sinh \frac{tE}{2} \ge |\sin \frac{tq_k}{2}|$, and $t \downarrow 0$ gives $E \ge |q_k|$. So $\mathcal{P}(\{E < \max(|q_1|, |q_2|)\}) = 0$.

(g) *Slab and point operators.* Let $\mathsf{l} = L^{-i}$, $Q := (v, 0) + (-\frac{\mathsf{l}}{2}, \frac{\mathsf{l}}{2})^2 \times (0, \mathsf{l})$, and let $X = (h_1, \dots, h_n)$ be a tuple of members with supports in Q at sup distances $\ge \delta$ from ∂Q and $\ge 2\delta$ from one another. The cell-insertion bound of Proposition YMM1:104.2, applied to a board one of whose cells is Q up to a shift of the order of a_{K_j}, bounds $|\sigma_j(\theta\bar{F}' \cdot X \cdot \tau_{\mathsf{l}e_3} F)|$, for $F, F' \in \mathbb{C}\mathfrak{S}^V(E_+)$, by the chessboard seminorm of the centred product of the fields of X times $\sigma_j(\theta\bar{F}' \cdot F')^{1/2}\sigma_j(\theta\bar{F} \cdot F)^{1/2}$.

By (b) and (c), in the limit there is exactly one bounded operator $\mathsf{B}_{\mathsf{l}}(X)$ on $\mathcal{H}(\sigma)$ with $\mathsf{B}_{\mathsf{l}}(X)[F] = [X \cdot \tau_{\mathsf{l}e_3} F]$, and $\|\mathsf{B}_{\mathsf{l}}(X)\| \le \mathsf{C}_n^{\mathrm{sl}}(g; \mathsf{l}, \delta) \prod_a \sup_x |h_a(x)|_\infty$, with a number $\mathsf{C}_n^{\mathrm{sl}}(g; \mathsf{l}, \delta)$ formed as in (c). Let $n = 1$ and $\delta = \mathsf{l}/16$. The translations act covariantly on these operators, and by the square cone of (f) the matrix elements of $\mathsf{B}_{\mathsf{l}}((\tau_y h))$ between vectors in the range of $\mathcal{T}_\delta$ are the restrictions to real y of functions holomorphic on $\{|\operatorname{Re} y_3| + |\operatorname{Im} y_1| + |\operatorname{Im} y_2| < \delta\}$.

The Cauchy estimate for the derivatives ∂_S, $S \subset \{1, 2, 3\}$, at $y = 0$ and an integration by parts in $\partial_1\partial_2\partial_3$ show that the form $h \mapsto \langle \mathcal{T}_\delta\psi', \mathsf{B}_{\mathsf{l}}((h))\mathcal{T}_\delta\psi\rangle$, on members with support in the points of Q at sup distance $> 3\delta$ from ∂Q, has a continuous density and is bounded by $6(80/\mathsf{l})^3\mathsf{C}_1^{\mathrm{sl}}(g; \mathsf{l}, \mathsf{l}/16)\|\psi'\| \, \|\psi\| \int |h(x)|_\infty \, dx$. These densities are the matrix elements of point

operators $\mathsf{B}(s,s';e)$, $s,s'>0$, $e\in V$, with $\|\mathsf{B}(s,s';e)\|\le \mathsf{C}^{\mathrm{fin}}(\min\{s,s'\})|e|_\infty$ for the finite function

$$\mathsf{C}^{\mathrm{fin}}(\eta) := 6(80/\mathsf{l}_\eta)^3\,\mathsf{C}_1^{\mathrm{sl}}(g;\mathsf{l}_\eta,\mathsf{l}_\eta/16), \qquad \mathsf{l}_\eta \text{ the largest power of } L \text{ with } \tfrac{9}{16}\mathsf{l}_\eta\le\eta;$$

and they give $|\sigma(\theta\bar F\cdot(h)\cdot F')|\le \mathsf{C}^{\mathrm{fin}}(\eta/2)\int|h(x)|_\infty\,dx\,\|[\tau_{-\eta e_3}F]\|\,\|[\tau_{-\eta e_3}F']\|$ for η, F, F' and h as in (II), the last bound of (II).

(h) *The trace part.* $\mathcal{O}_K^{\mathsf{T}}(f\mathbf{1})$ is the action-density field smeared with f, so $\sigma(f_1\mathbf{1},\dots,f_n\mathbf{1})$ is the limit of the centred moments of the scalar field. The map $F\mapsto F\mathbf{1}$ preserves the forms, as $\varrho(\theta)\mathbf{1}=\mathbf{1}$, and the closed span of the classes $[F\mathbf{1}]$ is invariant under the self-adjoint operators $\mathcal{T}_t$ and the unitary group $\mathcal{U}(v)$; so it reduces them and $\mathcal{P}$.

Remark 4.9 (Where the exponent $\frac{17}{2}$ and the factor b_*^{-1} come from). In Section 2 on the point bound, (III) is obtained from an estimate at a cutoff of one centred smeared field in one cell of side $a_i=L^{-i}$: for i past a threshold its chessboard norm is bounded by the power $a_i^{-11/2}$ times a power of $\log(1/a_i)$ times $(a_K\beta)^{-1}$ times the sup norm of the weight, at every cutoff past a threshold that reads i, uniformly in the cutoff, the first-passage datum, the cell, the side of the torus and the periodic Gibbs state; it uses a dilation to unit scale, a moment of mirror copies on the least torus, and the pressure gap. The factor $(a_K\beta)^{-1}$ comes from the bound on the moments of the sources at the working level (equation YMM1:(2322)), which carries a factor at most $(9/8)^{1/2}(a'\beta)^{-1}$ per field, a' the spacing of the dilated lattice; as the dilation multiplies the weight and the spacing by the same power of L, this is the factor $(a_K\beta)^{-1}$ per unit of the sup norm of the original weight.

As $a_{K_j}\beta_j\to b_*$ along a tensor limit, this factor is the origin of the factor b_*^{-1} in (III) and in Theorem Q(c). Multiple reflections in periodic Gibbs states turn the estimate into a bound, by the sup norm and with the factor b_*^{-1}, of the slab operator of height a_i for weights carried by a cube of side comparable to a_i; and an abstract lemma, which uses only the covariance under small translations and the spectral condition $E\ge\max(|q_1|,|q_2|)$, turns a sup-norm bound on cubes of half-side ρ into a bound by the L^1 norm at the price ρ^{-3}. So $\frac{17}{2}=\frac{11}{2}+3$, and the volume $\frac{4\pi}{3}(\eta/16)^3$ of the balls of (T5) gives back three powers: $\mathsf{p}_I=\mathsf{p}-3>\frac{11}{2}$.

4.4. **Estimates and proofs.**

Lemma 4.10 (Functions with matrix values)**.** Let f take values in $V_{\mathbb{C}}$; the norms are those of Definition 4.1.

(a) $\operatorname{supp} f^\varepsilon\subset\operatorname{supp} f$, and $\|f^\varepsilon\|\le\|f\|$ for $\varepsilon=0,1$ and each of $\|\cdot\|_\infty$, Lip, $\|\cdot\|_{C^1}$, $\|\cdot\|_\sharp$, $\|\cdot\|_{L^1}$.
(b) $\operatorname{Lip} f\le\sup|\nabla f|$; so $\|f\|_\sharp\le 40M\|f\|_{C^1}$ on $\mathbb{R}^3$, and $\|\mathfrak{a}\|_{C^1}=\max\{\|\mathfrak{a}\|_\infty,\operatorname{Lip}\mathfrak{a}\}$ for a label $\mathfrak{a}$.
(c) For $f\in C_c^1(\mathbb{R}^N;V_{\mathbb{C}})$, $u\mapsto\tau_u f$ is continuous for $\|\cdot\|_{C^1}$.
(d) $\|\chi f\|_\sharp\le(\|\chi\|_\infty+40M\operatorname{Lip}\chi)\|f\|_\sharp$ for every bounded Lipschitz $\chi\colon\mathbb{R}^3\to\mathbb{C}$.
(e) $f\mapsto rf$ is complex linear; $(rr')f=r(r'f)$, $\overline{rf}=r\bar f$, $(rf)^\varepsilon=rf^\varepsilon$, $\operatorname{supp} rf=r\operatorname{supp} f$ and $\|rf\|_\sharp=\|f\|_\sharp$. Hence every identity between products of isometries, as maps of points, holds for their actions on functions, on tuples and on $\mathbb{C}\mathfrak{S}^V(\mathbb{R}^3)$.
(f) For a profile α and a label $\mathfrak{a}$, $\alpha\otimes\mathfrak{a}\in C_c^1(\mathbb{R}^3;V_{\mathbb{C}})$ is complex bilinear in $(\alpha,\mathfrak{a})$ and real if both are; $\tau_y(\alpha\otimes\mathfrak{a})=(\tau_y\alpha)\otimes\mathfrak{a}$; $\theta\overline{(\alpha\otimes\mathfrak{a})}=(\bar\alpha\circ\theta)\otimes\mathfrak{a}^\theta$; $\|\alpha\otimes\mathfrak{a}\|_\infty\le\|\alpha\|_\infty\|\mathfrak{a}\|_\infty$, $\operatorname{Lip}(\alpha\otimes\mathfrak{a})\le\operatorname{Lip}\alpha\,\|\mathfrak{a}\|_\infty+\|\alpha\|_\infty\operatorname{Lip}\mathfrak{a}$ and $\|\alpha\otimes\mathfrak{a}\|_{C^1}\le\sqrt{2}\|\alpha\|_{C^1}\|\mathfrak{a}\|_{C^1}$. The map $\mathfrak{a}\mapsto\mathfrak{a}^\theta$ is an antilinear involution with $\lambda_{\mathfrak{a}^\theta}=\lambda_{\mathfrak{a}}$, $\|\mathfrak{a}^\theta\|_{C^1}=\|\mathfrak{a}\|_{C^1}$ and $\|\mathfrak{a}^\theta\|_{L^1}=\|\mathfrak{a}\|_{L^1}$.
(g) Let χ be the function of the scalar partition of unity, $r>0$, and $\mathfrak{a}_k(s):=\chi(s/4r-k)\mathfrak{a}(s)$, $k\in\mathbb{Z}$. Then $\mathfrak{a}=\sum_k\mathfrak{a}_k$, $\operatorname{supp}\mathfrak{a}_k\subset[4r(k-1),4r(k+1)]$, $\|\mathfrak{a}_k\|_\infty\le\|\mathfrak{a}\|_\infty$, $\operatorname{Lip}\mathfrak{a}_k\le(1+\frac{\pi}{8r})\|\mathfrak{a}\|_{C^1}$, each $\mathfrak{a}_k$ is real if $\mathfrak{a}$ is, and fewer than $\lambda_{\mathfrak{a}}/4r+3$ of the $\mathfrak{a}_k$ are non-zero.

■

Proof. Items (a), (b), (d) and (e) follow from $|E^\varepsilon|_2\le|E|_2$, $|\varrho(r)E|_2=|E|_2$, $\overline{\varrho(r)E}=\varrho(r)\bar E$ and from $f(x)-f(x')=\int_0^1\sum_\mu(x-x')_\mu\,\partial_\mu f(x'+s(x-x'))\,ds$; in (e), $((rr')f)(x)=\varrho(r^\circ)\varrho(r'^\circ)f(r'^{-1}r^{-1}x)=$

$(r(r'f))(x)$, so the tensor action is a left action. Item (c) is the continuity of translations of scalar C^1_c functions applied to the nine entries, together with $\|g\|_{C^1} \le \sum_{\lambda\lambda'} \|g_{\lambda\lambda'}\|_{C^1}$. In (f), θ keeps x_2, so

$$(\theta\overline{\alpha \otimes \mathfrak{a}})(x) = \varrho(\theta)\overline{\alpha(\theta y)\mathfrak{a}(x_2)} = \bar\alpha(\theta y)\, \mathfrak{a}^\theta(x_2);$$

this is the one rule that is new against the scalar case. Further $|\nabla(\alpha\otimes\mathfrak{a})|^2 = |\nabla\alpha|^2|\mathfrak{a}|_2^2 + |\alpha|^2|\mathfrak{a}'|_2^2 \le 2\|\alpha\|^2_{C^1}\|\mathfrak{a}\|^2_{C^1}$, and $\varrho(\theta)^2 = 1$ while $\varrho(\theta)$ and the bar keep $|\cdot|_2$. In (g), $0 \le \chi \le 1$, $\operatorname{supp}\chi = [-1,1]$, $\operatorname{Lip}\chi = \pi/2$ and $\sum_k \chi(s-k) = 1$; the Lipschitz bound is that of (d) in one variable; and if $\mathfrak{a}_k \neq 0$, the open interval $(4r(k-1), 4r(k+1))$ meets an interval of length $\lambda_\mathfrak{a}$ containing $\operatorname{supp}\mathfrak{a}$, which confines k to an open interval of length $\lambda_\mathfrak{a}/4r + 2$. □

Lemma 4.11 (Tubes)**.** (a) $d_{\mathrm{Tb}}(\xi+\xi') \ge d_{\mathrm{Tb}}(\xi) + d_{\mathrm{Tb}}(\xi')$, $d_{\mathrm{Tb}}(c\xi) = c\, d_{\mathrm{Tb}}(\xi)$ for $c > 0$, $d_{\mathrm{Tb}}(\xi + cn_0) = d_{\mathrm{Tb}}(\xi) + c$ for real c, and $d_{\mathrm{Tb}}(\xi + w) \ge d_{\mathrm{Tb}}(\xi) - |\operatorname{Re} w^0| - |\operatorname{Im} w^1|$. So Tb is an open convex cone, $\mathrm{Tb} + \overline{\mathrm{Tb}} \subset \mathrm{Tb}$ and $\overline{\mathrm{Tb}} = \{d_{\mathrm{Tb}} \ge 0\}$. Moreover $d_{\mathrm{Tb}}(\xi^*) = d_{\mathrm{Tb}}(\bar\xi) = d_{\mathrm{Tb}}(\xi) \le d_{\mathrm{Tb}}(\operatorname{Re}\xi)$; the star is additive and commutes with real factors, $n_0^* = n_0$ and $\xi^{**} = \xi$; $d_{\mathrm{Tb}}(y) = y^0$ at real y, so $\mathrm{Tb} \cap \mathbb{R}^2 = \mathbb{R}^2_+$ and $d_{\mathrm{Tb}}(dn_0 \pm y) = d \pm y^0$.

(b) The same holds for d_3, Tb_3 and $\mathfrak{z}^*$, with

$$d_3(\mathfrak{z} + w) \ge d_3(\mathfrak{z}) - |\operatorname{Re} w_3| - |\operatorname{Im} w_1| - |\operatorname{Im} w_2|$$

and $d_3(de_3 \pm x) = d \pm x_3$ at real x; besides $d_3(\xi \pm se_2) = d_{\mathrm{Tb}}(\xi)$ for $\xi \in \mathbb{C}^2$ and real s.

(c) $d_{\mathrm{Tb}}(\xi) = \min\{\operatorname{Re}\xi^+, \operatorname{Re}\xi^-\}$ and $(\xi^*)^\pm = \overline{\xi^\pm}$. For real τ,

$$d_{\mathrm{Tb}}(R_{i\tau}\xi) = \min\{e^{-\tau}\operatorname{Re}\xi^+, e^{\tau}\operatorname{Re}\xi^-\} \ge e^{-|\tau|} d_{\mathrm{Tb}}(\xi)$$

on $\overline{\mathrm{Tb}}$; hence $R_{i\tau}\mathrm{Tb} = \mathrm{Tb}$, and $d_{\mathrm{Tb}}(R_{i\tau}\xi) = e^{-|\tau|}\xi^0$ for real ξ with $\xi^0 > 0$. Further $(R_{i\tau}\xi)^* = R_{i\tau}\xi^*$, $\xi^* = -\theta\xi$ for real ξ, $(R_{-\upsilon}w)^0 = n_\upsilon \cdot w$ for real w, and $R_t R_\upsilon \mathrm{Tb} = R_{t+\upsilon}\mathrm{Tb}$ for real t, υ.

■

Proof. The real part is additive, $|\operatorname{Im}(u+v)| \le |\operatorname{Im} u| + |\operatorname{Im} v|$ and $\operatorname{Im}(-\bar u) = \operatorname{Im} u$; this gives (a) and (b). For (c), $\operatorname{Re}\xi^\pm = \operatorname{Re}\xi^0 \mp \operatorname{Im}\xi^1$, and $R_{i\tau}$ multiplies $\xi^\pm$ by $e^{\mp\tau}$; on $\overline{\mathrm{Tb}}$ both real parts are ≥ 0, which gives the inequality. The remaining identities are direct computations with $(R_\zeta\xi)^\pm = e^{\pm i\zeta}\xi^\pm$. □

Lemma 4.12 (Complex members)**.** Let σ be a tensor functional.

(a) If $X \cdot (H) \cdot Y$ and $X \cdot (H') \cdot Y$ are formed and $c \in \mathbb{R}$, then $\sigma(X \cdot (H + cH') \cdot Y) = \sigma(X\cdot(H)\cdot Y) + c\,\sigma(X\cdot(H')\cdot Y)$; σ vanishes at every tuple with a member 0; and $\overline{\sigma(F)} = \sigma(\bar F)$ for $F \in \mathbb{C}\mathfrak{S}^V(\mathbb{R}^3)$.

(b) $(H_1, \dots, H_n)_\mathbb{C} = (H_1)_\mathbb{C} \cdots (H_n)_\mathbb{C}$ and $r(H_1, \dots, H_n)_\mathbb{C} = (rH_1, \dots, rH_n)_\mathbb{C}$; under σ the sum that defines $(H_1, \dots, H_n)_\mathbb{C}$ may be taken over all $\varepsilon \in \{0,1\}^n$.

(c) $(H_a) \mapsto \sigma((H_1, \dots, H_n)_\mathbb{C})$ is n-linear over $\mathbb{C}$ on $\prod_a C^1_c(O_a; V_\mathbb{C})$ for open O_a with pairwise disjoint closures.

(d) $\overline{\sigma(A \cdot (H)_\mathbb{C} \cdot A')} = \sigma(\bar A \cdot (\bar H)_\mathbb{C} \cdot \bar A')$.

■

Proof. (a) The set $\operatorname{supp} H \cup \operatorname{supp} H'$ and the supports of the members of X and Y are finitely many compact, pairwise disjoint sets, at mutual distances $\ge \mathsf{d}$ for some $\mathsf{d} > 0$; their open $\mathsf{d}/3$-neighbourhoods have pairwise disjoint closures, and the multilinearity of σ applies; σ is real on tuples. (b) follows from Lemma 4.10 (e) and from (a). (c) The map is additive and real homogeneous by (a), and $(iH)^0 = -H^1$, $(iH)^1 = H^0$ give $u((iH)^0) + i\,u((iH)^1) = i\,(u(H^0) + i\,u(H^1))$ for the value u of σ as a function of the a-th member. (d) If $H^1 = 0$, both sides equal $\sigma(\bar A \cdot (H) \cdot \bar A')$; if $H^1 \neq 0$, the left side is $\sigma(\bar A \cdot ((H^0) - i(H^1)) \cdot \bar A')$ and $(\bar H)_\mathbb{C} = (H^0) + i(-H^1)$, and (a) applies. The restriction of the sum in Definition 4.2 (2) matters in $\mathbb{C}\mathfrak{S}^V$ itself only, where a tuple with a member 0 is a basis vector and not the zero vector. □

Lemma 4.13 (The form, the space, the reconstruction)**.** (a) Let σ have (T3). The form $\langle F,G\rangle_\sigma = \sigma(\theta\bar F\cdot G)$ on $\mathbb{C}\mathfrak{S}^V(E_+)$ is positive semi-definite and Hermitian, and $\|\Omega\|=1$. For open sets $O_1,\dots,O_n$ whose closures are compact, pairwise disjoint and contained in E_+, $(H_a)\mapsto[(H_1,\dots,H_n)_{\mathbb{C}}]$ is n-linear over $\mathbb{C}$ on $\prod_a C^1_c(O_a;V_{\mathbb{C}})$; the class of a tuple with a member 0 is 0.

(b) Let σ have (T1°), (T2) and (T3). There are exactly one family of bounded operators $\mathcal{T}_t$, $t\ge0$, and exactly one family $\mathcal{U}(v)$, $v\in e_3^\perp$, with $\mathcal{T}_t[F]=[\tau_{te_3}F]$ and $\mathcal{U}(v)[F]=[\tau_vF]$; $(\mathcal{T}_t)$ is a strongly continuous semigroup of self-adjoint operators with $0\le\mathcal{T}_t\le1$, $(\mathcal{U}(v))$ is a strongly continuous unitary group, all of them commute and fix Ω, and there is exactly one projection-valued measure $\mathcal{P}$ on $[0,\infty)\times e_3^\perp$ with $\mathcal{T}_t\mathcal{U}(v)=\int e^{-tE+iv\cdot q}\,d\mathcal{P}(E,q)$; moreover $\mathcal{P}(\{0\})\Omega=\Omega$.

(c) Let σ have (T1°) and (T3). Then $\sigma(\theta_cX)=\sigma(X)$ for every $X\in\mathfrak{S}^V(\mathbb{R}^3)$ none of whose supports meets $\{x_3=c\}$.

■

Proof. (a) For $X,Y\in\mathfrak{S}^V(E_+)$ the tuple $\theta X\cdot Y$ is formed, as θ maps E_+ onto $\{x_3<0\}$. The form is sesquilinear, and its quadratic form $\mathfrak{q}(F)=\langle F,F\rangle_\sigma$ is real and ≥0 by (T3); by polarisation, $\langle F,G\rangle_\sigma=\frac14\sum_{k=0}^3 i^{-k}\mathfrak{q}(F+i^kG)$, so it is Hermitian. $\|\Omega\|^2=\sigma(\emptyset)=1$. For multilinearity let $X[u]$ be the tuple whose a-th member is u, $u_1=H_a+cH_a'$, $u_2=H_a$, $u_3=H_a'$, $(\gamma_i)=(1,-1,-c)$ and $Z=\sum_i\gamma_iX[u_i]$; then $\|[Z]\|^2=\sum_{i,k}\gamma_i\gamma_k\,\sigma(\theta X[u_i]\cdot X[u_k])$, and $(u,u')\mapsto\sigma(\theta X[u]\cdot X[u'])$ is bilinear because the $2n$ open sets θO_b, O_b have pairwise disjoint closures and $u\mapsto\theta u$ is linear; so $\|[Z]\|^2=0$. Complex members are treated as in Lemma 4.12 (c).

(b) We apply the abstract reconstruction theorem to $\mathbb{C}\mathfrak{S}^V(E_+)$ with the form of (a), the vector $\emptyset$, the maps τ_{te_3}, $t\ge0$, and τ_v, $v\in e_3^\perp$. As maps of points $\tau_{te_3}\theta\tau_{te_3}=\theta$ and $\theta\tau_v=\tau_v\theta$; with Lemma 4.10 (e) and (T1°) the maps are symmetric, respectively isometric, for the form. For $F=\sum\zeta_iX_i$ there are $R<\infty$ and $\mathsf{d}>0$ such that every tuple $\theta X_i\cdot\tau_{te_3}X_k$, $t\ge0$, is of type $(\mathsf{d};R)$, so that

$$|\langle F,\tau_{te_3}F\rangle_\sigma|\le\sum_{i,k}|\zeta_i||\zeta_k|\max\{1,C^\sigma_{n_i+n_k}(\mathsf{d};R)\}\prod_{H\in X_i}\|H\|_\sharp\prod_{H\in X_k}\|H\|_\sharp,$$

a bound that does not see t. For weak continuity, with $Y=(f_1,\dots,f_n)$,

$$\sigma(\theta X\cdot\tau_uY)-\sigma(\theta X\cdot Y)=\sum_a\sigma(\theta X\cdot(\tau_uf_1,\dots,\tau_uf_{a-1},\tau_uf_a-f_a,f_{a+1},\dots,f_n))$$

by Lemma 4.12 (a); for $|u|<\mathsf{d}/3$ each tuple on the right is of type $(\mathsf{d}/3;R+\mathsf{d}/3)$, and (T2) with $\|\tau_uf_a-f_a\|_\sharp\le40M\|\tau_uf_a-f_a\|_{C^1}\to0$ (Lemma 4.10 (b), (c)) gives the continuity. The theorem gives $\mathcal{T}_t$ and $\mathcal{U}(v)$; the statement on the joint spectral measure gives $\mathcal{P}$ and $\mathcal{P}(\{0\})\Omega=\Omega$.

(c) By translation invariance, with $\theta_c=\tau_{ce_3}\theta\tau_{-ce_3}$, we may take $c=0$. Let $X=(H_1,\dots,H_n)$. The support of each H_a is compact and does not meet the closed plane $\{x_3=0\}$, so it lies at a positive distance from it, and H_a vanishes near the plane; hence $H_a^\pm:=H_a\mathbf{1}_{\{\pm x_3>0\}}$ lie in $C^1_c(\mathbb{R}^3;V)$, $\operatorname{supp}H_a^\pm\subset\operatorname{supp}H_a$, $H_a=H_a^++H_a^-$ and $\theta H_a=\theta H_a^++\theta H_a^-$. So all the tuples $(H_1^{s_1},\dots,H_n^{s_n})$, $s\in\{+,-\}^n$, and their images under θ are formed, and Lemma 4.12 (a), applied member after member, gives

$$\sigma(X)=\sum_{s\in\{+,-\}^n}\sigma(H_1^{s_1},\dots,H_n^{s_n}),\qquad\sigma(\theta X)=\sum_{s\in\{+,-\}^n}\sigma(\theta H_1^{s_1},\dots,\theta H_n^{s_n}).$$

In each term every member has its support in one of the open half-spaces $\{x_3>0\}$ and $\{x_3<0\}$ (the member 0 is admitted); so, by symmetry, the term of X is $\sigma(\theta A\cdot B)$ with real $A,B\in\mathfrak{S}^V(E_+)$, and the term of θX with the same s is $\sigma(\theta(\theta A\cdot B))$. As the form is Hermitian and σ is real on tuples,

$$\sigma(\theta A\cdot B)=\langle A,B\rangle_\sigma=\langle B,A\rangle_\sigma=\sigma(\theta B\cdot A)=\sigma(A\cdot\theta B)=\sigma(\theta(\theta A\cdot B)),$$

the last two equalities by symmetry and $\theta\theta = 1$; so the two sums agree term by term, and $\sigma(\theta X) = \sigma(X)$. □

Lemma 4.14 (The semigroups of the cone)**.** (a) Let σ have (T1°), (T2), (T3) and (T4). Then $\mathcal{P}$ is carried by $\mathsf{S}_1 := \{E \geq |q_1|\}$, on which $|e^{-\xi^0 E + i\xi^1 q_1}| \leq e^{-d_{\mathrm{Tb}}(\xi)E}$. The operators $T(\xi)$, $\xi \in \overline{\mathrm{Tb}}$, satisfy $\|T(\xi)\| \leq 1$, $T(\xi)T(\xi') = T(\xi+\xi')$, $T(0) = 1$, $T(\xi)^* = T(\xi^*)$ and $T(\xi)\Omega = \Omega$; $\xi \mapsto T(\xi)$ is strongly continuous on $\overline{\mathrm{Tb}}$ and holomorphic in norm on Tb; and $T(y) = \mathcal{T}_{y^0}\mathcal{U}(y^1 e_1)$, $T(y)[F] = [\tau_y F]$ for real y with $y^0 \geq 0$.

(b) Let σ have (T1), (T2), (T3) and (T4). For $w \in W_3$ with $we_3 = e_3$, $\mathcal{U}_w[F] := [wF]$ is a unitary operator that fixes Ω, commutes with $\mathcal{T}_t$ and satisfies $\mathcal{U}_w\mathcal{U}(v)\mathcal{U}_w^{-1} = \mathcal{U}(wv)$; hence $\mathcal{U}_w\mathcal{P}(B)\mathcal{U}_w^{-1} = \mathcal{P}(\{(E,wq) : (E,q) \in B\})$, $\mathcal{P}(\{E < |q_2|\}) = 0$, and $\mathcal{P}$ is carried by $\mathsf{S} := \{E \geq |q_1|,\ E \geq |q_2|\}$, on which $|e^{-\mathfrak{z}_3 E + i\mathfrak{z}_1 q_1 + i\mathfrak{z}_2 q_2}| \leq e^{-d_3(\mathfrak{z})E}$. The operators $T_3(\mathfrak{z})$, $\mathfrak{z} \in \overline{\mathrm{Tb}_3}$, have the properties of (a), with $\mathfrak{z}^*$, d_3, and $T_3(x)[F] = [\tau_x F]$ for real x with $x_3 \geq 0$; $T(\xi) = T_3(\xi^1, 0, \xi^0)$; and $\mathcal{U}_w T_3(\mathfrak{z})\mathcal{U}_w^{-1} = T_3(w\mathfrak{z})$. For $w \in W_3$ with $we_3 = e_\mu$, σ is reflection positive at the mirror $\{x_\mu = 0\}$, and $J_w[F] := [wF]^{(\mu)}$ is a unitary map of $\mathcal{H}(\sigma)$ onto the space $\mathcal{H}^{(\mu)}(\sigma)$ built with that mirror, which carries Ω, $\mathcal{T}_t$, $\mathcal{U}(v)$ and $\mathcal{P}$ to the vacuum, the time and space translations and the joint spectral measure of $\mathcal{H}^{(\mu)}(\sigma)$, the last through $(E,q) \mapsto (E,wq)$.

■

Proof. (a) By (T4), S_1 carries $\mathcal{P}$, and on S_1, $|e^{-\xi^0 E + i\xi^1 q_1}| = e^{-\mathrm{Re}\,\xi^0 E - \mathrm{Im}\,\xi^1 q_1} \leq e^{-d_{\mathrm{Tb}}(\xi)E} \leq 1$ for $\xi \in \overline{\mathrm{Tb}}$. The algebraic rules follow from the spectral calculus and the rule $\int \mathbf{1}_B\, d\mathcal{P} = \mathcal{P}(B)$, the adjoint from $\overline{e^{-\xi^0 E + i\xi^1 q_1}} = e^{-\overline{\xi^0}E - i\overline{\xi^1}q_1}$, and $T(\xi)\Omega = \Omega$ from $\Omega = \mathcal{P}(\{0\})\Omega$. Strong continuity follows by dominated convergence from $\|(T(\xi_j) - T(\xi))\psi\|^2 = \int_{\mathsf{S}_1} |e_{\xi_j} - e_\xi|^2\, d\langle\psi, \mathcal{P}\psi\rangle$, $e_\xi(E,q) = e^{-\xi^0 E + i\xi^1 q_1}$, the integrand being ≤ 4; holomorphy in norm, because the matrix elements are holomorphic and the family is bounded; the real points by Lemma 4.13 (b).

(b) As w commutes with θ and maps E_+ onto itself, (T1) gives $\sigma(\theta\overline{wF} \cdot wG) = \sigma(w(\theta\bar{F} \cdot G)) = \sigma(\theta\bar{F} \cdot G)$, so $\mathcal{U}_w$ is well defined and isometric, and onto because w^{-1} is of the same kind; the relations with $\mathcal{T}_t$ and $\mathcal{U}(v)$ hold on classes, and the uniqueness of the joint spectral measure gives the transformation of $\mathcal{P}$. Thus $B \mapsto \mathcal{U}_w\mathcal{P}(B)\mathcal{U}_w^{-1} = \mathcal{P}(\{(E,wq) : (E,q) \in B\})$ is the image of $\mathcal{P}$ under $(E,q) \mapsto (E, w^{-1}q)$, and for every bounded Borel function g

$$\mathcal{U}_w\, g(\mathcal{P})\, \mathcal{U}_w^{-1} = \int g(E, w^{-1}q)\, d\mathcal{P}(E,q).$$

For the w that exchanges e_1 and e_2, $\{E < |q_2|\}$ is the image of $\{E < |q_1|\}$. The assertions on T_3 that repeat those of (a) are (a) in three variables. For the rule $\mathcal{U}_w T_3(\mathfrak{z})\mathcal{U}_w^{-1} = T_3(w\mathfrak{z})$ take $g = \mathbf{1}_{\mathsf{S}} e_{\mathfrak{z}}$, $e_{\mathfrak{z}}(E,q) := e^{-\mathfrak{z}_3 E + i\mathfrak{z}_1 q_1 + i\mathfrak{z}_2 q_2}$, $\mathfrak{z} \in \overline{\mathrm{Tb}_3}$, $q = q_1 e_1 + q_2 e_2$. As w is a real orthogonal matrix with $we_3 = e_3$, it maps $e_3^\perp$ onto itself, $(w\mathfrak{z})_3 = \mathfrak{z}_3$ and $\mathfrak{z} \cdot (w^{-1}q) = (w\mathfrak{z}) \cdot q$, the dot being the bilinear product; so $e_{\mathfrak{z}}(E, w^{-1}q) = e_{w\mathfrak{z}}(E,q)$. The set S is stable under $(E,q) \mapsto (E,wq)$, and $d_3(w\mathfrak{z}) = d_3(\mathfrak{z})$, because $(w\mathfrak{z})_1, (w\mathfrak{z})_2$ are $\mathfrak{z}_1, \mathfrak{z}_2$ up to order and signs; so $w\mathfrak{z} \in \overline{\mathrm{Tb}_3}$ and $\mathcal{U}_w T_3(\mathfrak{z})\mathcal{U}_w^{-1} = \int \mathbf{1}_{\mathsf{S}} e_{w\mathfrak{z}}\, d\mathcal{P} = T_3(w\mathfrak{z})$ on all of $\overline{\mathrm{Tb}_3}$. For $we_3 = e_\mu$, $\theta^{(\mu)} := w\theta w^{-1}$ is the reflection in $\{x_\mu = 0\}$, and by (T1) $\sigma(\theta^{(\mu)}\bar{F} \cdot F) = \sigma(\theta\overline{w^{-1}F} \cdot w^{-1}F) \geq 0$ for F over $\{x_\mu > 0\}$; the same computation shows that J_w is isometric and onto. □

Lemma 4.15 (Slab operators)**.** Let σ have (T1°), (T2), (T3) and (T5$_N$), and let $l > 0$.

(a) For every $H \in C_c^1(\{0 < x_3 < l\}; V_{\mathbb{C}})$ there is exactly one bounded operator $B_l(H)$ on $\mathcal{H}(\sigma)$ with $B_l(H)[F] = [(H)_{\mathbb{C}} \cdot \tau_{le_3} F]$ for $F \in \mathbb{C}\mathfrak{S}^V(E_+)$. $H \mapsto B_l(H)$ is complex linear, and $\|B_l(H)\| \leq C(\mathcal{K}, l)\|H\|_\sharp$ if $\mathrm{supp}\, H \subset \mathcal{K}$, $\mathcal{K} \subset \{0 < x_3 < l\}$ compact, with a finite number $C(\mathcal{K}, l)$ that depends only on $\mathcal{K}$, l, M, c_I and N.

(b) $B_l(H) = \mathcal{T}_c B_{c'-c}(\tau_{-ce_3}H)\mathcal{T}_{l-c'}$ for $0 \leq c < c' \leq l$ and $\mathrm{supp}\, H \subset \{c < x_3 < c'\}$; $\mathcal{U}(v)B_l(H)\mathcal{U}(-v) = B_l(\tau_v H)$ for $v \in e_3^\perp$.

(c) $B_l(H)^* = B_l(\overline{\theta_{l/2}H})$, with the tensor action of $\theta_{l/2}$.
(d) $\|B_{\eta/2}(H)\| \le N(\eta)\|H\|_\sharp$ for $\eta \in (0,1]$ and real H with support in a ball $B(y, c_I\eta)$, $\eta/8 \le y_3 \le 3\eta/8$.
(e) $[(H_1,\dots,H_n)_{\mathbb{C}}] = B_{c_1}(H_1)B_{c_2-c_1}(\tau_{-c_1e_3}H_2)\cdots B_{c_n-c_{n-1}}(\tau_{-c_{n-1}e_3}H_n)\Omega$ for $0 = c_0 < c_1 < \cdots < c_n$ and $\operatorname{supp} H_a \subset \{c_{a-1} < x_3 < c_a\}$.

■

Proof. (d) Put $H_\circ := \tau_{-(\eta/4)e_3}H$, whose support lies in a ball $B(y', c_I\eta)$ with $|y'_3| \le \eta/8$, and $b(F,G) := \sigma(\theta\overline{\tau_{(\eta/4)e_3}F}\cdot(H_\circ)\cdot\tau_{(\eta/4)e_3}G)$ for $F, G \in \mathbb{C}\mathfrak{S}^V(E_+)$. By (T5$_N$), $|b(F,G)| \le N(\eta)\|H\|_\sharp\|[F]\|\,\|[G]\|$; this is the one place of the whole argument at which the insertion bound is used. So b is a bounded form on the classes and is given by a bounded operator A with $\|A\| \le N(\eta)\|H\|_\sharp$. By translation invariance and $\tau_{(\eta/4)e_3}\theta\tau_{(\eta/4)e_3} = \theta$, $b(F,G) = \langle[F], [(H)\cdot\tau_{(\eta/2)e_3}G]\rangle$; so $A = B_{\eta/2}(H)$.

(a) Uniqueness is clear, the classes being dense. For real H with support in $\mathcal{K}$ let $\delta := \min\{\min_{\mathcal{K}} x_3, l - \max_{\mathcal{K}} x_3\}$, $\eta := \min\{1, 4\delta\}$, $\mathsf{h} := c_I\eta/2$, and let $\chi_{\mathsf{h},k}$ be the scalar partition of unity at scale h. For each of the finitely many k with $\operatorname{supp}\chi_{\mathsf{h},k} \cap \mathcal{K} \neq \emptyset$ choose $c_k \in [0, l-\eta/2]$ with $|\mathsf{h}k_3 - \eta/4 - c_k| \le \mathsf{h}$; then $\tau_{-c_ke_3}(\chi_{\mathsf{h},k}H)$ is real, with support in a ball of radius $\sqrt{3}\mathsf{h} < c_I\eta$ whose centre has its third coordinate in $[\eta/8, 3\eta/8]$, and the identity $(H_k)\cdot\tau_{le_3}G = \tau_{c_ke_3}[(\tau_{-c_ke_3}H_k)\cdot\tau_{(\eta/2)e_3}(\tau_{(l-c_k-\eta/2)e_3}G)]$ in $\mathbb{C}\mathfrak{S}^V(E_+)$, together with (a) of Lemma 4.13, gives

$$B_l(H) = \sum_k \mathcal{T}_{c_k} B_{\eta/2}(\tau_{-c_ke_3}\chi_{\mathsf{h},k}H)\,\mathcal{T}_{l-c_k-\eta/2}, \qquad \|B_l(H)\| \le \sum_k N(\eta)\|\chi_{\mathsf{h},k}H\|_\sharp,$$

which is bounded by a multiple of $\|H\|_\sharp$ by (d), Lemma 4.10 (d) and $\operatorname{Lip}\chi_{\mathsf{h},k} \le \sqrt{3}\pi/2\mathsf{h}$. For complex H put $B_l(H) := B_l(H^0) + iB_l(H^1)$ and use Lemma 4.10 (a).

(b) and (e) follow from identities in $\mathbb{C}\mathfrak{S}^V(E_+)$: $(H)_{\mathbb{C}}\cdot\tau_{le_3}G = \tau_{ce_3}[(\tau_{-ce_3}H)_{\mathbb{C}}\cdot\tau_{(c'-c)e_3}(\tau_{(l-c')e_3}G)]$, and, for (e), induction on n with $[(H_1,\dots,H_n)_{\mathbb{C}}] = B_{c_1}(H_1)[\tau_{-c_1e_3}(H_2,\dots,H_n)_{\mathbb{C}}]$.

(c) Let $B = (H)_{\mathbb{C}}\cdot\tau_{le_3}G$. The form is Hermitian, so $\langle F, B\rangle_\sigma = \overline{\langle B, F\rangle_\sigma}$, and by one translation, $\tau_{le_3}\theta = \theta_{l/2}$, $\tau_{le_3}\theta\tau_{le_3} = \theta$, symmetry and Lemma 4.12 (d),

$$\langle B, F\rangle_\sigma = \sigma(\theta\overline{(H)_{\mathbb{C}}}\cdot\theta\tau_{le_3}\bar G\cdot F) = \sigma(\theta_{l/2}\overline{(H)_{\mathbb{C}}}\cdot\theta\bar G\cdot\tau_{le_3}F) = \sigma(\theta\bar G\cdot(\overline{\theta_{l/2}H})_{\mathbb{C}}\cdot\tau_{le_3}F),$$

which is $\langle[G], B_l(\overline{\theta_{l/2}H})[F]\rangle$. No invariance of σ under a reflection is used: the matrix index is moved only by the θ of the form. □

Lemma 4.16 (Centred slab operators)**.** Let σ be as in Lemma 4.15, $d > 0$ and $f \in C^1_c(\{|x_3| < d\}; V_{\mathbb{C}})$; then $B^c_d(f) = B_{2d}(\tau_{de_3}f)$.

(a) $f \mapsto B^c_d(f)$ is complex linear, and $B^c_d(f)^* = B^c_d(\overline{\theta f})$.
(b) $\mathcal{T}_{c+x_3}\mathcal{U}(\vec x)B^c_d(f)\mathcal{U}(-\vec x)\mathcal{T}_{c-x_3} = B^c_{d+c}(\tau_x f)$ for $x \in \mathbb{R}^3$, $\vec x = x_1e_1 + x_2e_2$, $c \ge |x_3|$; so $T(cn_0 + y)B^c_d(f)T(cn_0 - y) = B^c_{d+c}(\tau_y f)$ for $|y^0| \le c$ under (T4), and $T_3(ce_3 + x)B^c_d(f)T_3(ce_3 - x) = B^c_{d+c}(\tau_x f)$ for $|x_3| \le c$ under (T1) and (T4).
(c) $\|B^c_d(h)\| \le 40M\,C(de_3 + \mathcal{K}, 2d)\|h\|_{C^1}$ if $\operatorname{supp} h \subset \mathcal{K}$, $\mathcal{K} \subset \{|x_3| < d\}$ compact.
(d) $\|B^c_{\eta/4}(h)\| \le N(\eta)\|h\|_\sharp$ for $\eta \in (0,1]$ and real h with support in a ball $B(v, c_I\eta)$, $v_3 = 0$.
(e) $\langle[\tau_{-de_3}F], B^c_d(f)[\tau_{-de_3}F']\rangle = \sigma(\theta\bar F\cdot(f)_{\mathbb{C}}\cdot F')$ for $F, F' \in \mathbb{C}\mathfrak{S}^V(\{x_3 > d\})$.

■

Proof. (a) is Lemma 4.15 (c) at $l = 2d$, with $\theta_d\tau_{de_3} = \tau_{de_3}\theta$. (b) By Lemma 4.15 (b) the left side is $\mathcal{T}_{c+x_3}B_{2d}(\tau_{\vec x}\tau_{de_3}f)\mathcal{T}_{c-x_3}$, which the same clause, with $l = 2(d+c)$ and the slab $\{c + x_3 < x'_3 < c + x_3 + 2d\}$, identifies with $B_{2(d+c)}(\tau_{(d+c)e_3}\tau_x f) = B^c_{d+c}(\tau_x f)$; the forms with T and T_3 follow from the values at real points in Lemma 4.14. (c) is Lemma 4.15 (a) with Lemma 4.10 (b). (d) is Lemma 4.15 (d) after the translation by $(\eta/4)e_3$, as $\eta/4 \in [\eta/8, 3\eta/8]$. (e) follows from one translation by $-de_3$ and $\tau_{-de_3}\theta\tau_{-de_3} = \theta$. □

Proposition 4.17 (Regularised point plates; a bound that does not depend on the regularisation)**.** Let σ have (T1°), (T2), (T3), (T4) and (T5$_N$). Let $j_\delta := j_\delta^{(2)}$, and for $\mathfrak{a} \in \mathcal{L}_{\mathbb{C}}$, $\delta > 0$ and $d_{\mathrm{Tb}}(\xi), d_{\mathrm{Tb}}(\xi') \geq \delta$ put

$$A_\delta(\mathfrak{a}) := B^c_\delta(j_\delta \otimes \mathfrak{a}), \qquad B^\delta_{\mathfrak{a}}(\xi,\xi') := T(\xi - \delta n_0)\, A_\delta(\mathfrak{a})\, T(\xi' - \delta n_0).$$

(a) $B^\delta_{\mathfrak{a}}$ is complex linear in $\mathfrak{a}$ and holomorphic in norm on $\{d_{\mathrm{Tb}} > \delta\}^2$; $T(\kappa) B^\delta_{\mathfrak{a}}(\xi,\xi') T(\kappa') = B^\delta_{\mathfrak{a}}(\kappa+\xi, \xi'+\kappa')$ for $\kappa, \kappa' \in \overline{\mathrm{Tb}}$; $A_\delta(\mathfrak{a})^* = A_\delta(\mathfrak{a}^\theta)$ and $B^\delta_{\mathfrak{a}}(\xi,\xi')^* = B^\delta_{\mathfrak{a}^\theta}(\xi'^*, \xi^*)$; $B^\delta_{\mathfrak{a}}(dn_0 + y, dn_0 - y) = B^c_d((\tau_y j_\delta) \otimes \mathfrak{a})$ for $d \geq \delta + |y^0|$; and $\int \alpha(y) B^\delta_{\mathfrak{a}}(dn_0+y, dn_0-y)\, dy = B^c_d((\alpha * j_\delta)\otimes \mathfrak{a})$ for continuous α with compact support in $\{|y^0| < d - \delta\}$.

(b) For $0 < \eta \leq \min\{1, d_{\mathrm{Tb}}(\xi), d_{\mathrm{Tb}}(\xi')\}$ and $0 < \delta \leq c_I \eta/8$, $\|B^\delta_{\mathfrak{a}}(\xi,\xi')\| \leq 2 c_{\mathrm{plt}}\, \nu(\mathfrak{a}) N(\eta) \eta^{-4}$, without the factor 2 for real $\mathfrak{a}$; if σ has (T5$_N$) in the sup norm, also

$$\|B^\delta_{\mathfrak{a}}(\xi,\xi')\| \leq 2 \cdot 12 \cdot 8^2 \mathrm{mv}_0^2 c_I^{-3} \nu_\infty(\mathfrak{a}) N(\eta) \eta^{-3}.$$

(c) For $\varepsilon > 0$, $\eta_0 := \frac{1}{2}\min\{1, \varepsilon\}$, $b_\varepsilon := 2 c_{\mathrm{plt}} \nu(\mathfrak{a}) N(\eta_0) \eta_0^{-4}$ and $0 < \delta, \delta' \leq c_I \eta_0/8$:

$$\|B^\delta_{\mathfrak{a}}(\varepsilon n_0, \varepsilon n_0) - B^{\delta'}_{\mathfrak{a}}(\varepsilon n_0, \varepsilon n_0)\| \leq c\, b_\varepsilon \varepsilon^{-1} (\delta + \delta')$$

with an absolute number c. Hence $B_{\mathfrak{a}}(\xi,\xi') := \lim_{\delta\to 0} B^\delta_{\mathfrak{a}}(\xi,\xi')$ exists in norm on $\mathrm{Tb} \times \mathrm{Tb}$, uniformly on $\{d_{\mathrm{Tb}} \geq \varepsilon\}^2$, and has the properties (i)–(iv) of Theorem L (A); the bounds of (b) pass to it.

■

Proof. (a) By Lemma 4.10 (f), $\theta(\overline{j_\delta \otimes \mathfrak{a}}) = (j_\delta \circ \theta) \otimes \mathfrak{a}^\theta = j_\delta \otimes \mathfrak{a}^\theta$, so Lemma 4.16 (a) gives $A_\delta(\mathfrak{a})^* = A_\delta(\mathfrak{a}^\theta)$ in place of the scalar rule $A_\delta^* = A_\delta$; with $T(\xi)^* = T(\xi^*)$ and $(\xi - \delta n_0)^* = \xi^* - \delta n_0$ this is the adjoint rule. The shift rule and holomorphy come from Lemma 4.14 (a) and the calculus of operator functions. The value at $(dn_0 + y, dn_0 - y)$ is Lemma 4.16 (b) with $c = d - \delta$; the integral identity follows from it, the convergence of Riemann sums of $\alpha * j_\delta$ in $\|\cdot\|_{C^1}$, and Lemma 4.16 (c).

(b) Let $\mathfrak{a}$ be real, $r := c_I\eta/8$, ψ, ψ' unit vectors, and $u(z) := \langle \psi, B^\delta_{\mathfrak{a}}(\xi + z, \xi' - z)\psi'\rangle$ for $|z^0|, |z^1| < 2r$; there $d_{\mathrm{Tb}}(\xi \pm z) > \eta - 4r > \delta$, so u is holomorphic near the closed polydisc of radius r. By the mean-value formula, $u(0) = \int_{(-r,r)^2} dt \int u(y + it) \alpha^{(2)}_{r,t}(y)\, dy$. For fixed t let $\kappa_t := \xi - \frac{\eta}{4} n_0 + it$ and $\kappa_t' := \xi' - \frac{\eta}{4} n_0 - it$, which lie in Tb; by the shift rule $u(y + it) = \langle \psi_t, B^\delta_{\mathfrak{a}}(\frac{\eta}{4} n_0 + y, \frac{\eta}{4} n_0 - y)\psi_t'\rangle$ with $\psi_t := T(\kappa_t)^* \psi$, $\psi_t' := T(\kappa_t')\psi'$ of norms ≤ 1, and by (a) at $d = \eta/4$

$$\int u(y + it)\, \alpha^{(2)}_{r,t}(y)\, dy = \langle \psi_t, B^c_{\eta/4}(\gamma_t \otimes \mathfrak{a}) \psi_t' \rangle, \qquad \gamma_t := \alpha^{(2)}_{r,t} * j_\delta.$$

The profile γ_t is real, supported in $[-2r, 2r]^2$, with $\|\gamma_t\|_\infty \leq \mathrm{mv}_0^2 r^{-4}$ and $\mathrm{Lip}\, \gamma_t \leq \sqrt{2}\, \mathrm{mv}_0 \mathrm{mv}_1 r^{-5}$. We cut the label as in Lemma 4.10 (g), at the scale r; at most $3(\lambda_{\mathfrak{a}} + 1)/(c_I\eta)$ pieces $\mathfrak{a}_k$ are non-zero, and each $\gamma_t \otimes \mathfrak{a}_k$ is real, supported in the closed ball of radius $\sqrt{24}\, r < 8r = c_I\eta$ about $4rke_2$, with $\|\gamma_t \otimes \mathfrak{a}_k\|_\sharp \leq 40 M\, \mathrm{mv}_2 r^{-5} \|\mathfrak{a}\|_{C^1}$, since $\mathrm{Lip}(\gamma_t \otimes \mathfrak{a}_k) \leq \sqrt{2}\, \mathrm{mv}_0 \mathrm{mv}_1 r^{-5} \|\mathfrak{a}\|_{C^1} + \mathrm{mv}_0^2 r^{-4}(1 + \frac{\pi}{8r}) \|\mathfrak{a}\|_{C^1} \leq \mathrm{mv}_2 r^{-5} \|\mathfrak{a}\|_{C^1}$. Lemma 4.16 (d) bounds each piece, and

$$|u(0)| \leq (2r)^2 \cdot \frac{3(\lambda_{\mathfrak{a}} + 1)}{c_I \eta} \cdot N(\eta) \cdot 40 M\, \mathrm{mv}_2 r^{-5} \|\mathfrak{a}\|_{C^1} = 480 \cdot 8^3 \mathrm{mv}_2 M (c_I\eta)^{-4} N(\eta)\, \nu(\mathfrak{a})$$
$$= c_{\mathrm{plt}}\, \nu(\mathfrak{a}) N(\eta) \eta^{-4}.$$

The supremum over ψ, ψ' is the norm. A complex label is split as $\mathfrak{a} = \mathfrak{a}^0 + i\mathfrak{a}^1$, whence the factor 2. In the sup norm the slope of γ_t is not paid: $\|B^c_{\eta/4}(\gamma_t \otimes \mathfrak{a}_k)\| \leq N(\eta) \mathrm{mv}_0^2 r^{-4} \|\mathfrak{a}\|_\infty$, and the same sum gives $12 \cdot 8^2 \mathrm{mv}_0^2 (c_I\eta)^{-3} N(\eta) \nu_\infty(\mathfrak{a})$.

(c) For $|z^0|, |z^1| < \varepsilon/4$, $d_{\mathrm{Tb}}(\varepsilon n_0 \pm z) > \varepsilon/2 \geq \eta_0$, so by (b) at the one number η_0 the holomorphic function $z \mapsto B^\delta_{\mathfrak{a}}(\varepsilon n_0 + z, \varepsilon n_0 - z)$ is bounded by b_ε there, and the Cauchy estimate gives $\|B^\delta_{\mathfrak{a}}(\varepsilon n_0 + y, \varepsilon n_0 - y) - B^\delta_{\mathfrak{a}}(\varepsilon n_0, \varepsilon n_0)\| \leq c\, b_\varepsilon \varepsilon^{-1} |y|$ for real $|y| \leq \varepsilon/8$. Integrating against $j_{\delta'}$, which has mass 1

and support in $\{|y| \le \delta'/2\}$, and using (a), $\|B^c_\varepsilon((j_{\delta'} * j_\delta) \otimes \mathfrak{a}) - B^\delta_\mathfrak{a}(\varepsilon n_0, \varepsilon n_0)\| \le c\, b_\varepsilon \varepsilon^{-1}\delta'$; the same with δ and δ' exchanged, and $j_{\delta'} * j_\delta = j_\delta * j_{\delta'}$, give the estimate.

As the space of bounded operators is complete, $B_{[\varepsilon]} := \lim_\delta B^\delta_\mathfrak{a}(\varepsilon n_0, \varepsilon n_0)$ exists, and for $d_{\mathrm{Tb}}(\xi), d_{\mathrm{Tb}}(\xi') \ge \varepsilon$ the shift rule gives $B^\delta_\mathfrak{a}(\xi, \xi') = T(\xi - \varepsilon n_0) B^\delta_\mathfrak{a}(\varepsilon n_0, \varepsilon n_0) T(\xi' - \varepsilon n_0)$, so $B_\mathfrak{a}(\xi, \xi') = T(\xi - \varepsilon n_0) B_{[\varepsilon]} T(\xi' - \varepsilon n_0)$, with $\|B^\delta_\mathfrak{a}(\xi, \xi') - B_\mathfrak{a}(\xi, \xi')\| \le \|B^\delta_\mathfrak{a}(\varepsilon n_0, \varepsilon n_0) - B_{[\varepsilon]}\|$. Holomorphy, linearity, the bound (i), the shift rule and the adjoint (ii) pass to the limit. For (iii), let $\operatorname{supp}\alpha \subset \{|y^0| \le d'\}$, $d' < d$: on $\operatorname{supp}\alpha$, $d_{\mathrm{Tb}}(dn_0 \pm y) \ge d - d'$, so the left side of the integral identity of (a) converges in norm to $\int \alpha(y) B_\mathfrak{a}(dn_0 + y, dn_0 - y)dy$, while $\alpha * j_\delta \to \alpha$ in $\|\cdot\|_{C^1}$ with supports in a fixed compact subset of $\{|y^0| < d\}$, so that the right side converges to $B^c_d(\alpha \otimes \mathfrak{a})$ by Lemma 4.16 (c); the bound in (iii) follows from the norm bound of the integral.

For (iv), if B' is such a family, $g(y) := \langle \psi, (B' - B_\mathfrak{a})(dn_0 + y, dn_0 - y)\psi' \rangle$ is continuous on $\{|y^0| < d\}$ and $\int \alpha g = 0$ for all real profiles there; by the fundamental lemma $g = 0$, in particular $B'(dn_0, dn_0) = B_\mathfrak{a}(dn_0, dn_0)$ for all $d > 0$, and the shift rule gives

$$B'(\xi, \xi') = T(\xi - \varepsilon n_0) B'(\varepsilon n_0, \varepsilon n_0) T(\xi' - \varepsilon n_0) = B_\mathfrak{a}(\xi, \xi'), \qquad \varepsilon = \min\{d_{\mathrm{Tb}}(\xi), d_{\mathrm{Tb}}(\xi')\}.$$

□

Lemma 4.18 (Rules for the point plates)**.** Under the hypotheses of Theorem L (A), the family $B_\mathfrak{a}$ of Proposition 4.17 has property (v) of Theorem L (A). ■

Proof. For $0 < \varepsilon \le \min\{d_{\mathrm{Tb}}(\kappa_1), d_{\mathrm{Tb}}(\kappa_2)\}$ the shift rule gives $B_\mathfrak{a}(\xi, \kappa_1) = B_\mathfrak{a}(\xi, \varepsilon n_0) T(\kappa_1 - \varepsilon n_0)$ and $B_{\mathfrak{a}'}(\kappa_2, \xi') = T(\kappa_2 - \varepsilon n_0) B_{\mathfrak{a}'}(\varepsilon n_0, \xi')$, so that

$$B_\mathfrak{a}(\xi, \kappa_1) T(\kappa_0) B_{\mathfrak{a}'}(\kappa_2, \xi') = B_\mathfrak{a}(\xi, \varepsilon n_0)\, T(\varkappa - 2\varepsilon n_0)\, B_{\mathfrak{a}'}(\varepsilon n_0, \xi');$$

for two triples with the same sum we take ε below the four distances, and $(\frac{\varkappa}{2}, 0, \frac{\varkappa}{2})$ is such a triple by Lemma 4.11 (a). Further $B_\mathfrak{a}(\xi, \kappa)\Omega = B_\mathfrak{a}(\xi, \varepsilon n_0) T(\kappa - \varepsilon n_0)\Omega = B_\mathfrak{a}(\xi, \varepsilon n_0)\Omega$ and $\langle \Omega, B_\mathfrak{a}(\kappa, \xi)\psi \rangle = \langle T((\kappa - \varepsilon n_0)^*)\Omega, B_\mathfrak{a}(\varepsilon n_0, \xi)\psi \rangle = \langle \Omega, B_\mathfrak{a}(\varepsilon n_0, \xi)\psi \rangle$ for $\varepsilon \le \min\{d_{\mathrm{Tb}}(\kappa), d_{\mathrm{Tb}}(\kappa')\}$ and the comparison with κ'. □

Proposition 4.19 (Point fields)**.** Let σ have (T1), (T2), (T3), (T4) and (T5$_N$). With $j^{(3)}_\delta$ put $A_\delta(E) := B^c_\delta(j^{(3)}_\delta E)$ and $B^\delta_E(\mathfrak{z}, \mathfrak{z}') := T_3(\mathfrak{z} - \delta e_3) A_\delta(E) T_3(\mathfrak{z}' - \delta e_3)$ for $E \in V_\mathbb{C}$ and $d_3(\mathfrak{z}), d_3(\mathfrak{z}') \ge \delta$. Then $A_\delta(E)^* = A_\delta(\varrho(\theta)\bar{E})$, B^δ_E has the shift rule with T_3 and the adjoint $B^\delta_E(\mathfrak{z}, \mathfrak{z}')^* = B^\delta_{\varrho(\theta)\bar{E}}(\mathfrak{z}'^*, \mathfrak{z}^*)$, $B^\delta_E(de_3 + x, de_3 - x) = B^c_d((\tau_x j^{(3)}_\delta)E)$ for $d \ge \delta + |x_3|$, and for $0 < \eta \le \min\{1, d_3(\mathfrak{z}), d_3(\mathfrak{z}')\}$ and $0 < \delta \le c_I\eta/8$,

$$\|B^\delta_E(\mathfrak{z}, \mathfrak{z}')\| \le 2c_{\mathrm{pt}} |E|_2 N(\eta) \eta^{-4},$$

without the factor 2 for $E \in V$, and $\|B^\delta_E(\mathfrak{z}, \mathfrak{z}')\| \le 2 \cdot 8^4 \mathrm{mv}_0^3 c_I^{-3} |E|_2 N(\eta) \eta^{-3}$ if σ has (T5$_N$) in the sup norm. The limits $B_E(\mathfrak{z}, \mathfrak{z}') := \lim_{\delta \to 0} B^\delta_E(\mathfrak{z}, \mathfrak{z}')$ exist in norm and have the properties (i)–(iv) of Theorem L (D). ■

Proof. The proof of Proposition 4.17 is repeated with $\mathbb{R}^3$, x, $\mathfrak{z}$, T_3, e_3, d_3 and βE in place of $\mathbb{R}^2$, y, ξ, T, n_0, d_{Tb} and $\beta \otimes \mathfrak{a}$, with Lemmas 4.11 (b), 4.14 (b) and 4.16 (b), and without the cut of a label. For real E, $r = c_I\eta/8$ and $u(w) := \langle \psi, B^\delta_E(\mathfrak{z} + w, \mathfrak{z}' - w)\psi' \rangle$, $|w_i| < 2r$: there $d_3(\mathfrak{z} \pm w) > \eta - 6r > \delta$; $\kappa_t := \mathfrak{z} - \frac{\eta}{4} e_3 + it$ has $d_3(\kappa_t) > \frac{3}{4}\eta - 2r > 0$; the mean-value formula in three variables gives the profiles $\gamma_t = \alpha^{(3)}_{r,t} * j^{(3)}_\delta$, real, supported in $[-2r, 2r]^3$, hence in the ball of radius $2\sqrt{3}\, r < c_I\eta$ about 0, with $\|\gamma_t\|_\infty \le \mathrm{mv}_0^3 r^{-6}$, $\operatorname{Lip}\gamma_t \le \sqrt{3}\, \mathrm{mv}_0^2 \mathrm{mv}_1 r^{-7}$, so $\|\gamma_t E\|_\sharp \le 40M\, \mathrm{mv}_3 r^{-7} |E|_2$, and

$$|u(0)| \le (2r)^3 \cdot N(\eta) \cdot 40M\, \mathrm{mv}_3 r^{-7} |E|_2 = 320 \cdot 8^4 \mathrm{mv}_3 c_I^{-4} M\, \eta^{-4} N(\eta) |E|_2;$$

in the sup norm $(2r)^3 N(\eta) \mathrm{mv}_0^3 r^{-6} |E|_2 = 8^4 \mathrm{mv}_0^3 c_I^{-3} \eta^{-3} N(\eta) |E|_2$. The limit is taken at $(\varepsilon e_3, \varepsilon e_3)$ on the polydisc $|w_i| < \varepsilon/6$, where $d_3(\varepsilon e_3 \pm w) > \varepsilon/2$, by the Cauchy estimate and the comparison through $B^c_\varepsilon((j^{(3)}_{\delta'} * j^{(3)}_\delta)E)$. The slab formula (iii) is first obtained for $H = \beta E$ with scalar $\beta \in$

$C^1_c(\{|x_3|\le d'\};\mathbb{C})$, $d'<d$, as the limit $\delta\to 0$ of $\int \beta(x)B^\delta_E(de_3+x,de_3-x)\,dx = B^c_d((\beta * j^{(3)}_\delta)E)$, and then for every $H=\sum_c h_c b_c$ by linearity in E. Uniqueness and the rules are proved as in Propositions 4.17 (c) and Lemma 4.18, with the fundamental lemma in three variables. □

Proof of Theorem L. Step 1 ((A)). Lemmas 4.13, 4.14 (a), 4.15 and 4.16 provide $\mathcal{H}(\sigma)$, $T(\xi)$ and the slab operators; (A)(i)–(iv) is Proposition 4.17 (c), and (A)(v) is Lemma 4.18.

Step 2 (kernels and vectors; (KV1$_N$), (KV3)). By (A)(v), K_n and Ψ do not depend on κ; holomorphy comes from the calculus of operator functions, since the arguments are affine functions of ξ or x with values in Tb, and $\mathrm{Tb}^{(n)}$ is the preimage of Tb^n under a linear bijection. At $\kappa=n_0$ every argument has $d_{\mathrm{Tb}}\ge \min\{1,\frac12\min_k d_{\mathrm{Tb}}(\xi_k)\}$, and (A)(i), applied factor by factor, gives (KV1$_N$). The shift in (KV3) is the shift rule at the first factor. By (A)(ii) adjoints reverse the order, star the arguments and replace $\mathfrak{a}_k$ by $\mathfrak{a}_k^\theta$:

$$\langle\Psi(x;\mathbf{a}),\Psi(z;\mathbf{a}')\rangle=\langle\Omega,B_{\mathfrak{a}_n^\theta}(\kappa^*,p_n^*)\cdots B_{\mathfrak{a}_1^\theta}(q_1^*,x_1^*)\,B_{\mathfrak{a}'_1}(z_1,q'_1)\cdots B_{\mathfrak{a}'_{n'}}(p'_{n'},\kappa)\Omega\rangle,$$

with $q_k^*=p_{k+1}^*=\frac12(x_{k+1}-x_k)^*$ and $q'_k=p'_{k+1}=\frac12(z_{k+1}-z_k)$; by (A)(v) the arguments x_1^* and z_1 may be replaced by $\frac12(x_1^*+z_1)$ and κ^* by κ, which is the product that defines $K_{n+n'}$ at the stated arguments and labels. The two edge formulas are the cases $n=0$ and $n'=0$.

Step 3 (the formulas (KV2)). For supports time-ordered in $\mathbb{R}^2_+$ put $c_a:=g_a$ ($c_0=0$), $H_a:=\alpha_a\otimes\mathfrak{a}_a$, $d_a:=\frac12(c_a-c_{a-1})$, $m_a:=\frac12(c_a+c_{a-1})$. The product formula of Lemma 4.15 (e) writes $[(H_1,\dots,H_n)_{\mathbb{C}}]$ as a product of the factors $B^c_{d_a}((\tau_{-m_an_0}\alpha_a)\otimes\mathfrak{a}_a)$ applied to Ω; by (A)(iii) each factor is $\int\alpha_a(y)B_{\mathfrak{a}_a}(y-c_{a-1}n_0,c_an_0-y)\,dy$, so

$$[(H_1,\dots,H_n)_{\mathbb{C}}]=\int\prod_a\alpha_a(y_a)\,B_{\mathfrak{a}_1}(y_1,c_1n_0-y_1)B_{\mathfrak{a}_2}(y_2-c_1n_0,c_2n_0-y_2)\cdots B_{\mathfrak{a}_n}(y_n-c_{n-1}n_0,c_nn_0-y_n)\Omega\,dY.$$

At each junction the two neighbouring arguments add up to $y_{a+1}-y_a$, and by (A)(v) both may be replaced by $\frac12(y_{a+1}-y_a)$; the last argument may be replaced by κ; this gives the vector formula. The first formula follows from $\langle\Omega,[F]\rangle=\sigma(F)$ and the edge formula of Step 2; the general time-ordered case follows by one translation in time and the substitution $y_a\mapsto y_a+cn_0$, which keeps the differences.

Step 4 (conjugation, centring, uniqueness: (KV4), (KV5)). For real labels and $n\ge2$, $\gamma(Y):=\operatorname{Im}K_n(y_2-y_1,\dots;\mathbf{a})$ is continuous on $O=\{y_1^0<\cdots<y_n^0\}$, and for real profiles with $\prod_k\operatorname{supp}\alpha_k\subset O$ the supports are time-ordered and the left side of (KV2) is real; by the fundamental lemma $\gamma=0$. The function $\xi\mapsto\overline{K_n(\bar\xi;\mathbf{a})}$ is holomorphic on Tb^{n-1} and equals K_n on the real points, a non-empty open subset of $\mathbb{R}^{2(n-1)}$ of the connected set Tb^{n-1}; by the identity theorem it is K_n. For complex labels,

$$K_n(\xi;\mathbf{a})=\sum_\varepsilon i^{|\varepsilon|}K_n(\xi;\mathfrak{a}_1^{\varepsilon_1},\dots,\mathfrak{a}_n^{\varepsilon_n}),\qquad\overline{K_n(\xi;\mathbf{a})}=\sum_\varepsilon(-i)^{|\varepsilon|}K_n(\bar\xi;\mathfrak{a}_1^{\varepsilon_1},\dots)=K_n(\bar\xi;\bar{\mathbf{a}}).$$

If σ is centred, (KV2) at $n=1$ with a real profile of integral 1 gives $K_1(\mathfrak{a})=\sigma((\alpha\otimes\mathfrak{a}^0))+i\sigma((\alpha\otimes\mathfrak{a}^1))=0$. Uniqueness: the difference of two continuous densities is annihilated by all products of real profiles with $\prod\operatorname{supp}\alpha_k\subset O$, hence vanishes by the fundamental lemma, and every point of $(\mathbb{R}^2_+)^{n-1}$ is a tuple of differences of a point of O; then the identity theorem on Tb^{n-1}. For Ψ the same argument applies to $x\mapsto\langle\chi,\Psi(x;\mathbf{a})-\Psi'(x)\rangle$ on the real points of $\mathrm{Tb}^{(n)}$, for every vector χ.

Step 5 (the power, (C)). (T5) is (T5$_N$) at $N(\eta)=C_I\eta^{-\mathsf{p}_I}$; at $\eta=\frac12\min\{1,\rho\}$, $\rho=\min_k d_{\mathrm{Tb}}(\xi_k)$,

$$c_{\mathrm{plt}}N(\eta)\eta^{-4}=C_{\mathrm{plt}}\eta^{-\wp}=C_{\mathrm{plt}}2^{\wp}\min\{1,\rho\}^{-\wp},$$

and (KV1$_N$) gives (KV1) with $C_\flat=2^{\wp+1}C_{\mathrm{plt}}$, also at $n=1$ ($\eta=\frac12$). The finer bound and the plate bound are (A)(i) under (T5) at $\kappa=n_0$, factor by factor. The exponent $\wp=\mathsf{p}_I+4$ arises in Proposition 4.17 (b) as -5 from the norm $\|\cdot\|_\sharp$ of $\gamma_t\otimes\mathfrak{a}_k$ (height r^{-4}, slope r^{-1}), $+2$ from the

square of the imaginary parts t, and -1 from the number of pieces of the label. In the sup norm the slope is not paid, and the bound of Proposition 4.17 (b) in the sup norm gives (KV1) with $\wp'$, ν_∞ and $C'_\flat$.

Step 6 ((D)). (D) is Lemma 4.14 (b) and Proposition 4.19.

Step 7 (plates from point fields; the point bound, (E)). (i) The right side of $B_{\mathfrak a}(\xi,\xi') = \int B_{\mathfrak a(s)}(\xi + se_2, \xi' - se_2)ds$ is weakly continuous, has the shift rule because $T(\kappa) = T_3(\kappa^1, 0, \kappa^0)$ and $d_3(\xi \pm se_2) = d_{\mathrm{Tb}}(\xi)$, and satisfies the identity of (A)(iii), by (D)(iii) at $H = \alpha \otimes \mathfrak a$ and Fubini, since $de_3 \pm x = (dn_0 \pm y) \pm x_2 e_2$; by (A)(iv) it is $B_{\mathfrak a}$. The bounds follow from (D)(i), $|\mathfrak a(s)|_2$ and $|H(x)|_2$ under the integral, or $H = \sum_c \mathrm{tr}(b_c H)\, b_c$ with real b_c. (ii) The first two bounds on $\mathsf C_{\mathrm{pt}}$ are those of Proposition 4.19 at $\eta \le 1$. For η, H, F, G as in $(\mathrm{T5}_N)$, $\mathrm{supp}\, H \subset \{|x_3| < 3\eta/16\}$, and by Lemma 4.16 (e) and (D)(iii)

$$|\sigma(\theta\bar F\cdot(H)\cdot G)| \le \int \|B_{H(x)}(\tfrac\eta4 e_3 + x, \tfrac\eta4 e_3 - x)\|dx\, \|[\tau_{-(\eta/4)e_3}F]\|\, \|[\tau_{-(\eta/4)e_3}G]\| \le \mathsf C_{\mathrm{pt}}(\tfrac{\eta}{16})\|H\|_{L^1}\|\cdot\|\,\|\cdot\|,$$

as $d_3(\frac\eta4 e_3 \pm x) \ge \eta/16$ on $\mathrm{supp}\, H$; and $\|H\|_{L^1} \le \frac{4\pi}{3}(c_I\eta)^3\|H\|_\infty$. The consequences are arithmetic: $\mathsf C_{\mathrm{pt}}(\eta) \le C\eta^{-\mathsf p}$ gives $|\sigma(\theta\bar F\cdot(H)\cdot G)| \le C16^{\mathsf p}\frac{4\pi}{3}c_I^3\eta^{3-\mathsf p}\|H\|_\infty\|\cdot\|\,\|\cdot\|$, and (T5) gives $\mathsf C_{\mathrm{pt}}(\eta) \le C_{\mathrm{pt}}\eta^{-\mathsf p_I - 4}$.

Step 8 (reflections; other spaces of values, (F)). (a) is Lemma 4.13 (c). (b) In the parts of Definitions 4.1–4.5 that concern the plane, in Lemmas 4.10–4.13, 4.14 (a), 4.15, 4.16 (but for the form of (b) with T_3) and 4.18, in Proposition 4.17 and in Steps 1–5 above, of V, $|\cdot|_2$ and ϱ only the following enters: V is a real Euclidean space of finite dimension, $V_{\mathbb C}$ its complexification with $|E|^2 = |E^0|^2 + |E^1|^2$ and the conjugation, translations act on the argument alone, and $\varrho(\theta)$ is a real linear isometry ϑ with $\vartheta^2 = 1$; the isometries that act form the group generated by the translations and θ, and

$$\tau_v \mapsto 1, \qquad \tau_v\theta \mapsto \vartheta$$

is a homomorphism, which is all that Lemma 4.10 (e) asks (Lemma 4.10 (c) uses a basis of V'). So the proofs of (A), (B) and, under (T5), of (KV1) hold for V' and ϑ as they stand. □

Proof of Theorem M. Step 1 (plate vectors to plate vectors). Let $A := B_{\mathfrak b}(\xi,\xi')$; then $A^* = B_{\mathfrak b^\theta}(\xi'^*, \xi^*)$, and by Theorem L (A)(v)

$$A\,\Psi(z;\mathbf a') = \Psi\big((\xi, \xi+\xi'+z_1, \dots, \xi+\xi'+z_{n'}); \mathfrak b, \mathbf a'\big), \qquad A\Omega = \Psi(\xi;\mathfrak b),$$

the point lying in $\mathrm{Tb}^{(n'+1)}$; so $A\mathcal H_{\mathrm{pl}} \subset \mathcal H_{\mathrm{pl}}$, and likewise for A^*.

Step 2 (one matrix element). For plate vectors $\Psi_i = \Psi(x;\mathbf a)$, $\Psi_j = \Psi(z;\mathbf a')$ and $m \ge 1$, the Gram formula and the rules show that $\langle\Psi_i, (A^*A)^{2m}\Psi_j\rangle$ is $K_{n+4m+n'}$ at the sums of neighbouring arguments: $(x_{k+1} - x_k)^*$; $x_1^* + \xi'^*$; in turn $\xi^* + \xi$ and $\xi' + \xi'^*$; $\xi' + z_1$; $z_{k+1} - z_k$. By Lemma 4.11 (a) these have $d_{\mathrm{Tb}} \ge d_{\mathrm{Tb}}(\xi')$, $2d_{\mathrm{Tb}}(\xi)$, $2d_{\mathrm{Tb}}(\xi')$ and $d_{\mathrm{Tb}}(\xi')$, so if all inner differences of Ψ_i, Ψ_j have $d_{\mathrm{Tb}} \ge \rho_0 := \min\{1, 2d_{\mathrm{Tb}}(\xi), d_{\mathrm{Tb}}(\xi')\}$, the hypothesis and Lemma 4.10 (f) give

$$|\langle\Psi_i, (A^*A)^{2m}\Psi_j\rangle| \le c_i c_j \beta^{4m}, \qquad \beta := C'\nu(\mathfrak b)\rho_0^{-\varpi}, \quad c_i := \prod_k (C'\nu(\mathfrak a_k)\rho_0^{-\varpi}).$$

Step 3 (Schwarz's inequality, repeated). For a finite combination $\Phi = \sum\zeta_i\Psi_i$ of such vectors and of Ω, and $B := A^*A \ge 0$, $\|B^{2^k}\Phi\|^2 = \langle\Phi, B^{2^{k+1}}\Phi\rangle \le \|\Phi\|\,\|B^{2^{k+1}}\Phi\|$ gives by induction $\|B\Phi\| \le \|\Phi\|^{1-2^{-k}}\|B^{2^k}\Phi\|^{2^{-k}}$; with $m = 2^k$ and Step 2, $\|B^m\Phi\|^{1/m} \le (\sum|\zeta_i|c_i)^{1/m}\beta^2 \to \beta^2$. Hence $\|B\Phi\| \le \beta^2\|\Phi\|$ and $\|A\Phi\|^2 = \langle\Phi, B\Phi\rangle \le \beta^2\|\Phi\|^2$.

Step 4 (density). If $\chi \in \mathcal H_{\mathrm{pl}}$ is orthogonal to Ω and to all plate vectors whose inner differences have $d_{\mathrm{Tb}} > \rho_0$, then $x \mapsto \langle\chi, \Psi(x;\mathbf a)\rangle$ is holomorphic on the convex open set $\mathrm{Tb}^{(n)}$ and vanishes on the real points with $y_1^0 > 0$, $y_{k+1}^0 - y_k^0 > \rho_0$, a non-empty open subset of $(\mathbb R^2)^n$; by the identity theorem it vanishes, so $\chi = 0$. As A is bounded, $\|A\Phi\| \le \beta\|\Phi\|$ extends to $\mathcal H_{\mathrm{pl}}$.

Step 5 (the converse direction). At $\kappa = n_0$ the kernel is $\langle \Omega, B_{\mathfrak{a}_1}(n_0, \frac{\xi_1}{2}) \cdots B_{\mathfrak{a}_n}(\frac{\xi_{n-1}}{2}, n_0)\Omega\rangle$, every partial product applied to Ω lies in $\mathcal{H}_{\mathrm{pl}}$ by Step 1, and every factor is bounded on $\mathcal{H}_{\mathrm{pl}}$ by $C''\nu(\mathfrak{a}_k)\min\{1, \frac{1}{2}\min_k d_{\mathrm{Tb}}(\xi_k)\}^{-\varpi} \le 2^{\varpi}C''\nu(\mathfrak{a}_k)\min\{1, \min_k d_{\mathrm{Tb}}(\xi_k)\}^{-\varpi}$. □

Proof of Corollary 4.6. By Lemma 4.16 (e) and Theorem L (D)(iii),

$$\sigma(\theta\bar{F}\cdot(H)_{\mathbb{C}}\cdot F') = \langle [\tau_{-de_3}F], \int B_{H(x)}(de_3 + x, de_3 - x)\,dx\,[\tau_{-de_3}F']\rangle = \int \mathsf{v}_d(x; H(x))\,dx,$$

matrix elements passing under the integral. The function

$$w \mapsto \langle [\tau_{-de_3}F], B_E(de_3 + w, de_3 - w)[\tau_{-de_3}F']\rangle$$

is holomorphic where $d_3(de_3 \pm w) > 0$, that is on $\{|\mathrm{Re}\, w_3| + |\mathrm{Im}\, w_1| + |\mathrm{Im}\, w_2| < d\}$, by composition with an affine map (Lemma 4.11 (b)). Linearity and the bound are those of (D)(i), as $d_3(de_3 \pm x) \ge d - |x_3|$ at real x. □

Proof of Theorem N. Step 1 (the tubes). $R_\upsilon\mathrm{Tb}$ is an open convex cone that is stable under the conjugation and under Re (Lemma 4.11); so each $\mathcal{Z}(\mathfrak{s}, \upsilon)$, the preimage of $(R_\upsilon\mathrm{Tb})^{n-1}$ under a linear map, is open and convex and contains $\mathrm{Re}\, Z$, $\bar{Z}$, $R_{is}Z$ and $Z + (v, \dots, v)$ with Z; its real points are the configurations with $n_\upsilon \cdot y_{\mathfrak{s}(1)} < \cdots < n_\upsilon \cdot y_{\mathfrak{s}(n)}$, since $R_\upsilon\mathrm{Tb} \cap \mathbb{R}^2 = \{n_\upsilon \cdot w > 0\}$. As $R_{2\pi} = 1$ and the labels are turned by $\varrho(R_{-\upsilon})$, (a) holds, holomorphy coming from composition with linear maps.

Step 2 (the σ-formula on one tube, (b)). Since $\upsilon \in \frac{\pi}{2}\mathbb{Z}$, $R_{-\upsilon} \in W_3$, and $R_{-\upsilon}(\alpha \otimes \mathfrak{a}) = (\alpha \circ R_\upsilon) \otimes \varrho(R_{-\upsilon})\mathfrak{a}$, the rotation keeping x_2; this is the only point at which the tensor action meets a member. For profiles as in (b) the profiles $\alpha_{\mathfrak{s}(k)} \circ R_\upsilon$ have time-ordered supports, the largest time on one support being smaller than the least time on the next; so symmetry, (T1) at $R_{-\upsilon}$ and (KV2) give

$$\sigma(\alpha_1 \otimes \mathfrak{a}_1, \dots) = \sigma\big(R_{-\upsilon}(\alpha_{\mathfrak{s}(1)} \otimes \mathfrak{a}_{\mathfrak{s}(1)}, \dots)\big) = \int \prod_k (\alpha_{\mathfrak{s}(k)} \circ R_\upsilon)(y_k)\, K_n(\partial Y; \mathfrak{s}\varrho(R_{-\upsilon})\mathbf{a})\,dY$$
$$= \int \prod_k \alpha_k(y_k) K^{\mathfrak{s}}_\upsilon(Y; \mathbf{a})\,dY.$$

Step 3 (one function, (c)). If $\mathcal{Z}(\mathfrak{s}, \upsilon) \cap \mathcal{Z}(\mathfrak{s}', \upsilon')$ is not empty, it is convex, hence connected, and it contains real points, which form a non-empty open subset of $(\mathbb{R}^2)^n$. There both functions are continuous densities of σ by Step 2, so they agree by the fundamental lemma, and on the whole intersection by the identity theorem.

Step 4 (symmetries and bounds, (d), (e)). Invariance under the permutations of points and labels follows in the same way from the symmetry of σ, and translation invariance from the dependence on ∂Z. For $Z \in \mathcal{Z}(\mathfrak{s}, \upsilon)$, $R_{\pi/2}Z \in \mathcal{Z}(\mathfrak{s}, \upsilon + \frac{\pi}{2})$ and

$$K^{\mathfrak{s}}_{\upsilon+\pi/2}(R_{\pi/2}Z; \mathbf{a}) = K_n(R_{-\upsilon}\partial(\mathfrak{s}Z); \mathfrak{s}\varrho(R_{-\upsilon})\varrho(R_{-\pi/2})\mathbf{a}) = K^{\mathfrak{s}}_\upsilon(Z; \varrho(R_{-\pi/2})\mathbf{a}).$$

The conjugation rule follows from (KV4), as $R_{-\upsilon}$ and $\varrho(R_{-\upsilon})$ are real. (e) is (KV1) for the labels $\varrho(R_{-\upsilon})\mathfrak{a}_{\mathfrak{s}(k)}$, with $\nu(\varrho(R)\mathfrak{a}) = \nu(\mathfrak{a})$.

Step 5 (the Gram formula along boosts, (f)). By (KV3) at $R_{is}x$, $R_{is}z$, with $(R_{is}w)^* = R_{is}w^*$ and $w^* = -\theta w$ for real w (Lemma 4.11 (c)), the arguments of $K_{n_1+n_2}$ are R_{is} applied to the consecutive differences of X: $(R_{is}(x_{k+1} - x_k))^* = R_{is}(\theta x_k - \theta x_{k+1})$ and $(R_{is}x_1)^* + R_{is}z_1 = R_{is}(z_1 - \theta x_1)$. These lie in Tb, so $R_{is}X \in \mathcal{Z}(\mathrm{id}, 0)$ and the value is $\mathcal{K}_{n_1+n_2}(R_{is}X; \dots)$.

Step 6 (helicity labels, (g)). $R_t\epsilon_\pm = e^{\mp it}\epsilon_\pm$ and $R_t e_2 = e_2$, and each E_s is bilinear in two of $\epsilon_+, \epsilon_-, e_2$, so $\varrho(R_t)E_s = e^{-i\,\mathrm{hel}(s)t}E_s$; $\bar{\epsilon}_\pm = \epsilon_\mp$ and $\theta\epsilon_\pm = -\epsilon_\mp$, so $\varrho(\theta)\bar{E}_s = (-1)^{\mathrm{hel}(s)}E_s$, and for real φ, $(\varphi E_s)^\theta = (-1)^{\mathrm{hel}(s)}\varphi E_s$. The three formulas follow by linearity in each label from $\varrho(R_{-\upsilon})E_s = e^{i\,\mathrm{hel}(s)\upsilon}E_s$, from (d) and from (KV3).

Step 7 (harmonics, (h)). Let the points of X lie on a line with direction n_β, with coordinates $r_1, \dots, r_n$ along it. For real t choose $\upsilon \in \frac{\pi}{2}\mathbb{Z}$ with $|\beta + t - \upsilon| \le \frac{\pi}{4}$ modulo 2π, so that $\cos(\beta +$

$t-\upsilon)\ge 2^{-1/2}$, and $\mathfrak{s}$ ordering the points by increasing r_a; then $n_\upsilon\cdot(R_t y_{\mathfrak{s}(k+1)}-R_t y_{\mathfrak{s}(k)})\ge c_X:=\min\{1,2^{-1/2}\min_{a\ne b}|r_a-r_b|\}$, so $R_tX\in\mathcal{Z}(\mathfrak{s},\upsilon)$, and $R_{t+i\tau}X=R_{i\tau}R_tX$ lies there too. So $\zeta\mapsto\mathcal{K}_n(R_\zeta X;\mathbf{a})$ is entire, and by (g), $e^{-iS(\zeta+\pi/2)}\mathcal{K}_n(R_{\pi/2}R_\zeta X;\mathbf{a})=e^{-iS\zeta}\mathcal{K}_n(R_\zeta X;\mathbf{a})$: the function $f_X(\zeta):=e^{-iS\zeta}\mathcal{K}_n(R_\zeta X;\mathbf{a})$ is entire and $\frac{\pi}{2}$-periodic, hence a locally uniformly convergent series $\sum_m c_m(X)e^{4im\zeta}$, with $f_{R_tX}(\zeta)=e^{iSt}f_X(\zeta+t)$, which gives the rule for $c_m(R_tX)$. $k(E_s)=-\mathrm{hel}(s)$ is the identity $\varrho(R_t)E_s=e^{-i\,\mathrm{hel}(s)t}E_s$, put in the form $e^{ik(E_s)t}E_s$. Under (T5), by (e) and Lemma 4.11 (c), with $\zeta=t+i\tau$,

$$|f_X(t+i\tau)|\le e^{|S||\tau|}\prod_k C_\flat\nu(\mathfrak{a}_k)\cdot(e^{-|\tau|}c_X)^{-\wp n}=Ce^{(\wp n+|S|)|\tau|},$$

Put $A=\wp n+|S|$. The contour shift used in the proof of Proposition YMM1:96.3 gives, for every real s,

$$c_m=\frac{2}{\pi}\int_0^{\pi/2}f_X(t+is)e^{-4im(t+is)}\,dt,\qquad |c_m|\le Ce^{A|s|+4ms}.$$

The vertical sides cancel by periodicity. If $4|m|>A$, take $s\to-\infty$ for $m>0$ and $s\to+\infty$ for $m<0$; then $c_m=0$. Finally $|\mathrm{hel}|\le 2$ gives $|S|\le 2n$. □

Proof of Theorem O. Step 1 (point vectors and point kernels). By (D)(iv) of Theorem L, W_n and Ψ_3 do not depend on κ, and by (D)(ii) and (D)(iv), exactly as in Step 2 of the proof of Theorem L,

$$\langle\Psi_3(\mathfrak{x};\mathbf{E}),\Psi_3(\mathfrak{x}';\mathbf{E}')\rangle=W_{n+n'}((\mathfrak{x}_n-\mathfrak{x}_{n-1})^*,\dots,\mathfrak{x}_1^*+\mathfrak{x}_1',\mathfrak{x}_2'-\mathfrak{x}_1',\dots;\varrho(\theta)\bar E_n,\dots,\varrho(\theta)\bar E_1,E_1',\dots),$$

and $A:=B_E(\mathfrak{z},\mathfrak{z}')$ maps $\Psi_3(\mathfrak{x}';\mathbf{E}')$ to $\Psi_3((\mathfrak{z},\mathfrak{z}+\mathfrak{z}'+\mathfrak{x}_1',\dots);E,\mathbf{E}')$ and Ω to $\Psi_3(\mathfrak{z};E)$; so $A\mathcal{H}_{\mathrm{pt}}\subset\mathcal{H}_{\mathrm{pt}}$.

Step 2 (one matrix element). As in Step 2 of the proof of Theorem M, $\langle\Psi_i,(A^*A)^{2m}\Psi_j\rangle$ is W at arguments with $d_3\ge\rho_0:=\min\{1,2d_3(\mathfrak{z}),d_3(\mathfrak{z}')\}$, where $d_3(\mathfrak{z}+\mathfrak{z}^*)=2d_3(\mathfrak{z})$, and $|\varrho(\theta)\bar E|_2=|E|_2$; so it is bounded by $c_ic_j(C'|E|_2\rho_0^{-\varpi})^{4m}$.

Step 3 (Schwarz's inequality, repeated, and density). Steps 3 and 4 of the proof of Theorem M carry over, with the identity theorem on $\mathrm{Tb}_3^{(n)}$, whose real points with positive time differences form a non-empty open set; this gives the bound of $B_E(\mathfrak{z},\mathfrak{z}')$ on $\mathcal{H}_{\mathrm{pt}}$.

Step 4 (the arguments of the insertion). For H as stated, $\operatorname{supp}H\subset\{|x_3|\le 3\eta/16\}$; for x there, $\mathfrak{z}=\frac{\eta}{4}e_3+x$ and $\mathfrak{z}'=\frac{\eta}{4}e_3-x$ have $\min\{1,2d_3(\mathfrak{z}),d_3(\mathfrak{z}')\}\ge\eta/16$.

Step 5 (the insertion bound on $\mathcal{H}_{\mathrm{pt}}$). By Lemma 4.16 (e), (D)(iii) and Step 3, with $\psi:=[\tau_{-(\eta/4)e_3}G]\in\mathcal{H}_{\mathrm{pt}}$,

$$\begin{aligned}|\sigma(\theta\bar F\cdot(H)\cdot G)|&\le\|[\tau_{-(\eta/4)e_3}F]\|\int\|B_{H(x)}(\tfrac{\eta}{4}e_3+x,\tfrac{\eta}{4}e_3-x)\psi\|\,dx\\&\le 16^{\varpi}C'\eta^{-\varpi}\|H\|_{L^1}\|[\tau_{-(\eta/4)e_3}F]\|\,\|\psi\|,\end{aligned}$$

and $\|H\|_{L^1}\le\frac{4\pi}{3}(c_I\eta)^3\|H\|_\infty$. □

Lemma 4.20 (Bounds relative to the energy in a Fock space)**.** Let (Y,μ) be a σ-finite measure space, $\omega\colon\mathsf{Y}\to(0,\infty)$ measurable, $\mathscr{F}$ the symmetric Fock space over $L^2(\mathsf{Y},\mu)$ with the annihilation and creation forms $a(p)$, $a^*(p)$, and $\mathbf{H}_0:=d\Gamma(\omega)$. Put $\|g\|_\omega:=(\int|g|^2\omega^{-1}d\mu)^{1/2}$ and $\|K\|_\omega:=(\iint|K(p,p')|^2\omega(p)^{-1}\omega(p')^{-1}d\mu\,d\mu)^{1/2}$. Then, for vectors χ,ψ in the relevant domains,

$$\|a(g)\psi\|\le\|g\|_\omega\|\mathbf{H}_0^{1/2}\psi\|,\qquad\Big\|\iint K(p,p')a(p)a(p')\,d\mu\,d\mu\;\psi\Big\|\le\|K\|_\omega\|\mathbf{H}_0\psi\|,$$

$$\Big|\iint K(p,p')\,\langle a(p)\chi,A\,a(p')\psi\rangle\,d\mu\,d\mu\Big|\le\|K\|_\omega\|A\|\,\|\mathbf{H}_0^{1/2}\chi\|\,\|\mathbf{H}_0^{1/2}\psi\|$$

for every bounded operator A; at $A=1$ the left side is $|\langle\chi,\iint K(p,p')a^*(p)a(p')\,d\mu\,d\mu\;\psi\rangle|$. Further, $a(p)f(\mathbf{H}_0)=f(\mathbf{H}_0+\omega(p))a(p)$. ■

Proof. In the m-particle space, $(a(p)\psi)(k) = \sqrt{m}\,\psi(p,k)$; by Schwarz's inequality

$$|\int \bar g(p)\psi(p,k)d\mu(p)|^2 \le \|g\|_\omega^2 \int \omega(p)|\psi(p,k)|^2 d\mu(p),$$

and $m\int\omega(p)|\psi(p,k)|^2 d\mu(p)\,dk = \langle\psi, \mathbf{H}_0\psi\rangle$ by symmetry. In the same way, with two variables,

$$m(m-1)\int \omega(p)\omega(p')|\psi(p,p',k)|^2 \le \langle\psi,\mathbf{H}_0^2\psi\rangle,$$

because $\sum_{i\neq j}\omega_i\omega_j \le (\sum_i\omega_i)^2$; the mixed term is bounded by $\|A\|\iint|K|\,\|a(p)\chi\|\,\|a(p')\psi\|$ and Schwarz's inequality, with $\int\omega(p)\|a(p)\chi\|^2 d\mu(p) = \langle\chi,\mathbf{H}_0\chi\rangle$. The commutation rule holds sector by sector. □

Proof of Theorem P. Step 1 (the trace construction, (a)). $\operatorname{tr}\varrho(r)E = \operatorname{tr}E$ for $r\in\mathrm{O}(3)$, so $\operatorname{tr}(rH)$ is the scalar action of r on $\operatorname{tr}H$, and (T1) follows from (R1); $|\operatorname{tr}E|\le\sqrt{3}|E|_2$ gives $\|\operatorname{tr}H\|_\sharp \le \sqrt{3}\|H\|_\sharp$ and (T2) with $3^{n/2}C_n^{\sigma_0}$; $\operatorname{tr}(\theta H) = (\operatorname{tr}H)\circ\theta$ gives (T3) from (R3). Moreover

$$\langle F,G\rangle_\sigma = \langle \operatorname{tr}F, \operatorname{tr}G\rangle_{\sigma_0},$$

tr applied member by member, so $[F]_\sigma \mapsto [\operatorname{tr}F]_{\sigma_0}$ is an isometry that intertwines the translations; hence the spectral measure of each $[F]_\sigma$ equals that of $[\operatorname{tr}F]_{\sigma_0}$, which is carried by $\{E\ge|q_1|\}$, and (T4) follows, the classes being dense. The insertion bound of σ_0 at $\operatorname{tr}H$ gives (T5), or (T5$_N$), with the factor $\sqrt{3}$.

Step 2 (the free fields, (b): definition). By Wick's theorem, $\mathbb{E}[T_\varepsilon(H_1)\cdots T_\varepsilon(H_n)]$ is a finite sum over the pairings of the $2n$ factors $\partial_a\phi_\varepsilon^c$ in which no pair lies at one vertex; each pairing contributes an integral of a product of n covariances $\delta_{cc'}G^\varepsilon_{ab}(x_k-x_l)$, $G^\varepsilon_{ab} = -\partial_a\partial_b(j_\varepsilon^{(3)} * j_\varepsilon^{(3)} * G)$, with $k\neq l$. On the supports of a tuple of $\mathfrak{S}^V(\mathbb{R}^3)$, $|x_k-x_l|\ge \mathsf{d}>0$, and G^ε_{ab} converges uniformly on $\{|x|\ge\mathsf{d}\}$ to

$$G_{ab}(x) = -\partial_a\partial_b G(x) = \frac{\delta_{ab}|x|^2 - 3x_ax_b}{4\pi|x|^5}.$$

So the limit exists, is multilinear, vanishes for $n=1$, and is bounded by $c_n(c\mathsf{d}^{-3})^n\prod_k\|H_k\|_{L^1} \le c_n(c\mathsf{d}^{-3})^n(\frac{4\pi}{3}R^3)^n\prod_k\|H_k\|_\infty$ at tuples of type $(\mathsf{d};R)$: (T2).

Step 3 ((T1) and (T3) for (b)). $G_{ab}(r^\circ x) = (r^\circ G(x) r^{\circ\mathsf{T}})_{ab}$ for $r^\circ\in\mathrm{O}(3)$, so the limit is invariant under all isometries in the tensor action. For reflection positivity let $F = \sum\zeta_i X_i$ with $X_i\in\mathfrak{S}^V(E_+)$ and $F_\varepsilon := \sum_i\zeta_i\prod_{H\in X_i}T_\varepsilon(H)$; for small ε, F_ε is a square-integrable function of the fields in E_+, and the reflection of the fields, $\phi\mapsto\phi\circ\theta$, carries $T_\varepsilon(H)$ to $T_\varepsilon(\theta H)$, since $j_\varepsilon^{(3)}$ is even and $\partial_a(\phi\circ\theta) = \theta_{aa}(\partial_a\phi)\circ\theta$. Reflection positivity of the free fields gives $\mathbb{E}[\overline{\Theta F_\varepsilon}\,F_\varepsilon]\ge 0$, and as $\varepsilon\to0$ this tends to $\sigma(\theta\bar F\cdot F)$, because only the moments at the disjoint tuples $\theta X_i\cdot X_k$ enter.

Step 4 ((T4) for (b)). The reconstructed space of the free fields is the Fock space over $L^2(\mathbb{R}^2,\mu)\otimes\mathbb{C}^3$, $d\mu(p) = (2\pi)^{-2}(2|p|)^{-1}d^2p$, with $\omega(p) := |p|$, $\mathbf{H}_0 = d\Gamma(\omega)$ and $\mathbf{P}_0 = d\Gamma(p)$, in the following form. For real $f\in C_c(E_+)$ put $jf(p) := \int f(y)\,e^{ip\cdot y_\perp - \omega(p)y_3}\,dy$, $y_\perp = (y_1,y_2)$. As $G(z) = \int e^{ip\cdot z_\perp-\omega(p)|z_3|}\,d\mu(p)$ for $z_3\neq0$,

$$\langle jf, jg\rangle = \iint f(y)\,G(\theta y - y')\,g(y')\,dy\,dy' = \mathbb{E}[\phi^c(\theta f)\,\phi^c(g)],$$

so, by Wick's theorem, the map W defined on the Wick monomials of fields over E_+ by

$$\mathsf{W}(:\!\phi^{c_1}(f_1)\cdots\phi^{c_m}(f_m)\!:) := a^{c_1*}(jf_1)\cdots a^{c_m*}(jf_m)\Omega$$

satisfies $\langle\mathsf{W}A,\mathsf{W}B\rangle = \mathbb{E}[\overline{\Theta A}\,B]$ and $\|\mathsf{W}A\|^2\le\mathbb{E}[|A|^2]$. It therefore extends to all square-integrable functions of the fields in E_+, whatever the order in time of the arguments of the fields, and $\mathsf{W}(\tau_{te_3}A) = e^{-t\mathbf{H}_0}\mathsf{W}A$, $\mathsf{W}(\tau_vA) = e^{iv\cdot\mathbf{P}_0}\mathsf{W}A$ for $t\ge0$ and $v\in e_3^\perp$, the translations acting on the arguments of the fields, because $j(\tau_{te_3}f) = e^{-t\omega}jf$ and $j(\tau_vf) = e^{ip\cdot v}jf$. The vectors $\mathsf{V}_\varepsilon(F) := \mathsf{W}(F_\varepsilon)$ of the F_ε of Step 3 converge as $\varepsilon\to0$, since $\|\mathsf{V}_\varepsilon(F)-\mathsf{V}_{\varepsilon'}(F)\|^2$ is a combination of moments at the

disjoint tuples $\theta X_i \cdot X_k$ whose limits do not depend on the regularisation; so $\mathsf{V}[F] := \lim \mathsf{V}_\varepsilon(F)$ is an isometry of $\mathcal{H}(\sigma)$ into the Fock space with $\mathsf{V}\mathcal{T}_t = e^{-t\mathbf{H}_0}\mathsf{V}$ and $\mathsf{V}\mathcal{U}(v) = e^{iv\cdot\mathbf{P}_0}\mathsf{V}$. The image is closed and reduces $\mathbf{H}_0$ and $\mathbf{P}_0$, so $\mathcal{P}$ is the restriction of their joint spectral measure, which is carried by $\{E \geq |q|\}$, because on m particles $E = \sum_j |p_j| \geq |\sum_j p_j| = |q|$.

Step 5 ((T5) with $\mathsf{p}_I = 0$ for (b)). Put $u(p) := (-ip_1, -ip_2, \omega(p))$, so that $|u(p)|^2 = 2\omega(p)^2$, and, on the Fock space of Step 4 and for $E \in V_{\mathbb{C}}$,

$$B^c_a := \int u_a(p)\,(a^c(p) - a^{c*}(p))\,d\mu(p), \qquad :Q_E: := \sum_c \sum_{a,b} E_{ab}\, :B^c_a B^c_b:,$$

the colons denoting the normal order. With the time-zero fields $\phi^c_0(0) := \int (a^c(p) + a^{c*}(p))\,d\mu(p)$ and $\phi^c_0(\vec{x}) := e^{i\vec{x}\cdot\mathbf{P}_0}\phi^c_0(0)e^{-i\vec{x}\cdot\mathbf{P}_0}$, the forms B^c_1, B^c_2 are the spatial derivatives $\partial_1\phi^c_0$, $\partial_2\phi^c_0$ at $\vec{x} = 0$, and

$$B^c_3 = -[\mathbf{H}_0, \phi^c_0(0)] = [\phi^c_0(0), \mathbf{H}_0];$$

the sign is that of $\partial_{x_3}\big[e^{-(d+x_3)\mathbf{H}_0}\phi^c_0(0)e^{-(d-x_3)\mathbf{H}_0}\big] = e^{-(d+x_3)\mathbf{H}_0}\big(-[\mathbf{H}_0, \phi^c_0(0)]\big)e^{-(d-x_3)\mathbf{H}_0}$, $|x_3| < d$: in this sandwich, the form in which the fields enter below, the lower heights stand on the left. In normal order, $:Q_E:$ is the sum over c of the forms $\iint K\, a^c a^c$, $\iint K\, a^{c*}a^{c*}$ and $-2\iint K\, a^{c*}a^c$ with the kernel $K(p,p') := u(p)^{\mathsf{T}}Eu(p') = K(p',p)$, and $|K(p,p')| \leq |E|_2\,|u(p)|\,|u(p')| = 2|E|_2\,\omega(p)\omega(p')$. Moving half of $e^{-s\mathbf{H}_0}$ and of $e^{-s'\mathbf{H}_0}$ through the annihilation and creation operators by $a(p)f(\mathbf{H}_0) = f(\mathbf{H}_0 + \omega(p))a(p)$, and using Lemma 4.20, $\int \omega e^{-s\omega}d\mu = (4\pi s^2)^{-1}$ and $\|\mathbf{H}_0^\alpha e^{-s\mathbf{H}_0}\| \leq (\alpha/es)^\alpha$, one bounds the three terms of $e^{-s\mathbf{H}_0}{:}Q_E{:}e^{-s'\mathbf{H}_0}$ by absolute multiples of $|E|_2 s'^{-3}$, $|E|_2 s^{-3}$ and $|E|_2(ss')^{-3/2}$; in the last term the factor $e^{-(s+s')\mathbf{H}_0/2}$ stays between a^* and a and is the operator A of Lemma 4.20. So

$$\|e^{-s\mathbf{H}_0}\,{:}Q_E{:}\,e^{-s'\mathbf{H}_0}\| \leq c_0|E|_2 \min\{s,s'\}^{-3}$$

with an absolute number c_0, the power 3 being the scaling of a field of dimension three. The same bound holds, with $s-\varepsilon$ and $s'-\varepsilon$ in place of s and s', if the kernel K is replaced by $K(p,p')m(p)m(p')$ with $|m(p)| \leq e^{\varepsilon\omega(p)/2}$ and $0 < \varepsilon < \min\{s,s'\}$.

Let $0 \leq d' < d$, $F, G \in \mathbb{C}\mathfrak{S}^V(\{x_3 > d\})$ and $H \in C^1_c(\{|x_3| < d\}; V)$ with $\operatorname{supp} H \subset \{|x_3| \leq d'\}$. We show

$$\sigma(\theta\bar{F}\cdot(H)\cdot G) = \int \big\langle \mathsf{V}[\tau_{-de_3}F], e^{-(d+x_3)\mathbf{H}_0}e^{i\vec{x}\cdot\mathbf{P}_0}\,{:}Q_{H(x)}{:}\,e^{-i\vec{x}\cdot\mathbf{P}_0}e^{-(d-x_3)\mathbf{H}_0}\mathsf{V}[\tau_{-de_3}G]\big\rangle\,dx,$$

in which only the bounded operators $e^{-s\mathbf{H}_0}{:}Q_E{:}e^{-s'\mathbf{H}_0}$ with $s, s' \geq d - d'$ enter. Let $\varepsilon > 0$ be smaller than $\frac{1}{2}(d-d')$ and than the distance of the supports of the members of F and G from $\{x_3 = d\}$, and put $m_\varepsilon(p) := \int j^{(3)}_\varepsilon(z)e^{ip\cdot z_\perp - \omega(p)z_3}dz$. As $j^{(3)}_\varepsilon$ is even in each coordinate and supported in $\{|z| \leq \varepsilon/2\}$, m_ε is real, $|m_\varepsilon(p)| \leq e^{\varepsilon\omega(p)/2}$, and $m_\varepsilon(p) \to 1$ as $\varepsilon \to 0$. For real $f, g \in C_c(\{x_3 > d\})$ and $|x_3| \leq d'$, the formula for G in Step 4 gives the two contractions of a leg of the insertion:

$$\mathbb{E}[\partial_a\phi^c_\varepsilon(x)\,\phi^{c'}(g)] = \delta_{cc'}\int u_a m_\varepsilon\, e^{-ip\cdot\vec{x}+\omega x_3}\, jg\,d\mu, \qquad \mathbb{E}[\partial_a\phi^c_\varepsilon(x)\,\phi^{c'}(\theta f)] = -\,\delta_{cc'}\int u_a m_\varepsilon\, e^{ip\cdot\vec{x}-\omega x_3}\,\overline{jf}\,d\mu.$$

With $B^{c,\varepsilon}_a := \int u_a m_\varepsilon(a^c - a^{c*})\,d\mu$, the first is the matrix element of the annihilation part of $e^{i\vec{x}\cdot\mathbf{P}_0}B^{c,\varepsilon}_a e^{-i\vec{x}\cdot\mathbf{P}_0}$ between Ω and $e^{-(d-x_3)\mathbf{H}_0}\mathsf{W}(\phi^{c'}(\tau_{-de_3}g))$, and the second is that of its creation part between $e^{-(d+x_3)\mathbf{H}_0}\mathsf{W}(\phi^{c'}(\tau_{-de_3}f))$ and Ω: a leg contracted upwards acts as an annihilation operator, a leg contracted downwards as a creation operator. By Wick's product formula, F_ε and G_ε are finite sums of Wick monomials in fields smeared, with smooth kernels, over $\{x_3 > d\}$. For two such monomials A and B, Wick's theorem writes $\mathbb{E}[\overline{\Theta A}\,{:}\partial_a\phi^c_\varepsilon\partial_b\phi^c_\varepsilon{:}(x)\,B]$ as the sum over the pairings in which each of the two legs is paired with a factor of $\overline{\Theta A}$ or of B and the remaining factors of $\overline{\Theta A}$ are paired with those of B, the colons excluding the pair of the two legs.

The normal order gives the same sum for the matrix element of

$$e^{-(d+x_3)\mathbf{H}_0}e^{i\vec{x}\cdot\mathbf{P}_0}{:}B_a^{c,\varepsilon}B_b^{c,\varepsilon}{:}e^{-i\vec{x}\cdot\mathbf{P}_0}e^{-(d-x_3)\mathbf{H}_0}$$

between $\mathsf{W}(\tau_{-de_3}A)$ and $\mathsf{W}(\tau_{-de_3}B)$, as the matrix elements of normal-ordered polynomials between coherent vectors, expanded in their parameters, show: once the operators on either side of the normal product are moved onto the two vectors, a pair of a factor $\phi^c(\theta f)$ of $\overline{\Theta A}$ and a factor $\phi^c(g)$ of B gives $\langle jf, jg\rangle = \mathbb{E}[\phi^c(\theta f)\phi^c(g)]$, whatever x. Summing and integrating against $H(x)$, with $(\tau_{-de_3}F)_\varepsilon = \tau_{-de_3}F_\varepsilon$,

$$\mathbb{E}[\overline{\Theta F_\varepsilon}\,T_\varepsilon(H)\,G_\varepsilon] = \int \big\langle \mathsf{V}_\varepsilon(\tau_{-de_3}F), e^{-(d+x_3)\mathbf{H}_0}e^{i\vec{x}\cdot\mathbf{P}_0}\,{:}Q^\varepsilon_{H(x)}{:}\,e^{-i\vec{x}\cdot\mathbf{P}_0}e^{-(d-x_3)\mathbf{H}_0}\mathsf{V}_\varepsilon(\tau_{-de_3}G)\big\rangle\,dx,$$

where ${:}Q^\varepsilon_E{:}$ is formed with the $B_a^{c,\varepsilon}$, that is, with the kernel $K(p,p')m_\varepsilon(p)m_\varepsilon(p')$; by the bound above at $s-\varepsilon$, $s'-\varepsilon$, only bounded operators enter. Now let $\varepsilon\to 0$. The left side tends to $\sigma(\theta\bar F\cdot(H)\cdot G)$, by Step 2 at the tuples $\theta X_i\cdot(H)\cdot Y_k$, where $F=\sum\zeta_iX_i$ and $G=\sum\zeta'_kY_k$, and by $\Theta T_\varepsilon(H') = T_\varepsilon(\theta H')$ (Step 3). On the right, $\mathsf{V}_\varepsilon(\tau_{-de_3}F)\to\mathsf{V}[\tau_{-de_3}F]$ and $\mathsf{V}_\varepsilon(\tau_{-de_3}G)\to\mathsf{V}[\tau_{-de_3}G]$ in norm by Step 4, and $e^{-s\mathbf{H}_0}({:}Q^\varepsilon_E{:} - {:}Q_E{:})e^{-s'\mathbf{H}_0}\to 0$ in norm, uniformly for $s,s'\ge d-d'$ and $|E|_2\le 1$, because the kernels $K(p,p')(m_\varepsilon(p)m_\varepsilon(p')-1)$, weighted as in the bound above, tend to 0 in $\|\cdot\|_\omega$ by dominated convergence. So each factor of the integrand converges in norm, uniformly for $x\in\operatorname{supp}H$, and the identity follows.

At $d=\eta/4$ and for H as in (T5$_N$) with $c_I=\frac{1}{16}$, $\min\{d+x_3,d-x_3\}\ge\eta/16$, so $|\sigma(\theta\bar F\cdot(H)\cdot G)|\le c_0 16^3\eta^{-3}\frac{4\pi}{3}(\eta/16)^3\|H\|_\infty\|\cdot\|\,\|\cdot\| = \frac{4\pi}{3}c_0\|H\|_\infty\|\cdot\|\,\|\cdot\|$. For the duals of the field strengths of free photons the covariance off the diagonal is $+\partial_a\partial_b G$, the negative of G_{ab}; every pairing has n covariances, which gives the factor $(-1)^n$, and $[X]\mapsto(-1)^{n(X)}[X]$ carries all the assertions over.

Step 6 ((c): the class). $\sigma=\sigma_0\circ\mathrm{tr}$, where $\sigma_0(f_1,\dots,f_n) := \sum_\pi\prod_{\{k,l\}\in\pi}\iint f_k(x)S(x-y)f_l(y)\,dx\,dy$, the sum over the partitions π of $\{1,\dots,n\}$ into pairs, for real scalar C^1_c functions $f_1,\dots,f_n$ with pairwise disjoint supports, and $\sigma_0(\emptyset)=1$; the integrals are finite because S is smooth on $\mathbb{R}^3\setminus\{0\}$. As S is radial and bounded on $\{|x|\ge\mathsf{d}\}$ for every $\mathsf{d}>0$, the properties (R1) and (R2) of Definition YMM1:95.1 can be read off this formula. For $\Lambda<\infty$ let $S_\Lambda(x) := \int_0^\Lambda e^{\sqrt{m}}e^{-m|x|}(4\pi|x|)^{-1}dm \le \Lambda e^{\sqrt{\Lambda}}(4\pi|x|)^{-1}$, and let $\sigma_{0,\Lambda}$ be formed as σ_0 with S_Λ in place of S. S_Λ is locally integrable and a superposition with positive weights of the covariances of free fields of mass $m<\Lambda$; so there is a Gaussian field χ_Λ with covariance S_Λ, and $\sigma_{0,\Lambda}$ is the functional of its moments.

Steps 3 and 4, with one scalar field in place of the derivatives and without regularisation, apply to it, with the one-particle space $L^2((0,\Lambda)\times\mathbb{R}^2,\mu_\Lambda)$, $d\mu_\Lambda(m,p) = e^{\sqrt{m}}dm\,(2\pi)^{-2}d^2p/2\omega_m(p)$, $\omega_m(p)=(|p|^2+m^2)^{1/2}\ge|p|$, $jf(m,p) := \int f(y)e^{ip\cdot y_\perp-\omega_m(p)y_3}dy$, $\mathbf{H}_0=d\Gamma(\omega_m(p))$ and $\mathbf{P}_0=d\Gamma(p)$, as $S_\Lambda(z)=\int e^{ip\cdot z_\perp-\omega_m(p)|z_3|}d\mu_\Lambda(m,p)$ for $z_3\ne 0$: $\sigma_{0,\Lambda}$ is reflection positive, its reconstructed space is mapped isometrically into the Fock space by a map V_Λ that intertwines the translations, and its joint spectral measure $\mathcal{P}_\Lambda$ is carried by $\{E\ge|q|\}$, since on k particles $E=\sum_j\omega_{m_j}(p_j)\ge|\sum_j p_j|$.

On $\{|x|\ge\mathsf{d}\}$, $0\le S(x)-S_\Lambda(x)\le\int_\Lambda^\infty e^{\sqrt{m}-m\mathsf{d}}dm\,(4\pi\mathsf{d})^{-1}$, as $e^{-m|x|}/|x|$ decreases in $|x|$; so $S_\Lambda\to S$ uniformly there, and the moments of $\sigma_{0,\Lambda}$ at tuples with pairwise disjoint supports converge to those of σ_0. Hence (R3), an inequality between such moments, passes to σ_0.

(R4) passes as follows. Let F be a complex combination of scalar tuples over E_+, $t>0$, and $u_\Lambda(w) := \sigma_{0,\Lambda}(\theta\bar F\cdot\tau_wF) = \int e^{-w_3E+iw_\perp\cdot q}\,d\langle[F],\mathcal{P}_\Lambda[F]\rangle$ for $w_3\ge 0$. The function

$$f_t(E,q) := (1-e^{-tE})^2 - e^{-tE}|1-e^{itq_1}|^2 = 4e^{-tE}\big(\sinh^2\tfrac{tE}{2} - \sin^2\tfrac{tq_1}{2}\big)$$

is ≥ 0 on $\{E\ge|q_1|\}$, which carries $\mathcal{P}_\Lambda$, as $\sinh\frac{tE}{2}\ge\frac{tE}{2}\ge\frac{t|q_1|}{2}\ge|\sin\frac{tq_1}{2}|$ there; so

$$u_\Lambda(0) - 4u_\Lambda(te_3) + u_\Lambda(2te_3) + u_\Lambda(te_3+te_1) + u_\Lambda(te_3-te_1) = \int f_t\,d\langle[F],\mathcal{P}_\Lambda[F]\rangle \ge 0.$$

The left side is a combination of moments at disjoint supports; so the inequality passes to $\Lambda=\infty$, that is, $\langle\psi, f_t(\mathcal{P})\psi\rangle\ge 0$ for the classes $\psi=[F]$ of σ_0, and, by density, for all $\psi\in\mathcal{H}(\sigma_0)$, $\mathcal{P}$ being the joint spectral measure of σ_0. At $\psi=\mathcal{P}(\Delta)\psi'$, for all Borel sets Δ, this gives $f_t\ge 0$ almost everywhere for $\langle\psi',\mathcal{P}\psi'\rangle$, for all rational $t>0$ at once; there $\sinh\frac{tE}{2}\ge|\sin\frac{tq_1}{2}|$, and $t\downarrow 0$ gives $E\ge|q_1|$. So $\mathcal{P}(\{E<|q_1|\})=0$, which is (R4) of Definition YMM1:95.1.

The insertion bound is obtained at $\Lambda<\infty$ and passed to the limit. For the time-zero field $\chi_0(0)=a(1)+a^*(1)$ on the Fock space over $L^2((0,\Lambda)\times\mathbb{R}^2,\mu_\Lambda)$, Lemma 4.20 gives $\|e^{-s\mathbf{H}_0}\chi_0(0)e^{-s'\mathbf{H}_0}\|\le \mathsf{n}_\Lambda(\min\{s,s'\})\le \mathsf{n}(\min\{s,s'\})$, where n_Λ is given by the integral below over $m<\Lambda$ and

$$\mathsf{n}(s)^2:=c\int_0^\infty e^{\sqrt{m}}dm\int d^2p\,\frac{e^{-s\omega_m(p)}}{\omega_m(p)}\Big(1+\frac{1}{s\,\omega_m(p)}\Big)<\infty\qquad(s>0),$$

with an absolute number c; n decreases, and it is finite because $e^{-s\omega_m(p)}\le e^{-sm/2}e^{-s|p|/2}$, $e^{\sqrt{m}-sm/2}$ is integrable and $\int_0^1 dm\int_{|p|\le1}d^2p\,\omega_m(p)^{-2}<\infty$. As in Step 5, with one leg in place of two and without regularisation (the leg contracted upwards an annihilation, downwards a creation), for $0\le d'<d$, scalar tuples F,G over $\{x_3>d\}$ and real scalar $h\in C^1_c(\mathbb{R}^3)$ with support in $\{|x_3|\le d'\}$,

$$\sigma_{0,\Lambda}(\theta\bar F\cdot(h)\cdot G)=\int h(x)\langle \mathsf{V}_\Lambda[\tau_{-de_3}F],e^{-(d+x_3)\mathbf{H}_0}e^{i\vec{x}\cdot\mathbf{P}_0}\chi_0(0)e^{-i\vec{x}\cdot\mathbf{P}_0}e^{-(d-x_3)\mathbf{H}_0}\mathsf{V}_\Lambda[\tau_{-de_3}G]\rangle\,dx,$$

so that

$$|\sigma_{0,\Lambda}(\theta\bar F\cdot(h)\cdot G)|\le \mathsf{n}(d-d')\,\|h\|_{L^1}\,\|[\tau_{-de_3}F]\|_{\sigma_{0,\Lambda}}\|[\tau_{-de_3}G]\|_{\sigma_{0,\Lambda}}.$$

The left side and the squares of the two norms are combinations of moments at disjoint supports, so the bound passes to σ_0. At $d=\eta/4$ and $d'=3\eta/16$ it gives the scalar insertion bound, (R5) of Definition YMM1:95.1 with $c_I=\frac{1}{16}$ and with the finite function $N_0(\eta)=\frac{4\pi}{3}(\eta/16)^3\mathsf{n}(\eta/16)$ in place of $C_I\eta^{-\mathsf{p}_I}$. Then (a) gives (T1)–(T4) and (T5$_N$); centring holds because odd moments vanish.

Step 7 ((c): the growth of K_2). At real $\xi\in\mathbb{R}^2_+$, by (KV5) the kernel is the continuous density of the two-point σ-formula, $K_2(\xi;\mathfrak{a},\mathfrak{a}')=\iint S(\xi,s'-s)\,\mathrm{tr}\,\mathfrak{a}(s)\,\mathrm{tr}\,\mathfrak{a}'(s')\,ds\,ds'$, with (ξ,u) the point of $\mathbb{R}^3$ with $(x_3,x_1)=\xi$ and $x_2=u$. For $\mathfrak{a}=\mathfrak{a}'=\varphi\mathbf{1}$, $\varphi\ge c_\varphi>0$ on an interval, and small $t>0$,

$$K_2((t,0);\varphi\mathbf{1},\varphi\mathbf{1})\ge 9\min_{|u|\le t}S(t,0,u)\iint_{|s-s'|\le t}\varphi(s)\varphi(s')\,ds\,ds'\ge c\,t\cdot t^{-1}e^{1/(4\sqrt{2}\,t)-\sqrt{2}\,t},$$

since S is radial and decreasing, $|(t,0,u)|\le\sqrt{2}\,t$ for $|u|\le t$, and $\sqrt{m}-\sqrt{2}\,tm$ has the maximum $1/(4\sqrt{2}\,t)$ at $m=1/(8t^2)$ and stays above it minus $\sqrt{2}\,t$ on the next interval of length 1. (KV1) would give $|K_2((t,0);\cdot)|\le C\min\{1,t\}^{-2\wp}$; so it holds for no $\wp$, and by Theorem L (C) σ has (T5) for no p_I. □

Lemma 4.21 (An L^1 slab bound gives the insertion bound in the sup norm)**.** Let σ have (T1°), (T2) and (T3), and let $C>0$, $\mathsf{p}\ge 3$ be such that $|\sigma(\theta\bar F\cdot(h)\cdot G)|\le C\min\{1,d-d'\}^{-\mathsf{p}}\|h\|_{L^1}\|[\tau_{-de_3}F]\|\,\|[\tau_{-de_3}G]\|$ for all $0\le d'<d$, all real $h\in C^1_c(\mathbb{R}^3;V)$ with support in $\{|x_3|\le d'\}$ and all $F,G\in\mathbb{C}\mathfrak{S}^V(\{x_3>d\})$. Then σ has (T5) in the sup norm with $c_I=\frac{1}{16}$, $\mathsf{p}_I=\mathsf{p}-3$ and $C_I=\frac{4\pi}{3}\,16^{\mathsf{p}-3}C$. ■

Proof. For $\eta\in(0,1]$ and H with support in $B(y,\eta/16)$, $|y_3|\le\eta/8$, take $d=\eta/4$ and $d'=3\eta/16$, so that $d-d'=\eta/16\le1$, and use $\|H\|_{L^1}\le\frac{4\pi}{3}(\eta/16)^3\|H\|_\infty$:

$$|\sigma(\theta\bar F\cdot(H)\cdot G)|\le C(\tfrac{\eta}{16})^{-\mathsf{p}}\tfrac{4\pi}{3}(\tfrac{\eta}{16})^3\|H\|_\infty\|\cdot\|\,\|\cdot\|=\tfrac{4\pi}{3}\,16^{\mathsf{p}-3}C\,\eta^{-(\mathsf{p}-3)}\|H\|_\infty\|\cdot\|\,\|\cdot\|.\qquad\square$$

Lemma 4.22 (A finite slab bound gives (T5$_N$))**.** Let σ have (T1°), (T2) and (T3), and suppose that for every $\eta\in(0,1]$ there is a finite number $\mathsf{c}^\circ(\eta)$ with $|\sigma(\theta\bar F\cdot(h)\cdot F')|\le\mathsf{c}^\circ(\eta)\|h\|_{L^1}\|[\tau_{-\eta e_3}F]\|\,\|[\tau_{-\eta e_3}F']\|$ for all $F,F'\in\mathbb{C}\mathfrak{S}^V(\{x_3>\eta\})$ and all real $h\in C^1_c(\{|x_3|<\eta/2\};V)$. Then σ has (T5$_N$) with $c_I=\frac{1}{16}$ and $N(\eta)=\frac{4\pi}{3}\,16^{-3}\eta^3\,\mathsf{c}^\circ(\eta/8)$. ■

Proof. Let H have support in $B(y,\eta/16)$, $|y_3|\le\eta/8$, and $F,G\in\mathbb{C}\mathfrak{S}^V(\{x_3>\eta/4\})$. Put $h':=\tau_{-y_3e_3}H$, supported in $\{|x_3|<\eta/16\}$, $F':=\tau_{y_3e_3}F$ and $F'':=\tau_{-y_3e_3}G$, both over $\{x_3>\eta/8\}$. By translation invariance and $\tau_{-y_3e_3}\theta=\theta\tau_{y_3e_3}$, $\sigma(\theta\bar F\cdot(H)\cdot G)=\sigma(\theta\bar F'\cdot(h')\cdot F'')$, which the hypothesis at $\eta/8$ bounds by $\mathsf{c}^\circ(\eta/8)\|h'\|_{L^1}\|[\tau_{-(\eta/8)e_3}F']\|\,\|[\tau_{-(\eta/8)e_3}F'']\|$. Now

$$[\tau_{-(\eta/8)e_3}F']=\mathcal{T}_{\eta/8+y_3}[\tau_{-(\eta/4)e_3}F],\qquad [\tau_{-(\eta/8)e_3}F'']=\mathcal{T}_{\eta/8-y_3}[\tau_{-(\eta/4)e_3}G],$$

with $\eta/8\pm y_3\ge0$ and $\|\mathcal{T}_t\|\le1$; and $\|h'\|_{L^1}\le\frac{4\pi}{3}(\eta/16)^3\|H\|_\infty\le\frac{4\pi}{3}(\eta/16)^3\|H\|_\sharp$. □

Proof of Theorem Q. Step 1 ((a)). By (I), every Gibbs sequence at g has a subsequence that converges at every tuple of $\mathfrak{S}^V(\mathbb{R}^3)$, with a further subsequence along which $a_{K_j}\beta_j$ converges to a number $b_*\in[g^{-2},L(g^{-2}+\bar B)]$. By the step of this section that ends item (d) of the remark on how (I) and (II) are obtained (the density of C^1_c in C_c for the sup norm, the bound of (I), multilinearity and a telescoping sum), this further subsequence converges at every tuple of continuous V-valued functions with compact, pairwise disjoint supports, and its limit is a tensor limit at g with the number b_*; as a subsequence of the first, it converges in particular at every tuple of $\mathfrak{S}^V(\mathbb{R}^3)$.

Gibbs sequences at g exist. Indeed $g\le\gamma_W^{\mathrm{ref}}\le\gamma$, with the constant γ (the choice preceding equation YMM1:(2326)); so the interval $I(g)$, defined in (YMM1:(1527)), is not empty, and for every $\mathsf{b}\in I(g)$ the pairs $(K,L^K\mathsf{b})$, $K\in\mathbb{N}$, are first-passage data at g, with $a_KL^K\mathsf{b}=\mathsf{b}$ (Corollary YMM1:74.2). At each of them the set of the states of the tori is not empty and consists of periodic Gibbs states (Proposition YMM1:91.2); choosing one such state ν_K at each K gives the Gibbs sequence $(K,L^K\mathsf{b},\nu_K)_{K\ge1}$ at g, and what precedes, applied to it, gives a tensor limit at g.

Step 2 ((b)(i), (iii)). Each $\mathcal{O}^{\mathsf{T}}_K(H)$ is a real function of the configuration and linear in H. So, for open sets $O_1,\dots,O_n$ with pairwise disjoint closures, the numbers $\nu_j(\prod_a(\mathcal{O}^{\mathsf{T}}_{K_j}(H_a)-\nu_j(\mathcal{O}^{\mathsf{T}}_{K_j}(H_a))))$ are real and n-linear in $(H_a)\in\prod_a C^1_c(O_a;V)$, and so is their limit σ; with $\sigma(\emptyset)=1$, σ is a tensor functional. By (II), σ is symmetric and centred; the bounds of (II) with $\sup|H_a|_\infty\le\|H_a\|_\infty\le\|H_a\|_\sharp$ give (T2); the covariance of (II) is (T1); positivity at $\{x_3=0\}$ is (T3). The joint spectral measure of (II) is the measure $\mathcal{P}$ of Lemma 4.13 (b), by its uniqueness, so (T4) holds and $\mathcal{P}$ is carried by $\{E\ge\max(|q_1|,|q_2|)\}$. (iii) is part of (II).

Step 3 ((b)(ii)). As $\int|h(x)|_\infty dx\le\|h\|_{L^1}$, (II) makes $\mathsf{c}^\circ_\sigma(\eta)$ finite, and Lemma 4.22 gives (T5$_N$) with

$$c_I=\tfrac{1}{16},\qquad N(\eta)=\tfrac{4\pi}{3}\,16^{-3}\eta^3\,\mathsf{c}^\circ_\sigma(\eta/8).$$

Step 4 ((b)(iv)). By Steps 2 and 3, σ has (T1)–(T4) and (T5$_N$), which are the hypotheses of the clauses named.

Step 5 ((c)(i), (ii)). A tensor limit converges at every tuple of continuous members, in particular at every tuple of $\mathfrak{S}^V(\mathbb{R}^3)$, so σ^1 is the limit of a convergent Gibbs sequence. The classes of tuples of C^1 members span a closed subspace of the space reconstructed from tuples of continuous members, with the same scalar products; so the bound (III) on the centred slab operators gives, in matrix elements, $|\sigma^1(\theta\bar F\cdot(h)\cdot G)|\le\|B^c_d(h)\|\,\|[\tau_{-de_3}F]\|\,\|[\tau_{-de_3}G]\|$, and with $\int|h|_\infty\le\|h\|_{L^1}$ this is (i). Lemma 4.21 with $C=C_{\mathsf{p}}/b_*$ gives (ii); then (T1)–(T5) hold, and (C) of Theorem L in the sup norm gives (KV1) with $\wp'=\mathsf{p}_I+3=\mathsf{p}$.

Step 6 ((c)(iii)). By Proposition 4.17 and Lemma 4.16 (b) with $c=\varepsilon-\delta$, $B^\delta_{\mathfrak{a}}(\varepsilon n_0,\varepsilon n_0)=B^c_\varepsilon(j_\delta\otimes\mathfrak{a})$, and for real $\mathfrak{a}$, by (i) with $d'=\delta/2$ and $\|j_\delta\otimes\mathfrak{a}\|_{L^1}=\|\mathfrak{a}\|_{L^1}$,

$$\|B_{\mathfrak{a}}(\varepsilon n_0,\varepsilon n_0)\|=\lim_{\delta\to0}\|B^c_\varepsilon(j_\delta\otimes\mathfrak{a})\|\le C_{\mathsf{p}}b_*^{-1}\min\{1,\varepsilon\}^{-\mathsf{p}}\|\mathfrak{a}\|_{L^1}.$$

The shift rule with contractions extends this to $d_{\mathrm{Tb}}(\xi),d_{\mathrm{Tb}}(\xi')\ge\varepsilon$; a complex label is split, and $\|\mathfrak{a}^0\|_{L^1}+\|\mathfrak{a}^1\|_{L^1}\le\sqrt{2}\|\mathfrak{a}\|_{L^1}$. The kernel bound follows at $\kappa=n_0$, factor by factor, with $\min\{1,d_{\mathrm{Tb}}(p_k),d_{\mathrm{Tb}}(q_k)\}\ge\frac12\min\{1,\min_k d_{\mathrm{Tb}}(\xi_k)\}$.

Step 7 ((c)(iv)). The point bound is obtained as in Step 6 from Proposition 4.19 and $B^\delta_E(\varepsilon e_3,\varepsilon e_3)=B^c_\varepsilon(j^{(3)}_\delta E)$. For $w\in W_3$ with $we_3=e_3$, $\mathcal{U}_wB^c_d(H)\mathcal{U}_w^{-1}=B^c_d(wH)$, and the family

$\mathcal{U}_w^{-1} B_{\varrho(w)E}(w\mathfrak{z}, w\mathfrak{z}')\mathcal{U}_w$ is weakly continuous, has the shift rule by Lemma 4.14 (b), and satisfies the slab formula at hE, because $w(hE) = (h \circ w^{-1})\varrho(w)E$, $|\det w| = 1$ and $de_3 + wx = w(de_3 + x)$; by (D)(iv) it is B_E. The functions W_n do not depend on κ and are holomorphic and n-linear by (D) and the calculus; the bound follows at $\kappa = e_3$, factor by factor. The σ-formula is proved as (KV2) in Step 3 of the proof of Theorem L, with the product formula, the slab formula (D)(iii) in each factor and the rules (D)(iv):

$$[(h_1, \dots, h_n)] = \int B_{h_1(x_1)}(x_1, c_1 e_3 - x_1) B_{h_2(x_2)}(x_2 - c_1 e_3, c_2 e_3 - x_2) \cdots \Omega \, dx_1 \cdots dx_n$$

for heights $0 = c_0 < c_1 < \dots$ separating the supports, after a translation in time. For $w \in W_3$, $\sigma^1(X) = \sigma^1(w^{-1}X)$ by (T1), $(w^{-1}h)(x) = \varrho(w^{-1})h(wx)$, and the substitution $x_k \mapsto w^{-1}x_k$ gives the second form, as $(w^{-1}x)_3 = x \cdot we_3$.

Step 8 ((c)(v)). At $\kappa = n_0$ the factors of $\Psi(R_{is}z; \mathbf{a})$ have the arguments $R_{is}z_1$, $\frac{1}{2}R_{is}(z_{i+1} - z_i)$ and n_0, whose d_{Tb} are $e^{-|s|}z_1^0$, $\frac{1}{2}e^{-|s|}(z_{i+1} - z_i)^0$ and 1 by Lemma 4.11 (c), all $\geq e^{-|s|}c_{\mathcal{C}}$; the plate bound of (iii) gives

$$\|\Psi(R_{is}z; \mathbf{a})\| \leq \prod_i (\sqrt{2}\, C_{\mathsf{p}} b_*^{-1} \|\mathfrak{a}_i\|_{L^1}) \, (e^{-|s|}c_{\mathcal{C}})^{-\mathsf{p}j}. \qquad \square$$

4.5. **Scope.** Theorems L–P are statements on functionals, and Ω enters them only through $\|\Omega\| = 1$ and $T(\xi)\Omega = \Omega$. The trivial functional, with $\sigma(X) = 0$ for $X \neq \emptyset$, $\mathcal{H}(\sigma) = \mathbb{C}\Omega$ and $K_n = 0$, belongs to the class. All the bounds are short-distance bounds; at distances ≥ 1 they are constants. The formulas (KV2), and the formula for W_n in Theorem Q, hold at tuples whose members are ordered in time (for W_n, in a coordinate direction), with the members of (KV2) of the form $\alpha_k \otimes \mathfrak{a}_k$. Of the rotations, Theorem N uses the quarter turns about e_2.

5. Conservation and rotation covariance

The lattice supplies cubic symmetry, reflection positivity and a square spectral cone. Full rotation covariance requires more: conservation removes the two-point angular growth, and positivity propagates this fact to correlations with any number of insertions.

We first state the model and abstract results. The lattice estimates verify the abstract hypotheses; the analytic part uses point plates and their angular Fourier coefficients. The polygon argument controls the extreme coefficient, while the halving argument relates its degree to the two-point degree. The latter is zero by conservation and the off-diagonal bound.

5.1. **Notation and hypotheses.** *Constants and data.* The radius, the constants $(M, \alpha_0, \mathfrak{p}_0, \dots)$ and the fixed data are those fixed in the opening notation and hypotheses, with the common construction choice of Section YMM1:82; $L \geq 13$ is the odd blocking factor; $\gamma_W^{\mathrm{sd}} \leq \gamma_W^{\mathrm{ref}} \leq \gamma$ are the two ceilings of the choices in equations YMM1:(2326)–(2327), functions of the constants alone. A *reference coupling* is a number $0 < g \leq \gamma$ (Section YMM1:74). We write $a_K = L^{-K}$, $\mathbb{L}_K = a_K\mathbb{Z}^3$, and $\mathcal{G}_{K,\beta}^{\mathrm{per}}$ for the set of the Gibbs states of the Wilson weight $e^{-\beta\sum_p a_p}$ on $\mathbb{L}_K$ that are invariant under a subgroup of finite index of $a_K\mathbb{Z}^3$, the *periodic Gibbs states*.

For a reference coupling g, $\mathfrak{d}(g)$ is the set of the first-passage data (K, β) at g (Corollary YMM1:74.2), and $b = a_K\beta = L^{-K}\beta$ is the *label* of a datum. By Proposition YMM1:74.1 and Corollary YMM1:74.2 (the flow and the windows of first passage), $g^{-2} < b \leq L(g^{-2} + \bar{B})$ for $(K, \beta) \in \mathfrak{d}(g)$, and $(K, \beta) \in \mathfrak{d}(g)$ whenever $b \in (g^{-2} + \bar{B}, X_g - \bar{B}]$, where $X_g = L(g^{-2} + B_\sharp)$ and $\bar{B} = LB_\sharp/(L-1)$; so there are data at every K. The *run* of a datum $(K, \beta) \in \mathfrak{d}(g)$ is the flow $(x_0(\beta), \dots, x_K(\beta))$ of Proposition YMM1:74.1: $x_0(\beta) = \beta$ and $x_j(\beta) = L^{-1}x_{j-1}(\beta) - \mathsf{e}_j(\beta)$ with increments $|\mathsf{e}_j(\beta)| \leq B_\sharp$, so that, by YMM1:(1530) and YMM1:(1529),

$$|x_j(\beta) - L^{-(j-i)}x_i(\beta)| \leq \bar{B}(1 - L^{-(j-i)}) \quad (0 \leq i \leq j \leq K), \qquad g^{-2} < x_K(\beta) \leq X_g < x_{K-1}(\beta) < \dots < x_0(\beta);$$

the label $b = L^{-K}x_0(\beta)$ lies within $\bar B$ of $x_K(\beta)$. The run is not the line $x_k = L^{K-k}\mathsf{b}'$ of a label b', which enters the setting (Th) of Subsection 5.5. A side $\ell = 2L^m$ is *small over the run* if it satisfies the conditions (Sd.1)–(Sd.4) of equation YMM1:(2312): the first three make it admissible at every level, and the fourth makes it so small that the suppression of large fields at the last level beats the factor $e^{\mathsf{B}(x_K)\ell^3}$ of that definition. For $1 \le i \le K-1$ the *stopped coupling* $g_{(i)}$ of YMM1:(1536) is given by

$$g_{(i)}^{-2} = L^{-1}x_{K-i}(\beta) - B_\sharp, \qquad \text{so that} \qquad X_{g_{(i)}} = x_{K-i}(\beta);$$

$g_{(i)}^{-2}$ is the least value of g'^{-2} at which $(K-i,\beta)$ is a first-passage datum at g', and $g_{(i)} < g$; the run of $(K-i,\beta)$ is the cut $(x_0(\beta),\dots,x_{K-i}(\beta))$ of the run of (K,β), and its label is $L^i b$ (Corollary YMM1:74.3 and Lemma G.3). The sides at g form the unbounded set $\mathfrak{L}(g) = \{2L^m : m \ge m_{\mathfrak{L}}(g)\}$ of equation YMM1:(1528), with the least element ℓ'. For $g \le \gamma_W^{\mathrm{sd}}$ the least side ℓ' is small over the run of every first-passage datum at g (Lemma YMM1:126.3). $\langle\cdot\rangle_{K,\ell,\beta}$ is the Wilson measure on the torus T_ℓ of side ℓ at the spacing a_K, and $p_\ell = \ell^{-3}\log Z_{K,\ell,\beta}$ its pressure. Boards of $\mathbb{L}_K$, their cells and walls and the mirror copies $F^{[\kappa]}$ of a function F of one cell are those of Section B.1, and the chessboard seminorms $\|F\|_{\mathrm{ch},\ell}$ those of equation YMM1:(1756) and Corollary B.1; on the least torus with cells of side $\ell'/2$ the board has eight cells, and $\|F\|_{\mathrm{ch},\ell'}^8 = \langle\prod_\kappa F^{[\kappa]}\rangle_{K,\ell',\beta}$. We use the following statement, which collects Propositions YMM1:103.4 and YMM1:91.9:

(Per) *The periodic Gibbs states form a non-empty set, are the Gibbs states invariant under $a_K\mathbb{Z}^3$, and every $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ is invariant under $a_K\mathbb{Z}^3 \rtimes W_3$, reflection positive at the three families of coordinate lattice mirrors and the six families of diagonal lattice mirrors, and dominated at finitely many cells by chessboard seminorms along every sequence of sides $\ell_k \to \infty$ in $\mathfrak{L}(g)$: $|\nu(\prod_{k\in\mathcal{K}_0} F_k)| \le \liminf_k \prod_{k\in\mathcal{K}_0}\|F_k\|_{\mathrm{ch},\ell_k}$ for functions F_k of finitely many distinct cells of one board.*

The lattice tensor. We use the forms of Definition 2.1, with the same midpoint convention:

$$\mathcal{T}_K(H) = O_K^T(H) = \mathcal{O}(w_H) + Y[\mathsf{w}_H]. \tag{6}$$

Besides the differences $u_{b,\alpha}$ in the introduction, we use the sums

$$\mathbf{y}_{b,\alpha} = w(W_x(\mu,\alpha)) + w(W_x(\mu,-\alpha)), \qquad \mathbf{u}_{b,\alpha} = u_{b,\alpha}.$$

The same definitions apply on a torus.

Tuples and limits. An isometry $\mathsf{r} : x \mapsto \mathsf{R}x + v$ acts by $(\mathsf{r}H)(x) = \rho(\mathsf{R})H(\mathsf{r}^{-1}x)$. For an open set O, $\mathfrak{S}_V(O)$ is the set of the tuples $X = (H_1,\dots,H_n)$, $n \ge 0$, of members $H_a \in C_c(O;V)$ with pairwise disjoint supports, and $\mathbb{C}\mathfrak{S}_V(O)$ the set of their complex combinations; a tuple with members in $C_c(O;V_{\mathbb{C}})$ stands for its expansion into real and imaginary parts. Isometries act member by member, $X\cdot Y$ is the concatenation, (h) the tuple with the one member h, and X is of *type* $(\mathsf{d};R)$ if each support lies in a closed ball of radius R and any two supports are at distance $\ge \mathsf{d}$. For a state ν put $A_K^\nu(X) = \prod_a[\mathcal{T}_K(H_a) - \nu(\mathcal{T}_K(H_a))]$. Let $(K_j,\beta_j) \in \mathfrak{d}(g)$ with $K_j \to \infty$, $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$ and $a_{K_j}\beta_j \to b_*$. If

$$\sigma(X) = \lim_{j\to\infty} \rho_j\big(A_{K_j}^{\rho_j}(X)\big) \tag{7}$$

exists for every $X \in \mathfrak{S}_V(\mathbb{R}^3)$, we call σ a *tensor limit at g* with the *label* $b_* \in [g^{-2}, L(g^{-2}+\bar B)]$, and σ_0, its restriction to the tuples with members in $C_c(\mathbb{R}^3;V_0)$, its *scalar part*. For $\eta \in C_c^2(\mathbb{R}^3;\mathbb{R}^3)$ let

$$H_\eta = (\nabla\cdot\eta)\mathbf{1} - \nabla\eta - (\nabla\eta)^{\mathrm{T}}, \qquad (\nabla\eta)_{ij} = \partial_i\eta_j.$$

Then $\frac12\operatorname{Tr}(H_\eta T) = \sum_{i,j}\partial_i\eta_j(\frac12\delta_{ij}\operatorname{tr}T - T_{ij})$, so that $\int$ of it vanishes for all η exactly when $\frac12\delta_{ij}\operatorname{tr}T - T_{ij}$ is conserved, and $\mathsf{r}H_\eta = H_{\mathsf{r}\eta}$ with $(\mathsf{r}\eta)(x) = \mathsf{R}\eta(\mathsf{r}^{-1}x)$; $\|\eta\|_{C^2}$ is the sum of the suprema of the entries of η, $\nabla\eta$ and $\nabla^2\eta$.

Euclidean data. θ is the reflection $x_3 \mapsto -x_3$, acting on points and, through ρ, on values; θ_c is the reflection in the plane $x_3 = c$; $\mathbb{E}_+ = \{x_3 > 0\}$; W_3 is the group of the 48 signed permutation

matrices; R_t is the rotation about e_2 with $\mathsf{R}_t e_3 = \cos t\, e_3 + \sin t\, e_1$; τ_v is the translation by v; Σ is the diagonal plane $x_1 + x_3 = 0$ and $\theta_\Sigma \in W_3$ the reflection in it.

Definition 5.1. A real functional σ on $\mathfrak{S}_V(\mathbb{R}^3)$, continued linearly to complex combinations and to members with values in $V_{\mathbb{C}}$, is *labelled data* if

(D1) $\sigma(\varnothing) = 1$ and $\sigma((H)) = 0$; σ is symmetric and n-linear on $\prod_a C_c(O_a; V)$ for open sets O_a with pairwise disjoint closures; and $|\sigma(X)| \le C_n(\mathsf{d}; R) \prod_a |H_a|_\infty$ for X of type $(\mathsf{d}; R)$ with n members;

(D2) $\sigma(\mathsf{r}X) = \sigma(X)$ for $\mathsf{r} \in \mathbb{R}^3 \rtimes W_3$;

(D3) $\sigma(\theta_{\Sigma'} \bar{F} \cdot F) \ge 0$ for every plane Σ' of the form $x_\mu = c$ or $x_\mu \pm x_\nu = c$, with the reflection $\theta_{\Sigma'}$, and every $F \in \mathbb{C}\mathfrak{S}_V$ carried by one open side of Σ';

(D4) in the Hilbert space $\mathcal{H}(\sigma)$ of the form $\langle [F'], [F] \rangle = \sigma(\theta \bar{F}' \cdot F)$ on $\mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$, with $\Omega = [\varnothing]$, $e^{-tH}[F] = [\tau_{te_3} F]$, $e^{iv\cdot P}[F] = [\tau_{(v,0)} F]$ and the joint spectral measure $\mathcal{P}$ of H and P: $H \ge |P_1|$ and $H \ge |P_2|$.

Labelled data may have the following properties.

(S) For $l > 0$ and $h \in C_c(\{0 < x_3 < l\}; V_{\mathbb{C}})$ there is a bounded operator $\mathsf{B}_l(h)$ on $\mathcal{H}(\sigma)$ with $\mathsf{B}_l(h)[F] = [(h) \cdot \tau_{le_3} F]$ and $\|\mathsf{B}_l(h)\| \le \mathsf{C}(\mathcal{K}, l) |h|_\infty$ when $\operatorname{supp} h$ lies in a compact set $\mathcal{K}$; nothing is supposed of the numbers $\mathsf{C}(\mathcal{K}, l)$.

(O) There is C_{od} with $\sigma(\theta(h\,o), h\,o) \le C_{\mathrm{od}} |h|_\infty^2$ for every $o = o_{\mu\nu} = e_\mu e_\nu^{\mathrm{T}} + e_\nu e_\mu^{\mathrm{T}}$, $\mu \ne \nu$, every $0 < \mathsf{d} < 1$, and every real $h \in C_c(B(x_0, \mathsf{d}))$ with $x_{0,3} \in [\frac{3}{2}\mathsf{d}, 2\mathsf{d}]$.

(O$_a$) For one $a < 4$ there are C_a and a sequence $1 > \mathsf{d}_n \downarrow 0$ with $\sigma(\theta(h\,o), h\,o) \le C_a \mathsf{d}_n^{-a} |h|_\infty^2$ for all n, all o as in (O) and all real $h \in C_c(B(2\mathsf{d}_n e_3, \mathsf{d}_n))$.

(N) $\sigma(\theta H_\eta, H_\eta) = 0$ for every $\eta \in C_c^2(\mathbb{E}_+; \mathbb{R}^3)$; that is, $[(H_\eta)] = 0$ in $\mathcal{H}(\sigma)$.

(P) For one $p < \infty$ there is C with $\|\mathsf{B}_{2d}(\tau_{de_3} h)\| \le C \min\{1, d - d'\}^{-p} \|h\|_{L^1}$ whenever $0 \le d' < d$ and $h \in C_c(\{|x_3| \le d'\}; V_{\mathbb{C}})$, where $\|h\|_{L^1} = \int |h(x)|_\infty \, dx$.

(I$_0$) $\sigma(\mathsf{R}_t X) = \sigma(X)$ for all real t and all tuples X with members in $C_c(\mathbb{R}^3; V_0)$.

■

5.2. **Principal results.** The numbers called constants below are functions of the fixed construction data specified in the opening notation and hypotheses.

Theorem R. Let $0 < g \le \gamma$.

(a) *(Conservation at a cutoff.)* Let $q \ge 2$ and $\mathsf{d}, R > 0$. There are C, p and K_0, functions of the constants, g, q, d and R alone, such that for all $(K, \beta) \in \mathfrak{d}(g)$ with $K \ge K_0$, all $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, all $\eta \in C_c^2(\mathbb{R}^3; \mathbb{R}^3)$ and all bounded $H_2, \dots, H_q : \mathbb{R}^3 \to V$ whose supports, with $\operatorname{supp}\eta$, lie in a cube of side $2R$ at pairwise sup distances $\ge \mathsf{d}$,

$$|\nu(A^\nu_K(H_\eta, H_2, \dots, H_q))| \le C K^p L^{-K/36} \, \|\eta\|_{C^2} \prod_{a \ge 2} |H_a|_\infty; \tag{8}$$

the same bound holds for the joint cumulant of $\mathcal{T}_K(H_\eta), \mathcal{T}_K(H_2), \dots, \mathcal{T}_K(H_q)$ in ν, and, with numbers that depend also on the side, for the joint cumulant in $\langle\cdot\rangle_{K,\ell,\beta}$, $\ell \in \mathfrak{L}(g)$, of members on T_ℓ at pairwise sup distances $\ge \mathsf{d}$. For $q = 2$ and $H_2 = H_{\eta'}$ the right side may be replaced by $C K^p L^{-K/20} \|\eta\|_{C^2} \|\eta'\|_{C^2}$.

(a′) *(The mirror form.)* Let $h_0, R_0 > 0$ and $c < \frac{1}{10}$. There are C, p, K_0, functions of the constants, g, h_0, R_0 and c, such that for $(K, \beta) \in \mathfrak{d}(g)$, $K \ge K_0$, $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, the reflection θ_K in $x_3 = \frac{1}{2} a_K$ and $\eta \in C_c^2(\mathbb{R}^3; \mathbb{R}^3)$ with support in $\{x_3 \ge h_0,\ |x|_\infty \le R_0\}$,

$$0 \le \nu(A^\nu_K(\theta_K H^K_\eta, H^K_\eta)) \le b^{-2} \big(C K^p L^{-cK} \|\eta\|_{C^2}\big)^2,$$

H^K_η being H_η with the lattice differences of Lemma 5.23.

(b) *(Conservation in the limit.)* Every tensor limit σ at g satisfies $\sigma((H_\eta)\cdot X)=0$ for every $\eta\in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and every $X\in\mathfrak{S}_V(\mathbb{R}^3)$ whose members have supports disjoint from $\operatorname{supp}\eta$.
(c) *(Covariance.)* Every tensor limit σ at g satisfies $\sigma(\mathsf{R}X)=\sigma(X)$ for all $\mathsf{R}\in\mathrm{O}(3)$ and all $X\in\mathfrak{S}_V(\mathbb{R}^3)$.

■□

Let $K_3(u)=(3\hat u\hat u^{\mathrm T}-\mathbf{1})/(4\pi|u|^3)$, $\hat u=u/|u|$, and

$$\mathcal{W}(H_1,H_2)=\tfrac{3}{2}\iint \operatorname{Tr}\big[H_1(x)\,K_3(x-y)\,H_2(y)\,K_3(x-y)\big]\,dx\,dy.$$

For three free photon fields $B^{\mathsf a}$ with

$$\langle B^{\mathsf a}_\lambda(x)B^{\mathsf b}_{\lambda'}(y)\rangle=\mathsf b^{-1}\delta^{\mathsf{ab}}K_3(x-y)_{\lambda\lambda'}$$

and $T_{\lambda\lambda'}=\sum_{\mathsf a}{:}B^{\mathsf a}_\lambda B^{\mathsf a}_{\lambda'}{:}$, the covariance of $\frac12\int\operatorname{Tr}(H_1T)$ and $\frac12\int\operatorname{Tr}(H_2T)$ is $\mathsf b^{-2}\mathcal{W}(H_1,H_2)$; at $H_a=\phi_a\mathbf{1}$ it is

$$\frac{9}{16\pi^2}\mathsf b^{-2}\iint\phi_1(x)\phi_2(y)|x-y|^{-6},$$

and $|\mathcal{W}(H_1,H_2)|\le 24|H_1|_\infty|H_2|_\infty$ at the positions of Theorem S (i).

Theorem S. Let $0<g\le\gamma_W^{\mathrm{sd}}$. There are $\mathsf d_0(g)>0$ and a function e_g on $(0,\mathsf d_0(g))$, formed with the constants and g alone, with $e_g(\mathsf d)\to0$ as $\mathsf d\to0$ and $\sup_{\mathsf d}(\log\frac1{\mathsf d})^{\mathfrak p_0/4}e_g(\mathsf d)<\infty$, such that the following holds for every tensor limit σ at g with label b_*.

(i) For $0<\mathsf d_-<\mathsf d<\mathsf d_0(g)$, x_0,y_0 with $3\mathsf d\le|x_0-y_0|\le4\mathsf d$, and $H_1,H_2\in C^1_c(\mathbb{R}^3;V)$ with supports in the closed balls of radius $\mathsf d_-$ about x_0 and y_0,

$$|\sigma(H_1,H_2)-b_*^{-2}\mathcal{W}(H_1,H_2)|\le e_g(\mathsf d)\,b_*^{-2}|H_1|_\infty|H_2|_\infty.$$

(ii) The label b_* is determined by σ.
(iii) Let $w_0=\frac{1}{12}388^{-6}$, $e_g(\mathsf d)<w_0$, $x_0=\frac32\mathsf d e_3$, and $\varphi\in C^1_c(\mathbb{R}^3)$ with $\mathbf{1}_{B(x_0,\mathsf d/128)}\le\varphi\le\mathbf{1}_{B(x_0,\mathsf d/64)}$. Then $\sigma(\theta(\varphi E),\varphi E)\ge(w_0-e_g(\mathsf d))\,b_*^{-2}\operatorname{tr}E^2$ for every $E\in V$: the vectors $[(\varphi E)]$ are nonzero for $E\neq0$, and no nonzero real combination of the six fields vanishes in any tensor limit.
(iv) With the same e_g, the bound (i) holds for the limit functionals of Proposition 5.18 on every torus T_ℓ, $\ell\in\mathfrak L(g)$, at every label $\mathsf b\in(g^{-2}+\bar B,X_g-\bar B]$, for Lipschitz members, with $\mathsf b$ in the place of b_* and $\mathcal W$ formed with lifts of the members to balls about lifts of x_0,y_0 at the distance $|x_0-y_0|$.

■□

The next two theorems concern abstract data; no lattice occurs in them, and the kernels $\mathcal K_n$, the plate vectors Ψ, the tubes $\mathcal Z_n$, the weight labels and the imaginary rotations $\mathsf R_{is}$ in them are those of Subsection 5.6 and Lemma 5.25.

Theorem T. Let σ be labelled data with the properties (S), (O), (N) and (P). Then:

(i) $\sigma(\mathsf RX)=\sigma(X)$ for all $\mathsf R\in\mathrm{O}(3)$ and all $X\in\mathfrak S_V(\mathbb{R}^3)$;
(ii) $\sigma((H_\eta)\cdot X)=0$ for every $\eta\in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and every $X\in\mathfrak S_V(\mathbb{R}^3)$ with members off $\operatorname{supp}\eta$;
(iii) $\mathcal K_n(\mathsf R_{is}Z;\underline\lambda)=e^{\kappa(\underline\lambda)s}\mathcal K_n(Z;\underline\lambda)$ for all $n\ge2$, all tuples $\underline\lambda$ of weight labels, all $Z\in\mathcal Z_n$ and all real s;
(iv) $e^{-\kappa(\underline\lambda)s}\|\Psi(\mathsf R_{is}z;\underline\lambda)\|=\|\Psi(z;\underline\lambda)\|$ for all real configurations z in the domain of Ψ, all tuples of weight labels and all real s; and there is a unitary group $U(s)$ on the closed span of Ω and the plate vectors with $U(s)\Omega=\Omega$ and $U(s)\Psi(w;\underline\lambda)=e^{-\kappa(\underline\lambda)s}\Psi(\mathsf R_{is}w;\underline\lambda)$.

The same holds if (P) is replaced by any growth of the plate vectors along the imaginary rotations with exponents A_j such that $\liminf_j A_j/j^2 < 2$ (Proposition 5.34), and (O) may be replaced by (O_a) when (I_0) holds at pairs. Under (P), or under a growth with $\liminf_j (A_j - j^2)/j = -\infty$, it suffices that (D3) hold at the plane $x_3 = 0$ and, at tuples of one member, at the plane Σ. ■□

Theorem U. Let σ be labelled data with the properties (S), (O), (N) and (I_0). Then $\sigma(\mathsf{R}X) = \sigma(X)$ for all $\mathsf{R} \in \mathrm{O}(3)$ and all tuples $X = (H_1, H_2, f_1\mathbf{1}, \dots, f_n\mathbf{1}) \in \mathfrak{S}_V(\mathbb{R}^3)$, $n \geq 0$. The same holds for labelled data with (S) and (I_0) that are covariant under the R_t at all pairs. ■□

Tensor limits at $0 < g \leq \gamma_W^{\mathrm{sd}}$ have (S), (O) and (N) by Propositions 5.10, 5.13 and Theorem R (a), and their scalar part is invariant under $\mathbb{R}^3 \rtimes \mathrm{O}(3)$ by Theorem YMM1:AN (limit functionals along periodic Gibbs states), whose proof rests on Theorem YMM1:AK (the rotation theorem for the action density); so Theorem U gives Theorem R (c) at these tuples without the power of Proposition 5.15.

Corollary 5.2. Let $0 < g \leq \gamma_W^{\mathrm{sd}}$, σ a tensor limit at g with label b_*, σ^1 its restriction to the tuples with members in $C_c^1(\mathbb{R}^3; V)$, and $p > \frac{17}{2}$.

(A) σ^1 is invariant under all isometries of $\mathbb{R}^3$; it is reflection positive at $x_3 = 0$, with $\mathcal{H}(\sigma^1) = \mathcal{H}(\sigma)$ and the same Ω, H, P, $\mathcal{P}$; the spectral measure is carried by the cone $\{E \geq |q|\}$, that is $\mathcal{P}(\{E < |q|\}) = 0$; and $|\sigma(\theta\bar{F} \cdot (h) \cdot F')| \leq C_V \eta^{-p} \|h\|_{L^1} \|[\tau_{-\eta e_3} F]\| \, \|[\tau_{-\eta e_3} F']\|$ for $\eta \in (0, 1]$, F, F' over $\{x_3 > \eta\}$, $h \in C_c^1(\{|x_3| < \frac{1}{2}\eta\}; V)$, with $C_V = 2^p C_p b_*^{-1} \leq 2^p C_p g^2$, C_p the number of Proposition 5.15; so the number $2^p C_p g^2$ serves for all tensor limits at g.

(B) For every $n \geq 2$ there is exactly one continuous function $\mathsf{s}_n(x; e)$ on the configurations of n pairwise different points of $\mathbb{R}^3$ and $e \in V^n$, n-linear in e, with $\sigma(H_1, \dots, H_n) = \int \mathsf{s}_n(x; H_1(x_1), \dots, H_n(x_n))\, dx$ for all $X \in \mathfrak{S}_V(\mathbb{R}^3)$; it is real-analytic in x, symmetric under simultaneous permutations of points and values, invariant under $\mathsf{s}_n(\mathsf{r}x; \rho(\mathsf{R})e) = \mathsf{s}_n(x; e)$ for every isometry r, and $|\mathsf{s}_n(x; e)| \leq (\mathsf{c}\, C_V)^n \max\{1, 2n^2/\delta(x)\}^{pn} \prod_k |e_k|$, $\delta(x)$ the least distance of two points, c a pure number. The Schwinger functions satisfy the growth hypothesis in Proposition YMM1:93.5 with the constants $(\lceil p \rceil, 1, \mathsf{C}_E, 2p)$, so at $p = 9$: $|\mathsf{S}_n(\varphi)| \leq \mathsf{C}_E^n (n!)^{18} |\varphi|_{9n}$.

(C) By the reconstruction theorem among the construction results in its labelled form (Theorem YMM1:AO for members with values in V, with the changes listed at the end of Subsection 5.3), applied to σ^1, which by (A) has the data (Rec1)–(Rec4) so read: the span $\mathcal{D}_0$ of Ω and of the vectors $T(f_1) \cdots T(f_n)\Omega$ of the reconstructed fields is dense in $\mathcal{H}(\sigma)$; there is a strongly continuous unitary representation U of the proper orthochronous Poincaré group of $\mathbb{R}^{1+2}$ on $\mathcal{H}(\sigma)$ with $U(x, 1) = e^{itH} e^{i\vec{x}\cdot P}$, $U\Omega = \Omega$, spectrum in the closed forward cone, and $U(a, \Lambda) T(f) U(a, \Lambda)^{-1} = T(\hat{\Lambda} f(\Lambda^{-1}(\cdot - a))\hat{\Lambda}^{\mathrm{T}})$ on $\mathcal{D}_0$, $\hat{\Lambda} = \iota \Lambda \iota^{-1} \in \mathrm{SO}(3, \mathbb{C})$, $\iota(t, \vec{x}) = (\vec{x}, -it)$; and $T(f)T(f')\psi = T(f')T(f)\psi$ for $\psi \in \mathcal{D}_0$ and test tensors f, f' with spacelike separated supports, all six components with all six.

■□

5.3. **Construction estimates.** Besides Theorems YMM1:D, YMM1:AJ and YMM1:AD, the argument uses the statements among the construction results listed below, and, for Corollary 5.2 (C), the reconstruction theorem among the construction results in the labelled form stated at the end of this subsection.

The chain of renormalisation steps on one torus: the setting (Th) (Section B.13, Lemma YMM1:118.1); the cuts Cut_k (the definitions preceding Lemma YMM1:113.10, Lemma YMM1:113.10) and the classes of covariance, which give the radius of regularity of the backgrounds over the cuts (Section B.3 and Lemma B.4); one step as an identity at every point of the next cut (Lemma B.3); the one-step theorem with a complex plaquette weight of small size and small oscillation (Proposition E.7); the flows from a level for every system of early members (Proposition YMM1:114.2, Proposition YMM1:114.2), with the running numbers of equations YMM1:(2176)–(2177); the Lipschitz

form of forgetting (Proposition YMM1:114.3); parity in the fluctuation field (Proposition E.8); the orbital potential (Section H, Proposition H.1); the laws of the block fields at two consecutive cutoffs (Corollary B.30).

Two consecutive cutoffs on one torus: the setting of Section YMM1:113 with its threshold $\Theta_\star$, the data of the comparison (the setting preceding Lemma YMM1:113.8), the lower and the upper halves (Lemma YMM1:113.8), the comparison of the background actions at the cutoffs K and $K+1$ (Proposition YMM1:113.9), and the competitors and their excess (Proposition YMM1:113.5, Lemma YMM1:113.6, Proposition YMM1:113.7); the setting (E), the two depths with their conditions (k0)–(k6), and the block fields with their laws (Definitions B.13, B.13, B.29); the rarity of large-field regions on one torus (Proposition M.2).

One small torus: the data, the numbers, the parameter sets and the step map of the weighted progression (Section B.5 and equations YMM1:(2251)–(2252)), its height zero (the height-zero part of Proposition B.8), the small-field progression with sources, the weighted progression of Proposition YMM1:122.1, and its first derivatives at regular configurations (equation YMM1:(2264)); the setting of one lattice and the objects of the construction in it (Definition B.16, Proposition B.21), one exact step and the first step (Lemma B.19), the term of the history without large-field regions (Proposition YMM1:123.1), the quotients of the sources along it (equation YMM1:(2267) and Proposition YMM1:123.1), the quotients of a step and their tower (the quotient definitions in Section B.9 and equation YMM1:(2273)), and the one-step covariance of two sources (Lemma B.20); the sum over the level of the first large-field region (equation (314)) and the rarity of large fields on a small side (Lemma YMM1:125.3); the stopped datum (Corollary YMM1:74.3 and Lemma G.3); the small sides (equation YMM1:(2312), Lemma YMM1:126.3); the depth fitted to a scale (equation YMM1:(2321) and the argument immediately following it), with the value of the room constant (equation YMM1:(2320)); the working level and its arithmetic (equation YMM1:(2322), Lemma YMM1:126.1).

The first order and the two-point law on a small torus: a pointed family inserted to first order in one step and the families carried from it to the higher levels (equations YMM1:(2276)–(2277), YMM1:(2280) and Proposition YMM1:123.3); one level at a regular configuration (Lemma B.22); the flat top (Proposition YMM1:123.3, equation YMM1:(2283)); the plaquette angles at a small point of the chart and the plaquette terms to the second order (Section YMM1:124, Lemma YMM1:124.4); the step couplings (equation YMM1:(2299)); the Gaussian numbers of the slices of the covariance and the errors of the flat top (equations YMM1:(2303)–(2305)); the carried family at the flat top (Proposition YMM1:125.1); the value of the truncated two-point function, with its errors, its sizes and its tails (Theorem YMM1:AT, Lemmas YMM1:125.2, YMM1:125.4, YMM1:125.5), at the levels attached to the working level (equation YMM1:(2316)), in the settings that the construction satisfies (Lemma YMM1:126.2); the envelopes and the error functions of the depth (equations YMM1:(2328)–(2336), with the notation in (267), the depth estimates in equations YMM1:(2332) and YMM1:(2336) and their proofs); the two-point law on a torus of small side (Theorem YMM1:AU); the background kernel of a depth and the slices of the free curvature kernel, with their telescope and their decay (Section YMM1:120, YMM1:120.5 and YMM1:120.6, Lemma YMM1:120.1, Propositions YMM1:120.5 and YMM1:120.6).

The source zero: the canonical system of localised source energies (Lemma N.1), which gives the gap of the pressures between sides.

The lattice: the lattice calculus of fields of directions (Lemma J.1, the general field (301)), the lattice Ward identity with its cubic density (Proposition YMM1:112.1) and the summation by parts of the orbital remainder (Proposition H.1); local gauges on cubes, with the Hölder regularity of backgrounds (Theorem BT); the covariance of lattice objects under lattice isometries (Lemma G.1).

Periodic Gibbs states and tori: (Per) of Subsection 5.1; the chessboard estimate (Proposition YMM1:86.3, Corollary B.1); multiple reflections (Proposition YMM1:104.2); the lattice energy-momentum inequality (Proposition YMM1:99.3) and its five-point form (Lemma F.5); the admissible

labels on the tori of $\mathfrak{L}(g)$ (Lemma B.27); the limit functionals along periodic Gibbs states (Theorem YMM1:AN) and the rotation theorem for the action density (Theorem YMM1:AK); the statement on two points for scalar plates (the proof of Theorem YMM1:AK).

Functionals on separated tuples: the test spaces $\mathcal{S}_{\neq}$ and their norms (Section YMM1:93), the extension proposition (Proposition YMM1:93.3, with Lemma YMM1:93.2 for uniqueness), the growth hypothesis in Proposition YMM1:93.5, and the reconstruction theorem for Euclidean data (Theorem YMM1:AO), with the data (Rec) of Section YMM1:107 and the Wightman properties stated in Theorem YMM1:AO.

The reconstruction theorem in its labelled form. This is Theorem YMM1:AO for members with values in V, with the following changes. In the data (Rec): the isometries of $\mathbb{R}^3$, the reflection θ among them, act on a member also through ρ on its values, $(\mathsf{r}H)(x) = \rho(\mathsf{R})H(\mathsf{r}^{-1}x)$, in (Rec1) and in the positivity of (Rec2); the norm $\|h\|_{L^1}$ of (Rec4) is formed with a norm of V that ρ keeps, for instance $(\operatorname{tr} A^2)^{1/2} \geq |A|_\infty$; and the data are (Rec1)–(Rec4), so read. In the Wightman clauses: the test functions f take their values in $V_{\mathbb{C}}$, and $f^* = \rho(\theta)\bar{f}$ takes the place of $\bar{f}$ in the Hermiticity identity; a Lorentz transformation Λ acts on the values through $D(\Lambda)A = \hat{\Lambda}A\hat{\Lambda}^{\mathrm{T}}$, $\hat{\Lambda} = \iota\Lambda\iota^{-1} \in \mathrm{SO}(3,\mathbb{C})$, $\iota(t,\vec{x}) = (\vec{x}, -it)$, a homomorphism of the proper orthochronous Lorentz group into $\mathrm{GL}(V_{\mathbb{C}})$ with $D(1 \oplus \mathsf{R}) = \rho(\mathsf{R} \oplus 1)$ at a rotation R of the space coordinates, $D(B(s)) = \exp(is\, d\rho(\omega_1))$ at the boost $B(s)$ in the plane of x^0, x^1, $\omega_1 = e_1 e_3^{\mathrm{T}} - e_3 e_1^{\mathrm{T}}$, and $D(\Lambda)e^* = (D(\Lambda)e)^*$ for $e^* = \rho(\theta)\bar{e}$; Lorentz covariance reads $U(a,\Lambda)T(f)U(a,\Lambda)^{-1} = T(D(\Lambda)f(\Lambda^{-1}(\cdot - a)))$; locality and cyclicity are required for all the components; the unitary representation and spectrum conditions are retained, and uniqueness of the vacuum is imposed only when stated separately.

The statements among the construction results on the point operators, the functions $\mathbf{W}_n$, the kernels, the one holomorphic function on the union of the tubes, the field operators, their Lorentz covariance and their locality (Propositions YMM1:107.2, YMM1:108.2, YMM1:108.3, YMM1:109.1, YMM1:110.1, YMM1:110.2) hold in the labelled form with the same proofs: these use of a member only its linearity and the action of the isometries on it, and the labels enter through ρ and D alone.

5.4. **Bounds on the lattice.**

Lemma 5.3. Let $0 < g \leq \gamma$, $(K,\beta) \in \mathfrak{d}(g)$, and $G_g = C_{\mathrm{S}} + C_g + 2C_{\mathrm{tt}}C'_{\mathrm{tt}}E_0$, formed with the numbers of the canonical system of Lemma N.1 at the source zero.

(a) $|p_{\ell_1} - p_{\ell_2}| \leq G_g$ for all $\ell_1, \ell_2 \in \mathfrak{L}(g)$.

(b) $\|F\|_{\mathrm{ch},\ell} \leq e^{G_g \mathsf{l}^3} \|F\|_{\mathrm{ch},\ell'}$ for every function F of a cell of side l with $2\mathsf{l} \leq \ell'$ and every $\ell \in \mathfrak{L}(g)$ with $\ell \geq \ell'$.

(c) For $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, a board with cells of side $\ell'/2$ and any offset in $a_K\mathbb{Z}^3$, distinct cells $\square_1, \dots, \square_q$, real functions F_k of $\square_k$ and real numbers c_k: $|\nu(\prod_k (F_k - c_k))| \leq \prod_k e^{G_g(\ell'/2)^3} \|F_k - c_k\|_{\mathrm{ch},\ell'}$; in particular $|\nu(F_1) - c_1| \leq e^{G_g(\ell'/2)^3} \|F_1 - c_1\|_{\mathrm{ch},\ell'}$.

(d) *(Multiple reflections at several cells of one layer.)* Let a board of side l have the wall plane $\{x_3 = \gamma'\}$, let $\square_k$, $k \in \mathcal{K}_0$, be finitely many cells in the layer $\{\gamma' \leq x_3 \leq \gamma' + \mathsf{l}\}$, D_k local functions of $\square_k$, $D_k^\sharp$ the conjugate of the reflection of D_k in the middle plane of the layer, with $\|D_k^\sharp\|_{\mathrm{ch},\ell_k} \leq d_k$ along a sequence $\ell_k \to \infty$ in $\mathfrak{L}(g)$. Then for $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, local functions X, X' of $\{x_3 > \gamma'\}$ and $t, t' \in a_K\{0,1,2,\dots\}$,

$$\Big|\nu\Big(\overline{\theta_{\gamma'}\tau_{te_3}X'} \cdot \prod_{k\in\mathcal{K}_0} D_k \cdot \tau_{(\mathsf{l}+t')e_3}X\Big)\Big| \leq \prod_k d_k \, \|X'\|_{\nu,\gamma'} \, \|X\|_{\nu,\gamma'}, \qquad \|X\|^2_{\nu,\gamma'} = \nu\big(\overline{\theta_{\gamma'}X}\, X\big).$$

■

Proof. Lemma N.1 at the source zero gives $p_\ell = \ell^{-3}E_{K,\ell,\beta} + \vartheta_\ell$ with $-C_g \leq \vartheta_\ell \leq C_{\mathrm{S}}$, and $|\ell_1^{-3}E_{K,\ell_1,\beta} - \ell_2^{-3}E_{K,\ell_2,\beta}| \leq 2C_{\mathrm{tt}}C'_{\mathrm{tt}}E_0$: this is (a). The comparison of two sides in Corollary B.1 (e), $\|F\|_{\mathrm{ch},\ell} \leq \|F\|_{\mathrm{ch},\ell'} e^{\mathsf{l}^3(p_{\ell'} - p_\ell)}$ for $\ell \geq \ell' \geq 2\mathsf{l}$, gives (b). The domination in (Per), along $\ell_k \to \infty$, and

(b) give (c); a constant has the seminorm equal to its modulus. For (d) one follows the proof of Proposition YMM1:104.2 (multiple reflections): Schwarz' inequality at the wall planes $\theta_{\gamma'}$ and $\theta_{\gamma'+1}$ separates X' and X from the layer, the convexity step is taken before the quotient so that the product over all the cells of the layer is reflected at once, and the chessboard estimate in the layer bounds the reflected product by $\prod_k \|D_k^\sharp\|_{\mathrm{ch},\ell_k}$. □

Every estimate below is of short distance; Lemma 5.3 makes it uniform in the side and in the state.

Sources under majorants. The small-field progression with sources carries weights of the plaquettes ((200)); its proofs read a source only through the properties that the next definition names. Let data (Wp1)–(Wp5) of Definition B.7 be given on a torus T_ℓ at the spacing a_K, with a last height $k \geq 1$. $\mathcal{P}(X)$ is the set of the plaquettes with their four corners in a region X; the regions, the triples of the cores, the pointed families, the families without base point, the families in the fourth place, the bare arrays and their sizes are those that Section B.5 and Section YMM1:122 name.

Definition 5.4. (1) A *majorant* is a pair (s, S) of a number $\mathsf{s} > 0$ and a non-empty set S of plaquettes. Its *weight* is the real source $\mathsf{s}\mathbf{1}_S$ on the plaquettes, and the numbers $\mathsf{m}_j = 12M^3\alpha_0^2 L^{K-j}\mathsf{s}$ of (196) are formed at it.

(2) A *source under the majorant* (s, S) is a triple $\mathfrak{s} = (F, \mathbb{V}^\natural, (H^{(j)})_{1\leq j\leq k})$ with the following properties.

(So0) The *first member* F is a continuous complex function of the configurations, invariant under the gauge transformations of the bare lattice, with $|F(U)| \leq a_K^{-1}\mathsf{s}\sum_{p\in S} a_p(U)$ at every SU(2)-valued configuration U.

(So1) (*The height zero.*) $\mathbb{V}^\natural$ is a family in the fourth place at the height 0 (Section S.1), of size at most $\mathsf{c}^\flat\mathsf{m}_0$, $\mathsf{c}^\flat = 81C_P^2\mathsf{C}_{\mathcal{A}}^2/K_\Lambda$ the number of (196); its member at a region Y vanishes unless $\mathcal{P}(Y)$ meets S; and it sums to F, in the sense of (355), at every configuration W of the first level satisfying the background and chart conditions of Section S.1 at the height 0, as the bracketed action of a weight w of the plaquettes sums to $\mathcal{O}(w)$ (the height-zero sum rule in Proposition B.8).

(So2) (*The heights* $j \geq 1$.) $H^{(j)}$ is a family without base point of level j at the radii (α_0, α_1), of size at most $\frac{1}{2}\mathsf{m}_j$; its member at a region X vanishes unless $\mathcal{P}(X)$ meets S; and $\sum_X (H^{(j)}(X, U) - H^{(j)}(X, \mathbf{1})) = F(U)$ wherever the action of the bare arrays of the height j is defined. It takes the place of the weight member in the slot of the bare array of the height j ((200)).

The source is *real* if its first member is real.

(3) A *system of sources* is a tuple of sources $\mathfrak{s}_a = (F_a, \mathbb{V}_a^\natural, (H_a^{(j)})_j)$ under majorants (s_a, S_a), $1 \leq a \leq p$, $p \geq 1$. All the numbers and sets of equations (196)–(197), among them $\mathsf{m}_{j,a}$, $\mathsf{d}_{j,a}$, $\mathsf{n}_{j,a}$, $N_\star^{[j]}$ and the parameter sets Λ_j^{w}, and the numbers of Sections B.9 and YMM1:123–124 and YMM1:125–126 that are formed with the sources, are formed at the weights $\mathsf{s}_a\mathbf{1}_{S_a}$. For $\lambda \in \mathbb{C}^p$ put $F_\lambda = \sum_a \lambda_a F_a$. The *progression* $(E_\lambda'^{(j)})_j$ of the system is the weighted progression of (200), built with the same provisions, numbers of a step and counterterms, with $\sum_a \lambda_a \mathbb{V}_a^\natural$ in the place of the bracketed action at the height 0 and with $\sum_a \lambda_a H_a^{(j)}$ in the place of the weight member in the slot of the height j; $E^{(j)} = E_0'^{(j)}$ is the progression without sources.

(4) The system is *admissible* if the following holds.

(Ad1) For every j and every $\lambda \in \Lambda_{j-1}^{\mathrm{w}}$ the family $E_\lambda'^{(j)}$ is a pointed family of level j at (α_0, α_1); each of its values is holomorphic in λ and in the fields; and $\|E_\lambda'^{(j)} - E_{\lambda'}'^{(j)}\|_{j,(1+4\beta_{\mathrm{s}})\kappa} \leq \sum_a |\lambda_a - \lambda_a'|\,\mathsf{d}_{j,a}$.

(Ad2) The member of $E_\lambda'^{(j)}$ at a region X does not depend on λ_a unless $\mathcal{P}(X)$ meets S_a.

(Ad3) The progression is given by the step map: $E_\lambda'^{(j+1)} = E^{(j+1)} + \mathsf{St}^{[j]}(x^{[j]}, \mathfrak{f}'_{\lambda,j}) - \mathsf{St}^{[j]}(x^{[j]}, \mathfrak{f}'_{0,j})$, where $\mathfrak{f}'_{\lambda,j}$ is the bare array of the families $E_\lambda'^{(i)}$, $i \le j$, with the counterterms of the regular progression and with the member $\sum_a \lambda_a H_a^{(j)}$ in its slot.

(Ad4) Along the history without large-field regions up to the level t, the term of $\rho_0 e^{F_\lambda}$ is $\mathsf{r}_t'^{\lambda} \cdot \mathsf{m}_t$, $\mathsf{r}_t'^{\lambda}$ the exponential of the relative exponent in equation YMM1:(2265) formed with F_λ and the $E_\lambda'^{(i)}$ in the places of $\mathcal{O}(w_\lambda)$ and the $E_\lambda^{(i)}$, as in Proposition YMM1:123.1.

(Ad5) The irrelevant part $\mathrm{Irr}_a^{(t)}$ of the first derivative (the definitions following equation YMM1:(2267), with $\dot E_a'^{(i)} = \partial_{\lambda_a} E_\lambda'^{(i)}|_{\lambda=0}$) obeys the bound of equation YMM1:(2264) formed at the weight $\mathsf{s}_a \mathbf{1}_{S_a}$.

The *constants of the progression at the level t* are $\mathsf{c}_a^{(t)} = \sum_{i\le t} \sum_{(X,z)\in\mathcal{Q}_i} \dot E_a'^{(i)}(X, \mathbf{1}, z)$, the sums over the regions and sites $\mathcal{Q}_i$ of the height i (the finite index sets defined in Section B.9).

(5) A *kernel under the majorant* (s, S) is a real symmetric function t on the pairs of plaquettes that vanishes unless both plaquettes belong to S, with $2\sum_{p'} |\mathsf{t}(p,p')| \le \mathsf{s}$ for every p. A real source $\mathfrak{s}$ under (s, S) together with a kernel t under (s, S) is a *quadratic source* if

(So3) at every height i, every real point $(v, \mathcal{A})$ of the chart of equations YMM1:(2285)–(2286) and all real numbers $r \ge \|v\|_{T_\ell}$, $a \ge \sup|\mathcal{A}|$ with $\mathsf{rt} = \min\{\varrho_{\mathrm{ch}}/r, \varrho_{\mathrm{fl}}/a\} \ge 2$, as in Lemma YMM1:124.4,

$$\Big| a_K F\big(e^{i\eta_i A^{\mathrm{lw}}(v,\mathcal{A})}\big) - \sum_{p,p'} \mathsf{t}(p,p') \langle \mathsf{ang}_p(v,\mathcal{A}), \mathsf{ang}_{p'}(v,\mathcal{A})\rangle \Big| \le \mathsf{M}_{\mathrm{pl}}^2\, \eta_i^4\, \mathsf{rt}^{-3}\, (\#S)\, \mathsf{s} \ :$$

the second order of the first member at a small point of the chart is the quadratic form of the kernel in the plaquette angles of Section YMM1:124.

■

Lemma 5.5. Let $g' \le \gamma_W^{\mathrm{ref}}$ be a reference coupling, $(K,\beta) \in \mathfrak{d}(g')$, and T_ℓ a torus of a side $\ell \in \mathfrak{L}(g')$. For a complex function w of the bonds, not identically zero, let $S[\mathsf{w}]$ be the set of the plaquettes that contain a bond b with $\mathsf{w}(b) \ne 0$.

(a) For all data (Wp1)–(Wp5) on T_ℓ with a last height $k \ge 1$, the data of the weighted progression with at least one level (Proposition YMM1:122.1, Proposition YMM1:123.1), the bond form $Y[\mathsf{w}]$ is the first member of a source $\mathfrak{s}[\mathsf{w}]$ under the majorant $(59|\mathsf{w}|_\infty, S[\mathsf{w}])$, complex linear in w and real if w is real; in particular $|Y[\mathsf{w}](U)| \le 2a_K^{-1}|\mathsf{w}|_\infty \sum_{p\in S[\mathsf{w}]} a_p(U)$ at every SU(2)-valued configuration U. For a complex weight w of the plaquettes, not identically zero, $\mathcal{O}(w)$ is the first member of a source under $(|w|_\infty, \mathrm{supp}\, w)$, with the bracketed action at the height 0 and the weight members in the slots. A source under a majorant (s, S) is one under every (s', S') with $\mathsf{s}' \ge \mathsf{s}$, $S' \supset S$; sums of sources, member by member, are sources under $(\mathsf{s}+\mathsf{s}', S\cup S')$, and, for $c \ne 0$, $c\,\mathfrak{s}$ is one under $(|c|\mathsf{s}, S)$. So $\mathcal{T}_K(H) = \mathcal{O}(w_H) + Y[\mathsf{w}_H]$ is the first member of a source under the majorant $(60|H|_\infty, S_H)$, $S_H = \mathrm{supp}\, w_H \cup S[\mathsf{w}_H]$, for every bounded $H : \mathbb{R}^3 \to V_{\mathbb{C}}$ with $S_H \ne \varnothing$.

(b) In the setting of one lattice of Definition B.16, which the construction on T_ℓ along the run of (K,β) satisfies (Proposition B.21, Lemma YMM1:126.2), every system of sources under majorants (Definition 5.4 (3)), of any number and with complex first members, is admissible (Definition 5.4 (4)). So every finite tuple of forms $Y[\mathsf{w}_a]$, $\mathcal{O}(w_a)$, $\mathcal{T}_K(H_a)$, and of sums and multiples of them, is the tuple of the first members of an admissible system of sources under the majorants of (a).

(c) Let w be real. For a bond b of the direction μ and a direction $\lambda \ne \mu$, the linear part of $\mathbf{u}_{b,\lambda}$ in the angles Φ_p of the plaquettes, Φ a function of the plaquettes with values in the hermitian traceless 2×2 matrices, is $\mathsf{u}_{b,\lambda}(\Phi) = \sum_p c_{b,\lambda}(p)\Phi_p$, with $c_{b,\lambda}(p) = \pm\frac{1}{2}$ at the two plaquettes of the plane of e_μ, e_λ that contain b, the signs being those of their orientations,

and $c_{b,\lambda}(p)=0$ at the other plaquettes. Put

$$\mathsf{t}[\mathsf{w}](p,p')=-\tfrac12\sum_b \mathsf{w}(b)\,[c_{b,\lambda_b}(p)\,c_{b,\lambda'_b}(p')+c_{b,\lambda_b}(p')\,c_{b,\lambda'_b}(p)],$$

so that $\sum_{p,p'}\mathsf{t}[\mathsf{w}](p,p')\langle\Phi_p,\Phi_{p'}\rangle=-\sum_b\mathsf{w}(b)\langle\mathsf{u}_{b,\lambda_b}(\Phi),\mathsf{u}_{b,\lambda'_b}(\Phi)\rangle$. Then $\mathsf{t}[\mathsf{w}]$ is real, symmetric and carried by $S[\mathsf{w}]$, $|\mathsf{t}[\mathsf{w}](p,p')|\le\frac18|\mathsf{w}|_\infty$, $2\sum_{p'}|\mathsf{t}[\mathsf{w}](p,p')|\le 2|\mathsf{w}|_\infty$ and $\sum_{p,p'}|\mathsf{t}[\mathsf{w}](p,p')|\le\sum_b|\mathsf{w}(b)|$; and, for the standing data of Definition B.16 and the actual step setting of Section YMM1:124, $\mathfrak{s}[\mathsf{w}]$ with the kernel $\mathsf{t}[\mathsf{w}]$ is a quadratic source under $(59|\mathsf{w}|_\infty,S[\mathsf{w}])$. For a real weight w of the plaquettes the source of $\mathcal{O}(w)$ is quadratic under $(|w|_\infty,\operatorname{supp}w)$ with the kernel $\frac12 w(p)\delta_{pp'}$. Sums and real multiples of quadratic sources are quadratic sources; so for a real H the source of $\mathcal{T}_K(H)$ is quadratic under $(60|H|_\infty,S_H)$ with the kernel $\mathsf{t}_H(p,p')=\mathsf{t}[\mathsf{w}_H](p,p')+\frac12 w_H(p)\delta_{pp'}$, and $2\sum_{p'}|\mathsf{t}_H(p,p')|\le 3|H|_\infty$.

■

Proof. (a) *(So0).* At SU(2)-valued fields $|w(W)|^2=2a_p-a_p^2\le 2a_p$ for the loop W of a plaquette p, so $|\mathbf{u}_{b,\lambda}|^2\le a_p+a_{p'}$ for the two plaquettes p,p' of the plane of e_{μ_b},e_λ at b, and q_b is real with $|q_b|\le\frac12(|\mathbf{u}_{b,\lambda_b}|^2+|\mathbf{u}_{b,\lambda'_b}|^2)\le\frac12\sum_{p\ni b}a_p$. Summing over the four bonds of each plaquette, $|Y[\mathsf{w}](U)|\le a_K^{-1}\sum_p a_p(U)\,\frac12\sum_{b\subset\partial p}|\mathsf{w}(b)|\le 2a_K^{-1}|\mathsf{w}|_\infty\sum_{p\in S[\mathsf{w}]}a_p(U)$, and $2\le 59$; $Y[\mathsf{w}]$ is a gauge invariant polynomial in the entries of the bond variables. *(So1).* For a bond b let $X_0(b)$ be the union of the cubes of the partition of the height 0 that hold a corner of one of the four plaquettes at b: at most six cubes with a common corner, a region of the height 0 whose set $\mathcal{P}(X_0(b))$ holds these four plaquettes; one region is $X_0(b)$ for at most $18M^3$ bonds.

The family at the height 0 is the variation of the bond form along the fluctuation of the first step, $\mathbb{V}^\natural(Y;(P,B))=-a_K^{-1}\sum_{b:X_0(b)=Y}\mathsf{w}(b)\,[q_b(e^{iB'}\mathbf{U})-q_b(\mathbf{U})]$, formed at a triple P of the core and a scaled fluctuation B with the configuration $\mathbf{U}$ and the 1-form B' with which the bracketed action of a weight of the plaquettes is formed in the height-zero proof of Proposition YMM1:122.1; it is holomorphic, gauge covariant and vanishes at $B=0$ as that action does, q_b being a gauge invariant polynomial in the variables of the four plaquettes at b. At the triples of the core, with $\rho\le 2C_P\mathsf{C}_{\mathcal{A}}\mathsf{s}^{[0]}\alpha_0\le\frac{1}{128}$ the size of B' and $\zeta_0=\alpha_0L^{-2}$ that of the plaquette variables of the triple, the variation of q_b is at most $784\rho^2+132\rho\zeta_0\le 3138\,C_P^2\mathsf{C}_{\mathcal{A}}^2\mathsf{s}^{[0]}\alpha_0^2$, with $\mathsf{s}^{[0]}\le 1$ of (196) and the numbers C_P, $\mathsf{C}_{\mathcal{A}}$ of $\mathsf{c}^\flat$; so the size of $\mathbb{V}^\natural$ is at most $18\cdot 3138\,M^3C_P^2\mathsf{C}_{\mathcal{A}}^2\alpha_0^2a_K^{-1}|\mathsf{w}|_\infty/K_\Lambda$, while (So1) allows $\mathsf{c}^\flat\mathsf{m}_0=81\cdot 12\,M^3C_P^2\mathsf{C}_{\mathcal{A}}^2\alpha_0^2a_K^{-1}\mathsf{s}/K_\Lambda$ at a majorant (s,S).

As $18\cdot 3138=56484<57348=81\cdot 12\cdot 59$, the majorant $(59|\mathsf{w}|_\infty,S[\mathsf{w}])$ serves: whence the number 59. Each bond occurs at the one region $X_0(b)$, so the members of $\mathbb{V}^\natural$ at the restrictions of (P_W,gB) add up to the variation $Y[\mathsf{w}](U_0(V_W(B)))-Y[\mathsf{w}](U_1(W))$, q_b being constant on the gauge orbits: this is the sum rule (355). *(So2).* With $X_j(b)$ formed alike from the cubes of the partition of the height j, the slot member is $H^{(j)}(X,P)=-a_K^{-1}\sum_{b:X_j(b)=X}\mathsf{w}(b)\,q_b(\mathbf{U})$. At the triples of the core the bond variables have norm at most $e^{\eta_j\alpha_1}$ and the plaquette variables lie within $\alpha_0\eta_j^2$ of $\mathbf{1}$, so that $|q_b|\le 4e^{4\eta_j\alpha_1}\alpha_0^2\eta_j^4$ there; with at most $18M^3\eta_j^{-3}$ bonds at one region, the size of $H^{(j)}$ at the radii (α_0,α_1) is at most $72e^{4/13}M^3\alpha_0^2L^{K-j}|\mathsf{w}|_\infty<98M^3\alpha_0^2L^{K-j}|\mathsf{w}|_\infty$, while $\frac12\mathsf{m}_j=354M^3\alpha_0^2L^{K-j}|\mathsf{w}|_\infty$ at $\mathsf{s}=59|\mathsf{w}|_\infty$; its sum is $Y[\mathsf{w}]$, as $q_b(\mathbf{1})=0$.

For $\mathcal{O}(w)$ the three members are those of (200), with the properties of the height-zero part of Proposition B.8. A larger majorant loosens each of (So0)–(So2), the numbers m_j growing with s. Sums and multiples: (So0)–(So2) are linear conditions with subadditive sizes, $\mathsf{s}\mathbf{1}_S+\mathsf{s}'\mathbf{1}_{S'}\le(\mathsf{s}+\mathsf{s}')\mathbf{1}_{S\cup S'}$, and $|w_H|_\infty+59|\mathsf{w}_H|_\infty\le 60|H|_\infty$.

(b) The proofs of Proposition YMM1:122.1 (with the height-zero part of Proposition B.8), of Proposition YMM1:123.1 and of the first-derivative bounds in equations YMM1:(2264) and YMM1:(2268) read a source only through (So0)–(So2) and through numbers formed at its weight: at the height 0 through the family in the fourth place, its size, its locality and its sum rule; at the heights

$j \geq 1$ through the member in the slot of the bare array, its size, its locality and its action; and through the domination (So0), which bounds the source at the backgrounds of small fields as the action density of its weight is bounded there. The statements that these proofs cite besides are worded for every family in the fourth place, every bare array of the domain of the step map (equations YMM1:(2251)–(2252)), every bare array of $\mathsf{Arr}^{[j]}$ (Lemma B.19) and every bounded complex Borel function. Read with a system of sources in the place of the weights, these proofs give the progression of the system on the parameter sets Λ_j^{w} with (Ad1) and (Ad3), the locality (Ad2) from that of the members, (Ad4) from the first step and from one exact step at each height (Lemma B.19), and (Ad5) as in equation YMM1:(2264). None of these readings depends on the number of the sources or on their reality.

(c) *The coefficients.* For $b = \langle x, x + a_K e_\mu\rangle$, $\mathbf{u}_{b,\lambda} = -\frac{1}{2}[w(W_x(\mu,\lambda)) - w(W_x(\mu,-\lambda))]$, and to the first order $w(W_x(\mu,\pm\lambda))$ is the angle of the plaquette of the loop with the sign of its orientation; this gives $c_{b,\lambda}$. *The kernel.* Two different plaquettes have at most one bond in common; so $\mathsf{t}[\mathsf{w}](p,p') \neq 0$ only if p and p' contain one bond b with $\mathsf{w}(b) \neq 0$ and lie in the two different planes through b, and then just one of the two products in the bracket is not zero: $|\mathsf{t}[\mathsf{w}](p,p')| = \frac{1}{8}|\mathsf{w}(b)|$. A plaquette has four bonds, at each of them two partners: $2\sum_{p'} |\mathsf{t}[\mathsf{w}](p,p')| \leq 2 \cdot 8 \cdot \frac{1}{8}|\mathsf{w}|_\infty = 2|\mathsf{w}|_\infty \leq 59|\mathsf{w}|_\infty$; a bond gives eight ordered pairs: $\sum_{p,p'} |\mathsf{t}[\mathsf{w}](p,p')| \leq \sum_b |\mathsf{w}(b)|$.

(So3). $a_K Y[\mathsf{w}] = -\sum_b \mathsf{w}(b) q_b$. At a small real point of the chart the vector parts of the plaquette loops at b are, up to terms of the third order, the plaquette angles with the signs of the orientations, as for a_p in Lemma YMM1:124.4; this gives $|q_b(e^{i\eta_i A^{\mathrm{lw}}(v,\mathcal{A})}) - \langle \mathsf{u}_{b,\lambda_b}(\mathsf{ang}), \mathsf{u}_{b,\lambda_b'}(\mathsf{ang})\rangle| \leq 12\,\mathsf{M}_{\mathrm{pl}}^2 \eta_i^4 \mathsf{rt}^{-3}$, $\mathsf{ang} = \mathsf{ang}(v,\mathcal{A})$. Times $|\mathsf{w}(b)|$ and summed: as every bond lies in four plaquettes and every plaquette has four bonds, at most $\#S[\mathsf{w}]$ bonds carry w, and the remainder is at most $\mathsf{M}_{\mathrm{pl}}^2 \eta_i^4 \mathsf{rt}^{-3} (\#S[\mathsf{w}])\, 12|\mathsf{w}|_\infty$, with $12 \leq 59$.

For $\mathcal{O}(w)$, (So3) is the first inequality of Lemma YMM1:124.4, times $|w(p)|$, summed over the support. Sums and real multiples: the conditions on kernels are linear with subadditive bounds, and $(\#S)\mathsf{s} + (\#S')\mathsf{s}' \leq \#(S \cup S')(\mathsf{s} + \mathsf{s}')$; finally $2\sum_{p'} |\mathsf{t}_H(p,p')| \leq |H|_\infty + 2|H|_\infty$. □

Lemma 5.6. Let g' and (K,β) be as in Lemma 5.5, with $K \geq 3$, let T_ℓ be a torus whose side is small over the run of (K,β), and let s be a depth with $1 \leq s \leq K-2$; $\mathsf{k} = K - s \in [2, K-1]$ is the working level. Let $F_1, \dots, F_n$, $1 \leq n \leq \ell^3$, be the first members of an admissible system of sources under majorants (s_a, S_a) (Definition 5.4) such that the corners of the plaquettes of each S_a lie in the interior of one unit cell of a board of T_ℓ of side 1, and, if $n \geq 2$, any two of the sets S_a are at least $M\, u_*(n)$ units of the level k apart, where

$$u_*(m) = \max\Big\{4,\ \frac{2}{A_\flat}\big(m\,[c_2 + \log(4m)] + 3\log L + \log 3\big)\Big\} \qquad (m \geq 1),$$

with numbers $A_\flat \in (0,1]$ and c_2 of the constants, an increasing function of the order $m \log m$. Then, with the constants $c_a = \mathsf{c}_a^{(\mathsf{k})}$ of the progression at the level k (Definition 5.4 (4)), for every non-empty $B \subset \{1, \dots, n\}$

$$\Big|\Big\langle \prod_{a\in B} (F_a - c_a)\Big\rangle_{K,\ell,\beta}\Big| \leq \prod_{a\in B} 2n\, \mathsf{C}_1 L^{4s}\, \mathsf{s}_a,$$

C_1 a number of the constants that depends on none of g', K, β, ℓ, n, s and the sources. ■

Proof. Let $r = \#B$. The mean of the product $G_B = \prod_{a\in B}(F_a - c_a)$ is a sum over the level t of the first creation of a large field (equation (314)): $|\langle G_B\rangle| \leq \mathsf{q}_\mathsf{k} + \sum_{1\leq t\leq \mathsf{k}} \mathsf{q}_{t-1}\mathsf{w}_t$, where $\mathsf{q}_0 \geq \sup|G_B|$, q_t bounds the density of G_B at the level t along the histories without large fields, and w_t is the weight of a first creation at t. Along the histories without large fields the density is $\sum_\pi \prod_{\beta\in\pi} \mathsf{D}_t^\beta$ over the partitions π of B, by (Ad4) and the formula $\partial_B e^\Psi = e^\Psi \sum_\pi \prod_{\beta\in\pi} \partial_\beta \Psi$: the blocks of one element are the conditional means $\mathsf{c}_a^{(t)} - c_a + F_a(U_t) + \mathrm{Irr}_a^{(t)}$ of the progression, and those of several

elements are the sums over the regions and sites of the heights $i \le t$ of the mixed derivative families $\partial_\beta E'^{(i)}_\lambda|_{\lambda=0}$, which live on polymers joining the supports.

For these, put $c_\theta = \theta^{[j]} N_\star^{[j]}$, a number free of j, and $\hat g_{0,a} = \mathsf{c}^\flat \mathsf{m}_{0,a}/N_\star^{[0]}$, $\hat g_{j,a} = \mathsf{n}_{j,a}/N_\star^{[j]}$ for $j \ge 1$: the size of the source a in the array of the height j over the room $N_\star^{[j]}$ of the domain of the step map ((196)). The chain rule of all orders for the step map (equations YMM1:(2251)–(2252) give it for two variables; its proof, which reads the holomorphy and the Lipschitz bound of the step map on its domain, gives it for any number of variables), with Cauchy's estimate on the polydiscs of the radii $1/(4r\hat g_{j,a})$ in the variables λ_a, bounds the size of the mixed derivative family of a set β of $r \ge 2$ sources at the height j by $c_\theta (4r)^r \prod_{a\in\beta} \hat g_{j-1,a}$, times $e^{-4\beta_{\mathrm{s}}\kappa[\mathsf{D}_j/M-2]_+}$ in the distance D_j of the supports in units of the level j; these are exponentially small in the distance, and the separation $M\, u_*(n)$ makes them pay the combinatorial factors.

The sizes are $\sup|G_B| \le \prod \mathsf{C}_1 L^{4K} \mathsf{s}_a$ and, at the level t, $\mathrm{Bl}(r) \prod \mathsf{C}_1 L^{4(K-t)} \mathsf{s}_a$, $\mathrm{Bl}(r) \le r^r$ the number of partitions; for the blocks of several elements this uses $L^{\frac52(K-t)+1} \le L^{4(K-t)}$, that is $K - t \ge K - \mathsf{k} = s \ge 1$. On a small side the rarity of large fields (Lemma YMM1:125.3) gives $\sum_t L^{4(K-t+1)r} \mathsf{w}_t \le 1$ for every $r \le \ell^3$: the large fields pay for as many sources as the side has unit cells. □

For $0 < \mathsf{d} < 1$ and a reference coupling g' the *depth fitted to* d is the witness depth $s(\mathsf{d})$ of equation YMM1:(2321), the least integer $s \ge 0$ with $L^s \mathsf{d} \ge C_W(s)$, where $C_W(s) = \mathsf{c}_W Y_s^{2\mathfrak{p}_0}$, $Y_s = \log \bar x_s$, $\bar x_s = L^{s+1}(g'^{-2} + \bar B)$ and $\mathsf{c}_W = C_{W,0} A_0^2$, formed with the value $C_{W,0} = \max\{1, 4L^2 M/A_0^2\}$ of the room constant of equation YMM1:(2320), which serves throughout the section, so that $\mathsf{c}_W \ge 4L^2 M$; then $L^{s(\mathsf{d})}\mathsf{d} < L C_W(s(\mathsf{d}))$ by the minimality argument following equation YMM1:(2321). The next lemma bounds moments of eight sources at their natural size; unlike Lemma 5.6, it measures the sizes at the working level $\mathsf{k} = \max\{K - s, 2\}$ of equation YMM1:(2322), and not by a factor $L^{4(K-t)}$ per source and level.

Lemma 5.7. Let $0 < g' \le \gamma_W^{\mathrm{sd}}$, $(K, \beta) \in \mathfrak{d}(g')$, $b = a_K \beta$, T_ℓ the least torus at g', and $0 < \mathsf{d}' < 1$ with $s = s(\mathsf{d}') \le K$, the depth fitted to d' at g', and so small that $2Y_s^{2\mathfrak{p}_0} \ge u_*(8)$. Let $\mathsf{k} = \max\{K - s, 2\}$ be the working level and $s_{\mathsf{k}} = K - \mathsf{k} = \min\{s, K-2\}$ its depth (equation YMM1:(2322)), so that $s \ge 3$, $2 \le \mathsf{k} \le K - 1$ and $s - 2 \le s_{\mathsf{k}} \le s$ (Lemma YMM1:126.1), and put

$$\upsilon = \frac{L^{s_{\mathsf{k}}}}{x_{\mathsf{k}}(\beta)} = \big(a_{s_{\mathsf{k}}} x_{\mathsf{k}}(\beta)\big)^{-1},$$

the step coupling $\upsilon_{\mathsf{k}+1}$ of equation YMM1:(2299) (Lemma YMM1:126.1, equation YMM1:(2324)): the inverse of the coupling of the run at the working level, read in the units of that level. Let $F_1, \dots, F_8$ be the first members of an admissible system of sources under majorants (s_a, S_a) such that the barycentres of the plaquettes of each S_a lie in a ball of radius $\frac78 \mathsf{d}'$ and barycentres of plaquettes of two different sets S_a are at least $\frac54 \mathsf{d}'$ apart. Then, with the constants $c_a = \mathsf{c}_a^{(\mathsf{k})}$ of the progression at the level k, for every non-empty $B \subset \{1, \dots, 8\}$

$$\Big|\Big\langle \prod_{a\in B} (F_a - c_a) \Big\rangle_{K,\ell,\beta}\Big| \le \prod_{a\in B} \mathsf{A}_8(s)\, \upsilon\, \mathsf{s}_a, \qquad \mathsf{A}_n(s) = 2^{2\mathfrak{p}_0+1} n \max\{\mathsf{C}^{\mathrm{I}}, C_2 n^{3+\mathfrak{p}_0}\} \big(L C_W(s)\big)^3 \bar x_s Y_s^{2\mathfrak{p}_0},$$

where C^{I}, C_2 are numbers of the constants; υ is the natural size of a source of unit majorant at the working level, and

$$|b\,\upsilon - 1| \le \bar B g'^2 L^{2-s} \le \tfrac{1}{24}, \qquad \upsilon^2 \le \tfrac98 b^{-2}, \qquad |b^2\upsilon^2 - 1| \le 3\bar B g'^2 L^{2-s}.$$

In particular $\mathsf{A}_8(s(\mathsf{d}')) \le C \mathsf{d}'^{-1} \mathsf{Y}(\mathsf{d}')^{10\mathfrak{p}_0}$, with a number C of the constants and g' and a function Y that is affine in $\log \frac{1}{\mathsf{d}'}$. ■

Proof. As in the proof of Lemma 5.6, the mean of $G_B = \prod_{a\in B}(F_a - c_a)$ is a sum over the level t of the first creation of a large field (equation (314)), and along the histories without large fields

the density at the level t is a sum over the partitions of B, the blocks of one element being the conditional means of the progression and those of several elements the terms of its exponent on polymers joining the supports. *The distance.* Two corners of plaquettes of different sets S_a are at a sup distance $\ge \frac{5}{4\sqrt3}\mathsf{d}' - a_K$, so at least $\mathsf{D}_\mathsf{k} \ge \frac{5}{4\sqrt3}\hat{\mathsf{d}}'_\mathsf{k} - 1$ units of the level k, $\hat{\mathsf{d}}'_\mathsf{k} = L^{s_\mathsf{k}}\mathsf{d}'$.

By Lemma YMM1:126.1, equation YMM1:(2323), which reads the property $\mathsf{c}_W \ge 4L^2M$ of the room constant, $4MY_s^{2\mathfrak{p}_0} \le L^{-2}C_W(s) \le \hat{\mathsf{d}}'_\mathsf{k} < LC_W(s)$; so $\mathsf{D}_\mathsf{k} \ge 2.88\,MY_s^{2\mathfrak{p}_0} - 1 \ge 2MY_s^{2\mathfrak{p}_0} \ge M\,u_*(8)$, and at a level $j < \mathsf{k}$ the distance is $L^{\mathsf{k}-j}$ times larger: the terms on polymers joining the supports pay the combinatorial factors. *The sizes.* A source is now bounded by its natural size: at the working level it is a form in the field strength over a ball of the radius $\frac78\hat{\mathsf{d}}'_\mathsf{k} < LC_W(s)$ units of the level, at the coupling $x_\mathsf{k}(\beta) \le \bar{x}_s$ of the run (Lemma YMM1:126.1, equation YMM1:(2324)), so that each block is bounded at that level by a power of $\max\{\mathsf{C}^\mathrm{I}, C_2n^{3+\mathfrak{p}_0}\}(LC_W(s))^3\bar{x}_sY_s^{2\mathfrak{p}_0}$ times $\prod \upsilon\mathsf{s}_a$, and at a level $t < \mathsf{k}$ by $L^{4(\mathsf{k}-t)}(\mathsf{k}-t+2)^{2\mathfrak{p}_0}$ times more.

On the least side, which is small over the run (Lemma YMM1:126.3), the rarity of large fields (Lemma YMM1:125.3) pays these factors, and the sum over t gives $\mathsf{A}_8(s)$. *The number* υ. By the flow bound of Subsection 5.1, $|x_\mathsf{k}(\beta) - L^{-\mathsf{k}}\beta| \le \bar{B}$; multiplied by a_{s_k}, as $a_{s_\mathsf{k}}L^{-\mathsf{k}}\beta = a_K\beta = b$, this is $|\upsilon^{-1} - b| \le \bar{B}a_{s_\mathsf{k}} \le \bar{B}L^{2-s}$; and $x_\mathsf{k}(\beta) > L^{s_\mathsf{k}}g'^{-2}$ gives $\upsilon < g'^2$ (Lemma YMM1:126.1, equation YMM1:(2324)). So $|b\upsilon - 1| \le \bar{B}g'^2L^{2-s} \le \frac{13}{24L} \le \frac{1}{24}$, as $\bar{B}g'^2 \le \frac{13}{24}$ and $s \ge 3$; hence $(b\upsilon)^2 \le (\frac{25}{24})^2 \le \frac98$ and $|(b\upsilon)^2 - 1| \le 3\bar{B}g'^2L^{2-s}$.

For the last assertion: $L^s\mathsf{d}' < LC_W(s)$ gives $\bar{x}_s < L^2\mathsf{c}_WY_s^{2\mathfrak{p}_0}(g'^{-2} + \bar{B})/\mathsf{d}'$, and so $Y_s < \log(L^2\mathsf{c}_W/\mathsf{d}') + 2\mathfrak{p}_0\log Y_s + \log(g'^{-2} + \bar{B})$; with $2\mathfrak{p}_0\log Y_s \le \frac12 Y_s + 2\mathfrak{p}_0\log(4\mathfrak{p}_0)$ this bounds Y_s by a function $\mathsf{Y}(\mathsf{d}')$ affine in $\log\frac{1}{\mathsf{d}'}$, and $\mathsf{A}_8(s)$ is at most a number times $Y_s^{6\mathfrak{p}_0}\bar{x}_sY_s^{2\mathfrak{p}_0} \le C\mathsf{d}'^{-1}\mathsf{Y}(\mathsf{d}')^{10\mathfrak{p}_0}$. □

Proposition 5.8. Let $0 < g \le \gamma_W^{\mathrm{sd}}$ and $0 < \delta \le \frac14$. Put $\bar{x}_0 = L(g^{-2} + \bar{B})$, $c_E = \log(2\bar{x}_0)$, $\mathsf{Y}_i = 2[c_E + \log\frac{1}{a_i}]$, $q_E = 15r + 4$, r the exponent of the cube-size function R of Section YMM1:74, $R(x)$ being the least power L^j, $j \ge 0$, with $L^j \ge (\log x)^r$, $c_N = \max\{1, 8L^6M^3C_\mathrm{s}^3 2^{-3r}\}$, $\bar{N}_i = c_N\mathsf{Y}_i^{3r}$, s_i the least s with $\delta L^s \ge M\,u_*(\lceil\bar{N}_i\rceil)$, $K_E(i) = i + s_i + 2$, and $C_E = 480\,e^{G_g+1/8}c_N\mathsf{C}_1(LMc_u/\delta)^4\bar{x}_0$ with C_s the number of Section YMM1:74, C_1 that of Lemma 5.6, and a number c_u of the constants with $u_*(\lceil\bar{N}_i\rceil) \le c_u\mathsf{Y}_i^{3r+1}$. For every integer $i \ge 1$, every $(K,\beta) \in \mathfrak{d}(g)$ with $K \ge K_E(i)$, every board of $\mathbb{L}_K$ with cells of side a_i, every cell $\square$, every side $\ell \in \mathfrak{L}(g)$, every bounded $H : \mathbb{R}^3 \to V_\mathbb{C}$ that vanishes at the points at sup distance $< \delta a_i$ from the complement of $\square$, and for c the mean of $\mathcal{T}_K(H)$ in a $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ or on a torus T_{ℓ_1}, $\ell_1 \in \mathfrak{L}(g)$,

$$\|\mathcal{T}_K(H) - c\|_{\mathrm{ch},\ell} \le \mathsf{c}_E(i)\,b^{-1}|H|_\infty, \qquad \mathsf{c}_E(i) = 2C_E\,\mathsf{Y}_i^{q_E}a_i^{-11/2}. \tag{9}$$

In particular $\mathsf{c}_E(i) \le C_\flat a_i^{-6}$ with $C_\flat = 2C_E\sup_i \mathsf{Y}_i^{q_E}L^{-i/2} < \infty$. ■

Proof. Pieces. It suffices to treat four pieces of H: the real and the imaginary parts of the diagonal entries, which enter through $\mathcal{O}$, and of the off-diagonal ones, which enter through Y. *Dilation.* The dilation $x \mapsto L^ix$ carries $\mathbb{L}_K$ onto $\mathbb{L}_{K'}$, $K' = K - i$, the board onto a board with cells of side 1, the Wilson measures at (K,β) onto those at (K',β), the seminorms at the side ℓ onto those at the side $L^i\ell$, and $\mathcal{T}_K(H)$ onto $L^i\mathcal{T}_{K'}(H(L^{-i}\cdot))$. *The stopped datum.* (K',β) is a first-passage datum at the stopped coupling $g_{(i)} < g$, with label L^ib; its least side ℓ'' is small over the run, $L^i\ell \in \mathfrak{L}(g_{(i)})$, and $N = \ell''^3 \le c_N\mathsf{Y}_i^{3r}$. *The copies.* On $T_{\ell''}$ the N mirror copies of a piece are the first members of an admissible system of N sources (Lemma 5.5 (a), (b)), each carried by a whole unit cell with margin δ; two points in different cells, each at distance $\ge \delta$ from the walls, are $\ge 2\delta$ apart, so the corners of the plaquettes of different copies are $\ge 2(\delta - 2a_{K'}) \ge \delta$ apart, that is $\ge \delta L^s \ge M\,u_*(N)$ in units of the level $K' - s$, $s = s_i$; here $1 \le s \le K' - 2$, as $\delta < 4 \le Mu_*(\lceil\bar{N}_i\rceil)$ and $K \ge K_E(i)$. By Lemma 5.6, $|\langle\prod_{a\in B}(F_a - c_a)\rangle_{K',\ell'',\beta}| \le (2N\mathsf{C}_1L^{4s}\mathsf{s})^{\#B}$ for every set B of copies, s the weight of the piece. With m the common mean of the copies, $\prod_\kappa(F_\kappa - m) = \sum_B\prod_{\kappa\in B}(F_\kappa - c_\kappa)\prod_{\kappa\notin B}(c_\kappa - m)$ and $|c_\kappa - m| \le 2N\mathsf{C}_1L^{4s}\mathsf{s}$; so the seminorm on $T_{\ell''}$ of a piece less its mean is $\le 4N\mathsf{C}_1L^{4s}\mathsf{s}$. *The*

pressure gap. Lemma 5.3 (b) at $g_{(i)}$, with the bound (289), $C_{g_{(i)}} \le C_g + \frac{9}{2} i \log L + \frac{1}{8}$, carries the seminorm of a function of one unit cell from $T_{\ell''}$ to any side $L^i\ell$ at the price $e^{G_g+1/8} L^{9i/2}$. *Collecting.* The dilation contributes L^i and the pressure gap $L^{9i/2}$, together $a_i^{-11/2}$; N and L^{4s_i} are powers of Y_i. So, with $m' = L^i m$, m the common mean of the copies of the dilated piece on $T_{\ell''}$, $\|F - m'\|_{\mathrm{ch},\ell}$ is bounded, for a piece F and every side $\ell \in \mathfrak{L}(g)$, by the product of these factors, a bound uniform in the side. The change of the centring to the mean c of the piece in ν or on T_{ℓ_1} costs a factor 2, the means of the four pieces adding up to that of $\mathcal{T}_K(H)$: by the domination in (Per) at the one cell, along the sides $\ell_j \to \infty$ of $\mathfrak{L}(g)$, $|\nu(F) - m'| \le \liminf_j \|F - m'\|_{\mathrm{ch},\ell_j}$, and by the chessboard estimate on T_{ℓ_1}, $|\langle F\rangle_{K,\ell_1,\beta} - m'| \le \|F - m'\|_{\mathrm{ch},\ell_1}$ (Corollary B.1 (c)); both are at most the bound just obtained, and, the seminorm of a constant being its modulus, $\|F - c\|_{\mathrm{ch},\ell} \le \|F - m'\|_{\mathrm{ch},\ell} + |m' - c|$ is at most twice that bound. Each member stands once, in a cell of its own: no tensor source is put into an exponent. The power $\frac{11}{2} = 1 + \frac{9}{2}$ comes from the dilation and from the gap of the pressures; the natural power is 0. □

Remark 5.9. The stability clause of Theorems YMM1:AJ and YMM1:AD bounds the sourced expectation after removing a holomorphic normalising factor, the sourced vacuum constant. It does not provide a cutoff-uniform bound for the raw centred exponential. The free-photon analogue illustrates the distinction: on the orthogonal complement of the kernel of d, a constant diagonal source $H = c\mathbf{1}$, $0 < c < b$, has centred logarithmic generating function $3(N^3 - 1)[-\log(1 - c/b) - c/b]$, $N = \ell/a_K$. This grows like N^3 for fixed c/b.

Proposition 5.10. Let $0 < g \le \gamma_W^{\mathrm{sd}}$.

(a) *(The uniform bound.)* For $n \ge 1$ and $\mathsf{d}, R > 0$ let i be the least integer ≥ 1 with $2a_i \le \mathsf{d}$, K^G the least integer $\ge K_E(i)$ with $L^{K^G - i} \ge 8n$, and $C_n^G(\mathsf{d}; R) = [(16nR/a_i + 3)^3 \mathsf{c}_E(i)]^n$, both at $\delta = \frac{1}{8n}$. For all $(K, \beta) \in \mathfrak{d}(g)$ with $K \ge K^G$, all $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ and all X of type $(\mathsf{d}; R)$ with n members, $|\nu(A^\nu_K(X))| \le C_n^G(\mathsf{d}; R)\, b^{-n} \prod_a |H_a|_\infty$; the same holds with every member centred at its mean on a torus of a side in $\mathfrak{L}(g)$. The number $C_n^G(\mathsf{d}; R)$ depends on none of the cutoff, the datum, the side, the state and the positions; for small d it is a power of $1/\mathsf{d}$ up to logarithms.

(b) Every sequence $(K_j, \beta_j) \in \mathfrak{d}(g)$, $K_j \to \infty$, $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$, has a subsequence along which $a_{K_j}\beta_j$ converges and a tensor limit exists.

(c) Every tensor limit σ at g is labelled data, with $C_n(\mathsf{d}; R) = C_n^G(\mathsf{d}; R) b_*^{-n}$. *(Continuity in the members.)* If $X_j \to X$ member by member in the sup norm, with supports in one compact set and at mutual distances $\ge \mathsf{d} > 0$, then $\rho_j(A^{\rho_j}_{K_j}(X_j)) \to \sigma(X)$. The scalar part σ_0, taken at members $f\mathbf{1}$, $f \in C_c^1$, is the centred limit functional of the action density along (K_j, β_j, ρ_j) of Theorem YMM1:AN, invariant under $\mathbb{R}^3 \rtimes \mathrm{O}(3)$.

(d) *(Slab operators.)* σ has the property (S). For $i \ge 1$, $z_3 = \frac{1}{2}a_i$, $h \in C_c(\{|x - z|_\infty \le \frac{3}{8}a_i\}; V_{\mathbb{C}})$ and $F, F' \in \mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$,

$$|\sigma(\theta \bar{F}' \cdot (h) \cdot \tau_{a_i e_3} F)| \le \mathsf{c}_E(i)\, b_*^{-1} |h|_\infty \|[F']\|\, \|[F]\|, \tag{10}$$

with $\mathsf{c}_E(i)$ at $\delta = \frac{1}{16}$; with members $h_1, \dots, h_m$ in the place of h, in the cubes $o + a_i\mathbf{k}_a + [-\frac{3}{8}a_i, \frac{3}{8}a_i]^3$, $o = (t_1, t_2, \frac{1}{2}a_i)$, $\mathbf{k}_a \in \mathbb{Z}^3$ pairwise different with third entries 0, the right side becomes $\prod_a \mathsf{c}_E(i) b_*^{-1} |h_a|_\infty \|[F']\| \|[F]\|$. If $\operatorname{supp} h$ lies in a ball of radius R and a_i, $i \ge 1$ least, is at most the distance of $\operatorname{supp} h$ from the planes $x_3 = 0$ and $x_3 = l$, then $\|\mathsf{B}_l(h)\| \le ((16/3)R/a_i + 3)^3 \mathsf{c}_E(i) b_*^{-1} |h|_\infty$. Further $e^{-tH} \mathsf{B}_l(h) e^{-t'H} = \mathsf{B}_{l+t+t'}(\tau_{te_3} h)$, $e^{iv\cdot P} \mathsf{B}_l(h) e^{-iv\cdot P} = \mathsf{B}_l(\tau_{(v,0)} h)$, $\mathsf{B}_l(h)^* = \mathsf{B}_l(h^\star)$ with $h^\star(x) = \rho(\theta)\overline{h(x_1, x_2, l - x_3)}$, the products $\mathsf{B}_{l_1}(h_1) \cdots \mathsf{B}_{l_n}(h_n)\Omega$ are the classes of the tuples whose members lie in pairwise disjoint slabs, the eight elements of W_3 that fix e_3 act by unitary operators $[F] \mapsto [\mathsf{R}F]$ commuting with H, and the closed span $\mathcal{H}_0$ of the classes of the scalar tuples is $\mathcal{H}(\sigma_0)$ and reduces H, P and $\mathcal{P}$.

(e) *(The insertion bound with a power, in all six directions.)* Put $\mathsf{a}=\frac{1}{4L}$, $c_{\mathrm{I}}=\frac{3}{8}\mathsf{a}$. For $\eta\in(0,1]$, $h\in C_c(\mathbb{R}^3;V_{\mathbb{C}})$ in a closed ball $\bar B(y,c_{\mathrm{I}}\eta)$ with $|y_3|\le\frac{\eta}{8}$, and $F,G\in\mathbb{C}\mathfrak{S}_V(\{x_3>\frac{\eta}{4}\})$,

$$|\sigma(\theta\bar F\cdot(h)\cdot G)|\le 2C_E\mathsf{a}^{-11/2}\Big(2c_E+2\log\frac{1}{\mathsf{a}\eta}\Big)^{q_E}g^2\,\eta^{-11/2}|h|_\infty\,\|[\tau_{-(\eta/4)e_3}F]\|\,\|[\tau_{-(\eta/4)e_3}G]\|;$$

here C_E is taken at $\delta=\frac{1}{16}$; so the left side is $\le C_{\mathrm{I}}\eta^{-\mathsf{p}_{\mathrm{I}}}|h|_\infty\|[\tau_{-(\eta/4)e_3}F]\|\|[\tau_{-(\eta/4)e_3}G]\|$ for every $\mathsf{p}_{\mathrm{I}}>\frac{11}{2}$, with C_{I} a function of the constants, g and p_{I} that depends neither on σ nor on its label.

(f) *(Towers of one member.)* Put $\mathsf{a}'=\frac{1}{16L^2}$ and $\mathsf{n}_*=(32L^2+3)^3$. For $\eta'\in(0,\frac12]$, h with support in the closed ball of radius $\frac{\eta'}{16}$ about a point z with $z_3\in[\frac{\eta'}{4},\frac{3\eta'}{4}]$, with $h^\star$ as in (d) at $l=\eta'$, the tower $\mathbb{T}_k=(h^\star)\cdot\tau_{\eta' e_3}(h)\cdot\tau_{2\eta' e_3}(h^\star)\cdots\tau_{(2k-1)\eta' e_3}(h)$ of $2k$ floors, and the reflection ϑ_c in $x_1=c=z_1+\frac{\eta'}{8}$,

$$0\le\sigma(\vartheta_c\overline{\mathbb{T}_k}\cdot\mathbb{T}_k)\le\Big(\mathsf{n}_*\,2C_E\Big(2c_E+2\log\frac{1}{\mathsf{a}'\eta'}\Big)^{q_E}(\mathsf{a}'\eta')^{-11/2}\,g^2\,|h|_\infty\Big)^{4k},$$

with C_E at $\delta=\frac{1}{16}$; so the left side is at most $(C_{\mathsf{p}}\eta'^{-\mathsf{p}}|h|_\infty)^{4k}$ for every $\mathsf{p}>\frac{11}{2}$.

■

Proof. (a) Put $r=a_i/(8n)$ and $\lambda=L^{K-i}=a_i/a_K$, an odd integer $\ge 8n$ as $K\ge K^G$. Cut each member H_a by the tent partition of unity of the scale r, $H_a=\sum_{z\in r\mathbb{Z}^3}\chi^r_z H_a$, the tent χ^r_z being carried by the cube $\{|x-z|_\infty<r\}$ of half-side r; as the support of H_a lies in a closed ball of radius R, at most $(2R/r+3)^3=(16nR/a_i+3)^3$ of the pieces are not zero. Fix one piece of each member, carried by the cube about z_a. In each direction μ the wall planes of the boards with cells of side a_i lie at one of the λ positions $a_K(m+\frac12)+a_i\mathbb{Z}$, $0\le m<\lambda$; a piece excludes the positions that have a wall plane in the closed interval $[z_{a,\mu}-2r,z_{a,\mu}+2r]$ of length $4r=a_i/(2n)$, at most $\lambda/(2n)+1$ of them, and the n pieces exclude at most $\lambda/2+n<\lambda$ positions.

A free position in each direction gives one board on which the cube of every piece lies in the interior of one cell, at a sup distance $>r$ from its walls, so that the piece vanishes at the points at sup distance $<a_i/(8n)$ from the complement of its cell; different members lie in different cells because $\mathsf{d}\ge 2a_i>\sqrt{3}a_i$. Domination of ν at several cells of one board (Per) and Proposition 5.8 at $\delta=\frac{1}{8n}$, uniform in the side, bound each term by $\prod_a \mathsf{c}_E(i)b^{-1}|H_a|_\infty$, and there are at most $(16nR/a_i+3)^{3n}$ terms; the centring on a torus is allowed by Proposition 5.8. (b) The bound (a) gives equicontinuity on each type; extract diagonally along a countable dense set of tuples and along the labels, which lie in a compact interval. (c) (D1) and the continuity in the members follow from (a) and multilinearity; σ is real as a limit of real numbers. (D2): $\mathsf{r}\mathcal{T}_K(H)=\mathcal{T}_K(\mathsf{r}H)$ for lattice isometries, by the covariance of lattice objects (Lemma G.1), ν is invariant under $a_K\mathbb{Z}^3\rtimes W_3$ (Per), and the lattices are nested since L is odd, so that a translation or a mirror of one cutoff is one of every finer cutoff; with the continuity in the members, all translations follow. (D3): reflection positivity of periodic Gibbs states at the coordinate and diagonal lattice mirrors (Per), which keep $\mathcal{T}_K$, and the continuity in the members. (D4): e^{-tH} and $e^{iv\cdot P}$ exist by the iterated Schwarz inequality and (D1); the inequality

$$S_F(0)-4S_F(te_3)+S_F(2te_3)+S_F(te_3+te_k)+S_F(te_3-te_k)\ge 0,\qquad S_F(w)=\sigma(\theta\bar F\cdot\tau_w F),\ k=1,2,$$

passes from the five-point inequality (241) of Lemma F.5, a form of the lattice energy-momentum inequality, to the limit and gives $\mathcal{P}(\{E<\max(|q_1|,|q_2|)\})=0$. The scalar part: $\mathcal{T}_K(f\mathbf{1})=\mathcal{O}(f)$, and Theorem YMM1:AN applies to the sequence $(K_j,\beta_j,\rho_j,\rho_j)$. (d) Multiple reflections (Lemma 5.3 (d)) in the layer of cells of height a_i above the bond mirror $x_3=\frac12 a_{K_j}$ bound ρ_j of the reflected F', the centred cell observable and the translated F by the chessboard seminorm of the cell observable, uniformly in the side, times the two mirror norms; Proposition 5.8 at $\delta=\frac{1}{16}$ (the support is $\ge\frac18 a_i-\frac12 a_{K_j}\ge\frac{1}{16}a_i$ from the walls once $a_{K_j}\le\frac18 a_i$) and the continuity in the members give (10), and the same with several cells of one layer. A partition of unity at the one scale a_i, at most

$((16/3)R/a_i+3)^3$ pieces, gives the bound of $\mathsf{B}_l(h)$, and the operator itself exists by F. Riesz's theorem. The relations are identities between classes, which follow from (D2); the dihedral operators are unitary by (D2), and $\mathcal{H}_0$ is invariant under the semigroup, the translations and the dihedral group, which are generated on it by the scalar tuples. (e) Let i be the least integer ≥ 1 with $a_i \leq \frac{\eta}{4}$; then $\mathsf{a}\eta \leq a_i \leq \frac{\eta}{4}$. Inside the slab of width $\frac{\eta}{2}$ about the ball there is a cell of the scale a_i about the ball as in (d); two contractions e^{-cH}, $c \geq 0$, bridge the remaining heights, and (d) gives the bound, with $b_*^{-1} < g^2$. (f) Let i_2 be the least integer ≥ 1 with $a_{i_2} \leq \frac{\eta'}{16}$, $i = i_2 + 1$ and $\rho = \frac{1}{16}a_i$. Then $a_{i_2-1} > \frac{\eta'}{16}$: for $i_2 \geq 2$ by the choice of i_2, and for $i_2 = 1$ because $a_0 = 1 > \frac{1}{32} \geq \frac{\eta'}{16}$. So $a_i = L^{-2}a_{i_2-1} > \frac{\eta'}{16L^2} = \mathsf{a}'\eta'$ and $\frac{2\eta'}{a_i} < 32L^2$; with $\mathsf{Y}_i \leq 2c_E + 2\log\frac{1}{\mathsf{a}'\eta'}$ this bounds $\mathsf{c}_E(i)$, at $\delta = \frac{1}{16}$, by $2C_E(2c_E + 2\log\frac{1}{\mathsf{a}'\eta'})^{q_E}(\mathsf{a}'\eta')^{-11/2}$, and $\mathsf{c}_E(i_2) \leq \mathsf{c}_E(i)$. *Claim:* for $u, v \in C_c(\mathbb{R}^3; V_{\mathbb{C}})$ with supports in $\bar{B}(\zeta, \frac{\eta'}{16})$ and $\bar{B}(\zeta + \frac{\eta'}{4}e_1, \frac{\eta'}{16})$, $\zeta_3 \in [\frac{\eta'}{4}, \frac{3\eta'}{4}]$, and $F, F' \in \mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$,

$$|\sigma(\theta\bar{F}' \cdot (u) \cdot (v) \cdot \tau_{\eta' e_3} F)| \leq \mathsf{n}_*^2\, \mathsf{c}_E(i)^2\, b_*^{-2} |u|_\infty |v|_\infty \, \|[F']\| \, \|[F]\|.$$

Cut u and v by tents of the scale ρ; each has at most $(\frac{2\eta'}{a_i}+3)^3 \leq \mathsf{n}_*$ pieces, centred at heights in $[\frac{3\eta'}{16} - \rho, \frac{13\eta'}{16} + \rho]$, and the pieces of v lie at least $\frac{\eta'}{8} - 2\rho$ further along e_1 than those of u. For a pair of pieces whose heights differ by at least a_i, (10) at the scale i, applied twice, each time to one piece moved by a translation along e_3 into the layer of (d), with the heights left free above and below it at least $\frac{1}{2}a_i$, bounds the pair by $\mathsf{c}_E(i)^2 b_*^{-2}|u|_\infty|v|_\infty\|[F']\|\|[F]\|$. For a pair whose heights differ by less than a_i, the two pieces lie, after a translation along e_3, in a slab of half-width $\frac{9}{16}a_i \leq \frac{3}{8}a_{i_2}$; an offset in the first two coordinates of its own for this pair puts them in the inner cubes of two cells of one layer of the board of side a_{i_2}, distinct because $\frac{\eta'}{8} - 2\rho > \frac{3}{4}a_{i_2}$, with the heights left free above and below the layer at least $\frac{1}{2}a_{i_2}$; the bound of (d) for several cells of one layer at the scale i_2 bounds the pair alike.

Summing over the at most n_*^2 pairs gives the claim. *The column.* Let $u_m = h^\star$ for even m and $u_m = h$ for odd m, $0 \leq m < 2k$, be the untranslated floor profiles, and let $v_m = \vartheta_c \bar{u}_m$; ϑ_c moves z_1 to $z_1 + \frac{\eta'}{4}$ and commutes with the translations along e_3, and $|v_m|_\infty = |h|_\infty$. Put $Y_{2k} = \varnothing$ and $Y_m = (u_m) \cdot (v_m) \cdot \tau_{\eta' e_3} Y_{m+1}$, a tuple in $\mathbb{E}_+$. The claim at $F' = Y_m$, $F = Y_{m+1}$ gives $\|[Y_m]\|^2 \leq \mathsf{M}\|[Y_m]\| \, \|[Y_{m+1}]\|$ with $\mathsf{M} = \mathsf{n}_*^2 \mathsf{c}_E(i)^2 b_*^{-2}|h|_\infty^2$, so $\|[Y_0]\| \leq \mathsf{M}^{2k}$; Y_0 is $\vartheta_c \overline{\mathbb{T}_k} \cdot \mathbb{T}_k$ in another order, and $|\sigma(Y_0)| = |\langle \Omega, [Y_0]\rangle| \leq \mathsf{M}^{2k}$, with $b_*^{-1} \leq g^2$.

As $\mathbb{T}_k$ lies in $\{x_1 < c\}$, (D3) at the plane $x_1 = c$ gives the sign. □

The bound on off-diagonal members rests on two lemmas: a decay of the background kernel, which fixes the number C_{k}, and the factorisation of the moments of close pairs of bond forms that are far from one another.

Lemma 5.11. Let (ℓ, K) be a lattice, $0 \leq s \leq K$, and let p, q be plaquettes with $\mathsf{r} = |x(p) - x(q)|_\infty > 0$. The background kernel $C_{K,s}^{\mathrm{bg}}$ of the depth s (Section YMM1:120) satisfies

$$|C_{K,s}^{\mathrm{bg}}(p,q)| \leq [C_{\mathrm{tp}}\mathsf{S}_3 \mathsf{r}^{-3} + C_{\mathrm{tp}}^{\mathrm{bg}}] a_K^3, \qquad \mathsf{S}_3 = \sup_{t>0} \sum_{n \in \mathbb{Z}} (tL^n)^3 e^{-\delta_{\mathrm{tp}} t L^n} < \infty,$$

with the numbers C_{tp}, $C_{\mathrm{tp}}^{\mathrm{bg}}$, δ_{tp} of Propositions YMM1:120.5 and YMM1:120.6. So, for $0 < \mathsf{d} < 1$ and $|x(p) - x(q)| \geq \mathsf{d}$,

$$|C_{K,s}^{\mathrm{bg}}(p,q)| \leq C_{\mathsf{k}} \Big(\frac{a_K}{\mathsf{d}}\Big)^3, \qquad C_{\mathsf{k}} = 3^{3/2} C_{\mathrm{tp}} \mathsf{S}_3 + C_{\mathrm{tp}}^{\mathrm{bg}},$$

a number of the constants. ■

Proof. By the telescope YMM1:(2227) at the depths s and 0, $C_{K,s}^{\mathrm{bg}} = C_{K,0}^{\mathrm{bg}} + \sum_{K-s<j\leq K} \mathcal{C}_{(j)}$. By Proposition YMM1:120.6 at $n = K - j + 1 \in \{1, \dots, s\}$, $|\mathcal{C}_{(j)}(p,q)| \leq C_{\mathrm{tp}} a_K^3 L^{3n} e^{-\delta_{\mathrm{tp}} \mathsf{r} L^n} =$

$C_{\rm tp}a_K^3\mathsf{r}^{-3}(\mathsf{r}L^n)^3e^{-\delta_{\rm tp}\mathsf{r}L^n}$, and by Proposition YMM1:120.5 at the depth 0, $|C^{\rm bg}_{K,0}(p,q)|\le C^{\rm bg}_{\rm tp}a_K^3$. The series of S_3 does not change when t is multiplied by L, and for $t\in[1,L]$ it converges uniformly, its terms being at most $(tL^n)^3$ for $n<0$ and decaying like $e^{-\delta_{\rm tp}L^n}$ for $n>0$. For $|x(p)-x(q)|\ge\mathsf{d}$, $\mathsf{r}\ge\mathsf{d}/\sqrt{3}$, and $a_K^3\le(a_K/\mathsf{d})^3$ as $\mathsf{d}<1$. □

Lemma 5.12. Let $0<g\le\gamma_W^{\rm ref}$, $(K,\beta)\in\mathfrak{d}(g)$, $b=a_K\beta$, T_ℓ a torus whose side is small over the run of (K,β), and $0<\mathsf{d}<1$ with $s=s(\mathsf{d})\le K$; let k, s_k and υ be as in Lemma 5.7, at g and d, and $C^{\rm bg}=C^{\rm bg}_{K,s_\mathsf{k}}$ the background kernel of the depth s_k. Let $n\ge1$, and number the members of n pairs $a=(\tau,\iota)$, $\tau=1,\dots,n$, $\iota=1,2$. For each member let $z_a\in T_\ell$ be a point and w_a a real weight of the bonds of one direction, not identically zero, with $|x_b-z_a|\le\mathsf{d}-2a_K$ where $\mathsf{w}_a(b)\ne0$, such that $3\mathsf{d}\le|z_{(\tau,1)}-z_{(\tau,2)}|\le4\mathsf{d}$ for each pair, and that corners of plaquettes of $S[\mathsf{w}_a]$ and of $S[\mathsf{w}_{a'}]$ are at a sup distance $\ge11M$ whenever a and a' belong to different pairs.

Put $F_a=Y[\mathsf{w}_a]$, the first member of the quadratic source under $(\mathsf{s}_a,S_a)=(59|\mathsf{w}_a|_\infty,S[\mathsf{w}_a])$ with the kernel $\mathsf{t}_a=\mathsf{t}[\mathsf{w}_a]$ (Lemma 5.5), $\hat m_a=\upsilon\mathsf{s}_a$, $P_\tau=F_{(\tau,1)}F_{(\tau,2)}$, $\hat m_\tau=\hat m_{(\tau,1)}\hat m_{(\tau,2)}$, and, for a non-empty set J of pairs, $P_J=\prod_{\tau\in J}P_\tau$ and $\hat m_J=\prod_{\tau\in J}\hat m_\tau=59^{2\#J}\upsilon^{2\#J}\prod_{\tau\in J}|\mathsf{w}_{(\tau,1)}|_\infty|\mathsf{w}_{(\tau,2)}|_\infty$; let

$$G_\tau=6\,\upsilon^2\sum_{p,p',q,q'}\mathsf{t}_{(\tau,1)}(p,p')\,\mathsf{t}_{(\tau,2)}(q,q')\,C^{\rm bg}(p,q)\,C^{\rm bg}(p',q')$$

be the Gaussian value of the pair τ. Then $|G_\tau|\le106\,C_\mathsf{k}^2\upsilon^2|\mathsf{w}_{(\tau,1)}|_\infty|\mathsf{w}_{(\tau,2)}|_\infty$, with the number C_k of Lemma 5.11. And there are an integer $s_{2n}(g)$ and a function $\omega_{g,2n}$ of the depth, formed with the constants, g and n, with $\omega_{g,2n}(s)\to0$ as $s\to\infty$, such that for $s_{2n}(g)\le s(\mathsf{d})\le K$ and every non-empty set J of pairs

$$\Big|\langle P_J\rangle_{K,\ell,\beta}-\prod_{\tau\in J}G_\tau\Big|\le\omega_{g,2n}(s(\mathsf{d}))\,\hat m_J.$$

■

Proof. The data. At the $2n$ majorants the working level, the step couplings and the upper level T attached to the working level (equations YMM1:(2299), YMM1:(2316) and YMM1:(2322)) are formed, and the settings of Sections YMM1:125–126 hold for the construction on T_ℓ along the run of (K,β) (Lemmas YMM1:126.1, YMM1:126.2); the forms F_a are the first members of an admissible system of quadratic sources (Lemma 5.5). *The bound of G_τ.* The barycentres of plaquettes of the two members of a pair are at least $3\mathsf{d}-2(\mathsf{d}-\frac32a_K)>\mathsf{d}$ apart, so $|C^{\rm bg}(p,q)|\le C_\mathsf{k}(a_K/\mathsf{d})^3$ at the plaquettes that count (Lemma 5.11); $\sum_{p,p'}|\mathsf{t}_a(p,p')|\le\sum_b|\mathsf{w}_a(b)|$ (Lemma 5.5 (c)), and at most $\frac{4\pi}{3}(\mathsf{d}/a_K)^3$ bonds of one direction have their midpoints in a ball of radius $\mathsf{d}-2a_K$; so $|G_\tau|\le6(\frac{4\pi}{3})^2C_\mathsf{k}^2\upsilon^2|\mathsf{w}_{(\tau,1)}|_\infty|\mathsf{w}_{(\tau,2)}|_\infty$, and $6(\frac{4\pi}{3})^2=105.3<106$.

So $|G_\tau|\le\mathsf{g}_0\hat m_\tau$, $\mathsf{g}_0=106C_\mathsf{k}^2/59^2$. *The moments.* The mean of P_J is a sum over the level of the first creation of a large field (equation (314)), and along the histories without large fields the quotient of a product of the forms at the level t is the sum over the partitions of the products of its blocks, as in the proof of Lemma 5.6, now with $c_a=0$. Four kinds of terms occur. (i) *Blocks that join two pairs.* Their supports are at least $11ML^{K-i}$ units of the level i apart, and the mixed derivative families decay exponentially in this distance (proof of Lemma 5.6); such a block is at most $\mathsf{far}_{g,2n}(s)\prod_a\hat m_a$, with a function $\mathsf{far}_{g,2n}$ of the depth, formed with the constants, g and n, that is a power of L^s times $e^{-11L^{s-2}/\mathsf{Lm}_s}$, Lm_s the number in (267), and so tends to 0. (ii) *A member alone.* The mean of q_b on the torus vanishes, by the reflection through b in the direction λ_b; so the mean of F_a vanishes, and by the identity of the first creation at F_a (equation (314)), with the sizes and the tails of Lemmas YMM1:125.2 and YMM1:125.4 at the weight of the majorant, the quotient of F_a at the upper level T is at most $\mathsf{e}_g(s)\hat m_a$, with a function e_g of the depth that tends to 0. (iii) *The block of one pair.* At the upper level it is G_τ up to $\epsilon_g(s)\hat m_\tau$, ϵ_g the error function in equation YMM1:(2330), with the coefficient fixed in Lemma D.1. Step by step: the conditional

covariance of the two members in one step is the total of the pointed family $\mathsf{K}^{(j)}$ of the level j that the mixed derivative of the step map in the two slot members gives (Lemma B.20, read for the slot members of the two sources, which enter the array of the step as the weight members of plaquette sources do); it vanishes off the regions that meet both supports. It is carried to the upper level by the first-order statement (equations YMM1:(2276)–(2277), YMM1:(2280) and Proposition YMM1:123.3) and by the tower of the quotients (equation YMM1:(2273)); at the upper level the carried family is flat on the small fields (Lemma B.22 and the carried-family proof of Proposition YMM1:123.3); and its total at the trivial configuration is the Gaussian number of the slices of the covariance, formed with the kernels $\mathsf{t}_{(\tau,1)}$, $\mathsf{t}_{(\tau,2)}$ and the step couplings υ_j, up to the error of the flat top of Proposition YMM1:125.1, with the same constants.

Indeed the proof of that Proposition reads a source only through its second order at a small point of the chart, which is (So3) with a kernel of two indices in the place of the diagonal kernel $\frac{1}{2}w(p)\delta_{pp'}$ of an action density, and through the sizes formed at the weights of the majorants. The Gaussian numbers of the slices $\mathcal{C}_{(j)}$ of the steps above the working level, with the couplings υ_j, add up, by the telescope YMM1:(2227) and up to the errors of Theorem YMM1:AT at the attached levels (Lemma YMM1:125.5), to G_τ, the Gaussian value at the background kernel of the working level. (iv) *The large fields.* On the small side the rarity of large fields (Lemma YMM1:125.3) bounds the contributions of the levels below the upper level by $\mathsf{tl}_{g,2n}(s)\prod_a \hat{m}_a$, with a function $\mathsf{tl}_{g,2n}$ of the depth that tends to 0. *The sum over the partitions*, with $\delta_g = \epsilon_g + \mathsf{e}_g^2$ the error of a pair block together with its two singletons, gives the bound with

$$\omega_{g,2n}(s) = n\,\delta_g(s)\big(1+\mathsf{g}_0+\delta_g(s)\big)^{n-1} + \mathrm{Bl}(2n)\,\mathsf{far}_{g,2n}(s)\big(1+\mathsf{g}_0+\epsilon_g(s)\big)^{n} + \mathsf{sm}_g(s)(1+\mathsf{g}_0)^n + \mathsf{tl}_{g,2n}(s),$$

sm_g the function in (267) and $\mathrm{Bl}(2n)$ the number of the partitions of $2n$ elements. Each of these functions tends to 0 as $s\to\infty$, by the asymptotics of the envelopes in the depth (the depth estimates in equations YMM1:(2332) and YMM1:(2336) and their proofs); $s_{2n}(g)$ is the least depth, not below the least depth of the two-point law of Theorem YMM1:AU, from which the thresholds of the proof, $\mathsf{far}_{g,2n}(s)\le 1$, $\mathsf{e}_g(s)\le 1$, the smallness of $s\,\mathsf{sm}_g(s)$ and the condition on the mixed derivative families of $2n$ sources, hold at every larger depth. □

Proposition 5.13. Let $0<g\le\gamma_W^{\mathrm{sd}}$ and $\mathsf{l}=\ell'/2$. Let C_{k} be the number of Lemma 5.11, $s_8(g)$ the integer and $\omega_{g,8}$ the function of Lemma 5.12 at four pairs, and $\bar{\omega}_{g,8}=\sup_{s\ge s_8(g)}\omega_{g,8}(s)<\infty$; these are formed with the constants and g. With the depth $s(\mathsf{d})$ fitted to d at the coupling g, put $C_8=(\frac{9}{8})^4[(106C_{\mathsf{k}}^2)^4+59^8\bar{\omega}_{g,8}]$, $\mathsf{d}_\flat = L^{-s_8(g)}$ and

$$C_\infty(g)=\max\{e^{2G_g\mathsf{l}^3}C_8^{1/4},\ \bar{C}(g,\mathsf{d}_\flat)\},$$

where $\bar{C}(g,\mathsf{d}_\flat)$ is the number $C_2^G(\mathsf{d}_\flat;1)$ of Proposition 5.10 (a), raised, with the bound $|Y[\mathsf{w}]|\le 2a_K^{-1}|\mathsf{w}|_\infty\sum_{p\in S[\mathsf{w}]}a_p$ of Lemma 5.5, so as to cover also the finitely many cutoffs below the threshold of that proposition. Then the following holds for all $(K,\beta)\in\mathfrak{d}(g)$, all $0<\mathsf{d}<1$ with $s(\mathsf{d})\le K$, and all real weights w carried by bonds of one direction with $|x_b-x_0|\le \mathsf{d}-2a_K$ on the support.

(a) For every lattice mirror $x_3=c$, $c\in a_K(\mathbb{Z}+\frac{1}{2})$, with $x_{0,3}-c\in[\frac{3}{2}\mathsf{d},2\mathsf{d}]$, and every $\nu\in\mathcal{G}^{\mathrm{per}}_{K,\beta}$:

$$0\le \nu(\theta_c Y[\mathsf{w}]\cdot Y[\mathsf{w}])\le C_\infty(g)\,b^{-2}|\mathsf{w}|_\infty^2.$$

On every torus T_ℓ of a side $\ell\in\mathfrak{L}(g)$, $0\le\langle\theta_cY[\mathsf{w}];Y[\mathsf{w}]\rangle_{K,\ell,\beta}\le C_\infty(g)b^{-2}|\mathsf{w}|_\infty^2$ for the reflection θ_c of T_ℓ in the lattice planes $x_\mu=c$ and $x_\mu=c+\frac{\ell}{2}$, $c\in a_K(\mathbb{Z}+\frac{1}{2})$, in each of the three directions μ, whenever $x_{0,\mu}-c$ lies in $[\frac{3}{2}\mathsf{d},\frac{\ell}{2}-\frac{3}{2}\mathsf{d}]$ modulo ℓ.

(b) On every torus T_ℓ, $\ell\in\mathfrak{L}(g)$: for weights $\mathsf{w}_1,\mathsf{w}_2$ as above about two centres x_1,x_2 at a sup distance $|x_1-x_2|_\infty\ge 3\mathsf{d}+a_K$ in T_ℓ, $|\langle Y[\mathsf{w}_1];Y[\mathsf{w}_2]\rangle_{K,\ell,\beta}|\le C_\infty(g)b^{-2}|\mathsf{w}_1|_\infty|\mathsf{w}_2|_\infty$. In periodic Gibbs states the statement is the mirror form of (a), at the heights $x_{0,3}-c\in[\frac{3}{2}\mathsf{d},2\mathsf{d}]$.

(c) Every tensor limit at g has (O) with $C_{\mathrm{od}}=C_\infty(g)b_*^{-2}$.

(d) *(All six components, with a power.)* There are $\mathsf{d}'_\flat > 0$, $C_\flat(g)$ and an affine function Y_g of $\log\frac{1}{\mathsf{d}}$ such that for $0 < \mathsf{d} \le \mathsf{d}'_\flat$, $\frac{3}{2}\mathsf{d} \le x_{0,3} - c \le \frac{1}{2}\mathsf{l}$, every $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ at large K, and every bounded $H : \mathbb{R}^3 \to V_{\mathbb{C}}$ vanishing off $\bar{B}(x_0, \mathsf{d})$,

$$0 \le \nu(A^\nu_K(\theta_c \bar{H}, H)) \le E_g(\mathsf{d})^2 b^{-2} |H|^2_\infty, \qquad E_g(\mathsf{d}) \le C_\flat(g)\, \mathsf{d}^{-1} \mathsf{Y}_g(\mathsf{d})^{10\mathfrak{p}_0}.$$

So every tensor limit at g has (O_a) for every $a \in (2,4)$.

■

Proof. (a) The lower bound is reflection positivity at the bond mirror (Per), and on T_ℓ that of the torus measure (Corollary B.1 (a)). Take the board with cells of side l that has $x_3 = c$ as a wall plane and x_0 in the middle of a cell in the two other directions; $Y[\mathsf{w}]$ and $\theta_c Y[\mathsf{w}]$ are functions of the two cells that θ_c exchanges, and by Lemma 5.3 (c) $\nu(\theta_c Y[\mathsf{w}] \cdot Y[\mathsf{w}]) \le e^{2G_g \mathsf{l}^3} \|Y[\mathsf{w}]\|^2_{\mathrm{ch},\ell'}$. The eighth power M_8 of the seminorm is the mean on $T_{\ell'}$ of the eight mirror copies of $Y[\mathsf{w}]$; as the period of the torus is $2\mathsf{l}$, they form four close pairs, each a copy and its image across a wall, at distances in $[3\mathsf{d}, 4\mathsf{d}]$.

The copies are $Y[\mathsf{w}_a]$, w_a the mirror images of w, real weights of the bonds of one direction with $|\mathsf{w}_a|_\infty = |\mathsf{w}|_\infty$; corners of plaquettes of copies of different pairs are at a sup distance $\ge \mathsf{l} - 2\mathsf{d} \ge LM - 2 \ge 11M$, as $\mathsf{l} \ge LM$ for a small side (the second inequality of equation YMM1:(2312)). So Lemma 5.12 applies at four pairs, on the least torus, which is small over the run (Lemma YMM1:126.3). With J the set of the four pairs, $M_8 = \langle P_J \rangle_{K,\ell',\beta}$; $|G_\tau| \le 106 C_{\mathsf{k}}^2 \upsilon^2 |\mathsf{w}|^2_\infty = (106 C_{\mathsf{k}}^2/59^2)\hat{m}_\tau$, uniformly in d, as natural scaling demands: the covariance of two quadratic forms in the field strength at a distance of the order d, integrated over volumes of the order d^3, is dimensionless.

So at $s(\mathsf{d}) \ge s_8(g)$, $|\langle P_J \rangle| \le ((106 C_{\mathsf{k}}^2/59^2)^4 + \omega_{g,8}(s(\mathsf{d})))\hat{m}_J$, and $\hat{m}_J = 59^8 \upsilon^8 |\mathsf{w}|^8_\infty \le 59^8 (\frac{9}{8})^4 b^{-8} |\mathsf{w}|^8_\infty$ (Lemma 5.7); hence $0 \le M_8 \le C_8 b^{-8} |\mathsf{w}|^8_\infty$, which gives the constant $e^{2G_g \mathsf{l}^3} C_8^{1/4}$. For $\mathsf{d}_\flat \le \mathsf{d} < 1$ the two members $\theta_c Y[\mathsf{w}]$ and $Y[\mathsf{w}]$, which are $\mathcal{T}_K$ of bounded off-diagonal members, are of the type $(\mathsf{d}_\flat; 1)$, and the proof of Proposition 5.10 (a), which applies to bounded members, gives $\bar{C}(g, \mathsf{d}_\flat)$. On a torus T_ℓ, $\ell \in \mathfrak{L}(g)$, the same two arguments, with the chessboard estimate on T_ℓ (Corollary B.1 (b)) and Lemma 5.3 (b) in the place of Lemma 5.3 (c) and of the domination in (Per), give the bound when $x_{0,\mu} - c \in [\frac{3}{2}\mathsf{d}, 2\mathsf{d}]$, in each direction by the invariance under W_3; the means of the q_b vanish, so these forms are the truncated ones.

For the other heights let Y_h be the translate of $Y[\mathsf{w}]$ along e_μ whose centre lies at the height h over the plane $x_\mu = c$, $h \in x_{0,\mu} - c + a_K\mathbb{Z}$. By the invariance of the torus measure under the translations along e_μ, $\langle \theta_c Y_u \cdot Y_v \rangle_{K,\ell,\beta}$ depends on $u+v$ alone; Schwarz' inequality for the positive form $(F,G) \mapsto \langle \overline{\theta_c F}\, G \rangle_{K,\ell,\beta}$ on the functions of $\{c < x_\mu < c + \frac{\ell}{2}\}$ then gives, for $f(h) = \langle \theta_c Y_h \cdot Y_h \rangle_{K,\ell,\beta} \ge 0$,

$$f(h)^2 = \langle \theta_c Y_{h-a_K} \cdot Y_{h+a_K} \rangle^2_{K,\ell,\beta} \le f(h - a_K)\, f(h + a_K) \qquad (\tfrac{3}{2}\mathsf{d} < h < \tfrac{\ell}{2} - \tfrac{3}{2}\mathsf{d}).$$

So the maximum of f over the heights in $[\frac{3}{2}\mathsf{d}, \frac{\ell}{2} - \frac{3}{2}\mathsf{d}]$ is attained at the lowest or at the highest of them: at the leftmost interior point h of a maximum $M > 0$ one would have $M^2 \le f(h-a_K) f(h+a_K) < M^2$. These two heights lie in $[\frac{3}{2}\mathsf{d}, 2\mathsf{d}]$ over the plane $x_\mu = c$, resp. in $[\frac{3}{2}\mathsf{d}, 2\mathsf{d}]$ under the plane $x_\mu = c + \frac{\ell}{2}$, which θ_c fixes as well, and there the bound holds. (b) Let μ be a direction with $|x_{1,\mu} - x_{2,\mu}| \ge 3\mathsf{d} + a_K$ on the circle $\mathbb{R}/\ell\mathbb{Z}$. On the shorter arc between $x_{1,\mu}$ and $x_{2,\mu}$ there is $c \in a_K(\mathbb{Z} + \frac{1}{2})$ at distances $\ge \frac{3}{2}\mathsf{d}$ from both, and these distances are at most $\frac{\ell}{2} - \frac{3}{2}\mathsf{d}$; the two weights lie on the two sides of the reflection θ_c of T_ℓ. As the means of the q_b vanish, Schwarz' inequality for θ_c gives

$$\big|\langle Y[\mathsf{w}_1]\, Y[\mathsf{w}_2] \rangle_{K,\ell,\beta}\big| \le \langle Y[\mathsf{w}_1] \cdot \theta_c Y[\mathsf{w}_1] \rangle^{1/2}_{K,\ell,\beta}\, \langle \theta_c Y[\mathsf{w}_2] \cdot Y[\mathsf{w}_2] \rangle^{1/2}_{K,\ell,\beta},$$

and (a) on T_ℓ bounds both factors, the form being the same for a centre on either side of the plane by the invariance under W_3. (c) $\mathcal{T}_K(h\, o) = Y[\mathsf{w}]$ with $\mathsf{w}(b) = h(x_b)$ on the bonds normal to the plane of e_μ, e_ν; $\nu(q_b) = 0$ by the reflection through b in the direction λ_b, an element of $a_K\mathbb{Z}^3 \rtimes W_3$

(Per); and the continuity of Proposition 5.10 (c). (d) The cell of side l of the least torus with the wall plane $x_3 = c$ and the centre above x_0 holds $\bar B(x_0, \mathsf{d})$ at distance $\geq \frac12 \mathsf{d}$ from its walls. Cut $\mathcal{T}_K(H)$ into the at most 54 diagonal and off-diagonal forms of 27 boxes of side $\frac23\mathsf{d}$; put $\mathsf{d}' = \frac34 \mathsf{d}$. The eight mirror copies of each form are the first members of an admissible system of real sources (Lemma 5.5 (a), (b)) under the majorants (s, S_κ) with $\mathsf{s} \leq 59|H|_\infty$; the barycentres of the plaquettes of each S_κ lie within $\frac78\mathsf{d}'$ of the image of the centre of its box, and those of two different copies are at least $\frac54\mathsf{d}'$ apart, since two points of different cells, each at a distance $\geq \frac23\mathsf{d}'$ from the walls, are $\geq \frac43\mathsf{d}'$ apart.

Lemma 5.7 at the depth $s = s(\mathsf{d}')$ gives numbers c_κ with $|\langle \prod_{\kappa\in B}(F_\kappa - c_\kappa)\rangle_{K,\ell',\beta}| \leq (\mathsf{A}_8(s)\upsilon\mathsf{s})^{\#B}$ for every set B of copies; with m the common mean of the copies, $|c_\kappa - m| \leq \mathsf{A}_8(s)\upsilon\mathsf{s}$, and expanding $\prod_\kappa(F_\kappa - m)$ as in the proof of Proposition 5.8 bounds the seminorm on $T_{\ell'}$ of each form less its mean by $2\mathsf{A}_8(s)\upsilon\mathsf{s}$, with $\mathsf{A}_8(s) \leq C\mathsf{d}^{-1}\mathsf{Y}_g(\mathsf{d})^{10\mathfrak{p}_0}$ by Lemma 5.7 and $\upsilon^2 \leq \frac98 b^{-2}$. Lemma 5.3 carries the bound to all sides and to every periodic Gibbs state; the reflection is an element of $a_K\mathbb{Z}^3 \rtimes W_3$, and reflection positivity gives the sign.

The power d^{-2} up to logarithms is $\leq C_a\mathsf{d}^{-a}$ for every $a > 2$. □

Lemma 5.14. Let $\mathcal{P}$ be a projection-valued measure on $[0,\infty)\times\mathbb{R}^2$ carried by $\{E \geq \max(|q_1|,|q_2|)\}$, $e^{-tH}\mathcal{U}(v) = \int e^{-tE+iv\cdot q}\,d\mathcal{P}$, $Q = \{|x-z|_\infty \leq \varrho\}$, $\varepsilon \geq 12\varrho$, and b a linear map from the continuous functions with support in Q to the bounded operators, with $\|\mathsf{b}(\mathsf{f})\| \leq \mathsf{c}\sup|\mathsf{f}|$ and

$$e^{-\varepsilon H}\mathsf{b}(\tau_u\mathsf{f})e^{-\varepsilon H} = e^{-(\varepsilon+u_3)H}\mathcal{U}(\vec u)\mathsf{b}(\mathsf{f})\mathcal{U}(-\vec u)e^{-(\varepsilon-u_3)H}$$

whenever $|u|_\infty \leq 2\varrho$ and f, $\tau_u\mathsf{f}$ have support in Q; here $\vec u = (u_1,u_2)$. Then $\|e^{-\varepsilon H}\mathsf{b}(h)e^{-\varepsilon H}\| \leq 4\mathsf{c}\,\varrho^{-3}\|h\|_{L^1}$. ■

Proof. Let χ be the tent of mass one on Q and $\mathsf{f}_u(y) = \chi(y)h(y+u)$; then $h = \int \tau_u\mathsf{f}_u\,du$, and the covariance gives $\langle\psi', e^{-\varepsilon H}\mathsf{b}(h)e^{-\varepsilon H}\psi\rangle = \int\langle\psi'_u, \mathsf{b}(\mathsf{f}_u)\psi_u\rangle du$ with $\psi_u = \mathcal{U}(-\vec u)e^{-(\varepsilon-u_3)H}\psi$, and likewise ψ'_u. On the carrier of $\mathcal{P}$ one has $|q_k| \leq E$, so $\psi_u = \sum_\alpha \frac{u^\alpha}{\alpha!}A^\alpha e^{-\varepsilon H}\psi$ with $\|A^\alpha e^{-\varepsilon H}\| \leq \sup_E E^{|\alpha|}e^{-\varepsilon E} \leq |\alpha|!\,\varepsilon^{-|\alpha|}$, a series that converges for $|u|_1 < \varepsilon$. Exchanging sums and integral, $\int u^\gamma \mathsf{b}(\mathsf{f}_u)du = \mathsf{b}(k_\gamma)$ with $\sup|k_\gamma| \leq \varrho^{-3}(2\varrho)^{|\gamma|}\|h\|_{L^1}$, and with $\sum_{|\alpha|=n} n!/\alpha! = 3^n$ the double series is $(\sum_n(6\varrho/\varepsilon)^n)^2 \leq 4$. So a point mass is as good as a bump once $e^{-\varepsilon H}$ makes the translates analytic, at the price of three powers of the scale. □

Proposition 5.15. Let $0 < g \leq \gamma_W^{\mathrm{sd}}$. For every $p > \frac{17}{2}$ there is C_p, a function of the constants, g and p, such that every tensor limit at g has (P) with $C = C_p b_*^{-1}$. Equivalently: for $\eta \in (0,1]$, $F, F' \in \mathbb{C}\mathfrak{S}_V(\{x_3 > \eta\})$ and $h \in C_c(\{|x_3| < \frac12\eta\}; V_\mathbb{C})$, $|\sigma(\theta\bar F\cdot(h)\cdot F')| \leq 2^p C_p b_*^{-1}\eta^{-p}\|h\|_{L^1}\|[\tau_{-\eta e_3}F]\|\,\|[\tau_{-\eta e_3}F']\|$. ■

Proof. Let $\vartheta = d - d'$, i the least integer ≥ 1 with $a_i \leq \vartheta$, $\varrho = a_i/32$, $\varepsilon = 12\varrho = \frac38 a_i$. A tent partition of unity at the scale ϱ cuts $\tau_{de_3}h$ into pieces on cubes Q of side 2ϱ whose L^1 norms add up to $\|h\|_{L^1}$. For a cube centred at the height z_3, Lemma 5.14 applies to $\mathsf{b}(\mathsf{f}) = \mathsf{B}_{a_i}(\tau_{(\frac12 a_i - z_3)e_3}\mathsf{f})$, by Proposition 5.10 (d) and the relations $e^{-tH}\mathsf{B}_l(h)e^{-t'H} = \mathsf{B}_{l+t+t'}(\tau_{te_3}h)$, $e^{iv\cdot P}\mathsf{B}_l(h)e^{-iv\cdot P} = \mathsf{B}_l(\tau_{(v,0)}h)$; the remaining distances to the planes $x_3 = 0$ and $x_3 = 2d$ are $\geq \frac{15}{32}a_i > \varepsilon$ and are bridged by contractions e^{-tH}. So

$$\|\mathsf{B}_{2d}(\tau_{de_3}h)\| \leq 4\cdot 32^3 a_i^{-3}\mathsf{c}_E(i)b_*^{-1}\|h\|_{L^1}, \qquad a_i^{-3}\mathsf{c}_E(i) = 2C_E\mathsf{Y}_i^{q_E}a_i^{-17/2} \leq C_p\min\{1,\vartheta\}^{-p}$$

for $p > \frac{17}{2}$, as $a_i \geq \min\{1,\vartheta\}/L$. The equivalent form follows with $d = \eta$, $d' = \frac12\eta$ and two contractions. □

Proposition 5.16. Let $0 < g \leq \gamma_W^{\mathrm{sd}}$ and σ a tensor limit at g.

(a) There is c_4, a function of the constants and g, such that for $n \geq 1$, $0 < \mathsf{d} \leq 1$ and $X \in \mathfrak{S}_V(\mathbb{R}^3)$ with n members whose supports lie in balls of radius 1 at pairwise distances $\geq \mathsf{d}$,

$$|\sigma(X)| \leq (\mathsf{c}_4 g^2 e^{35/2})^n (n!)^{35/2} \mathsf{d}^{-19n/2} \prod_a |H_a|_\infty .$$

(b) For every $n \geq 1$ there is exactly one complex linear functional S_n on the functions $\varphi : \mathbb{R}^{3n} \to V_{\mathbb{C}}^{\otimes n}$ whose components lie in the space $\mathcal{S}_{\neq}(\mathbb{R}^{3n})$ of Section YMM1:93, of Schwartz functions flat off the configurations of pairwise different points, that is bounded for one of the norms $|\varphi|_k$ (the largest of the norms $|\cdot|_k$ of Section YMM1:93 of the 6^n components) and has $\mathsf{S}_n(H_1 \otimes \cdots \otimes H_n) = \sigma(H_1, \dots, H_n)$ at smooth tuples with compact, pairwise disjoint supports; and $|\mathsf{S}_n(\varphi)| \leq \mathsf{C}^n (n!)^{51/2} |\varphi|_{18n}$, C a function of the constants and g: σ satisfies the growth hypothesis in Proposition YMM1:93.5 with the constants $(18, 1, \mathsf{C}, \frac{51}{2})$, in its form for members with values in V.

■

Proof. (a) At a cutoff, Proposition 5.10 (a) at the scale i at which both the bound of Proposition 5.8 holds at the margin $\delta_n = \frac{1}{8n}$ and $a_i \leq \frac{1}{4}\mathsf{d}$, applied to the mean in one periodic Gibbs state of a product centred in another, gives $(\mathsf{c}_4 n^{35/2} \mathsf{d}^{-19/2} b^{-1})^n \prod |H_a|_\infty$: the number of pieces, the factor δ_n^{-4} of C_E and $a_i^{-11/2} \mathsf{Y}_i^{q_E}$ are powers of n and of $1/\mathsf{d}$. With $b^{-1} < g^2$, $n^n \leq e^n n!$ and the continuity of Proposition 5.10 (c) this passes to σ. (b) The extension proposition, Proposition YMM1:93.3, gives, for a multilinear map with $|\mathsf{T}(X)| \leq \mathsf{c}_\mathsf{T} \max\{1, \mathsf{d}^{-\mathsf{a}}\} \prod \|f_i\|_\sharp$ at tuples with $R(X) \leq 1$ and separation $\mathsf{d}(X) \geq \mathsf{d}$, exactly one extension $\tilde{\mathsf{T}}$ to $\mathcal{S}_{\neq}(\mathbb{R}^{3n})$ bounded for one of the norms, with $|\tilde{\mathsf{T}}(\varphi)| \leq \mathsf{C}_{\neq}^{n+\mathsf{a}} M^n (n!)^8 \mathsf{c}_\mathsf{T} |\varphi|_{8n+\mathsf{a}-1}$.

Applied component by component with $\mathsf{a} = 10n$, as $\min\{1, \mathsf{d}\}^{-19n/2} \leq \max\{1, \mathsf{d}^{-10n}\}$, with $\mathsf{c}_\mathsf{T} = (\mathsf{c}_4 g^2 e^{35/2})^n (n!)^{35/2}$, and with $|f|_\infty \leq \|f\|_\sharp$, this gives the factorial power $8 + \frac{35}{2} = \frac{51}{2}$ and the index $8n + 10n - 1 \leq 18n$. Uniqueness is that of Lemma YMM1:93.2, component by component. □

The convergence on a torus along the full sequence of cutoffs rests on a comparison of two consecutive cutoffs at one label. For a side $\ell = 2L^m$ and a cutoff K, $\Lambda_{K,\ell} = a_K \mathbb{Z}^3 / \ell\mathbb{Z}^3$ is the lattice of T_ℓ at the spacing a_K, and $\mathcal{M}$ is the block averaging map of one renormalisation step, from the configurations on $\Lambda_{k+1,\ell}$ to those on $\Lambda_{k,\ell}$ (Definition B.29 (3)); for a configuration U on $\Lambda_{K,\ell}$ and a depth $0 \leq d \leq K$, $\mathcal{M}^{K-d} U$ is its *block field of the depth* d, a configuration on $\Lambda_{d,\ell}$. A *weight on the sites* is a complex function v on the sites of $\Lambda_{K,\ell}$.

For $\{\lambda, \lambda', \mu\} = \{1, 2, 3\}$ put $\mathcal{T}_{\lambda\lambda'}[\mathsf{v}] := Y[\mathsf{w}]$ with $\mathsf{w}(\langle x, x + a_K e_\mu \rangle) := \mathsf{v}(x)$ and $\mathsf{w} := 0$ at the bonds of the two other directions, and $\mathcal{T}_{\lambda\lambda}[\mathsf{v}] := 2\mathcal{O}(w)$ with $w(p_{\kappa\kappa'}(x)) := \mathsf{v}(x)$ at the plaquettes of the plane $\{\kappa, \kappa'\}$ normal to e_λ, $p_{\kappa\kappa'}(x)$ the plaquette of that plane with the lowest corner x, and $w := 0$ at the other plaquettes. Then $\mathcal{T}_K(H) = \frac{1}{2} \sum_{\lambda,\lambda'} \mathcal{T}_{\lambda\lambda'}[\mathsf{v}^{\mathrm{pt}}_{\lambda\lambda'}]$ with the *point readings* $\mathsf{v}^{\mathrm{pt}}_{\lambda\lambda'}(x) = H_{\lambda\lambda'}(x + \frac{1}{2} a_K e_\mu)$ for $\lambda \neq \lambda'$ and $\mathsf{v}^{\mathrm{pt}}_{\lambda\lambda}(x) = H_{\lambda\lambda}(x + \frac{1}{2} a_K (e_\kappa + e_{\kappa'}))$.

The *cell reading* of a bounded Borel function ψ on T_ℓ is the weight $\psi^{(K)}(x) := a_K^{-3} \int_{x + a_K [-\frac{1}{2}, \frac{1}{2})^3} \psi$, and the *cell average* of a bounded Borel H is $\mathcal{T}^{\mathrm{av}}_K(H) := \frac{1}{2} \sum_{\lambda,\lambda'} \mathcal{T}_{\lambda\lambda'}[H^{(K)}_{\lambda\lambda'}]$. The sites of $\Lambda_{K+1,\ell}$ in the cell $y + a_K [-\frac{1}{2}, \frac{1}{2})^3$ of a site y of $\Lambda_{K,\ell}$ form its *block* $B(y)$ of L^3 sites, and the *block mean* of a weight v_f on the sites of $\Lambda_{K+1,\ell}$ is the weight $\mathsf{v}_\mathrm{A}(y) := L^{-3} \sum_{x \in B(y)} \mathsf{v}_\mathrm{f}(x)$ on the sites of $\Lambda_{K,\ell}$. As L is odd, the cell of y is the disjoint union of the cells of the $x \in B(y)$; so $\psi^{(K)}$ is the block mean of $\psi^{(K+1)}$.

Lemma 5.17. Let $0 < g \leq \gamma_W^{\mathrm{ref}}$, let b and $\ell = 2L^m$ be as in Proposition 5.18 below, so that the setting (E) of Section B.13 holds at the label b on the side ℓ, and let $q \geq 2$ and $\mathsf{d} > 0$. We compare the lattice $\mathrm{A} = \Lambda_{K,\ell}$ at $\beta = L^K \mathsf{b}$ with the lattice $\mathrm{B} = \Lambda_{K+1,\ell}$ at $\beta = L^{K+1} \mathsf{b}$, $\langle \cdot \rangle_K = \langle \cdot \rangle_{K,\ell,L^K \mathsf{b}}$; their block fields of a depth d, the images $\mathcal{M}^{K-d} U$ and $\mathcal{M}^{K+1-d} U$ of the configurations, are configurations on one lattice $\Lambda_{d,\ell}$.

(a) *(The laws of the block fields.)* Let $K_{\rm bf}$ and $\mathsf{C}_{\rm bf}$ be the numbers of Definition B.29 (5) at the interval of labels $\{\mathfrak{b}\}$, and $\mathfrak{p}_0 = 2\mathfrak{p}_0 + \frac{1}{2}$. For every cutoff $K \geq K_{\rm bf}$, every depth $0 \leq d \leq \lceil K/1260 \rceil$ and every bounded gauge invariant Borel function F of the configurations on $\Lambda_{d,\ell}$, $|\langle F(\mathcal{M}^{K+1-d}U)\rangle_{K+1} - \langle F(\mathcal{M}^{K-d}U)\rangle_K| \leq \mathfrak{o}_K \sup|F|$ with $\mathfrak{o}_K \leq \mathsf{C}_{\rm bf}\ell^3 K^{\mathfrak{p}_0} L^{-K/10}$.

(b) *(Tied sources.)* Let $K \geq K_{\rm bf}$, and let $1 \leq s < \varpi$ be depths with $\varpi \leq \min\{K-1, \lceil K/1260 \rceil\}$ and $L^{\varpi}\mathfrak{b} \geq \Theta_\star$, the threshold of equation YMM1:(2148), and with s so large that $L^s\mathsf{d} \geq 3M$ and that the data of the weighted progression of the depth s are given on both lattices (Proposition YMM1:122.1, read along the run up to the level $K-s$, resp. $K+1-s$; the two smallness conditions on the numbers of the run that this asks hold for all large s). A *small block field of the depth* ϖ is a configuration V on $\Lambda_{\varpi,\ell}$ with $|\partial V(p) - \mathbf{1}| < \varepsilon_{\rm r} := 2c_\rho\,\varepsilon(L^{\varpi}\mathfrak{b})$ at every plaquette, where $\varepsilon(x) = A_0 x^{-1/2}(\log x)^{\mathfrak{p}_0}$ is the threshold of YMM1:(634) and c_ρ, set in Section B.13, is the number of the constants in the radii of the cuts (the definitions preceding Lemma YMM1:113.10); over it the background $U^{\rm A}(V)$ of $t := K - \varpi$ renormalisation steps in A and the background $U^{\rm B}(V)$ of $t+1$ steps in B exist (the setting preceding Lemma YMM1:113.8, equation YMM1:(2149)), and a gauge invariant function takes one value on each of their minimal orbits.

Let $F_a^{\rm A}$ on A and $F_a^{\rm B}$ on B, $1 \leq a \leq q$, be the first members of sources under majorants $(\mathsf{s}_a, S_a^{\rm A})$, resp. $(\mathsf{s}_a, S_a^{\rm B})$ (Definition 5.4), with one number $\mathsf{s}_a > 0$ for the two lattices, for these data (in the sense of Lemma 5.5, which holds at them on the side ℓ: see the proof), and so, on each lattice, the first members of an admissible system of sources (Lemma 5.5 (a), (b)), the corners of the plaquettes of $S_a^\bullet$ and of $S_{a'}^\bullet$, $a \neq a'$, being at sup distances $\geq \mathsf{d}$; and let them be *tied at the depth* ϖ *with the defects* τ_a: $|F_a^{\rm B}(U^{\rm B}(V)) - F_a^{\rm A}(U^{\rm A}(V))| \leq \tau_a$ at every small block field V of the depth ϖ.

At these backgrounds $|F_a^\bullet| \leq \mathsf{S}_a := \frac{3}{2}B_3^2\ell^3 L^{4\varpi}\mathsf{s}_a$, where $B_3 \geq 1$ is the constant of Section YMM1:52.7 through which equation YMM1:(2149) bounds the backgrounds. Then, for every real $\mathfrak{b} \geq 4q$,

$$\big|\langle F_1^{\rm B};\dots;F_q^{\rm B}\rangle_{K+1} - \langle F_1^{\rm A};\dots;F_q^{\rm A}\rangle_K\big| \leq \mathsf{E}_q \prod_a \mathsf{s}_a + \mathfrak{c}_q \sum_a \tau_a \prod_{b\neq a} \mathsf{S}_b + q\,\mathfrak{c}_q\,\mathfrak{o}_K \prod_a \mathsf{S}_a,$$

where $\mathfrak{c}_q = \sum_\pi (|\pi|-1)!$, the sum over the partitions π of a set of q elements, and

$$\mathsf{E}_q := 2\,\mathfrak{K}'_q\Big[2L^{4q}\,\mathsf{V}_\ell(\mathfrak{b})\,L^{-(\mathfrak{b}+1)s} + q\,\epsilon_{\rm fg}(\varpi - s) + 2e^{3-L^s\mathsf{d}/M}\Big](4\ell^3 L^{4s})^q$$

is the sum of the weight of the large fields, of the error of forgetting from the depth ϖ to the depth s, $\epsilon_{\rm fg}(\nu) = C_{\rm fg}(\nu+1)^{2\mathfrak{p}_0+2}L^{-\nu/2}$, and of the terms on polymers joining two supports, which are exponentially small in $L^s\mathsf{d}$, each times the size $(4\ell^3L^{4s})^q\prod_a \mathsf{s}_a$ of the sources at the depth s, the factor 2 counting the two lattices. Here $\mathfrak{K}'_q$ is a number of the constants, q and $L^{4q}\mathsf{V}_\ell(\mathfrak{b})L^{-(\mathfrak{b}+1)s}$, bounded by a number of the constants and q when this last is at most 1, and $\mathsf{V}_\ell(\mathfrak{b})$, a number of the constants, g, ℓ and $\mathfrak{b}$ that carries the side through a factor $\ell^3 e^{\mathsf{B}(X_g)\ell^3}$, bounds the weights w_t of a first creation of a large field at the level t: $\sum_{t\leq K-s} L^{4q(K-s-t)}\mathsf{w}_t \leq L^{-(\mathfrak{b}+1)s}\mathsf{V}_\ell(\mathfrak{b})$, by the rarity of large-field regions on one torus (Proposition M.2), read along the run on the side ℓ.

(c) *(Cell averages.)* For a weight $\mathsf{v}_{\rm f}$ on the sites of B, its block mean $\mathsf{v}_{\rm A}$ and every pair (λ,λ'), the pair formed by $\mathcal{T}_{\lambda\lambda'}[\mathsf{v}_{\rm A}]$ on A and $\mathcal{T}_{\lambda\lambda'}[\mathsf{v}_{\rm f}]$ on B is tied at every depth ϖ as in (b), with the defect $\tau \leq \mathsf{K}_{\rm av}\ell^3 L^{4\varpi}K^{1/2}L^{-(K-\varpi)/2}\sup|\mathsf{v}_{\rm f}|$, $\mathsf{K}_{\rm av}$ a number of the constants. Let $\varpi := \lfloor K/(1260q)\rfloor$, $s := \lfloor \varpi/(8q+3)\rfloor$, $\mathfrak{b} := 4q+1$ and $\vartheta_q := 1/(1260q(8q+3))$. There are numbers $\mathsf{C}^{\rm av}$, p of the constants, the label $\mathfrak{b}$ and q, and an integer K_1 of the constants, g, $\mathfrak{b}$, ℓ, q and d, such that for $K \geq K_1$ and all real bounded Borel functions $\psi_1,\dots,\psi_q$ on T_ℓ that vanish off closed sets at pairwise sup distances $\geq \mathsf{d}$, the right side of (b) for the cell entries $\mathcal{T}_{\lambda_a\lambda'_a}[\psi_a^{(K)}]$ on A and $\mathcal{T}_{\lambda_a\lambda'_a}[\psi_a^{(K+1)}]$ on B is at most $2^q\mathsf{C}^{\rm av}\ell^{3(q+1)}K^{\mathsf{p}}L^{-\vartheta_q K}\prod_a\sup|\psi_a|$; so, by multilinearity,

the joint cumulants of the cell averages of $\mathcal{T}_K(H_a)$ and of $\mathcal{T}_{K+1}(H_a)$, for bounded Borel H_a with values in $V_{\mathbb{C}}$ that vanish off such sets, differ by at most $18^q \mathsf{C}^{\mathrm{av}} \ell^{3(q+1)} K^{\mathsf{p}} L^{-\vartheta_q K} \prod_a |H_a|_\infty$. ■

Proof. (a) is Corollary B.30 (a): at $n = 1$ the depth u of Section B.13 is $\lceil K/1260 \rceil$, and at $K \geq K_{\mathrm{bf}}$ the conditions under which that Corollary is stated hold.

(b) *Sources on every side.* The admission of Lemma 5.5 holds for all data of the weighted progression with at least one level, on every torus: a source enters the progression only through its domination by the plaquette action with its weight, its slot members, its family in the fourth place at the height zero and its sum rules, and none of these reads the side, so that the admission of the bond forms holds for all such data. So, at the data of the depth s on every side $\ell \in \mathfrak{L}(g)$, $g \leq \gamma_W^{\mathrm{ref}}$, $\mathcal{O}(w)$ is the first member of a source under $(|w|_\infty, \operatorname{supp} w)$ and $Y[\mathsf{w}]$ of one under $(59|\mathsf{w}|_\infty, S[\mathsf{w}])$; sums and multiples of sources are sources; and a source under (s, S) is one under every (s', S') with $\mathsf{s}' \geq \mathsf{s}$, $S' \supset S$. A side that is small over the run is read only by the rarity of large fields, in Lemmas 5.6 and 5.7; here the rarity on the side ℓ enters through the number $\mathsf{V}_\ell(\mathfrak{b})$. *One lattice.* In each of the two lattices the truncated function of the sources is, up to $\frac{1}{2}\mathsf{E}_q \prod_a \mathsf{s}_a$, that of the functions $\mathsf{X}_a^\bullet$ of the block field of the depth ϖ that take the values $F_a^\bullet(U^\bullet(V))$ at the small block fields V and vanish at the others. The moments are sums over the level of the first creation of a large field (equation (314)); the histories in which one is created cost $2L^{4q}\mathsf{V}_\ell(\mathfrak{b})L^{-(\mathfrak{b}+1)s}$; along the histories without large fields, the progression of the depth s and the one in which the sources enter at the depth ϖ give conditional means that differ by $q\,\epsilon_{\mathrm{fg}}(\varpi - s)$, the error of the Lipschitz form of forgetting (Proposition YMM1:114.3); and the terms of the exponent on polymers joining two supports are at most $2e^{3-L^s\mathsf{d}/M}$, exponentially small in the distance in units of the level $K - s$; each of the three times the size of the sources at the depth s, with the number $\mathfrak{K}'_q$ for the passage from moments to cumulants.

At a background of a small block field $a_p < \frac{1}{2}B_3^2\varepsilon_{\mathrm{r}}^2\eta_t^4$, $\eta_t = L^{-t}$, at every bare plaquette (equation YMM1:(2149)); with $\varepsilon_{\mathrm{r}} \leq 1$ the domination by the plaquette action gives $|\mathsf{X}_a^\bullet| \leq \mathsf{S}_a$. *Two backgrounds, two laws.* A joint cumulant of q bounded functions is multilinear, a polynomial in their mixed moments with coefficients of q alone, and at most $\mathfrak{c}_q \prod \sup|\cdot|$. Under one law, replacing $\mathsf{X}_a^{\mathrm{A}}$ by $\mathsf{X}_a^{\mathrm{B}}$, one index a at a time, changes the cumulant by at most $\mathfrak{c}_q\tau_a \prod_{b\neq a}\mathsf{S}_b$, by the tie. The products $\prod_{a\in B}\mathsf{X}_a^{\mathrm{A}}$ are bounded gauge invariant Borel functions of the block field of the depth $\varpi \leq \lceil K/1260 \rceil$, and by (a) their means under the laws of the block fields of B and of A differ by at most $\mathfrak{o}_K \prod_{a\in B}\mathsf{S}_a$; through the formula of the cumulant by moments this costs $q\,\mathfrak{c}_q\,\mathfrak{o}_K \prod_a \mathsf{S}_a$.

(c) *The tie.* Let V be a small block field of the depth ϖ, $t = K - \varpi$, $\eta_t = L^{-t}$, $N_t = \ell^3 L^{3\varpi}$ the number of its sites, $U^{\mathrm{A}} = U^{\mathrm{A}}(V)$, $U^{\mathrm{B}} = U^{\mathrm{B}}(V)$, and $U' := \mathcal{M}(U^{\mathrm{B}})$, a configuration on $\Lambda_{K,\ell}$. It is a competitor at the level t of A over the same block field, $\mathcal{M}^t U' = V$, and $\mathsf{ab}^{\mathrm{A}} \leq A^{\eta_t}(U') \leq (1+\mathsf{j}_t)^2\mathsf{ab}^{\mathrm{B}}$, $\mathsf{ab}^\bullet$ the actions of the two backgrounds and $\mathsf{j}_t \leq \frac{2}{5}$ (Lemma YMM1:113.8); with $|\mathsf{ab}^{\mathrm{B}} - \mathsf{ab}^{\mathrm{A}}| \leq \mathsf{K}_u\varepsilon_{\mathrm{r}}^2\eta_t N_t$ (equation YMM1:(2155)) the energy that the one averaging step from B to A loses at the background of B is small: the sum Jd over the plaquettes of A of the defects of Jensen's inequality of the averaging, with errors of the third order, is at most $c\,\varepsilon_{\mathrm{r}}^2\eta_t^2 N_t$, one power of η_t below the energy $\sum_p a_p(U^{\mathrm{B}}) \leq \frac{3}{2}B_3^2\varepsilon_{\mathrm{r}}^2\eta_{t+1}N_t$. *(i) The fine form against the coarse one, over one block field.* About a site y of $\Lambda_{K,\ell}$, on the box formed by the 27 blocks $B(y')$, $y' - y \in a_K\{-1,0,1\}^3$, a gauge brings U^{B} to e^{ia} with a real 1-form a, $\sup|a| \leq 3\pi L\varpi_{\mathrm{r}}$, $\varpi_{\mathrm{r}} := B_3\varepsilon_{\mathrm{r}}\eta_{t+1}^2$; let $g_p := a(\partial p)$ be the fine curvatures and $\bar{G}_l(y)$ the fine curvature at the coarse site y in the plane of a loop l. The vector part of a loop of a plaquette is $\pm$ its curvature up to $c_{\mathrm{f}}\varpi_{\mathrm{r}}^2$; the coarse curvatures are the sums $G'_{p'} = \sum_p \mathsf{W}(p',p)g_p$ of the fine ones under the kernel W of the block averaging, $\sum_p \mathsf{W}(p',p) = L^2$, up to $c_{\mathrm{c}}\varpi_{\mathrm{r}}^2$; and the variance $\sum_p \mathsf{W}(p',p)|g_p - L^{-2}G'_{p'}|^2$ is at most the defect of Jensen's inequality at p' plus an error of the third order. So $D_x^l := g_{p(x,l)} - \bar{G}_l(y)$ has $\sum_{x\in B(y)}|D_x^l|^2 \leq 12L^4V_y$, V_y the variances of the four coarse plaquettes at y in the plane of l, with $\sum_y V_y \leq 4\,\mathsf{Jd}$: the variation of the curvature inside a

block is bounded by the lost energy, and not by the energy. With $Q_x(l,l') = \langle \mathbf{w}(W_{x,l}), \mathbf{w}(W_{x,l'})\rangle$ the product of the vector parts of the loops l, l' at x and $\sigma(l) = \pm 1$ their orientations,

$$\big|Q_x(l,l')(U^{\mathrm{B}}) - \sigma(l)\sigma(l')\langle \bar G_l, \bar G_{l'}\rangle(y)\big| \le 2\varpi_{\mathrm{r}}(|D^l_x| + |D^{l'}_x| + 2c_{\mathrm{f}}\varpi_{\mathrm{r}}^2) \qquad (x \in B(y)),$$

and likewise for $L^{-4}Q_y(l,l')(U')$ at the coarse site, through the same Jd. Cauchy's and Schwarz' inequality over the $\eta_t^{-3}L^3N_t$ fine sites gives $\sum_x |D^l_x| \le (\eta_t^{-3}L^3N_t)^{1/2}(48L^4\mathsf{Jd})^{1/2}$; and when v_{A} is the block mean of v_{f}, $L\sum_{x\in B(y)}\mathsf{v}_{\mathrm{f}}(x) = L^4\mathsf{v}_{\mathrm{A}}(y)$, so that the weights cancel exactly at the common term $\langle \bar G_l, \bar G_{l'}\rangle(y)$ ($a_{K+1}^{-1}L^3 = a_K^{-1}L^4$). Hence

$$\Big|\eta_{t+1}^{-1}\sum_x \mathsf{v}_{\mathrm{f}}(x)Q_x(l,l')(U^{\mathrm{B}}) - \eta_t^{-1}\sum_y \mathsf{v}_{\mathrm{A}}(y)Q_y(l,l')(U')\Big| \le \mathsf{K}_0^{\mathrm{cf}}\sup|\mathsf{v}_{\mathrm{f}}|\,\varepsilon_{\mathrm{r}}^2N_t\,\eta_t^{1/2},$$

$\mathsf{K}_0^{\mathrm{cf}}$ a number of the constants. *(ii) The competitor against the background of* A*, over one block field.* A nearly minimal competitor has nearly the loops of the background. By the level-by-level comparison in the proof of Lemma YMM1:113.6, the configurations $\hat U$, $\check U$ of two consecutive levels of the competitor are related by $\hat U = (e^{iA'}\check U)^u$ with a real 1-form A' and one gauge transformation u, so that the loops at every corner differ by at most $\rho(p)$, $\eta_k^{-1}\sum_p \rho(p)^2 \le 2C_{\mathrm{nrg}}\|\mathcal{A}_k\|^2$; Cauchy's and Schwarz' inequality over the plaquettes and over the t levels, $L^tA(\cdot) \le A^{\eta_t}(U')$ at the backgrounds of the levels, and the bound YMM1:(2144) of the fields $\mathcal{A}_k$ by the excess give, as in the proof of Proposition YMM1:113.7,

$$\Big|\eta_t^{-1}\sum_y \mathsf{v}(y)\big[Q_y(l,l')(U') - Q_y(l,l')(U^{\mathrm{A}})\big]\Big| \le 12\sup|\mathsf{v}|\big(C_{\mathrm{nrg}}\gamma_{\mathrm{r}}^{-1}\,t\,\mathsf{exc}_t(U')\,A^{\eta_t}(U')\big)^{1/2},$$

with $\mathsf{exc}_t(U') = A^{\eta_t}(U') - \mathsf{ab}^{\mathrm{A}} \le 2\mathsf{K}_u\varepsilon_{\mathrm{r}}^2\eta_tN_t$ and $A^{\eta_t}(U') \le 3B_3^2\varepsilon_{\mathrm{r}}^2N_t$ (Lemma YMM1:113.8): this is $\varepsilon_{\mathrm{r}}^2N_t(t\eta_t)^{1/2}$ up to a number, and here the factor $t^{1/2} \le K^{1/2}$ enters. *(iii) The components.* $q_b = \frac14\sum_{\varepsilon,\varepsilon'=\pm}\varepsilon\varepsilon' Q_x((\mu,\varepsilon\lambda),(\mu,\varepsilon'\lambda'))$ at $b = \langle x, x + a_Ke_\mu\rangle$, the loops being named by their two directions; so $\mathcal{T}_{\lambda\lambda'}[\mathsf{v}]$, $\lambda \ne \lambda'$, is a mean of four forms $a_K^{-1}\sum_x \mathsf{v}(x)Q_x(l,l')$; and $2a_p = Q_x(l_m,l_m) + a_p^2$ for the loop l_m of the plaquette $p = p_{\kappa\kappa'}(x)$, with $a_p^2 < \frac14 B_3^4\varepsilon_{\mathrm{r}}^4\eta_t^8$ at the backgrounds, does the same for $\mathcal{T}_{\lambda\lambda}[\mathsf{v}]$. In the units of the depth ϖ, $a_K^{-1} = L^\varpi\eta_t^{-1}$ and $a_{K+1}^{-1} = L^\varpi\eta_{t+1}^{-1}$; with $\varepsilon_{\mathrm{r}} \le 1$, $t \le K$ and $\eta_t \le (t\eta_t)^{1/2}$, (i) and (ii) give the defect $\mathsf{K}_{\mathrm{av}}\ell^3L^{4\varpi}K^{1/2}L^{-(K-\varpi)/2}\sup|\mathsf{v}_{\mathrm{f}}|$. *The rate.* At $\varpi = \lfloor K/(1260q)\rfloor$, $s = \lfloor\varpi/(8q+3)\rfloor$, $\mathfrak{b} = 4q+1$: $\varpi \le \lceil K/1260\rceil$, $\varpi - s \ge (8q+2)s$, $s \ge \vartheta_qK - 2$ and $4q\varpi \le K/315$. Let $K_1 \ge K_{\mathrm{bf}}$ be the least cutoff from which on $s \ge 1$, $L^s\mathsf{d} \ge 6M$, the data of the depth s are given, $L^{4q}\mathsf{V}_\ell(\mathfrak{b})L^{-s} \le 1$, $2e^{3-L^s\mathsf{d}/(2M)}L^{(4q+1)s} \le 1$, $L^\varpi\mathsf{b} \ge \Theta_\star$ and $6a_K \le \mathsf{d}$. The cell entries are first members of sources under the majorants $(59\sup|\psi_a|, S_a^\bullet)$, $S_a^\bullet$ the plaquettes all of whose corners are within $\frac32 a_{K^\bullet}$ of the closed set off which ψ_a vanishes, at corner distances $\ge \mathsf{d} - 3a_K \ge \frac12\mathsf{d}$; so (b) applies at $\frac12\mathsf{d}$, with the ties of the first part of (c), $\psi^{(K)}$ being the block mean of $\psi^{(K+1)}$. Then $q\,\epsilon_{\mathrm{fg}}(\varpi - s)L^{4qs} \le qC_{\mathrm{fg}}K^{2\mathfrak{p}_0+2}L^{-s}$, and the three parts of E_q are at most a number times $K^{2\mathfrak{p}_0+2}\ell^{3q}L^{-s}$, $L^{-s} \le L^2L^{-\vartheta_qK}$; the ties contribute $(\ell^3L^{4\varpi})^qL^{-(K-\varpi)/2} \le \ell^{3q}L^{-K/3}$ times $K^{1/2}$, and the laws $(\ell^3L^{4\varpi})^qL^{-K/10} \le \ell^{3q}L^{-K/11}$ times $K^{\mathfrak{p}_0}$; and $\vartheta_q < \frac{1}{11}$. □

Proposition 5.18. Let $0 < g \le \gamma_W^{\mathrm{ref}}$, $\mathsf{b} \in (g^{-2} + \bar B, X_g - \bar B]$, $\ell \in \mathfrak{L}(g)$ and $\langle\cdot\rangle_K = \langle\cdot\rangle_{K,\ell,L^K\mathsf{b}}$, so that $(K, L^K\mathsf{b}) \in \mathfrak{d}(g)$ for every K. Let $n \ge 2$ and $\mathsf{d} > 0$.

(a) There are K_1 and $\mathsf{C}_n^\flat(\mathsf{d})$, functions of the constants, g, b, ℓ, n and d, such that for $K \ge K_1$ the joint cumulants of $\mathcal{T}_K(H_1), \dots, \mathcal{T}_K(H_n)$, for $H_a \in C(T_\ell; V_{\mathbb{C}})$ with supports at pairwise sup distances $\ge \mathsf{d}$, are at most $18^n\mathsf{C}_n^\flat(\mathsf{d})\prod_a |H_a|_\infty$.

(b) The limit $\mathfrak{S}_n(H_1,\dots,H_n)=\lim_{K\to\infty}\langle \mathcal{T}_K(H_1);\dots;\mathcal{T}_K(H_n)\rangle_K$ exists along the full sequence of cutoffs, with a rate: the difference at K is at most

$$18^n \mathsf{C}^{\mathrm{av}}\ell^{3(n+1)}\sum_{K'\geq K}K'^{\mathsf{p}}L^{-\vartheta_n K'}\prod_a|H_a|_\infty + 18^n\mathsf{C}_n^\flat(\mathsf{d})\sum_a\omega_a(a_K)\prod_{b\neq a}|H_b|_\infty,$$

with the numbers $\mathsf{C}^{\mathrm{av}},\mathsf{p}>0$ and $\vartheta_n=1/(1260n(8n+3))$ of Lemma 5.17 and ω_a the modulus of continuity of H_a. It is symmetric, n-linear, real at real members, bounded by $18^n\mathsf{C}_n^\flat(\mathsf{d})\prod|H_a|_\infty$, and it extends to bounded Borel members vanishing off closed sets at pairwise distances $\geq\mathsf{d}$, continuously under bounded pointwise convergence. For the normalized plaquette and corner forms of Theorem BU (c), the limit depends only on their common quadratic symbol, with the planes and orientation signs fixed there. In indices, the corresponding curvature bilinears tend to $\sum_{\lambda\lambda'}\varepsilon_{ij\lambda}\varepsilon_{kl\lambda'}T_{\lambda\lambda'}$, antisymmetric in (ij) and in (kl) and symmetric under their exchange.

(c) The centred functional $\sigma_\ell(X)=\sum_\pi\prod_{J\in\pi}\mathfrak{S}_{|J|}(X_J)$, the sum over the partitions into blocks of at least two members, is $\lim_K\langle A_K(X)\rangle_K$, A_K centred in $\langle\cdot\rangle_K$; it is invariant under the translations of T_ℓ and under W_3, acting on values through ρ, and reflection positive at every coordinate plane of T_ℓ.

(d) If $z\geq 0$ is an integer such that $(L^z\mathsf{b},L^z\ell)$ is admitted at some reference coupling, then $\mathfrak{S}_n^{\mathsf{b},\ell}(H_\bullet)=L^{zn}\mathfrak{S}_n^{L^z\mathsf{b},L^z\ell}(H_\bullet(L^{-z}\cdot))$.

(e) *(Conservation.)* For every C^2 vector field η on T_ℓ and all Lipschitz $H_2,\dots,H_n:T_\ell\to V$ whose supports are pairwise disjoint and disjoint from $\operatorname{supp}\eta$,

$$\mathfrak{S}_n(H_\eta,H_2,\dots,H_n)=0;$$

by (d), the same holds at every label and side reached by a dilation.

■

Proof. The cell entries of bounded Borel functions are first members of sources under majorants (Definition 5.4) at the data of the depth s on T_ℓ, and so first members of an admissible system of sources (Lemma 5.5 (a), (b), which hold at these data on every side $\ell\in\mathfrak{L}(g)$, as in the proof of Lemma 5.17 (b)), and the cell readings of a function at the cutoffs K' and $K'+1$ are tied, the one at K' being the block mean of the one at $K'+1$. *A uniform bound for weights of no regularity.* Let K_1 be the integer of Lemma 5.17 (c) at $(q,\mathsf{d})=(n,\frac12\mathsf{d})$, and

$$\mathsf{C}_n^\flat(\mathsf{d}):=\mathfrak{c}_n(2\ell^3L^{4K_1})^n+\mathsf{C}^{\mathrm{av}}\ell^{3(n+1)}\sum_{K'\geq K_1}K'^{\mathsf{p}}L^{-\vartheta_nK'}.$$

For $K\geq K_1$, all pairs (λ_a,λ_a') and all weights v_a on the sites of $\Lambda_{K,\ell}$ whose sets $\{\mathsf{v}_a\neq0\}$ are at pairwise sup distances $\geq\frac12\mathsf{d}+a_K$,

$$\big|\langle\mathcal{T}_{\lambda_1\lambda_1'}[\mathsf{v}_1];\dots;\mathcal{T}_{\lambda_n\lambda_n'}[\mathsf{v}_n]\rangle_K\big|\leq 4^n\,\mathsf{C}_n^\flat(\mathsf{d})\prod_a\sup|\mathsf{v}_a|.\qquad\text{(UB)}$$

Indeed, for real v_a, the weight v_a at the cutoff K is the cell reading at K of the step function $\psi_a:=\sum_x\mathsf{v}_a(x)\mathbf{1}_{x+a_K[-\frac12,\frac12)^3}$, with $\sup|\psi_a|=\sup|\mathsf{v}_a|$, and ψ_a vanishes off the union of the closed cells of the sites of $\{\mathsf{v}_a\neq0\}$, closed sets at pairwise sup distances $\geq\frac12\mathsf{d}$. From K down to K_1 the joint cumulants of the cell entries of the ψ_a change from K' to $K'+1$ by at most $\mathsf{C}^{\mathrm{av}}\ell^{3(n+1)}K'^{\mathsf{p}}L^{-\vartheta_nK'}\prod_a\sup|\psi_a|$ (for the cell entries $\mathcal{O}(w)$ of one plane and $Y[\mathsf{w}]$ of one direction), by Lemma 5.17 (c), which reads no regularity of the functions.

At K_1 the crude bounds $|\mathcal{O}(w)|\leq2\ell^3L^{4K_1}|w|_\infty$ for a weight carried by the plaquettes of one plane ($a_p\leq2$, $\ell^3L^{3K_1}$ such plaquettes) and $|Y[\mathsf{w}]|\leq\ell^3L^{4K_1}|\mathsf{w}|_\infty$ for a weight carried by the bonds of one direction ($|q_b|\leq1$) hold, a cumulant of n bounded functions being at most $\mathfrak{c}_n\prod\sup$. The

factor 2 of a diagonal component and the splitting of a complex weight into its real and imaginary parts give 4^n. *(a), (b).* $\mathcal{T}_K(H) = \frac12 \sum_{\lambda,\lambda'} \mathcal{T}_{\lambda\lambda'}[\mathsf{v}^{\mathrm{pt}}_{\lambda\lambda'}]$, nine terms with the factor $\frac12$, and $\mathcal{T}^{\mathrm{av}}_K(H)$ is the same with the weights $H^{(K)}_{\lambda\lambda'}$; both weights vanish at the sites at sup distance $> \frac12 a_K$ from $\operatorname{supp} H$, so that at $12a_K \le \mathsf{d}$, which holds for $K \ge K_1$, the sites of two members are $\ge \mathsf{d} - a_K \ge \frac12 \mathsf{d} + a_K$ apart; and $|\mathsf{v}^{\mathrm{pt}}_{\lambda\lambda'} - H^{(K)}_{\lambda\lambda'}| \le \omega(a_K)$, ω the modulus of continuity of H for the sup distance, as a point of the cell of x and the point of the point reading are within a_K.

By multilinearity and (UB) the joint cumulants of the $\mathcal{T}_K(H_a)$ and of the $\mathcal{T}^{\mathrm{av}}_K(H_a)$ are at most $18^n \mathsf{C}^{\flat}_n(\mathsf{d}) \prod_a |H_a|_\infty$, which is (a), and they differ by at most $18^n \mathsf{C}^{\flat}_n(\mathsf{d}) \sum_a \omega_a(a_K) \prod_{b\ne a} |H_b|_\infty$; the cumulants of the cell averages converge, by Lemma 5.17 (c) applied to the real and imaginary parts, with the rate $18^n \mathsf{C}^{\mathrm{av}} \ell^{3(n+1)} \sum_{K'\ge K} K'^{\mathsf{p}} L^{-\vartheta_n K'} \prod_a |H_a|_\infty$. This gives the existence and the rate in (b). For bounded Borel members the cumulants of the cell averages converge in the same way, with the bound of (a); at a fixed cutoff they are polynomials in the finitely many cell readings, which converge under bounded pointwise convergence by dominated convergence, and with the rate, uniform in such sequences, the limit is continuous under bounded pointwise convergence.

For the last assertion of (b), use Theorem BU (c) and its proof. Each class insertion is reduced to the canonical corner loops: a shift costs a_K times the Lipschitz constant, loops in the same planes are exchanged with their orientation signs by Lemma C.6 (c), and $a_p = (Q_x(l_\lambda, l_\lambda) + a_p^2)/2$, with a_p^2 of fourth order at the backgrounds. At the same site weights there is no shift cost. In particular, the difference of two such lattice forms, with a complex weight v on the sites, has at one cutoff joint cumulants with $n-1$ sources under majorants (s_a, S_a) far from it of at most $C\ell^{3n} K^{2\mathsf{p}_0+2} L^{-\vartheta_n K} \sup|\mathsf{v}| \prod_{a\ge 2} \mathsf{s}_a$, for weights of any regularity. (c) The formula for centred moments by cumulants; lattice isometries of T_ℓ keep the Wilson measure and map $\mathcal{T}_K$ covariantly, with translations of T_ℓ reached by limits; reflection positivity of the Wilson measure at the lattice planes of the torus passes to the limit, the planes of one cutoff being planes of every finer cutoff (L odd). (d) The dilation of the lattice is exact: $\mathcal{T}_K(H)$ on the torus of side ℓ is $L^z \mathcal{T}_{K-z}(H(L^{-z}\cdot))$ on that of side $L^z\ell$, the two being one abstract lattice. (e) The supports are compact and pairwise disjoint, hence at a positive sup distance d; H_η is Lipschitz.

By Theorem R (a) on T_ℓ the joint cumulants of $\mathcal{T}_K(H_\eta), \mathcal{T}_K(H_2), \dots, \mathcal{T}_K(H_n)$ in $\langle\cdot\rangle_K$ are at most $CK^p L^{-K/36} \|\eta\|_{C^2} \prod_{a\ge 2} |H_a|_\infty$, and by (b) they converge to $\mathfrak{S}_n(H_\eta, H_2, \dots, H_n)$. At other labels and sides, $H_\eta(L^{-z}\cdot) = H_{\eta^{[z]}}$ with $\eta^{[z]}(x) = L^z \eta(L^{-z}x)$, and (d) applies. □

5.5. **Conservation at a cutoff.** Here $0 < g \le \gamma$. The setting (Th) of Section B.13 is used on a torus T_ℓ, $\ell = 2L^m$, with data (K, b', m, t), $\gamma^{-2} \le \mathsf{b}_- \le \mathsf{b}' \le \mathsf{b}_+$, $MR(\mathsf{b}_+) \le L^m$; $x_k = L^{K-k}\mathsf{b}'$ is the line of the label b' of (Th3), which is not the run of a datum of Subsection 5.1, and $\rho_0\, dU$ is the bare measure. $\mathcal{V}_k$ is the set of the configurations of the level k, on the lattice of T_ℓ of the spacing a_{K-k}, and $\mathcal{M}^k : \mathcal{V}_0 \to \mathcal{V}_k$ is the block map of k renormalisation steps, $\mathcal{M}$ that of one step. *The cuts* (the definitions preceding Lemma YMM1:113.10, Lemma YMM1:113.10): with the radius $\mathsf{e}^{\mathrm{c}}_k := c_\rho\, \varepsilon(x_k)$, $\varepsilon(x) = A_0 x^{-1/2} (\log x)^{\mathsf{p}_0}$ the threshold of YMM1:(634) and c_ρ a number of the constants, Cut_0 is the set of the bare configurations V with $\max_p |\partial V(p) - \mathbf{1}| < \mathsf{e}^{\mathrm{c}}_0$, and for $1 \le k \le t$, $\mathsf{Cut}_k \subset \mathcal{V}_k$ is the set of the V over which the background exists and every U of its minimal orbit has $L^{2k} \max_p |\partial U(p) - \mathbf{1}| < \mathsf{e}^{\mathrm{c}}_k$, the maximum over the bare plaquettes.

These sets are open and gauge invariant, and they are stable downward: for $W \in \mathsf{Cut}_{k+1}$ and every fluctuation field B in its range, the configuration $V_W(B)$ of the level k lies in Cut_k. Every U of the minimal orbit over $V \in \mathsf{Cut}_k$, $k \ge 1$, is *regular of level k at the radius*

$$\varepsilon_k := 2\, \mathsf{e}^{\mathrm{c}}_k / \varepsilon_{\mathcal{W}} \le \alpha_0,$$

that is $|\partial U(p) - \mathbf{1}| < \varepsilon_k L^{-2k}$ and $|J^{(k)}(U)| < \varepsilon_k$ at all bare plaquettes and bonds, $J^{(k)}$ the current at the spacing of the level k (Definition P.3; Lemma B.4(1), $\varepsilon_{\mathcal{W}}$ a number of the constants), and U lies on the minimal orbit over $\mathcal{M}^j U \in \mathsf{Cut}_j$ for $1 \le j \le k$ (Lemma B.4(2)); besides, $\varepsilon_k^2 \le CK^{2\mathsf{p}_0} L^{-(K-k)}$,

C a number of the constants and b_+. The weight of the chain is

$$p_k(U) := \mathbf{1}_{\mathsf{Cut}_k}(V_k) \prod_{j<k} [\mathbf{1}_{\mathsf{Cut}_j}\, \mathfrak{G}_j[x_j]\, \chi^{\mathrm{sf}}_{x_j}](V_j), \qquad V_j = \mathcal{M}^j U,$$

with the bounded Borel functions $\mathfrak{G}_j[x_j] \geq 0$ and the small-field indicators $\chi^{\mathrm{sf}}_{x_j}$ of the steps (the definitions preceding Proposition YMM1:115.2, where the small-field weight of the level t is $(\mathbf{1}_{\mathsf{In}_t} \circ \mathcal{M}^t)\, p_t$). For the least torus at g these data are admissible for all labels of $\mathfrak{d}(g)$, by Lemma B.27 on the tori of $\mathfrak{L}(g)$. A *source* w is a complex weight of the plaquettes in the class of sources Src of (Th1); $\rho_0^w = \rho_0 e^{\mathcal{O}(w)}$.

Definition 5.19. A *local observable* of order $m \geq 2$ is a finite sum $\mathfrak{J}(U) = \sum_\iota \varkappa_\iota \mathsf{j}_\iota(U|_{Q_\iota})$ over boxes Q_ι of at most $3 \times 3 \times 3$ sites that extend in at least two directions, where $\varkappa_\iota \in \mathbb{C}$, j_ι is a gauge invariant polynomial in the entries of the bond matrices of Q_ι, taken in $\mathrm{SL}(2,\mathbb{C})$, with $|\mathsf{j}_\iota| \leq \hat{c}$ where these matrices have norm ≤ 2 and $|\mathsf{j}_\iota| \leq c\,\delta^m$ where besides all plaquette variables of Q_ι lie within $\delta \leq 1$ of $\mathbf{1}$, and every site is the lowest site of at most N boxes; $(m, c, \hat{c}, N)$ is its *type* and $|\varkappa|_\infty = \max_\iota |\varkappa_\iota|$. The *conditional mean after t steps* is $\mathsf{Q}_{t\leftarrow 0} = \mathsf{Q}_{t-1} \circ \cdots \circ \mathsf{Q}_0$, where Q_k sends a bounded complex Borel function h of the field of the level k to the function that vanishes off Cut_{k+1} and is, at every point of Cut_{k+1}, the integral over the fluctuation field of the step k of h times the integrand of that step at the source $w = 0$, divided by the integral of that integrand alone; the denominators do not vanish on the cut, and Borel functions go to Borel functions. ■

The cubic density with the orbital potential taken off, $\mathfrak{r}^\sharp_\lambda(p)$ of Lemma 5.21 below, is a local observable of order 3 on a box of $2 \times 2 \times 3$ sites, of the type $(3, 2^{36}\hat{c}_\sharp, \hat{c}_\sharp, N)$ with $\hat{c}_\sharp = 23185$ and a pure number N: the bound $\hat{c}_\sharp$ at bond matrices of norm at most 2 is the sum of the bounds of the terms of its closed form there. The families in the fourth place that represent it at the levels of the chain have sizes bounded through the pure number $48M^3\hat{c}_\sharp$.

Lemma 5.20. Let $0 < \phi < \frac{1}{42}$, K_ϕ the least integer $K \geq 2$ with $(1-\phi)K \geq 2$ and $L^{\phi K}\gamma^{-2} \geq \mathsf{t}_\natural$, $\mathsf{t}_\natural$ the calibration of Section B.13, formed from the numbers of (Th1). For $K \geq K_\phi$, $\mathsf{b}' \in [\mathsf{b}_-, \mathsf{b}_+]$, $u = \lceil \phi K \rceil$ and $t = K - u$ the setting (Th) holds with (K, b', m, t), and the running numbers $\theta_k = K^{\mathrm{d}} K_\Lambda \mathsf{s}^{\mathrm{abs}}_k$ of the setting (equations YMM1:(2176)–(2177)) satisfy $L\theta_k \leq \Theta_K L^{-(K-k)/2}$ and $\prod_k (1 + L\theta_k) \leq C_{\mathrm{fg}}$, $\Theta_K = \max\{1, \frac{13}{72}(L-1)(1 + K c_{\log})^{\mathfrak{p}_0}\}$. Let $\mathfrak{J}_1, \dots, \mathfrak{J}_q$ be local observables of orders ≥ 2.

(a) *(The chain with observables, at every source.)* For one observable $\mathfrak{J}$ put

$$\mathsf{m}_j = 8NM^3 c\, \alpha_0^m |\varkappa|_\infty L^{-(2m-3)j},$$

the size of $\mathfrak{J}$ as a pointed family at the level $j \geq 1$, $\mathsf{n}^{\mathrm{f}}_{\mathfrak{J}}$ its size as a family in the fourth place at the height zero,

$$\mathsf{d}_1 = K^{\mathrm{d}} \mathsf{n}^{\mathrm{f}}_{\mathfrak{J}},$$

$\mathsf{n}_j = \sum_{i \leq j} L^{-(j-i)} \mathsf{d}_i$, $\mathsf{d}_{j+1} = \theta_j(\mathsf{n}_j + \mathsf{m}_j)$, and

$$r_{\mathfrak{J}} = \min\{w_\star/(32\mathsf{n}^{\mathrm{f}}_{\mathfrak{J}}), E_0/(16(\mathsf{d}_1 + \mathsf{m}_1))\},$$

with the numbers K^{d} and $w_\star$ of (275) and E_0 of (Th1). There are numbers $\mathsf{c}_i(w,s)$ and functions $\Phi^{w,s}_k$ on Cut_k, defined by a recursion that carries $s\mathfrak{J}$ as one more early member, such that for every source w, complex sources included, every $|s| < r_{\mathfrak{J}}$ and $1 \leq k \leq t$,

$$(\mathcal{M}^k)_*(p_k\, e^{s\mathfrak{J}} \rho_0^w\, dU) = \exp\Big[\sum_{i \leq k} \mathsf{c}_i(w,s)\Big] \mathbf{1}_{\mathsf{Cut}_k} e^{\Phi^{w,s}_k}\, dV,$$

a bounded complex Borel density; the families $E^{(i)}[w,s]$ of the recursion are systems of early members with $\|E^{(i)}[w,s]\| < \frac{15}{16}E_0 + \mathbf{1}_{\{i=1\}}|s|\mathsf{d}_1$, Lipschitz in s with the numbers d_i, local in w and in $\mathfrak{J}$, and holomorphic in (w,s) and in the fields. The same holds for several

observables, $s\mathfrak{J}$ replaced by $\sum_a s_a\mathfrak{J}_a$ with $\sum_a |s_a|/r_a < 1$, holomorphically in all variables. At the source $w = 0$, $|\Phi^s_t - \Phi^{s'}_t| \le \sum_a |s_a - s'_a|\, \mathsf{o}_t(\mathfrak{J}_a)$ on Cut_t, with $\mathsf{o}_t(\mathfrak{J}) \le CK^{2\mathfrak{p}_0}L^{4u-K}|\varkappa|_\infty$ at order 2 and $\mathsf{o}_t(\mathfrak{J}) \le CK^{3\mathfrak{p}_0}L^{4u-3K/2}|\varkappa|_\infty$ at higher orders, C a function of the constants, m, b_+ and the type.

(b) $\mathsf{Q}_{t\leftarrow 0}\mathfrak{J}$ differs from a constant by at most $\mathsf{o}_t(\mathfrak{J})$ on Cut_t.

(c) *(Cumulants from oscillations.)* If $2 \le q \le 8$ and $|\mathsf{Q}_{t\leftarrow 0}\mathfrak{J}_a - \mathsf{a}_a| \le \epsilon_a$ on Cut_t, the joint cumulant of $\mathfrak{J}_1, \dots, \mathfrak{J}_q$ under $\langle\cdot\rangle_{K,\ell,L^K\mathsf{b}'}$ is at most $c_q \prod_a \epsilon_a + 4\,\mathsf{op}_q \mathsf{R}_t \prod_a \sup|\mathfrak{J}_a|$ plus a term that is exponentially small in the distance of the carriers in units of the level t; $c_q = 1 + 3.1^q \mathsf{op}_q \mathrm{Bl}_q$ and op_q are pure numbers, Bl_q the number of partitions of q elements, and $\mathsf{R}_t \le C_{\mathrm{R}} L^{3u} e^{-c' A_0^2 (\phi K \log L)^{2\mathfrak{p}_0}}$ is the large-field weight of the frame, smaller than every power of L^{-K}.

(d) A lattice isometry with diagonal linear part carries a local observable of type $(m, c, \hat{c}, N)$ to one of type $(m, 64^m \max\{c, \hat{c}\}, \hat{c}, 27N)$.

■

Proof. The frame: (Th3) of Section B.13 asks an integer t with $1 \le t \le K-1$ and $x_t \ge \mathsf{t}_\natural$, and $x_t = L^u\mathsf{b}' \ge L^{\phi K}\gamma^{-2}$; the bounds on θ_k are those of equations YMM1:(2176)–(2177), with $1+x \le e^x$. (a) An observable of order m is a pointed family at the heights ≥ 1, of the size m_j at the level j, and a family in the fourth place at the height zero. The term $s\mathfrak{J}$ is carried as one more early member: the flow from a level exists for every system of early members (Proposition YMM1:114.2), the one-step theorem holds for every family in the fourth place of size $\le w_\star/4$ (Proposition E.7), one step is an identity at every point of the next cut (Lemma B.3), and $|s| < r_{\mathfrak{J}}$ keeps all norms in the domains.

At the first step the family in the fourth place is the one of the source, less its weight, plus s times that of $\mathfrak{J}$. The Lipschitz numbers in s propagate by $\mathsf{d}_{j+1} = \theta_j(\mathsf{n}_j + \mathsf{m}_j)$, by the Lipschitz form of forgetting (the proof of Proposition YMM1:114.3), and their contribution at t is o_t; locality in the observable gives several observables at once. (b) is the derivative of (a) at $s = 0$, with Cauchy's estimate. (c) By polarisation the cumulant under the small-field functional is an alternating sum of derivatives of the logarithms of total masses; the exponents split into parts of single observables and terms that live on polymers joining two carriers, exponentially small in their distance, and the main term is a cumulant under a probability measure of the functions $\mathsf{Q}_{t\leftarrow 0}\mathfrak{J}_a - \mathsf{a}_a$; the Wilson measure differs from the small-field functional by the weight R_t. (d) The image of a box of at most $3\times 3\times 3$ sites is such a box with another lowest site, so that a site is the lowest site of at most $27N$ image boxes; the plaquette variables at the new base points are conjugate to the old ones by products of at most three bond matrices of norm ≤ 2, so they lie within 64δ of $\mathbf{1}$ when the old ones lie within δ, and where $64\delta > 1$ the bound $\hat{c}$ serves. □

Lemma 5.21. For a field Ξ on T_ℓ, three real functions on the barycentres of the plaquettes, let $\mathsf{H}(\Xi)$ be the largest of their suprema plus the largest of their Lipschitz constants in the sup distance of the torus, and

$$\mathcal{S}[\Xi] = \sum_p L^{2K}\, \Xi_{\lambda(p)}(x(p))\, \mathfrak{r}^\sharp_{\lambda(p)}(p), \qquad \mathfrak{r}^\sharp_\lambda(p) = \mathfrak{r}_\lambda(p) - \Psi_\lambda(p) + \Psi_\lambda(p - a_K e_\lambda),$$

with the cubic density $\mathfrak{r}_\lambda$ of the lattice Ward identity (Proposition YMM1:112.1) and the orbital potential Ψ_λ of Section H. Let $0 < \phi < \frac{1}{42}$. There are C_{HR}, p_{HR} and K_{HR}, functions of the constants, m, b_+ and ϕ, such that for all integers $K \ge K_{\mathrm{HR}}$, all $\mathsf{b}' \in [\gamma^{-2}, \mathsf{b}_+]$, $t = K - \lceil \phi K \rceil$, and every field Ξ there is a number a with

$$\big|(\mathsf{Q}_{t\leftarrow 0}\mathcal{S}[\Xi])(V) - \mathsf{a}\big| \le C_{\mathrm{HR}}\mathsf{H}(\Xi) K^{p_{\mathrm{HR}}} L^{-(1/14 - 3\phi)K} \qquad \text{for } \nu_t\text{-almost every } V \in \mathsf{Cut}_t;$$

for $0 < \phi < \frac{1}{30}$ the same holds with $\frac{1}{10}$ in the place of $\frac{1}{14}$. Both rates concern the conditional mean $\mathsf{Q}_{t\leftarrow 0}$ of Definition 5.19, which is formed at the source zero. ■

Proof. Apply Proposition 3.21 to the same zero-source chain with $\eta = \Xi/\mathsf{b}'$, so that $\mathcal{S}[\mathsf{b}'\eta] = \mathcal{S}[\Xi]$ and $\mathsf{H}(\eta) \le \gamma^2 \mathsf{H}(\Xi)$. The hypotheses on the torus and the label interval are the standing hypotheses here. With $(\psi, \kappa_\star) = (1/7, 3/4)$ choose $\tau = \min\{1/4, 21\phi\}$. The rate in that proposition is then $\min\{1/14 - \tau/7, 1/14 - 3\phi\} = 1/14 - 3\phi$.

For the second rate take $(\psi, \kappa_\star) = (1/5, 9/10)$ and $\tau = \min\{1/4, 15\phi\}$, giving $1/10 - \max\{\tau/5, 3\phi\} = 1/10 - 3\phi$. The choices of τ explain the permitted ϕ dependence of the constants and of the power of K. The localized inversion split, the Hölder gain and the stopping of the carried families are given in the proof of Proposition 3.21, using Lemmas 3.17 and 3.19.

□

Remark 5.22. The cubic density has a Gaussian illustration at fixed parameters. Fix a finite torus, a regulator $\mathsf{m} > 0$, and a gauge fixing of the following class: $\mathsf{D}_{\bar U}$ and $\mathsf{G}_{\bar U} \ge 0$ are real analytic in the background, $\mathsf{D}_{\mathbf{1}} = d$, and $\mathsf{G}_{\mathbf{1}}$ is a convolution with a real even function, the same for the three colours. For a real background direction $\bar A$ put $\bar U_\lambda = e^{i\lambda \bar A}$ and

$$\langle A, \mathsf{H}_{\bar U} A\rangle = \mathrm{Hs}_{\bar U}(A) + \langle \mathsf{D}^*_{\bar U} A, \mathsf{G}_{\bar U} \mathsf{D}^*_{\bar U} A\rangle + \mathsf{m}^2 \|A\|^2, \qquad \mathrm{Hs}_{\bar U}(A) = \frac{d^2}{d\mathsf{g}^2}\Big|_{\mathsf{g}=0} \sum_q a_q(e^{i\mathsf{g}A}\bar U).$$

At $\lambda = 0$ this form is positive definite, and for sufficiently small real λ it defines a centred Gaussian with covariance $C_\lambda = \mathsf{H}^{-1}_{\bar U_\lambda}$. The size of this neighbourhood may depend on all the fixed parameters. Here $\mathsf{g} = \beta^{-1/2}$ serves only as an expansion parameter.

Let $T_p(\lambda)$ be the coefficient of g^2 in the Gaussian mean of $\mathfrak{r}^\sharp_{\lambda(p)}(p)(e^{i\mathsf{g}A}\bar U_\lambda)$, and let $\Phi_p^{(r,s)}$ be its density term of degree r in A and degree s in $\bar A$. The cancellation proved in Proposition H.1 shows that the density has no term of total degree at most two. Its cubic term is $\frac14 \sum_{\sigma=\pm} \sigma \sum_{j\in\mathbb{Z}_4} (\mathsf{z}^\sigma_j \times \mathsf{z}^\sigma_{j+1}) \cdot \mathsf{x}$, where x is the field strength at p and z^σ_j are the legs at the four side faces above and below p.

Write $C_\lambda = C_0 + \lambda C_1 + O(\lambda^2)$, with $C_1 = -C_0 \mathsf{H}_1 C_0$ and $\mathsf{H}_1 = \partial_\lambda \mathsf{H}_{\bar U_\lambda}\big|_0$. The matrix C_0 is diagonal in the colours. Thus $\Phi_p^{(2,0)} = 0$, and every term of $\langle \Phi_p^{(2,1)}\rangle_{C_0}$ contracts an antisymmetric colour tensor with that diagonal matrix, so it is zero. Consequently

$$T_p(\lambda) = \lambda^2 \mathsf{q}_p[\bar A] + O(\lambda^3), \qquad \mathsf{q}_p = \langle \Phi_p^{(2,1)}\rangle_{C_1} + \langle \Phi_p^{(2,2)}\rangle_{C_0}.$$

Brackets with C_1 denote linear Gaussian contraction with that symmetric matrix; C_1 need not be positive. All parameters except λ are fixed in this expansion.

Lemma 5.23. For all K, all $\beta > 0$ and every $\eta \in C^2_c(\mathbb{R}^3; \mathbb{R}^3)$, on $\mathbb{L}_K$ (and, with any C^2 vector field, on a torus), identically in U,

$$b\, \mathcal{T}_K(H^K_\eta) = \mathcal{Z}_\eta + X''[\eta] + \mathfrak{Y}[\eta], \tag{11}$$

where the signs are the following. *Lattice differences* of a function φ, with $a = a_K$: the centred one $(\nabla^{\mathrm c}_\rho \varphi)(y) = a^{-1}[\varphi(y + \frac a2 e_\rho) - \varphi(y - \frac a2 e_\rho)]$, the symmetric one $(\nabla^{\mathrm s}_\rho \varphi)(y) = (2a)^{-1}[\varphi(y + ae_\rho) - \varphi(y - ae_\rho)]$, the forward and the backward ones $(\nabla^\pm_\rho \varphi)(y) = \pm a^{-1}[\varphi(y \pm ae_\rho) - \varphi(y)]$, and $(\delta^2_\nu \varphi)(y) = \varphi(y + \frac a2 e_\nu) + \varphi(y - \frac a2 e_\nu) - 2\varphi(y)$; $\nabla^{\mathrm s} \cdot \eta = \sum_\kappa \nabla^{\mathrm s}_\kappa \eta^\kappa$. *The lattice tensor.* H^K_η is H_η with the entries that $\mathcal{T}_K$ reads replaced by lattice ones: at the barycentre of a plaquette p with the normal $\lambda = \lambda(p)$ the diagonal entry $(\nabla^{\mathrm s} \cdot \eta - 2\nabla^{\mathrm s}_\lambda \eta^\lambda)(x(p))$, and at the midpoint of a bond b the off-diagonal entry $-(\nabla^{\mathrm c}_{\lambda'} \eta^\lambda + \nabla^{\mathrm c}_\lambda \eta^{\lambda'})(x_b)$, $\{\lambda, \lambda'\} = \{\lambda_b, \lambda'_b\}$; as $|\nabla^{\mathrm s}_\rho \varphi - \partial_\rho \varphi| \le \frac a2 \sup |\partial^2_\rho \varphi|$ and $|\nabla^{\mathrm c}_\rho \varphi - \partial_\rho \varphi| \le \frac a4 \sup |\partial^2_\rho \varphi|$, $|H^K_\eta - H_\eta|_\infty \le \frac 32 a_K \|\nabla^2 \eta\|_\infty$.

The null terms. For a field of directions $\mathbf{X}$, $\mathfrak{v}_{\mathbf X}$ is the derivation along it and its null term is $\beta \mathfrak{v}_{\mathbf X} \sum_p a_p - \operatorname{div} \mathfrak{v}_{\mathbf X}$; $\mathcal{N}_\eta$ is the null term of $\mathbf{X}_\eta(b) = a^{-1} \sum_\rho \eta^\rho(x_b) \mathbf{u}_{b,\rho}$, and $\mathcal{N}_{\mathsf k}$, for a vector field $\mathsf k$, that of $\mathbf{X}^{\mathsf k}(b) = \sum_\rho \mathsf{k}^\rho(x_b) \mathbf{y}_{b,\rho}$, with $\mathbf{u}_{b,\mu_b} = \mathbf{y}_{b,\mu_b} := 0$. With $\mathsf{k}^\rho_\eta := \nabla^+_\rho \eta^\rho$ and the number $c_{\mathsf k} := 6 \sum_b \sum_{\rho \ne \mu_b} \mathsf{k}^\rho(x_b)$, free of U, $\mathcal{Z}_\eta = \mathcal{N}_\eta - \frac14 \mathcal{N}_{\mathsf{k}_\eta} - \frac14 c_{\mathsf{k}_\eta}$ is the number $-\frac14 c_{\mathsf{k}_\eta}$ plus null terms.

The nine observables.

$$X''[\eta] = \sum_{v=1}^{9} \mathfrak{J}_v[\eta],$$

a sum of local observables of the orders $3, 2, 2, 2, 2, 2, 3, 4, 4$:

$$\mathfrak{J}_1 = -\mathcal{S}[b\eta], \quad (\mathfrak{J}_2, \mathfrak{J}_3, \mathfrak{J}_4, \mathfrak{J}_7, \mathfrak{J}_8) = (\mathfrak{J}_{0,1}, \mathfrak{J}_{0,2}, \mathfrak{J}_{0,3}, \mathfrak{J}_{0,4}, \mathfrak{J}_{0,5})[\mathsf{k}_\eta], \quad \mathfrak{J}_5 = -\tfrac{3}{2} a\, \mathcal{O}(w_\eta), \quad \mathfrak{J}_6 = -E_2[\eta], \quad \mathfrak{J}_9 = -E_4[\eta],$$

where $w_\eta(p) = \sum_{\rho \in \mathsf{P}(p)} (\nabla^{\mathrm{c}}_\rho \eta^\rho)(x(p))$, $\mathsf{P}(p)$ the two directions of the plane of p;

$$E_4[\eta] = -\frac{\beta}{2} \sum_b \sum_{\nu \neq \mu_b} (\nabla^{\mathrm{c}}_\nu \eta^\nu)(x_b) \big(a^2_{p(b,\nu)} + a^2_{p(b,-\nu)}\big), \qquad E_2[\eta] = -\frac{\beta}{2a} \sum_b \sum_{\rho, \nu \neq \mu_b} (\delta^2_\nu \eta^\rho)(x_b)\, \langle \mathbf{u}_{b,\rho}, \mathbf{y}_{b,\nu} \rangle,$$

$p(b, \pm\nu)$ the plaquette of the loop $W_x(\mu_b, \pm\nu)$, $b = \langle x, x + a e_{\mu_b} \rangle$; and, for a vector field k, the five pieces of the orbital bilinear

$$\begin{aligned}
\mathfrak{J}_{0,1}[\mathsf{k}] &= \sum_p \Big[\tfrac{3}{4} \mathsf{e}^{\mathsf{k}}_{\mathsf{P}(p)}(x(p)) - \tfrac{1}{4} \beta a^2 \sum_\rho (\nabla^-_\rho \nabla^+_\rho \mathsf{k}^\rho)(x(p)) \Big] a_p, \\
\mathfrak{J}_{0,2}[\mathsf{k}] &= \tfrac{\beta}{4} \sum_{p,\rho} \sum_{b \subset \partial p} \big(\mathsf{k}^\rho(x_b) - \mathsf{k}^\rho(x(p)) \big) \\
&\qquad \langle \mathbf{y}_{b,\rho}, \mathbf{w}(W_{b,p}) \rangle, \\
\mathfrak{J}_{0,3}[\mathsf{k}] &= -\tfrac{\beta a}{2} \sum_{p,\rho} (\nabla^+_\rho \mathsf{k}^\rho)(x(p))\, \Psi_\rho(p), \\
\mathfrak{J}_{0,4}[\mathsf{k}] &= \tfrac{\beta}{4} \sum_p \mathsf{k}^{\lambda(p)}(x(p))\, \mathfrak{e}_{\lambda(p)}(p), \\
\mathfrak{J}_{0,5}[\mathsf{k}] &= -\tfrac{\beta}{2} \sum_p \Big(\sum_{\rho \in \mathsf{P}(p)} \mathsf{k}^\rho(x(p)) \Big) a^2_p,
\end{aligned}$$

with $\mathsf{e}^{\mathsf{k}}_{\mathsf{P}}(y) = \sum_{\rho \in \mathsf{P}} [\mathsf{k}^\rho(y + \frac{a}{2} e_\rho) + \mathsf{k}^\rho(y - \frac{a}{2} e_\rho)]$, $W_{b,p}$ the loop of p that starts along b ($W_x(\mu_b, \pm\nu)$ at $p = p(b, \pm\nu)$), the orbital potential $\Psi_\rho(p)$ of Section H, $p_\pm = p \pm a e_\rho$, and the density

$$\mathfrak{e}_\rho(p) := \sum_{b \subset \partial p} \langle \mathbf{y}_{b,\rho}, \mathbf{w}(W_{b,p}) \rangle + 2[\Psi_\rho(p) + \Psi_\rho(p_-)] + [a_{p_+} + a_{p_-} - 2a_p],$$

which is of the order 3 at the normal direction. When $b = a_K \beta \leq \mathsf{b}_+$ the weights of the nine observables are at most $(3 + 5\mathsf{b}_+) L^{\omega_K} \|\eta\|_{C^2}$, $\omega = 2, 0, 0, 0, 0, 0, 1, 1, 1$, and every site of a box with a weight $\neq 0$ lies within $4a_K$ of $\operatorname{supp} \eta$. The *orbital remainder* of the lattice Ward identity is $X'[\eta] := X''[\eta] + E_4[\eta] + E_2[\eta]$, the sum of the seven observables other than $\mathfrak{J}_6$ and $\mathfrak{J}_9$. And

$$\mathfrak{Y}[\kappa] = \frac{\beta}{4} \sum_b \sum_{\nu \neq \mu_b} \kappa_{\mu_b \nu}(x_b)\, |\mathbf{y}_{b,\nu}|^2, \qquad \mathfrak{Y}[\eta] = \mathfrak{Y}[\kappa] \text{ at } \kappa_{\mu\nu} = \nabla^{\mathrm{c}}_\nu \eta^\nu.$$

For every Gibbs state ν at (a_K, β) and every torus measure, $\nu(\mathcal{N} Y) = 0$ for every bounded Borel Y that does not depend on the bonds at which the field of directions of $\mathcal{N}$ is not zero; so every joint cumulant with the member $\mathcal{N}$ and further members that do not depend on those bonds vanishes. The coefficient of $\mathcal{T}_K$ in (11) is exactly b. ■

Proof. All the identities are identities between polynomials in the matrices at finitely many bonds; they are proved on a torus, and they hold on $\mathbb{L}_K$ for a field of compact support, whose bonds may be placed on a torus without wrapping. Write $A = \sum_p a_p$, $\mathfrak{d}_{b,p,\rho} = \langle \mathbf{u}_{b,\rho}, \mathbf{w}(W_{b,p}) \rangle$, and recall

$|\mathbf{w}(W)|^2 = 2a_q - a_q^2$ for a loop W of a plaquette q: for $W = c\mathbf{1} + is\mathsf{n}$ with $c^2 + s^2 = 1$ and a unit vector n of the Lie algebra, $\mathbf{w}(W) = s\mathsf{n}$ and $a_q = 1 - c$.

1. The variation along η. The lattice calculus of Lemma J.1, with the general field (301) at the constant weight β and the divergence (302), gives $\beta\mathfrak{v}_{\mathbf{X}_\eta} A = \mathfrak{K}^{\mathrm{v}}[\beta\eta] - b\,\mathcal{O}(\nabla^{\mathrm{s}}\cdot\eta) + \Theta_\beta[\eta]$, with $\Theta_\beta[\eta] = \beta\sum_p a^{-1}\sum_{b\subset\partial p}\sum_\rho(\eta^\rho(x_b) - \eta^\rho(x(p)))\,\mathfrak{d}_{b,p,\rho}$, and $\operatorname{div}\mathfrak{v}_{\mathbf{X}_\eta} = -\frac{3}{2}a\,\mathcal{O}(w_\eta)$. So the *stress insertion* $\mathsf{St}_K[\eta] := \Theta_\beta[\eta] - b\,\mathcal{O}(\nabla^{\mathrm{s}}\cdot\eta)$ is $\mathcal{N}_\eta - \mathfrak{K}^{\mathrm{v}}[\beta\eta] - \frac{3}{2}a\,\mathcal{O}(w_\eta)$. The summation by parts (297) at the vector weight $\beta\eta$, with $\beta a^{-1} = bL^{2K}$, gives $\mathfrak{K}^{\mathrm{v}}[\beta\eta] = \mathcal{S}[b\eta] - \mathfrak{J}^{\mathrm{II}}[\mathsf{k}_\eta]$, where

$$\mathfrak{J}^{\mathrm{II}}[\mathsf{k}] := \beta\sum_p\sum_\rho \mathsf{k}^\rho(x(p))\,\Psi_\rho(p)$$

is the *orbital bilinear*: an observable of the order 2 with the weight $\beta = L^K b$, which the power counting of Lemma 5.20 does not make small.

2. The orbital bilinear is a null term up to observables that power counting bears. For every vector field k, identically in U,

$$\mathfrak{J}^{\mathrm{II}}[\mathsf{k}] = -\tfrac{1}{4}\mathcal{N}_{\mathsf{k}} + \sum_{v=1}^{5}\mathfrak{J}_{0,v}[\mathsf{k}] - \tfrac{1}{4}c_{\mathsf{k}}.$$

By Lemma J.1, $\partial_b^{\mathsf{a}} a_p = \langle\sigma_{\mathsf{a}}, \mathbf{w}(W_{b,p})\rangle$ for $p \ni b$ and $\partial_b^{\mathsf{a}}\langle\sigma_{\mathsf{a}}, \mathbf{w}(W_{b,p})\rangle = 1 - a_p$; so $\mathfrak{v}_{\mathbf{X}^{\mathsf{k}}} a_p = \sum_{b\subset\partial p}\langle\mathbf{X}^{\mathsf{k}}(b), \mathbf{w}(W_{b,p})\rangle$ and

$$\operatorname{div}\mathfrak{v}_{\mathbf{X}^{\mathsf{k}}} = 3\sum_b\sum_{\rho\neq\mu_b}\mathsf{k}^\rho(x_b)\,[2 - a_{p(b,\rho)} - a_{p(b,-\rho)}] = c_{\mathsf{k}} - 3\sum_p a_p\,\mathsf{e}^{\mathsf{k}}_{\mathsf{P}(p)}(x(p)),$$

the last sum ordered by the plaquettes: $p = p(b, \mp\rho)$ exactly for $\rho \in \mathsf{P}(p)$ and the bond b of p with $x_b = x(p) \pm \frac{a}{2}e_\rho$. In $\mathfrak{v}_{\mathbf{X}^{\mathsf{k}}} A$ write $\mathsf{k}^\rho(x_b) = \mathsf{k}^\rho(x(p)) + (\mathsf{k}^\rho(x_b) - \mathsf{k}^\rho(x(p)))$; the first part is $\sum_{p,\rho}\mathsf{k}^\rho(x(p))\{-2[\Psi_\rho(p) + \Psi_\rho(p_-)] - [a_{p_+} + a_{p_-} - 2a_p] + \mathfrak{e}_\rho(p)\}$, by the definition of $\mathfrak{e}_\rho$. If ρ lies in the plane of p, then $\mathfrak{e}_\rho(p) = -2a_p^2$: at the two bonds b_1, b_2 of p of the other direction, $\langle\mathbf{w} + \mathbf{w}', \mathbf{w}\rangle = \frac{1}{2}|\mathbf{w} + \mathbf{w}'|^2 + \frac{1}{2}|\mathbf{w}|^2 - \frac{1}{2}|\mathbf{w}'|^2$ with $\mathbf{w} = \mathbf{w}(W_{b,p})$, $|\mathbf{w}(W)|^2 = 2a_q - a_q^2$, and the first form of (298), $|\mathbf{y}_{b_2,\rho}|^2 = -4\Psi_\rho(p) - a_p^2 - a_{p_+}^2$ and $|\mathbf{y}_{b_1,\rho}|^2 = -4\Psi_\rho(p_-) - a_{p_-}^2 - a_p^2$, give $\sum_{b\subset\partial p}\langle\mathbf{y}_{b,\rho}, \mathbf{w}(W_{b,p})\rangle = -2[\Psi_\rho(p) + \Psi_\rho(p_-)] - [a_{p_+} + a_{p_-} - 2a_p] - 2a_p^2$.

Shifting $p \mapsto p \pm ae_\rho$, $\sum_p \mathsf{k}^\rho(x(p))\Psi_\rho(p_-) = \sum_p \mathsf{k}^\rho(x(p) + ae_\rho)\Psi_\rho(p)$ and $\sum_p \mathsf{k}^\rho(x(p))[a_{p_+} + a_{p_-} - 2a_p] = a^2\sum_p(\nabla_\rho^-\nabla_\rho^+\mathsf{k}^\rho)(x(p))\,a_p$. Solving for $\sum_{p,\rho}\mathsf{k}^\rho(x(p))\Psi_\rho(p)$, multiplying by $\beta = ba^{-1}$, writing $\beta\mathfrak{v}_{\mathbf{X}^{\mathsf{k}}} A = \mathcal{N}_{\mathsf{k}} + \operatorname{div}\mathfrak{v}_{\mathbf{X}^{\mathsf{k}}}$ and using the value of $\mathfrak{e}_\rho$ in the plane gives the identity with the five pieces of the statement. Their densities a_p, $\langle\mathbf{y}_{b,\rho}, \mathbf{w}(W_{b,p})\rangle$, $\Psi_\rho(p)$ are of the order 2, $\mathfrak{e}_{\lambda(p)}(p)$ is of the order 3 (its part of the total order at most two in the logarithms of the bond variables cancels) and a_p^2 is of the order 4, each on a box within $\frac{3}{2}a$ of $x(p)$; their weights are at most $3\|\mathsf{k}\|_\infty + \frac{3}{2}b\operatorname{Lip}_\infty\mathsf{k}$, $\frac{1}{8}b\operatorname{Lip}_\infty\mathsf{k}$, $\frac{1}{2}b\operatorname{Lip}_\infty\mathsf{k}$, $\frac{1}{4}\beta\|\mathsf{k}\|_\infty$, $\beta\|\mathsf{k}\|_\infty$, and a weight at an index of p vanishes unless $x(p)$ is within a of $\operatorname{supp}\mathsf{k}$.

3. Two forms of the stress insertion. Steps 1 and 2 give $\mathsf{St}_K[\eta] = \mathcal{Z}_\eta + X'[\eta]$. On the other hand, order Θ_β by the bonds: b lies in the four plaquettes $p(b, \pm\nu)$, $\nu \neq \mu_b$, with $x(p(b, \pm\nu)) = x_b \pm \frac{a}{2}e_\nu$, and the vector parts $\mathbf{w}_\pm = \mathbf{w}(W_x(\mu_b, \pm\nu))$ are $\frac{1}{2}\mathbf{y}_{b,\nu} \mp \mathbf{u}_{b,\nu}$; so

$$\Theta_\beta[\eta] = \beta\sum_b\sum_{\rho,\nu\neq\mu_b}(\nabla_\nu^{\mathrm{c}}\eta^\rho)(x_b)\langle\mathbf{u}_{b,\rho}, \mathbf{u}_{b,\nu}\rangle + E_2[\eta].$$

The terms with $\rho \neq \nu$ are $b\,Y[\mathsf{w}]$ at the off-diagonal entries of H_η^K, because $\langle\mathbf{u}_{b,\lambda_b}, \mathbf{u}_{b,\lambda_b'}\rangle = q_b$. In the terms with $\rho = \nu$ the parallelogram law and $|\mathbf{w}(W)|^2 = 2a_q - a_q^2$ give $|\mathbf{u}_{b,\nu}|^2 = (a_{p(b,\nu)} + a_{p(b,-\nu)}) - \frac{1}{2}(a_{p(b,\nu)}^2 + a_{p(b,-\nu)}^2) - \frac{1}{4}|\mathbf{y}_{b,\nu}|^2$; the second and the third part give $E_4[\eta]$ and $-\mathfrak{Y}[\eta]$, and the first, ordered by the plaquettes with $(\nabla_\nu^{\mathrm{c}}\eta^\nu)(x(p) \pm \frac{a}{2}e_\nu) = (\nabla_\nu^{\pm}\eta^\nu)(x(p))$ and $\nabla^+ + \nabla^- = 2\nabla^{\mathrm{s}}$, is $b\,\mathcal{O}(w)$

with $w(p) = 2\sum_{\nu\in\mathsf{P}(p)}(\nabla^{\mathrm{s}}_\nu\eta^\nu)(x(p))$; less $b\,\mathcal{O}(\nabla^{\mathrm{s}}\cdot\eta)$ this is $b\,\mathcal{O}$ at the diagonal entries of H^K_η. So $\mathsf{St}_K[\eta] = b\,\mathcal{T}_K(H^K_\eta) - \mathfrak{Y}[\eta] + E_4[\eta] + E_2[\eta]$.

4. The two forms together give (11), with $X'' = X' - E_4 - E_2$; the coefficient b of $\mathcal{T}_K$ is that of the variation of the action itself. The orders and the weights of $\mathfrak{J}_1$, $\mathfrak{J}_5$, E_2, E_4 are read off their formulas ($|\delta^2_\nu\varphi| \le \frac{a^2}{4}\sup|\partial^2_\nu\varphi|$; $\langle \mathbf{u}_{b,\rho}, \mathbf{y}_{b,\nu}\rangle$ is a density of the order 2), and those of the five pieces at k_η follow from $\|\mathsf{k}_\eta\|_\infty \le \|\nabla\eta\|_\infty$, $\mathrm{Lip}_\infty\,\mathsf{k}_\eta \le 3\|\nabla^2\eta\|_\infty$ and $b \le \mathsf{b}_+$. *The null property.* Let the field of directions $\mathbf{X}$ of $\mathcal{N}$ vanish off a finite set Λ of bonds, and let Y not read the bonds of Λ: invariance of Haar measure (Lemma J.1) gives $\int(\mathrm{div}\,\mathfrak{v}_{\mathbf{X}} - \beta\mathfrak{v}_{\mathbf{X}}A)\,Y\,e^{-\beta\sum_{p\cap\Lambda\neq\emptyset}a_p}\prod_{b\in\Lambda}dU(b) = 0$, so the Gibbs kernel of Λ annihilates $\mathcal{N}Y$, and the DLR equations give $\nu(\mathcal{N}Y) = 0$. □

Proposition 5.24. Let $r > 0$, and consider on the least torus $T_{\ell'}$ a board with cells of side $\ell'/2$; let $t_0 = K - \lceil K/400\rceil$. There are C, p, K_8, functions of the constants, g, r and the rate c below, such that for all $(K,\beta) \in \mathfrak{d}(g)$ with $K \ge K_8$, with $\langle\cdot\rangle = \langle\cdot\rangle_{K,\ell',\beta}$, and for objects carried by one cell at sup distance $\ge r$ from its walls:

(a) $\|X''[\eta] - \langle X''[\eta]\rangle\|_{\mathrm{ch},\ell'} \le CK^pL^{-cK}\|\eta\|_{C^2}$ for every $c < \frac{1}{10}$, at every offset of the board in $a_K\mathbb{Z}^3$; the same for the orbital remainder $X'[\eta] = X''[\eta] + E_4[\eta] + E_2[\eta]$ of the lattice Ward identity, the sum of the seven pieces of $X''[\eta]$ other than $\mathfrak{J}_6 = -E_2[\eta]$ and $\mathfrak{J}_9 = -E_4[\eta]$ (Lemma 5.23); and the joint cumulants of $2 \le q' \le 8$ of the nine pieces $\mathfrak{J}_v[\eta]$ in different cells are at most $(CK^pL^{-cK}\|\eta\|_{C^2})^{q'}$;

(b) $\|\mathfrak{Y}[\kappa] - \langle\mathfrak{Y}[\kappa]\rangle\|_{\mathrm{ch},\ell'} \le CK^pL^{-cK}\sup|\kappa|$ for every $c < \frac{2}{11}$ and six bounded real functions $\kappa_{\mu\nu}$;

(c) $\|\mathcal{T}_K(H') - \langle\mathcal{T}_K(H')\rangle\|_{\mathrm{ch},\ell'} \le CK^{2\mathfrak{p}_0}L^{K/100}|H'|_\infty$ for every bounded H', at offsets in $a_{K-t_0}\mathbb{Z}^3$;

(d) $\|\mathcal{T}_K(H_\eta) - \langle\mathcal{T}_K(H_\eta)\rangle\|_{\mathrm{ch},\ell'} \le CK^pL^{-cK}\|\eta\|_{C^2}$ for every $c < \frac{1}{10}$, at offsets in $a_{K-t_0}\mathbb{Z}^3$.

■

Proof. The eight copies of an observable carried by one cell are local observables: the mirror maps are diagonal lattice isometries, and Lemma 5.20 (d) gives the copies of a local observable of the type $(m, c, \hat{c}, N)$ the type $(m, 64^m\max\{c,\hat{c}\}, \hat{c}, 27N)$. Their carriers are $\ge 2(r - 4a_K) \ge r$ apart once $8a_K \le r$, as the boxes of a piece reach at most $4a_K$ beyond the support of η (Lemma 5.23), that is $\ge rL^{K-t}$ in units of the level t. The mean of the product of eight centred copies is a sum over the 715 partitions of the eight copies into blocks of at least two elements of products of joint cumulants, which Lemma 5.20 (c) bounds by oscillations of conditional means, the large-field term and the term on polymers joining two carriers being negligible. (a) The cubic term is bounded by Lemma 5.21 with $\Xi = b\eta$, $\mathsf{H}(b\eta) \le 4\mathsf{b}_+\|\eta\|_{C^2}$, at a ϕ so small that $\frac{1}{10} - 3\phi > c$, in each of the eight copies: for a diagonal lattice isometry $\mathsf{r} : x \mapsto \mathrm{diag}(s_1,s_2,s_3)x + v$, the covariance Proposition H.1(c) of $\mathfrak{r}^\sharp$ under the lattice isometries gives $\mathsf{r}\,\mathcal{S}[\Xi] = \mathcal{S}[\Xi^{\mathsf{r}}]$ with $\Xi^{\mathsf{r}}_\rho = s_\rho\,\Xi_\rho\circ\mathsf{r}^{-1}$, and $\mathsf{H}(\Xi^{\mathsf{r}}) = \mathsf{H}(\Xi)$; so Lemma 5.21, which holds for every field, applies to each copy.

The other eight terms have orders $m \ge 2$ and weights $\le L^{\omega K}$ with $\omega = 1$ only for $m \ge 3$, and Lemma 5.20 (a), (b), at the types of the copies, give oscillations $\le CK^{3\mathfrak{p}_0}L^{4u-K/2}$. (b) The mirror copies of $\mathfrak{Y}[\kappa]$ are forms of the same kind: for a diagonal lattice isometry r and b^{r} the positively oriented one of the bonds $\mathsf{r}b$, $\overline{\mathsf{r}b}$, $\mathsf{r}|\mathbf{y}_{b,\nu}|^2 = |\mathbf{y}_{b^{\mathsf{r}},\nu}|^2$, by the covariance of the holonomies (Lemma G.1), so that $\mathsf{r}\,\mathfrak{Y}[\kappa] = \mathfrak{Y}[\kappa^{\mathsf{r}}]$ with a weight κ^{r} of the same sup norm, and the bound below holds for every bounded weight. $\mathfrak{Y}[\kappa]$ is an observable of order 2 with weights of the size $\beta = L^Kb$; but at every U of the minimal orbit over $V \in \mathsf{Cut}_n$, which is regular of level n at the radius ε_n of Subsection 5.5, each $\mathbf{y}_{b,\nu}$, the sum of the vector parts of the two plaquettes opposite at b, is a lattice derivative of the field strength and is one power of the scale smaller than each part:

$$|\mathbf{y}_{b,\nu}(U)| \le 48\,\mathsf{c}_{\mathrm{g}}(\beta_{\mathrm{H}})\rho_{\mathrm{H}}\,\varepsilon_nL^{-(2+\beta_{\mathrm{H}})n},$$

with the Hölder exponent $0 \le \beta_{\mathrm{H}} < 1$ and the numbers $\mathsf{c}_{\mathrm{g}}(\beta_{\mathrm{H}})$, ρ_{H}, a_{g} of the local gauges on cubes (Theorem BT), once $\rho_{\mathrm{H}}\varepsilon_n \le a_{\mathrm{g}}$, $\mathsf{c}_{\mathrm{g}}(\beta_{\mathrm{H}})\rho_{\mathrm{H}}\varepsilon_n \le 1$ and $6\rho_{\mathrm{H}} < L^{m+K-n}$, which hold for large

K. Indeed, on the cube of the side $2\rho_{\mathrm{H}}$, in units of the level n, about a site there is a gauge in which $U = e^{iL^{-n}A}$ with $|A|, |\nabla A| < \mathsf{c}_{\mathrm{g}}\rho_{\mathrm{H}}\varepsilon_n$ and a Hölder bound of the exponent β_{H} and the number $\mathsf{c}_{\mathrm{g}}(\beta_{\mathrm{H}})\rho_{\mathrm{H}}\varepsilon_n$ on ∇A; there the sum of the vector parts of the two loops opposite at b is L^{-2n} times the difference of the field strength at two neighbouring plaquettes, up to $O(\varepsilon_n^2 L^{-3n})$.

Cutting the chain at the level $n_0 = K - \lceil \psi K \rceil$, where $\varepsilon_{n_0}^2 \le CK^{2\mathfrak{p}_0}L^{-\psi K}$, what is born below n_0 is born at a small coupling, and above n_0 the conditional mean is a mean of the value at n_0; the oscillation decays at the rate $\min\{\frac{\psi}{2} - 4\phi, \frac{1}{2} - 4\phi, 2\beta_{\mathrm{H}} - (3 + 2\beta_{\mathrm{H}})\psi\}$, which is $\frac{1}{14}$ at $(\beta_{\mathrm{H}}, \psi, \phi) = (\frac{1}{2}, \frac{1}{6}, \frac{1}{336})$ and approaches $\frac{2}{11}$ as $\phi \to 0$, $\beta_{\mathrm{H}} \to 1$, $\psi = \frac{4}{11}$. (c) $\mathcal{T}_K(H')$ is an observable of order 2 with weights $\le L^K|H'|_\infty$; Lemma 5.20 at $\phi = \frac{1}{400}$ gives the oscillation $CK^{2\mathfrak{p}_0}L^{4u}|H'|_\infty$, $4u \le \frac{K}{100} + 4$. (d) Insert (11).

In the mean of the eight centred copies every term that contains a null term of one copy vanishes, since the other copies do not depend on its bonds; so (a), (b) and (c) for $\mathcal{T}_K(H_\eta - H_\eta^K)$, whose sup norm is $\le \frac{3}{2}a_K\|\nabla^2\eta\|_\infty$, give (d), as $b > g^{-2}$. □

The *stress insertion* $\mathsf{St}_K[\eta] = \Theta_\beta[\eta] - b\,\mathcal{O}(\nabla^{\mathrm{s}} \cdot \eta)$ of the lattice Ward identity (the proof of Lemma 5.23) is $\mathcal{Z}_\eta + X'[\eta] = b\,\mathcal{T}_K(H_\eta^K) - \mathfrak{Y}[\eta] + (X'[\eta] - X''[\eta])$; it differs from $b\,\mathcal{T}_K(H_\eta^K)$ by $X'[\eta] - X''[\eta] - \mathfrak{Y}[\eta] = E_4[\eta] + E_2[\eta] - \mathfrak{Y}[\eta]$. By Proposition 5.24 (a), (b) this difference has the eight-copy seminorm $\le CK^pL^{-cK}\|\eta\|_{C^2}$. With Proposition 5.24 (c) and the two-cell argument of the proof of Theorem R, and with $A^\nu[F] := F - \nu(F)$: for $\mathsf{d}, R > 0$ there are C, p, K_0, functions of the constants, g, d and R, such that for $K \ge K_0$ and in every periodic Gibbs state $|\nu(A^\nu[\mathsf{St}_K[\eta] - b\mathcal{T}_K(H_\eta)]\,A^\nu[Z])| \le CK^pL^{-K/60}\|\eta\|_{C^2}\mathsf{z}$, for $Z = \mathcal{T}_K(H')$, $\mathsf{z} = |H'|_\infty$, and for Z a further stress insertion, $\mathsf{z} = \|\eta'\|_{C^2}$, with supports in a cube of the side $2R$ at sup distance $\ge \mathsf{d}$. So the limits of the correlations of the stress insertion are those of b_* times the tensor at H_η: the coefficient is exactly one, and no other combination of the components enters.

5.6. **Abstract data.** In this subsection no lattice occurs. We write $y = (y^0, y^1) = (x_3, x_1)$ for the plane of the rotations R_t and $x = (y, x_2)$; for $\xi \in \mathbb{C}^2$, $\xi^\pm = \xi^0 \pm i\xi^1$, $(\mathsf{R}_\zeta\xi)^\pm = e^{\pm i\zeta}\xi^\pm$ for $\zeta \in \mathbb{C}$, $d(\xi) = \min \mathrm{Re}\,\xi^\pm$, $\mathsf{Tb} = \{d > 0\}$, whose real points form the half plane $\mathbb{R}^2_+ = \{y \in \mathbb{R}^2 : y^0 > 0\}$, $\xi^* = (\overline{\xi^0}, -\overline{\xi^1})$, $n_\alpha = (\cos\alpha, \sin\alpha)$, and $\mathsf{T}(\xi) = \int e^{-\xi^0 E + i\xi^1 q_1}\,d\mathcal{P}$, a contraction for $\xi \in \overline{\mathsf{Tb}}$, holomorphic in norm on Tb, with $\mathsf{T}(\xi)\mathsf{T}(\xi') = \mathsf{T}(\xi + \xi')$, $\mathsf{T}(\xi)^* = \mathsf{T}(\xi^*)$, $\mathsf{T}(\xi)\Omega = \Omega$ and $\mathsf{T}(y)[F] = [\tau_y F]$ at real y with $y^0 \ge 0$; for real s, $d(\mathsf{R}_{is}\xi) \ge e^{-|s|}d(\xi)$, with equality $d(\mathsf{R}_{is}y) = e^{-|s|}y^0$ at real y with $y^0 > 0$. The *weight basis*

$$\varepsilon_{\mp 2} = u_\pm u_\pm^{\mathrm{T}}, \quad \varepsilon_{\mp 1} = u_\pm e_2^{\mathrm{T}} + e_2 u_\pm^{\mathrm{T}}, \quad \varepsilon_0 = e_3 e_3^{\mathrm{T}} + e_1 e_1^{\mathrm{T}}, \quad \varepsilon_0' = e_2 e_2^{\mathrm{T}}, \qquad u_\pm = e_3 \pm i e_1,$$

of $V_{\mathbb{C}}$ has $\rho(\mathsf{R}_t)a = e^{ik(a)t}a$ with $k(\varepsilon_{\mp 2}) = \mp 2$, $k(\varepsilon_{\mp 1}) = \mp 1$, $k(\varepsilon_0) = k(\varepsilon_0') = 0$, and $a^\dagger := \rho(\theta)\bar{a} = (-1)^{k(a)}a$ on it; $\mathbf{1} = \varepsilon_0 + \varepsilon_0'$. A *label* is $\lambda = (\varphi, a)$, $\varphi \in C_c^1(\mathbb{R})$ real, $a \in V_{\mathbb{C}}$; it is a *weight label* if $\pm a$ belongs to the weight basis, and then $k(\lambda) = k(a)$; a *scalar label* is a label $(\varphi, \mathbf{1})$, written φ, of weight 0, with the point operators $\mathsf{B}_\varphi = \mathsf{B}_{(\varphi,\mathbf{1})}$ of Lemma 5.25; $(\alpha \otimes \lambda)(x) = \alpha(y)\varphi(x_2)a$ is a *plate* with the profile α; $\lambda^\dagger = (\varphi, \rho(\theta)\bar{a})$, $\bar{\lambda} = (\varphi, \bar{a})$, and $\kappa(\underline{\lambda}) = \sum_k k(\lambda_k)$.

At a weight label $\mathsf{R}_t(\alpha \otimes \lambda) = e^{ik(\lambda)t}(\alpha \circ \mathsf{R}_{-t}) \otimes \lambda$. For a permutation $\mathfrak{s}$ and a *frame* $\upsilon \in \frac{\pi}{2}\mathbb{Z}$ the *tube* $\mathcal{Z}(\mathfrak{s}, \upsilon)$ is the set of $Z \in (\mathbb{C}^2)^n$ whose consecutive differences after the permutation, $\partial(\mathfrak{s}Z)$, lie in $(\mathsf{R}_\upsilon\mathsf{Tb})^{n-1}$, and $\mathcal{Z}_n$ is the union of the tubes. The tubes are open convex cones, invariant under common complex translations, under R_{is} for real s and under conjugation; a real configuration lies in $\mathcal{Z}_n$ if and only if its times, or its abscissae, are pairwise different.

A *fan* of j points is a real z with $z_1 = r_0 n_{\alpha_0}$, $z_{i+1} - z_i = r_i n_{\alpha_i}$, $r_i > 0$, $|\alpha_i| < \frac{5\pi}{16}$; a *pencil* is a real configuration whose consecutive differences make angles $< \frac{\pi}{16}$ with n_0.

Lemma 5.25. Let σ be labelled data with (S).

(a) For every label λ there is exactly one family of bounded operators $\mathsf{B}_\lambda(\xi, \xi')$, $(\xi, \xi') \in \mathsf{Tb}^2$, continuous in norm, with $\mathsf{T}(\kappa)\mathsf{B}_\lambda(\xi, \xi')\mathsf{T}(\kappa') = \mathsf{B}_\lambda(\kappa + \xi, \xi' + \kappa')$ for $\kappa, \kappa' \in \overline{\mathsf{Tb}}$ and $\mathsf{B}_l(\alpha \otimes \lambda) =$

$\int \alpha(y)\mathsf{B}_\lambda(y, ln_0 - y)\,dy$ for $\alpha \in C_c(\{0 < y^0 < l\})$. It is holomorphic in norm, complex linear in a, real linear in φ; $\mathsf{B}_\lambda(\xi,\xi')^* = \mathsf{B}_{\lambda^\dagger}(\xi'^*, \xi^*)$; $\|\mathsf{B}_\lambda(\xi,\xi')\|$ depends on $\operatorname{Re}\xi^\pm$, $\operatorname{Re}\xi'^\pm$ alone and does not increase in them; and for $\epsilon > 0$, $d(\xi), d(\xi') > 4\epsilon$,

$$\mathsf{B}_\lambda(\xi,\xi') = \int_{|b|_\infty \le \epsilon} \mathsf{T}(\xi + ib - 3\epsilon n_0)\, \mathsf{B}_{6\epsilon}\big((\tau_{3\epsilon n_0}\chi_{\epsilon,b}) \otimes \lambda\big)\, \mathsf{T}(\xi' - ib - 3\epsilon n_0)\, db,$$

so that $\|\mathsf{B}_\lambda(\xi,\xi')\| \le 4c_0\epsilon^{-2}\mathsf{C}(\mathcal{K}, 6\epsilon)|\varphi|_\infty|a|_\infty$, $\mathcal{K} = \{2\epsilon \le x_3 \le 4\epsilon,\ |x_1| \le \epsilon,\ x_2 \in I\}$, $\operatorname{supp}\varphi \subset I$; here $\chi_{\epsilon,b}(a') = \chi_\epsilon(a' + ib)$, $\chi_\epsilon(w) = c_\chi\epsilon^{-4}\mathsf{X}(|w^+|^2/\epsilon^2)\mathsf{X}(|w^-|^2/\epsilon^2)$, with a fixed smooth $\mathsf{X} \ge 0$ supported in $[0,1]$ and c_χ fixed, is a bump of total mass one on the polydisc $\{|w^\pm| \le \epsilon\}$ of $\mathbb{C}^2$, and $|\chi_{\epsilon,b}| \le c_0\epsilon^{-4}$.

(b) The *plate vectors* $\Psi(x;\underline{\lambda}) = \mathsf{B}_{\lambda_1}(x_1, \frac{1}{2}(x_2 - x_1)) \cdots \mathsf{B}_{\lambda_n}(\frac{1}{2}(x_n - x_{n-1}), \kappa)\Omega$, for $x_1, x_{k+1} - x_k \in \mathsf{Tb}$, and the *kernels* $\mathsf{K}_n(\xi;\underline{\lambda}) = \langle \Omega, \mathsf{B}_{\lambda_1}(\kappa, \frac{1}{2}\xi_1) \cdots \mathsf{B}_{\lambda_n}(\frac{1}{2}\xi_{n-1}, \kappa)\Omega\rangle$, $\xi \in \mathsf{Tb}^{n-1}$, do not depend on $\kappa \in \mathsf{Tb}$ and are holomorphic and multilinear; $\mathsf{K}_1 = 0$; K_n is the density of σ at plates with time-ordered supports, $\sigma(\alpha_1 \otimes \lambda_1, \dots, \alpha_n \otimes \lambda_n) = \int \prod \alpha_a(y_a)\mathsf{K}_n(y_2 - y_1, \dots; \underline{\lambda})\,dY$; and

$$\langle \Psi(x;\underline{\lambda}), \Psi(z;\underline{\lambda}')\rangle = \mathsf{K}_{n+n'}((x_n - x_{n-1})^*, \dots, (x_2 - x_1)^*, x_1^* + z_1, z_2 - z_1, \dots; \lambda_n^\dagger, \dots, \lambda_1^\dagger, \underline{\lambda}').$$

(c) For weight labels there is exactly one holomorphic function $\mathcal{K}_n(\cdot;\underline{\lambda})$ on $\mathcal{Z}_n$ that equals $e^{-i\kappa v}\mathsf{K}_n(\mathsf{R}_{-v}\partial(\mathfrak{s}Z); \mathfrak{s}\underline{\lambda})$ on every tube $\mathcal{Z}(\mathfrak{s}, v)$; it is invariant under permutations of points with their labels and under common translations, $\mathcal{K}_n(\mathsf{R}_{\pi/2}Z;\underline{\lambda}) = e^{-i\kappa\pi/2}\mathcal{K}_n(Z;\underline{\lambda})$, $\overline{\mathcal{K}_n(Z;\underline{\lambda})} = \mathcal{K}_n(\bar{Z};\bar{\underline{\lambda}})$, and for real s and real x, z in the domains of the plate vectors

$$\langle \Psi(\mathsf{R}_{is}x;\underline{\mu}), \Psi(\mathsf{R}_{is}z;\underline{\mu}')\rangle = \mathcal{K}_{j+j'}(\mathsf{R}_{is}(\theta x_j, \dots, \theta x_1, z_1, \dots, z_{j'}); \mu_j^\dagger, \dots, \mu_1^\dagger, \underline{\mu}'),$$

$\underline{\mu}$ and $\underline{\mu}'$ being tuples of j and j' weight labels and θ acting on points of the plane by $y^0 \mapsto -y^0$.

(d) If σ has (P), then

$$\|\mathsf{B}_\lambda(\xi,\xi')\| \le C|a|_\infty\|\varphi\|_{L^1}\min\{1, d(\xi), d(\xi')\}^{-p};$$

for every compact set $\mathcal{C}$ of fans of j points and every tuple of j weight labels,

$$\sup_{s\in\mathbb{R},\, z\in\mathcal{C}} e^{-pj|s|}\|\Psi(\mathsf{R}_{is}z;\underline{\lambda})\| < \infty.$$

The kernels satisfy

$$|\mathsf{K}_n(\xi;\underline{\lambda})| \le \prod_k (2^p C|a_k|_\infty\|\varphi_k\|_{L^1})\min\{1, \min_k d(\xi_k)\}^{-pn}.$$

(e) If instead σ has only an insertion bound in the sup norm,

$$|\sigma(\theta\bar{F}\cdot(h)\cdot G)| \le N(\eta)|h|_\infty\|[\tau_{-(\eta/4)e_3}F]\|\,\|[\tau_{-(\eta/4)e_3}G]\|$$

at the positions of Proposition 5.10 (e), then

$$|\mathsf{K}_n(\xi;\underline{\lambda})| \le \prod_k (2c_{\mathrm{plt}}(\lambda_{\varphi_k} + 1)\|\varphi_k\|_{C^1}|a_k|_\infty)(N(\eta)\eta^{-4})^n$$

for every $\eta \in (0, \frac{1}{2}\min\{1, \min_k d(\xi_k)\}]$, λ_φ the length of the least interval holding $\operatorname{supp}\varphi$ and c_{plt} a number of the constants and c_{I}; with $N(\eta) = C_{\mathrm{I}}\eta^{-\mathsf{p}_{\mathrm{I}}}$ this is the power $\mathsf{p}_{\mathrm{I}} + 4$.

■

Proof. (a) The obstacle is that (S) bounds a plate by the sup norm of its profile, which blows up as the profile shrinks to a point; but the slab operator of a translate of a plate is that of the plate multiplied by $\mathsf{T}(\kappa)$ on the left and $\mathsf{T}(\kappa')$ on the right, also at complex κ, κ', and a holomorphic function is its own mean over a polydisc of $\mathbb{C}^2$, a set of four real dimensions of which two are taken by the profile and two by the complex translations. So put $\mathsf{M}_\epsilon(\beta;\zeta,\zeta') = \mathsf{T}(\zeta - 3\epsilon n_0)\mathsf{B}_{6\epsilon}((\tau_{3\epsilon n_0}\beta)\otimes\lambda)\mathsf{T}(\zeta' - 3\epsilon n_0)$;

it is linear and bounded in β, holomorphic in (ζ,ζ'), and $\mathsf{M}_\epsilon(\tau_x\beta;\zeta,\zeta') = \mathsf{M}_\epsilon(\beta;\zeta+x,\zeta'-x)$ for small real x, by the relation $\mathsf{T}(\kappa)\mathsf{B}_l(h)\mathsf{T}(\kappa') = \mathsf{B}_{l+\kappa^0+\kappa'^0}(\tau_\kappa h)\mathsf{T}((0,\kappa^1+\kappa'^1))$.

The displayed integral defines $\mathsf{B}^\epsilon(\xi,\xi')$; the mean value property on the polydisc shows that $\int\beta(x)\mathsf{B}^\epsilon(\xi+x,\xi'-x)dx = \mathsf{M}_\epsilon(\beta;\xi,\xi')$ for small β, so the families for different ϵ agree on an open set and, by the identity theorem, everywhere; a partition of unity gives the integral formula. The adjoint comes from (D2) at the reflection $x_3\mapsto l-x_3$, and the monotony from the semigroup law, the imaginary parts acting by unitaries. Uniqueness: the integral formula and continuity fix $\mathsf{B}_\lambda(dn_0,dn_0)$, and $\mathsf{B}_\lambda(\xi,\xi') = \mathsf{T}(\xi-dn_0)\mathsf{B}_\lambda(dn_0,dn_0)\mathsf{T}(\xi'-dn_0)$ at $d=\min\{d(\xi),d(\xi')\}$. (b) Products depend on their inner arguments through their sums alone; the density and the Gram formula follow from the integral formula, (S) applied from the right, and (D2); $\mathsf{K}_1=0$ is $\sigma((H))=0$. (c) By (D2) at the quarter turn $\mathsf{R}_{\pi/2}\in W_3$ and the symmetry of σ, each of the functions displayed is the density of σ at the plates whose supports lie in its tube; two of them agree at the real points of the convex intersection of their tubes, hence on it, and $\mathcal{Z}_n$ is connected. Conjugation: σ is real at real tuples, so $\overline{\mathsf{K}_n(\xi;\underline{\lambda})} = \mathsf{K}_n(\xi;\bar{\underline{\lambda}})$ at real points, and $\xi\mapsto\overline{\mathsf{K}_n(\bar\xi;\underline{\lambda})}$ is holomorphic. The scalar products are the Gram formula of (b) at boosted points, taken in the tube $\mathcal{Z}(\mathrm{id},0)$. (d) Approximate $\mathsf{B}_\lambda(dn_0,dn_0)$ by $\mathsf{B}_{2d}(\alpha_\epsilon\otimes\lambda)$, with bumps $\alpha_\epsilon\ge0$ of mass one shrinking to dn_0, and apply (P) with $d'=\epsilon$; other points by (a) with two contractions. As $d(\mathsf{R}_{is}\xi)\ge e^{-|s|}d(\xi)$ and $\Psi(\mathsf{R}_{is}z;\underline{\lambda})$ is a product of j point operators at rotated arguments from a compact set of pairs of points of Tb, applied to Ω, the growth follows; in K_n take $\kappa=n_0$: every argument has $d\ge\frac12\min\{1,\min_k d(\xi_k)\}$. (e) The same construction, with the insertion bound in the place of (P): a point plate is the mean of slab operators of bumps against the semigroup, a bump of size η costs η^{-4} in the sup norm of its profile on the polydisc, and the label, of class C^1, is cut into at most $\lambda_\varphi/\eta+3$ pieces. □

Lemma 5.26. Let σ be labelled data and σ^1 its restriction to the tuples with members in $C^1_c(\mathbb{R}^3;V)$. (a) The classes of the tuples of C^1 members are dense in $\mathcal{H}(\sigma)$; the identification of $\mathcal{H}(\sigma^1)$ with $\mathcal{H}(\sigma)$ carries Ω, the semigroup, the translations and the spectral measure into one another, and an insertion bound of σ holds for σ^1 with the same numbers. (b) If $\sigma^1(\mathsf{r}X)=\sigma^1(X)$ for one $\mathsf{r}\in\mathrm{O}(3)$ and all tuples of C^1 members, then $\sigma(\mathsf{r}X)=\sigma(X)$ for all $X\in\mathfrak{S}_V(\mathbb{R}^3)$. ■

Proof. Mollify the members with a radial mollifier j_ϵ: $(\mathsf{r}H)*j_\epsilon = \mathsf{r}(H*j_\epsilon)$ for $\mathsf{r}\in\mathrm{O}(3)$, the supports stay in fixed neighbourhoods, and the bound (D1) at one type gives the convergence of both sides of each identity, and of the classes in $\mathcal{H}(\sigma)$. □

Lemma 5.27. Let σ be labelled data; (S) is not supposed. Let $l>0$, $c'\in\mathbb{R}$, $G=(g_1,\dots,g_m)$ a tuple with complex members in the slab $\{0<x_3<l\}$, at any heights, with supports in $\{x_1<c'\}$; $G^\star = \theta\overline{\tau_{-le_3}G}$ its mirror image in the middle plane of the slab, $g^\star(x) = \rho(\theta)\overline{g(x_1,x_2,l-x_3)}$; $\mathbb{T}_n(G) = G^\star\cdot\tau_{le_3}G\cdot\tau_{2le_3}G^\star\cdots\tau_{(2n-1)le_3}G$ the tower of $2n$ floors; $\vartheta_{c'}$ the reflection in $x_1=c'$, and

$$\beta_G = \limsup_{n\to\infty}\sigma\big(\vartheta_{c'}\overline{\mathbb{T}_n(G)}\cdot\mathbb{T}_n(G)\big)^{1/4n}\in[0,\infty].$$

If $\beta_G<\infty$, there is exactly one bounded operator $\mathbb{B}(G;l)$ on $\mathcal{H}(\sigma)$ with $\mathbb{B}(G;l)[F] = [G\cdot\tau_{le_3}F]$ for all $F\in\mathbb{C}\mathfrak{S}_V(\mathbb{E}_+)$, $\|\mathbb{B}(G;l)\|\le\beta_G$, and $\mathbb{B}(G;l)^*[F] = [G^\star\cdot\tau_{le_3}F]$. ■

Proof. For F carried by the quarter space $\{x_3>0,\ x_1>c'\}$ put $\mathsf{s}_n = \sigma(\theta\bar F\cdot\mathbb{T}_n(G)\cdot\tau_{2nle_3}F)$, so that $\mathsf{s}_0 = \|[F]\|^2$ and $\mathsf{s}_1 = \|[G\cdot\tau_{le_3}F]\|^2$. Positivity at $x_3=0$ and Schwarz' inequality, iterated as in the proof of the chessboard estimate with the convexity step taken before any quotient, give $\mathsf{s}_1^n\le\mathsf{s}_0^{n-1}\mathsf{s}_n$, although no operator is known to exist yet. Schwarz' inequality at the second mirror $x_1=c'$, positive by (D3), gives $\mathsf{s}_n\le\sigma(\vartheta_{c'}\overline{\mathbb{T}_n(G)}\cdot\mathbb{T}_n(G))^{1/2}\sigma(\vartheta_{c'}\overline{Y_n}\cdot Y_n)^{1/2}$ with $Y_n=\theta\bar F\cdot\tau_{2nle_3}F$; the last factor is a value at four groups of copies of F that stay at mutual distances bounded below independently of n, so it is at most a number C_F free of n, by (D1). Hence $\mathsf{s}_1\le\mathsf{s}_0\beta'^2(C_F^{1/2}/\mathsf{s}_0)^{1/n}$ for every $\beta'>\beta_G$ and large n, and $\|[G\cdot\tau_{le_3}F]\|\le\beta_G\|[F]\|$. The classes over the quarter space are dense by the cone (D4), and the adjoint identity, applied to all pairs, carries the operator to all classes. □

For a tensor limit and one member h as in Proposition 5.10 (f), with $l = \eta'$ and $c' = z_1 + \frac{\eta'}{8}$, the lemma gives $\|\mathbb{B}((h);\eta')\| \le C_{\mathsf{p}}\eta'^{-\mathsf{p}}|h|_\infty$ for every $\mathsf{p} > \frac{11}{2}$, at every $\eta' \in (0, \frac12]$.

A curve in a Hilbert space is smooth, or real-analytic, in norm as soon as its Gram kernel is so across the diagonal alone.

Lemma 5.28. Let $\mathcal{H}$ be a Hilbert space, $N \ge 1$ an integer, $\varsigma, \delta, \mathsf{M} > 0$, $I = (-\varsigma, \varsigma)^N$, $v : I \to \mathcal{H}$ continuous in norm, and $f(x,y) := \langle v(x-y), v(x+y)\rangle$ at the points $(x,y) \in \mathbb{R}^N \times \mathbb{R}^N$ with $x \pm y \in I$. No regularity of f in x is supposed.

(a) Let $m \ge 1$, $k = 2(N+m+1)$, and let the derivatives $\partial^c_{y_j} f$, $1 \le j \le N$, $0 \le c \le k$, exist, be continuous and satisfy $|\partial^c_{y_j} f| \le \mathsf{M}^2(c/e\delta)^c$. Then v is m times continuously differentiable in norm on $(-\frac58\varsigma, \frac58\varsigma)^N$, and there $\|\partial^\gamma v\| \le c_{N,m}(\varsigma,\delta)\,\mathsf{M}$ for $|\gamma| \le m$, $c_{N,m}(\varsigma,\delta)$ a number of N, m, ς and δ.

(b) If $N = 1$ and the bounds of (a) on the derivatives in y hold for all $c \ge 0$, then on $(-\frac58\varsigma, \frac58\varsigma)$, with $\mathsf{y} = \frac{48}{\varsigma} + \frac{2}{e\delta}$, $\|v^{(m)}\| \le \frac{4\varsigma}{\pi}\mathsf{M}\big(\frac12(m+2)\mathsf{y}\big)^{m+1}$ for every $m \ge 0$, and v is real-analytic in norm: its Taylor series at s_0 converges in norm to $v(s)$ for $|s - s_0| < 2/(e\mathsf{y})$. ∎

Proof. Let $w \in C^k_c(I)$ be a window with values in $[0,1]$, equal to 1 on $(-\frac58\varsigma, \frac58\varsigma)^N$. The norm square of the Fourier transform $\hat V(p) = \int w(s)e^{-ip\cdot s}v(s)\,ds$ reads the Gram kernel at the frequency $(p,-p)$ alone, that is across the diagonal: with $s = x - y$, $s' = x + y$,

$$\|\hat V(p)\|^2 = \iint w(s)w(s')e^{ip\cdot(s-s')}\langle v(s), v(s')\rangle\,ds\,ds' = 2^N \iint w(x-y)\,w(x+y)\,f(x,y)\,e^{-2ip\cdot y}\,dx\,dy.$$

At fixed x, k integrations by parts in the coordinate y_j with $|p_j| = |p|_\infty$ and Leibniz' rule give $\|\hat V(p)\|^2 \le (2\varsigma)^{2N}\mathsf{M}^2\,c_w\,(2|p|_\infty)^{-k}$, c_w a number of the bounds of the derivatives of w up to the order k and of the numbers $(c/e\delta)^c$, $c \le k$. As $k - 2m = 2N + 2$, the functions $p^\gamma\hat V(p)$, $|\gamma| \le m$, are integrable in norm, and Fourier inversion, applied to the scalar functions $\langle\psi, wv\rangle$, $\psi \in \mathcal{H}$, shows that wv is m times continuously differentiable in norm, with $\partial^\gamma(wv)(s) = (2\pi)^{-N}\int(ip)^\gamma e^{ip\cdot s}\hat V(p)\,dp$; this is (a). For (b) take, at the order m, $q = m + 2$ and the window $w_q = \mathbf{1}_{[-\frac34\varsigma, \frac34\varsigma]} * \beta_q^{*(2q+1)}$, β_q the normalised indicator of an interval of the length $\varsigma/(4(2q+1))$ about 0: it lies in C^{2q}, has values in $[0,1]$, equals 1 on $[-\frac58\varsigma, \frac58\varsigma]$, vanishes off $[-\frac78\varsigma, \frac78\varsigma]$, and $|w_q^{(c)}| \le (24q/\varsigma)^c$ for $c \le 2q$, one factor β_q being spent for each derivative.

The multinomial theorem then gives $\|\hat V_q(p)\| \le 2\varsigma\mathsf{M}\min\{1, (q\mathsf{y}/2|p|)^q\}$, so that

$$(2\pi)^{-1}\int |p|^m\|\hat V_q(p)\|\,dp \le \frac{4\varsigma}{\pi}\mathsf{M}\big(\frac12 q\mathsf{y}\big)^{m+1},$$

which bounds $v^{(m)}$ on the inner interval; Taylor's formula with these bounds and $\mathsf{m}! \ge (\mathsf{m}/e)^{\mathsf{m}}$ gives the convergence of the Taylor series. □

Lemma 5.29. Let σ be labelled data. For every $X \in \mathfrak{S}_V(\mathbb{E}_+)$ and $\epsilon > 0$ there are finitely many tuples $X_1, \dots, X_q \in \mathfrak{S}_V(\mathbb{E}_+)$, each with as many members as X, whose members lie in pairwise disjoint slabs $\{c < x_3 < c'\}$, the a-th member of each being $\psi \cdot (H_a * \phi')$ with a mollifier ϕ' and a function $0 \le \psi \le 1$ in $C^\infty_c(\mathbb{R}^3)$, such that $\|[X] - \sum_i [X_i]\| < \epsilon$. So Ω and the classes of the tuples in pairwise disjoint slabs are total in $\mathcal{H}(\sigma)$, and two labelled data that agree at all such tuples over $\mathbb{E}_+$ are equal. If σ has (S), Ω and the vectors $\mathsf{B}_{l_1}(h_1)\cdots\mathsf{B}_{l_n}(h_n)\Omega$ are total. ∎

Proof. Smooth members, small pieces. By (D1) the classes are multilinear in the members and bounded by their sup norms, with numbers that read no position; so, mollifying the members to $H_a * \phi_\varepsilon$ and telescoping, it suffices to treat smooth members. Let d_X be the least sup distance of two supports and t_X the least height of a point of a support, choose $r > 0$ with $4(n+1)r \le \mathsf{d}_X$ and $4r \le t_X$, put $t_1 = \frac14 t_X$, and cut every member by the smooth partition of unity $\chi_z(x) = \prod_\mu \chi((x_\mu - z_\mu)/r)$,

$z \in r\mathbb{Z}^3$, $0 \le \chi \le 1$, $\operatorname{supp}\chi_z \subset z + [-\frac{5}{8}r, \frac{5}{8}r]^3$. Then $[X]$ is a finite sum of classes of tuples $Y = (g_1, \dots, g_n)$ on *frames*: g_a is carried by a box Q_a with sides of lengths $\le 2r$ in $\{x_3 \ge 2t_1\}$, and $\operatorname{dist}_\infty(Q_a, Q_b) \ge 4nr$ for $a \ne b$. A pair $\{a, b\}$ is *bad* if the projections of Q_a and Q_b to the x_3-axis meet; a tuple on a frame without bad pairs is ordered. We show by induction on the number of bad pairs, at fixed n, r, t_1, that $[Y]$ is a limit of sums of ordered classes. *A cut.* Let $\{a, b\}$ be bad. As Q_a, Q_b are $4nr$ apart in the sup distance and their third sides meet, they are $4nr$ apart in a direction $\mu \in \{1, 2\}$; among the planes $x_\mu = c$ between them, an interval of the length $\ge (4n-2)r$, the $n-2$ other boxes forbid intervals of the total length $\le (4n-8)r$. So there is c such that every box lies in $\{x_\mu \le c - r\}$ or in $\{x_\mu \ge c + r\}$, Q_a in the first half space and Q_b in the second; let Y_L, Y_R be the two groups of members. *The two groups move smoothly against one another in the height.* For $s \in (-t_1, t_1)^2$ put $v(s) = [\tau_{s_1 e_3} Y_\mathsf{L} \cdot \tau_{s_2 e_3} Y_\mathsf{R}]$. As $\theta \tau_{te_3} = \tau_{-te_3}\theta$ and σ is symmetric, the Gram kernel at $s = x - y$, $s' = x + y$ is $\langle v(s), v(s')\rangle = \sigma(A_{x_1} \cdot \tau_{(y_2 - y_1)e_3} B_{x_2})$, with $A_t = \tau_{-te_3}\theta Y_\mathsf{L} \cdot \tau_{te_3} Y_\mathsf{L}$ and $B_t = \tau_{-te_3}\theta Y_\mathsf{R} \cdot \tau_{te_3} Y_\mathsf{R}$: the variable y moves each group together with its mirror copy, rigidly, and no regularity in x is needed. The plane $x_\mu = c$ parts A_t from B_t with the margin r. By (D2), with the element of W_3 that exchanges e_μ and e_3 and a translation, and by (D4), $\sigma(A \cdot \tau_{\eta e_3} B) = \langle \Phi_A, e^{-rH} e^{i\eta P_\mu} \Phi_B\rangle$ for two vectors with $\|\Phi_A\|^2 = \sigma(\vartheta A \cdot A)$, ϑ the reflection in the plane $x_\mu = c - \frac{r}{2}$, and likewise for B with the plane $x_\mu = c + \frac{r}{2}$; as $|P_\mu| \le H$ on the carrier of the spectral measure, the derivatives of the order c in η are at most $(c/er)^c \|\Phi_A\| \|\Phi_B\|$. $\|\Phi_{A_t}\|^2$ is a value of σ at $4\#\mathsf{L}$ members with the sup norms $|g_e|_\infty$, of the type $(\min\{r, 2t_1\}; \sqrt{3}r)$, so by (D1) it is bounded by a number free of t and of the positions; and the same for B_t.

So Lemma 5.28 (a) at $N = 2$ makes v twice continuously differentiable in norm, with bounds by the sup norms of the members, and

$$\partial_{s_1} v(0) = -\sum_{e \in \mathsf{L}} [Y[e : \partial_3 g_e]], \qquad \partial_{s_2} v(0) = -\sum_{e' \in \mathsf{R}} [Y[e' : \partial_3 g_{e'}]], \qquad \partial_{s_1}\partial_{s_2} v(0) = \sum_{e \in \mathsf{L},\, e' \in \mathsf{R}} [Y[e : \partial_3 g_e, e' : \partial_3 g_{e'}]],$$

$Y[e : g]$ being Y with g in the place of g_e. The same argument about every $\varrho_0 \ge 0$, with Lemma 5.28 (b), makes the lift $u(\varrho) = [Y_\mathsf{L} \cdot \tau_{\varrho e_3} Y_\mathsf{R}]$ real-analytic in norm on $(-\frac{5}{8}t_1, \infty)$. *$L^1$ in the height, in two members at once.* The derivative formulas bound $[Y]$, with g_a replaced by $\partial_3 G$, or g_b by $\partial_3 G'$, or both, by the sup norms of G, G' and of the other members and of their derivatives $\partial_3 g_e$. Writing $g_a = \partial_3 G + \kappa_a \int g_a \, dx_3$ with a fixed bump $\kappa_a \ge 0$ of the integral 1 in the third side of Q_a, so that $|G|_\infty \le 2\|g_a\|_{\infty,1}$, $\|g\|_{\infty,1} := \sup_{x_1, x_2} \int |g(x_1, x_2, t)| \, dt$, and the same for g_b, one gets

$$\|[Y]\| \le \mathsf{K} \, \|g_a\|_{\infty,1} \|g_b\|_{\infty,1} \prod_{e \ne a,b} \max\{|g_e|_\infty, |\partial_3 g_e|_\infty\},$$

K a number of n, r, t_1, the two bumps and the numbers of (D1), free of the members. *Layers.* Cut g_a and g_b by the partition of unity $\chi(Nx_3 - k)$, $k \in \mathbb{Z}$, of the height: $[Y] = \sum_{k,k'} [Y_{kk'}]$, with at most $2rN + 3$ values of k and of k'. For $|k - k'| \ge 2$ the pair $\{a, b\}$ of $Y_{kk'}$, a tuple on a frame with smaller boxes, is good, and no new bad pair arises; by the induction $[Y_{kk'}]$ is a limit of sums of ordered classes. For $|k - k'| \le 1$, at most $3(2rN + 3)$ terms, each layer has $\|\cdot\|_{\infty,1} \le |g|_\infty / N$, so that their sum has the norm $\le 3(2rN + 3)\, \mathsf{K}\, N^{-2} |g_a|_\infty |g_b|_\infty \prod_{e \ne a,b} \max\{|g_e|_\infty, |\partial_3 g_e|_\infty\}$, which tends to 0 as $N \to \infty$. So $[Y]$ is a limit of sums of ordered classes, and the approximants of $[X]$ are sums, with the coefficients 1, of ordered tuples whose a-th member is $H_a * \phi_\varepsilon$ times a finite product of the functions χ_z and $\chi(N \cdot - k)$, each with values in $[0, 1]$; they are formed with X, ε, r and the numbers N of the stages alone.

This is the first assertion, and Ω and the ordered classes are total. The lift gives the totality too: for ϱ large the frame of $Y_\mathsf{L} \cdot \tau_{\varrho e_3} Y_\mathsf{R}$ has fewer bad pairs, so by the induction $u(\varrho)$ lies in the closed span of the ordered classes, and the scalar product of $u(\varrho)$ with a vector orthogonal to that span is a real-analytic function of ϱ on $(-\frac{5}{8}t_1, \infty)$ that vanishes for large ϱ, hence at $\varrho = 0$. *Equality of data.*

$|\sigma(F)| = |\langle \Omega, [F]\rangle| \le \|[F]\|$. Taking at every stage ε so small and N so large that the errors are small in the norms of both data, which the approximants allow as they are formed with X, ε, r and N alone, $|\sigma(X) - \sigma'(X)|$ is at most twice the error when σ and σ' agree at the ordered tuples over $\mathbb{E}_+$; by (D2) at a translation along e_3 this reaches every $X \in \mathfrak{S}_V(\mathbb{R}^3)$. The last assertion follows from (S) applied from the right. □

Lemma 5.30. Let σ be labelled data.

(a) If a slab $\{|x_\mu - c| < \delta\}$ parts the supports of Y_I from those of Y_J and $u \perp e_\mu$ is a unit vector, then $s \mapsto \sigma(Y_I \cdot \tau_{su} Y_J)$ is the restriction to $\mathbb{R}$ of a function holomorphic on $\{|\operatorname{Im} s| < \sqrt{2}\,\delta\}$, and on $\{|\operatorname{Im} s| < 2\delta\}$ if u is a coordinate vector.

(b) Let $\delta H = \frac{d}{dt}\mathsf{R}_t H|_{t=0}$ and $\mathsf{D}(X) = \sum_a \sigma(\dots, \delta H_a, \dots)$ for tuples of C^1 members; then $\frac{d}{dt}\sigma(\mathsf{R}_t X) = \mathsf{D}(\mathsf{R}_t X)$. If $\mathsf{D}(X) = 0$ at every tuple X of n members of class C^1 whose projections to the x_3-axis are pairwise disjoint, then $\mathsf{D} = 0$ at all tuples of n members of class C^1, and $\sigma(\mathsf{R}_t X) = \sigma(X)$ for all real t and all $X \in \mathfrak{S}_V(\mathbb{R}^3)$ of n members.

(c) If σ has (N), then $\sigma((H_\eta)\cdot X) = 0$ for every $\eta \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and every X with members off $\operatorname{supp}\eta$, among any number of members; in particular $\sigma(H_\eta, H') = 0$ at disjoint supports.

■

Proof. (a) By (D2), with an element of W_3 that turns e_μ into e_3 and u into a unit vector $u' = (u'_1, u'_2, 0)$, and a translation, the function is $\langle [\tau_{-\delta e_3}\theta Y_I], e^{-2\delta H} e^{is(u'_1 P_1 + u'_2 P_2)} [\tau_{-\delta e_3} Y_J]\rangle = \int e^{-2\delta E + is(u'_1 q_1 + u'_2 q_2)} dm(E,q)$ for a finite complex measure m carried by $\{E \ge \max(|q_1|, |q_2|)\}$ (D4). There $|u'_1 q_1 + u'_2 q_2| \le (|u'_1| + |u'_2|)E \le \sqrt{2}E$, and $\le E$ if u' is a coordinate vector. (b) The derivative formula is the product rule under (D1). Cut the members into small pieces and argue by induction on the number of pairs of pieces with overlapping x_3-projections. Such a pair is parted by a slab normal to e_1 or e_2; sliding the group on one side along e_3 by s lowers the number for large s, and since $\delta(\tau_{se_3} H) = \tau_{se_3}[\delta H - s\,\partial_1 H]$ the derivative at the slid tuple is $f_0(s) + s f_1(s)$ with f_0, f_1 real-analytic by (a): it vanishes for large s, hence at $s = 0$.

Continuous members follow by mollification and (D1). (c) Put $\Lambda(\eta; X) = \sigma((H_\eta)\cdot X)$; it is linear in η and in each member, by (D1). *Step 0.* If $\operatorname{supp}\eta \subset \{x_3 > c\}$ and the members of X lie in $\{x_3 < c\}$, then $\Lambda(\eta; X) = 0$: by (D2) let $c = 0$; $F = \theta X$ is a real tuple over $\mathbb{E}_+$ with $\theta\bar{F} = X$, and $\Lambda(\eta; X) = \langle [F], [(H_\eta)]\rangle = 0$ by (N). *Step 1.* If the x_3-intervals of $\operatorname{supp}\eta$ and of the supports of the members are pairwise disjoint, then $\Lambda(\eta; X) = 0$. Let J be the set of the members whose x_3-interval lies above that of $\operatorname{supp}\eta$; if J is empty, this is Step 0.

Else a slab $\{|x_3 - c| < \delta\}$ parts the members of J, above it, from $\operatorname{supp}\eta$ and the other members, below it; put $Y_I = (H_\eta)\cdot(H_a)_{a\notin J}$ and $Y_J = (H_a)_{a\in J}$. By (a) at $\mu = 3$, $u = e_1$, the function $f(s) = \sigma(Y_I \cdot \tau_{se_1} Y_J)$ is real-analytic on $\mathbb{R}$. For $s > s_0$ the x_1-intervals of the members of $\tau_{se_1} Y_J$ lie to the right of all those of Y_I, with a gap; fix such an s. Then a slab normal to e_1 parts $\tau_{se_1} Y_J$ from Y_I, and by (a) at $\mu = 1$, $u = e_3$, the function $g(s') = \sigma(Y_I \cdot \tau_{-s'e_3}\tau_{se_1} Y_J)$ is real-analytic on $\mathbb{R}$; for $s' > s'_0$ all the members of $\tau_{-s'e_3}\tau_{se_1} Y_J$ lie below $\operatorname{supp}\eta$, as the members outside J do, and $g(s') = 0$ by Step 0.

So $g = 0$, and $f(s) = g(0) = 0$ for every $s > s_0$; so $f = 0$, and $\Lambda(\eta; X) = f(0) = 0$. *Step 2.* Let the supports of η and of the n members be at mutual distances $\ge \mathsf{d} > 0$, let $(n+3)\epsilon < \mathsf{d}/\sqrt{3}$, and cut η and the members by a smooth partition of unity (χ_k) with supports in cubes of side ϵ: $H_\eta = \sum_k H_{\chi_k \eta}$ with $\chi_k\eta \in C^2_c$, and $\Lambda(\eta; X)$ is the sum of the values at the tuples of pieces, one piece of η and one of each member; a tuple with a piece 0 gives 0. In such a tuple two pieces whose x_3-intervals meet have, in the direction e_1 or e_2, intervals at a distance $> (n+1)\epsilon$; the other $n-1$ intervals in that direction, of lengths $\le \epsilon$, leave in this gap a level $x_\mu = c$ at a positive distance from all of them, which splits the pieces into two groups.

Argue by induction on the number of the pairs of pieces with meeting x_3-intervals: slide the group on one side of such a level along e_3 by s; the value is real-analytic in s by (a); the slid tuple

is again a tuple of pieces of this kind, as $\tau_{se_3} H_{\chi\eta} = H_{\tau_{se_3}(\chi\eta)}$ and the intervals in the directions e_1, e_2 do not move; and for large s it has fewer such pairs, so that the value vanishes there, hence at $s = 0$. At the end of the induction the x_3-intervals are pairwise disjoint: Step 1. □

Proposition 5.31. (a) Labelled data with (O) and (N) satisfy $\sigma(\mathsf{R}H, \mathsf{R}H') = \sigma(H, H')$ for all $\mathsf{R} \in \mathrm{O}(3)$ and all pairs with disjoint supports. If besides (S) holds, then $\mathcal{K}_2(\mathsf{R}_{is} Z; \lambda, \lambda') = e^{(k(\lambda)+k(\lambda'))s} \mathcal{K}_2(Z; \lambda, \lambda')$ on $\mathcal{Z}_2$ for all weight labels and real s, and at weight labels $\mathsf{K}_2(r n_\vartheta; (\varphi, a), (\psi, b)) = \ell_0(r) e^{-i(k(a)+k(b))\vartheta}$, $|\vartheta| < \frac{\pi}{2}$: every harmonic $m \neq 0$ vanishes at every pair of labels.

(b) The same conclusions hold for labelled data with (N), (O_a) and (I_0) at pairs, and it suffices that (D3) hold at the plane $x_3 = 0$ and, for tuples of one member, at the plane Σ.

(c) If labelled data are covariant at pairs under the rotations about e_3, the spectral measure of every vector $[(h)]$, $h \in C_c(\mathbb{E}_+; V_{\mathbb{C}})$, is carried by the cone $\{E \geq |q|\}$.

■

Proof. (a) *Kernel.* By (D3) at $x_3 = 0$ and (D4) there is a matrix M_{ab} of complex measures on the cone $\{E \geq \max(|q_1|, |q_2|)\}$, antilinear in the first label, with $(\mathsf{M}_{a_i a_j})_{ij}$ a positive matrix of measures, and $\sigma(H, H') = \iint \mathcal{G}(x' - x)(H(x), H'(x'))\, dx\, dx'$ at disjoint supports, where $\mathcal{G}(u)(a, b) = \int e^{-u_3 E + i(u_1 q_1 + u_2 q_2)} d\mathsf{M}_{a^\dagger b}$ at $u_3 > 0$; by (D2) the kernel continues to a real-analytic function on $\mathbb{R}^3 \setminus \{0\}$ with $\mathcal{G}(\mathsf{w}u)(\rho(\mathsf{w})a, \rho(\mathsf{w})b) = \mathcal{G}(u)(a, b)$, $\mathsf{w} \in W_3$. With $\Gamma_a(t) = \int e^{-tE} d\mathsf{M}_{aa}$, non-increasing, and $\Gamma_*(t) = \max\{\Gamma_{\rho(\mathsf{w})a}(t), \Gamma_{\rho(\mathsf{w})b}(t) : \mathsf{w} \in W_3\}$: on the polydisc $|v_k - u_k| \leq |u|/6\sqrt{3}$ the function $\mathcal{G}(\cdot)(a, b)$ is holomorphic and bounded by $\Gamma_*(|u|/2\sqrt{3})$, after a turn by an element of W_3 that makes the largest coordinate of u the third; so $\mathcal{G}$ is bounded on $|u| \geq 1$. *Conservation.* By (N) and Lemma 5.30 (c), $\sigma(H'', H_\eta) = 0$ at disjoint supports; integrating by parts, $2\partial_i \mathcal{G}_{ij}(u; b) = \partial_j \operatorname{Tr} \mathcal{G}(u; b)$, $\mathcal{G}_{ij}(u; b)$ the kernel at the first label $e_i e_j^{\mathrm{T}}$, symmetrised. *Growth.* (O) and a test function whose transform has no zero on the cone give $\Gamma_o(t) \leq c\, C_{\mathrm{od}} t^{-6}$, $t \leq 1$, at off-diagonal o, and W_3 maps off-diagonal labels to off-diagonal ones up to signs; Cauchy's estimate on the polydisc gives $|\partial_\mu \partial_\nu \mathcal{G}(u)(o, o')| \leq C|u|^{-8}$ for $|u| \leq 2$. With $\bar{a}_\mu = 2 e_\mu e_\mu^{\mathrm{T}} - \mathbf{1}$ and $o_{\mu\nu} = e_\mu e_\nu^{\mathrm{T}} + e_\nu e_\mu^{\mathrm{T}}$, the o of (O), conservation gives $\partial_\mu \mathcal{G}(\bar{a}_\mu, b) = -\sum_{\nu \neq \mu} \partial_\nu \mathcal{G}(o_{\mu\nu}, b)$, hence $\partial_\mu^2 \mathcal{G}(\bar{a}_\mu, \bar{a}_\mu) = \sum_{\nu, \nu' \neq \mu} \partial_\nu \partial_{\nu'} \mathcal{G}(o_{\mu\nu}, o_{\mu\nu'})$, and two integrations in u_μ give $|\mathcal{G}(u)(\bar{a}_\mu, \bar{a}_\mu)| \leq C(1 + |u|^{-6})$.

Put $\Gamma_{\varphi a}(t) = \int e^{-tE} |\hat{\varphi}(q_2)|^2 d\mathsf{M}_{aa} = \iint \varphi(s)\varphi(s') \mathcal{G}((0, s' - s, t))(a^\dagger, a)\, ds\, ds'$; with $\int (t^2 + \tau^2)^{-3} d\tau = \frac{3\pi}{8} t^{-5}$ this gives $\Gamma_{\varphi a}(t) \leq C_\varphi \max\{1, t^{-1}\}^5$ at $a = \bar{a}_\mu$ and at off-diagonal a; these span $V_{\mathbb{C}}$ ($\mathbf{1} = -\sum_\mu \bar{a}_\mu$), and $\mathsf{M}_{a+a', a+a'} \leq 2\mathsf{M}_{aa} + 2\mathsf{M}_{a'a'}$, so the bound holds at every label. The scalar label $\mathbf{1} = \varepsilon_0 + \varepsilon_0'$, of weight 0, is reached by conservation and the off-diagonal bound alone. *Harmonics.* For weight labels a, b, $\kappa = k(a) + k(b)$, and real $\varphi, \psi \in C_c^1(\mathbb{R})$, the function $\Upsilon(\zeta) = \iint \varphi(s)\psi(s') \mathcal{G}(\mathsf{R}_\zeta(r n_0), s' - s)(a, b)\, ds\, ds'$, the first argument of $\mathcal{G}$ being the point of the plane y and the second the coordinate x_2, continues to an entire function with $\Upsilon(\zeta + \frac{\pi}{2}) = e^{-i\kappa\pi/2} \Upsilon(\zeta)$ and $|\Upsilon(\vartheta + is)| \leq C e^{5|s|}$; so

$$\Upsilon(\zeta) = \sum_{|4m - \kappa| \leq 5} \ell_m(r)\, e^{i(4m - \kappa)\zeta}.$$

Two mirrors. For labels (φ_i, a_i) put $\ell_m^{ij} = \ell_m(r; \varphi_i a_i^\dagger, \varphi_j a_j)$. The matrix $(\sum_m \ell_m^{ij} x^m)_{ij}$ is positive semi-definite for $x > 0$, by (D3) at $x_3 = 0$, and for $x < 0$, by (D3) at Σ for tuples of one member, a positive definite function that continues to a strip being the Laplace transform of a positive measure there. A Laurent polynomial that is ≥ 0 on $\mathbb{R} \setminus \{0\}$ has even extreme powers; so at the diagonal entries only $m \in \{0, \mp 1, \mp 2\}$ survive at the labels of weight ∓ 2 and only $m = 0$ at the others. Off the diagonal $|\sum_m \ell_m^{ij} x^m|^2 \leq (\sum_m \ell_m^{ii} x^m)(\sum_m \ell_m^{jj} x^m)$ on $\mathbb{R} \setminus \{0\}$; comparing the orders as $x \to 0$ and as $x \to \infty$, the powers of an off-diagonal entry lie between the half sum of the least powers and the half sum of the greatest powers of the two diagonal entries. Hence at two labels of weights of modulus ≤ 1 only $m = 0$ survives, at a label of weight ∓ 2 and one of weight of modulus ≤ 1 only $m \in \{0, \mp 1\}$, and at two labels of weight ∓ 2 only $m \in \{0, \mp 1, \mp 2\}$; and by positivity all the ℓ_m

with $m \neq 0$ vanish once the extreme ones do. *The remaining harmonics vanish.* With $z = u_3 + iu_1$, conservation contracted with u_+ reads $\partial_z \mathcal{G}(\varepsilon_{-2}, b) = \partial_{\bar z}\mathcal{G}(\varepsilon_0', b) - \frac{1}{2}\partial_2 \mathcal{G}(\varepsilon_{-1}, b)$. Here $z = re^{i\vartheta}$ at the point rn_ϑ of the plane y, and $\partial_z = \frac{1}{2}e^{-i\vartheta}(\partial_r - \frac{i}{r}\partial_\vartheta)$ lowers the frequency $4m - \kappa$ of a harmonic by one, $\partial_{\bar z}$ raises it by one, and ∂_2 keeps it. For $|k(b)| \leq 1$ only $m = 0$ survives on the right side, at (ε_0', b) and at (ε_{-1}, b), with the frequency $1 - k(b)$, while $m \in \{0, -1\}$ on the left side; so the frequency $-3 - k(b)$, of $m = -1$, occurs on the left side alone, and gives

$$\ell_{-1}' - \frac{2 + k(b)}{r}\,\ell_{-1} = 0, \qquad \ell_{-1} = c\, r^{2+k(b)},$$

bounded as $r \to \infty$ because $\mathcal{G}$ is bounded on $|u| \geq 1$; so $\ell_{-1} = 0$. Then at $b = \varepsilon_{-2}$ only $m \in \{0, -1\}$ survive on the right side, at $(\varepsilon_0', \varepsilon_{-2})$ and at $(\varepsilon_{-1}, \varepsilon_{-2})$, with the frequencies 3 and -1, while the left side has the frequencies 3, -1, -5; so the frequency -5, of $m = -2$, occurs on the left side alone and gives $\ell_{-2} = c\, r^4 = 0$; the least power of the diagonal entry at ε_{-2} being even, its harmonic $m = -1$ vanishes too; and likewise for ε_{+2}. So all ℓ_m with $m \neq 0$ vanish, $\mathcal{G}(\mathsf{R}_t u)(\rho(\mathsf{R}_t)a, \rho(\mathsf{R}_t)b) = \mathcal{G}(u)(a, b)$, and σ is covariant at pairs under the R_t; with W_3 they generate $\mathrm{O}(3)$. Under (S) the function $e^{i\kappa\zeta}\mathsf{K}_2(\mathsf{R}_\zeta w)$, $w = rn_{\vartheta_0}$, is holomorphic on the strip $|\operatorname{Re}\zeta + \vartheta_0| < \frac{\pi}{2}$ and constant on its real interval, hence on the strip, which gives the law of $\mathcal{K}_2$ along R_{is}. (b) Here the momentum picture is used. Let $\mathsf{Tb}^\square = \{u \in \mathbb{C}^3 : \operatorname{Re} u_3 > |\operatorname{Im} u_1| + |\operatorname{Im} u_2|\}$, the tube of the square cone, and let $\beta_\tau(E, q_1, q_2) = (E\cosh\tau + q_1 \sinh\tau,\, q_1\cosh\tau + E\sinh\tau,\, q_2)$ be the boost of the momenta; under it $p_\pm = E \pm q_1$ are multiplied by $e^{\pm\tau}$, and $E \circ \beta_\tau \geq e^{-|\tau|}E$ on $\{E \geq |q_1|\}$. The matrix $\mathsf{M}(e, e')$ of measures on the cone, antilinear in e, with $\langle[(ke)], \mathcal{P}(B)[(k'e')]\rangle = \int_B \overline{F_k}F_{k'}\, d\mathsf{M}(e, e')$ for $k, k' \in C_c(\mathbb{E}_+; \mathbb{C})$, $F_k(E, q) = \int k(x)e^{-x_3E + i(x_1q_1 + x_2q_2)}dx$, exists without a point bound: the sup norms of (D1) are unchanged by a modulation $h \mapsto he^{-i\kappa\cdot x}$, and, averaged over κ against $e^{-\mathsf{d}(|\kappa_1| + |\kappa_2|)}$ at a bump h of the size d, they become bounds of $\int e^{-7\mathsf{d}E}d\mathsf{M}(e, e)$ at every $\mathsf{d} > 0$ (the modulation bound).

The kernel $\mathcal{G}(u)(a, b) = \int e^{-u_3E + i(u_1q_1 + u_2q_2)}d\mathsf{M}(a^\dagger, b)$ is holomorphic on $\mathsf{Tb}^\square$; its transforms by the elements of W_3 agree where their domains meet, so that it is one holomorphic function on the union of the images of $\mathsf{Tb}^\square$ under W_3, whose real points are $\mathbb{R}^3 \setminus \{0\}$; and an imaginary rotation acts on M as the boost: $\mathcal{G}(\mathsf{R}_{i\tau}u)(a^\dagger, b) = \int e^{-u_3E + i(u_1q_1 + u_2q_2)}d(\beta_\tau)_*\mathsf{M}(a, b)$ at real u with $u_3 > 0$. Conservation, contracted with u_+, u_- and e_2, becomes three linear relations between the entries of M with the coefficients $p_\pm$ and q_2:

$$-p_-\mathsf{M}(e, \varepsilon_{-2}) + iq_2\mathsf{M}(e, \varepsilon_{-1}) + p_+\mathsf{M}(e, \varepsilon_0') = 0, \qquad -p_+\mathsf{M}(e, \varepsilon_2) + iq_2\mathsf{M}(e, \varepsilon_1) + p_-\mathsf{M}(e, \varepsilon_0') = 0,$$

$$p_-\mathsf{M}(e, \varepsilon_{-1}) + p_+\mathsf{M}(e, \varepsilon_1) = 2iq_2\big[\mathsf{M}(e, \varepsilon_0') - \mathsf{M}(e, \varepsilon_0)\big];$$

and (I_0) at pairs makes the scalar entry $\mathsf{M}(\mathbf{1}, \mathbf{1})$ invariant under the boosts. *The growth.* For a height $t > 0$ let $\tau_n = \log(t/7\mathsf{d}_n)$, so that $te^{-\tau_n} = 7\mathsf{d}_n$ and $\tau_n \to \infty$. (O_a) at d_n and the modulation bound give $\int e^{-7\mathsf{d}_nE}d\mathsf{M}(o, o) \leq C\mathsf{d}_n^{-6-a}$ at every off-diagonal o, so $\int e^{-tE\circ\beta_{\pm\tau_n}}d\mathsf{M}(o, o) \leq \int e^{-7\mathsf{d}_nE}d\mathsf{M}(o, o) \leq C(t)e^{(6+a)\tau_n}$; the scalar entry does not move under the boosts; conservation passes the bound to $e_3e_3^{\mathrm{T}}$, and to $e_1e_1^{\mathrm{T}}$ off $\{|q_1| < \frac{1}{2}E\}$, while on $\{|q_1| \leq \frac{1}{2}E\}$ a boost does not lower the energy below its half, $E \circ \beta_\tau \geq \frac{1}{2}E$; and $e_2e_2^{\mathrm{T}} = \mathbf{1} - e_1e_1^{\mathrm{T}} - e_3e_3^{\mathrm{T}}$.

So $\int e^{-tE\circ\beta_{\pm\tau_n}}d\mathsf{M}(e, e) \leq C(t)|e|^2e^{(6+a)\tau_n}$ at every e. This bound along the sequence $\pm\tau_n$ alone suffices: for real u with $(u_3, u_1) \neq 0$ the function $f(\zeta) = \mathcal{G}(\mathsf{R}_\zeta u)(e, e')$ is entire and of period 2π, its Fourier coefficients $f_\nu = \frac{1}{2\pi}\int_0^{2\pi} f(t' + is)e^{-i\nu(t' + is)}dt'$ do not depend on s, and $|f_\nu| \leq Ce^{(6+a)\tau_n \mp \nu\tau_n} \to 0$ for $\pm\nu > 6 + a$. So f is a trigonometric polynomial with $|\nu| \leq 6 + a$, and by Vandermonde's determinant the boosted matrix is a finite sum $(\beta_\tau)_*\mathsf{M} = \sum_{|\nu|\leq 6+a} e^{-\nu\tau}\mathsf{M}_\nu$, with $(\beta_\tau)_*\mathsf{M}_\nu = e^{-\nu\tau}\mathsf{M}_\nu$.

The harmonics. By the quarter turn $\mathsf{R}_{\pi/2} \in W_3$, at weight labels $\mathsf{M}_\nu(e, e') = 0$ unless $\nu = 4m - k(e) - k(e')$ with an integer m. The *harmonic of number* m is the matrix $\mathsf{M}^{(m)} = (\mathsf{M}_{4m-k(e)-k(e')}(e, e'))_{e,e'}$ over the weight basis, with $\mathbf{1}$ in the place of ε_0; its number is the m of (a),

of the frequency $4m-\kappa$; it is *wrong* if $m \neq 0$; and $\nu = 4m-k(e)-k(e')$ is the index of its entry at (e,e'). Each $\mathsf{M}^{(m)}$ satisfies the three relations: $p_\pm$ carry the boost weights ±1, so that a relation taken at one power $e^{-\lambda\tau}$ links the indices $\lambda+1$, λ, $\lambda-1$, as in $-p_-\mathsf{M}_{\lambda+1}(e,\varepsilon_{-2})+iq_2\mathsf{M}_\lambda(e,\varepsilon_{-1})+p_+\mathsf{M}_{\lambda-1}(e,\varepsilon'_0)=0$, and at $\lambda = 4m-k(e)+1$ these are entries of one $\mathsf{M}^{(m)}$.

The lowest and the highest $\mathsf{M}^{(m)}$ that are not zero are positive matrices (multiply the positive matrix $(e^{-(k(e)+k(e'))\tau}(\beta_\tau)_*\mathsf{M}(e,e'))_{e,e'} = (\sum_m e^{-4m\tau}\mathsf{M}^{(m)}(e,e'))_{e,e'}$ by $e^{4m\tau}$ and let $\tau\to\pm\infty$), and the diagonal mirror makes $\sum_m(-1)^m\mathsf{M}^{(m)}(e,e)$ positive at each weight label e. Let the lowest wrong harmonic have the number $-k$, $k\geq1$ (the highest is treated alike). If k is odd, it is both positive and negative at each label, hence zero. If k is even, $k\geq2$, its diagonal entries at the labels ε_1, ε_2 carry the indices $-4k-2$, $-4k-4$, of modulus ≥10, outside the window because $6+a<10$, and vanish, and so does its diagonal entry at the scalar label $\mathbf{1}$, the scalar entry having no wrong harmonic; by positivity the rows of these labels vanish; the three relations then push the remaining entries onto $\{p_-=0\}$ and the entry at ε'_0 onto $\{0\}$, where the boost scales it by $e^{4k\tau}$; and a positive measure on $\{p_-=0\}$ whose mass on a smaller set is $e^{|\nu|\tau}$ times its mass on a larger one, $\nu\neq0$, is zero.

So all wrong harmonics vanish. (c) A rotation S about e_3 keeps $\mathbb{E}_+$ and commutes with θ; covariance at pairs makes $[(h)]\mapsto[(\mathsf{S}h)]$ unitary on the closed span of the vectors of one member, with $e^{-tH}e^{iv\cdot P}$ turned into $e^{-tH}e^{i(\mathsf{S}v)\cdot P}$; so the spectral measure of $[(\mathsf{S}h)]$ is the image of that of $[(h)]$ under $(E,q)\mapsto(E,\mathsf{S}q)$. As $[(\mathsf{S}h)]$ is again a vector of one member, its spectral measure is carried by the square cone (D4); so that of $[(h)]$ is carried by the preimage of the square cone under $(E,q)\mapsto(E,\mathsf{S}q)$, for every S, and hence by the intersection of these preimages, the cone $\{E\geq|q|\}$: a point with $E<|q|$ lies outside the preimage for an open set of angles of S, so that countably many S suffice. □

Lemma 5.32. Let σ be labelled data with (S).

(a) If $\sigma(\mathsf{R}_tX)=\sigma(X)$ for all real t at the pairs of plates, then for weight labels λ,λ', $\xi,\xi'\in\mathsf{Tb}$ and real s: $\langle\Psi(\mathsf{R}_{is}\xi;\lambda),\Psi(\mathsf{R}_{is}\xi';\lambda')\rangle = e^{(k(\lambda)+k(\lambda'))s}\langle\Psi(\xi;\lambda),\Psi(\xi';\lambda')\rangle$.

(b) If $\sigma(\mathsf{R}_tX)=\sigma(X)$ for all real t at all tuples of plates, there is a unitary group $U(s)$ on the closed span $\mathcal{H}_{\rm pl}$ of Ω and the plate vectors with $U(s)\Omega=\Omega$, $U(s)\Psi(w;\underline{\lambda}) = e^{-\kappa(\underline{\lambda})s}\Psi(\mathsf{R}_{is}w;\underline{\lambda})$, and $\mathsf{B}_\lambda(\mathsf{R}_{is}\xi,\mathsf{R}_{is}\xi') = e^{k(\lambda)s}U(s)\mathsf{B}_\lambda(\xi,\xi')U(-s)$ on $\mathcal{H}_{\rm pl}$; so $e^{-\kappa s}\|\Psi(\mathsf{R}_{is}z;\underline{\lambda})\| = \|\Psi(z;\underline{\lambda})\|$.

■

Proof. At a strictly time-ordered X let $I_X\ni0$ be the open interval of the real t for which R_tX is time-ordered. For $\zeta=t+is$, $d(\mathsf{R}_\zeta\xi)=e^{-|s|}(\mathsf{R}_t\xi)^0$ at real ξ with $(\mathsf{R}_t\xi)^0>0$, so $\mathsf{R}_\zeta\partial X\in\mathsf{Tb}^{n-1}$ for $\zeta\in I_X+i\mathbb{R}$, and $g(\zeta)=e^{i\kappa\zeta}\mathsf{K}_n(\mathsf{R}_\zeta\partial X;\underline{\lambda}) = e^{i\kappa\zeta}\mathcal{K}_n(\mathsf{R}_\zeta X;\underline{\lambda})$ is holomorphic on $I_X+i\mathbb{R}$. By the hypothesis at plates carried by small discs about the points of X, g is constant on I_X, hence on $I_X+i\mathbb{R}$: $\mathcal{K}_n(\mathsf{R}_{is}X)=e^{\kappa s}\mathcal{K}_n(X)$ for all real s. By Lemma 5.25 (c) the Gram matrix of Ω and the vectors $e^{-\kappa s}\Psi(\mathsf{R}_{is}x;\underline{\mu})$ at real points does not depend on s ($\langle\Omega,\Psi(z;\lambda)\rangle=\mathsf{K}_1=0$); at pairs this is (a), after holomorphic continuation in ξ,ξ'. The vectors at real points span a dense subspace of $\mathcal{H}_{\rm pl}$ (a vector orthogonal to them gives a holomorphic function vanishing at real points), so the isometry they define extends to a unitary group, which acts as stated at complex points by holomorphy; the formula for B_λ follows on the total set of plate vectors. □

Lemma 5.33. Let σ be labelled data with (S) and (I_0). A *scalar label* is a label $(\varphi,\mathbf{1})$, written φ, of weight 0, with the point operators $\mathsf{B}_\varphi=\mathsf{B}_{(\varphi,\mathbf{1})}$; $\mathbb{R}^2_+=\{y\in\mathbb{R}^2:y^0>0\}$ is the set of the real points of Tb. For $n\geq1$, real scalar labels $\varphi_1,\dots,\varphi_n$ and a compact set $\mathcal{V}\subset(\mathbb{R}^2_+)^{n+1}$ there is $c_\mathcal{V}<\infty$ with

$$\big\|\mathsf{A}_{\underline{\varphi}}(\mathsf{R}_{is}v_0,\dots,\mathsf{R}_{is}v_n)\,\Psi(\xi;\lambda)\big\|\leq c_\mathcal{V}\|\Psi(\xi;\lambda)\|$$

for all $\underline{v}\in\mathcal{V}$, real s, labels λ and $\xi\in\mathsf{Tb}$, where $\mathsf{A}_{\underline{\varphi}}(\xi_0,\dots,\xi_n)=\mathsf{B}_{\varphi_1}(\xi_0,\frac12\xi_1)\cdots\mathsf{B}_{\varphi_n}(\frac12\xi_{n-1},\xi_n)$ is the product of the scalar point operators. ■

Proof. Put $\mathsf{A}_s = \mathsf{A}_{\underline{\varphi}}(\mathsf{R}_{is}\underline{v})$ and $P_s = \mathsf{A}_s^*\mathsf{A}_s$, a bounded positive operator. Let $R = 1 + \sup_{\underline{v}\in\mathcal{V}} \sum_j |v_j^1|$, let λ, λ' be weight labels, and let η, η' be real points of $\mathbb{R}^2_+$ with $R < \eta^1 < \eta'^1$. *The stack.* P_s^k is a product of $2kn$ scalar point operators along a vertical stack $Z_k = (q_1, \dots, q_{2kn})$ of points with the period $2l\, n_0$, $l = \sum_j v_j^0$, and with abscissae $|q_i^1| < R$, so that, by Lemma 5.25 (b), (c), $m_k = \langle \Psi(\mathsf{R}_{is}\eta;\lambda), P_s^k \Psi(\mathsf{R}_{is}\eta';\lambda')\rangle$ is the kernel of the labels $\lambda^\dagger$, the $2kn$ scalar labels of the stack and λ' at the time-ordered configuration $(\theta\eta, q_1, \dots, q_{2kn}, 2kl\, n_0 + \eta')$, boosted by R_{is}; its two tensor points lie beyond the vertical line $y^1 = R$, the stack before it.

The doubled stack costs β per point. Reflect the periodic stack in the line $y^1 = R$. For all but finitely many small angles ϵ the doubled stack, turned by R_ϵ, has its points at time gaps $\geq 2\tau > 0$; by continuity and the compactness of $\mathcal{V}$ one τ and finitely many angles serve all of $\mathcal{V}$, and then by (S) the scalar kernel of M' points of the turned doubled stack is at most $\beta^{M'}$, $\beta = \max\{1, \max_j \|\mathsf{B}_{\varphi_j}(\tau n_0, \tau n_0)\|\}$. *The frame e_1.* Take the abscissae as times in m_k, after small shifts of the points of the stack that make their abscissae pairwise different and $< R$: in the order of the abscissae come the points of the stack, then $\theta\eta$, then $2kl\, n_0 + \eta'$, and by the Gram formula in this frame and Schwarz' inequality $|m_k|$ is at most the product of the norms of two plate vectors.

The first is made of the $2kn$ scalar plates of the stack; its squared norm is the scalar kernel of the stack together with its mirror image in $y^1 = R$, which does not move with s, since by (I_0) the scalar kernels are invariant under the R_t and so, by holomorphy, under the R_{is}; turned by one of the angles ϵ it is at most β^{4kn}. The second is $\mathsf{B}_{\lambda^\dagger}(\mathsf{R}_{is}u', \mathsf{R}_{is}\delta)\, \mathsf{T}(\mathsf{R}_{is}(0, -\Lambda_k))\, \Psi(\mathsf{R}_{is}\delta;\lambda')$, with $u' = (\eta^1 - R, \eta^0)$ and $\delta = (\frac{1}{2}(\eta'^1 - \eta^1), 0)$, both in $\mathbb{R}^2_+$ because $\eta^1 > R$ and $\eta'^1 > \eta^1$, and $\Lambda_k = 2kl + \eta^0 + \eta'^0$: a point operator of $\lambda^\dagger$, a unitary, and a one-member vector of λ'; its norm is a number C_1 that may depend on s, η, η' in any way, but not on k.

So $|m_k| \leq C_1 \beta^{2nk}$. *The root.* Let E_s be the spectral measure of P_s;

$$\mu = \langle \Psi(\mathsf{R}_{is}\eta;\lambda), E_s(\cdot)\Psi(\mathsf{R}_{is}\eta';\lambda')\rangle$$

is a finite complex measure on $[0, \|P_s\|]$ with the moments m_k, and a finite complex measure on $[0, M]$ whose moments are at most Cc^k, $k \geq 0$, has no mass on $(c, M]$; the k-th root removes the number C_1, which may depend on s. So

$$\langle \Psi(\mathsf{R}_{is}\eta;\lambda), \mathsf{E}\, \Psi(\mathsf{R}_{is}\eta';\lambda')\rangle = 0$$

for $\mathsf{E} = E_s((\beta^{2n}, \infty))$ and all real η, η' with $R < \eta^1 < \eta'^1$. The function

$$(\eta, \eta') \mapsto \langle \Psi(\mathsf{R}_{is}\bar{\eta};\lambda), \mathsf{E}\, \Psi(\mathsf{R}_{is}\eta';\lambda')\rangle'$$

$\bar{\eta}$ the conjugate point, is holomorphic on $\mathsf{Tb} \times \mathsf{Tb}$ and vanishes on a non-empty open set of real points; so it vanishes, and at $\lambda' = \lambda$, $\eta' = \xi$, $\eta = \bar{\xi}$ it gives $\mathsf{E}\, \Psi(\mathsf{R}_{is}\xi;\lambda) = 0$.

As R_{is} maps Tb onto itself and every label is a combination of weight labels, $\mathsf{E}\, \Psi(\xi;\lambda) = 0$ for all $\xi \in \mathsf{Tb}$ and all labels λ, and

$$\|\mathsf{A}_s \Psi(\xi;\lambda)\|^2 = \langle \Psi(\xi;\lambda), P_s \Psi(\xi;\lambda)\rangle \leq \beta^{2n} \|\Psi(\xi;\lambda)\|^2$$

Thus $c_{\mathcal{V}} = \beta^n$. □

Proposition 5.34. Let σ be labelled data with (S), and suppose that for every $j \geq 1$, every tuple $\underline{\lambda}$ of j weight labels and every compact set $\mathcal{C}$ of fans of j points, $\sup_{s\in\mathbb{R},\, z\in\mathcal{C}} e^{-A_j|s|} \|\Psi(\mathsf{R}_{is}z;\underline{\lambda})\| < \infty$, nothing being asked of the suprema, where $\liminf_j A_j/j^2 < 2$. If $\liminf_j (A_j - j^2)/j = -\infty$ (for instance $\liminf_j A_j/j^2 < 1$, or $A_j = pj$), it suffices below that (D3) hold at the diagonal plane Σ for tuples of one member. If $\sigma(\mathsf{R}_t H, \mathsf{R}_t H') = \sigma(H, H')$ for all real t and all pairs, then $\mathcal{K}_n(\mathsf{R}_{is}Z;\underline{\lambda}) = e^{\kappa(\underline{\lambda})s}\mathcal{K}_n(Z;\underline{\lambda})$ for all $n \geq 2$, weight labels, $Z \in \mathcal{Z}_n$ and real s, and $\sigma(\mathsf{R}X) = \sigma(X)$ for all $\mathsf{R} \in \mathrm{O}(3)$ and $X \in \mathfrak{S}_V(\mathbb{R}^3)$. ■

Proof of Proposition 5.34. We first obtain a finite angular expansion. Its extreme coefficient is a positive kernel at a coordinate line and satisfies a modulus Schwarz inequality at every line. A regular polygon forces that coefficient to vanish unless its frequency satisfies a divisibility condition. The Schwarz inequality propagates this vanishing from the polygon to an arc with half as many vertices. Real analyticity then removes the other points. Iterating this argument gives the divisibility condition at every order. The resulting convex integer sequence is linear under either growth hypothesis in the statement.

Finite angular expansions. We may replace A_j by $\max\{A_j, 0\}$; either growth hypothesis in the statement is preserved. Put

$$\mathsf{A}_n = A_{\lfloor n/2 \rfloor} + A_{\lceil n/2 \rceil} + 2n, \qquad A_0 = 0.$$

Call $X = (y_1, \dots, y_n)$ a pencil if $y_{j+1} - y_j = r_j n_{\vartheta_j}$ with $r_j > 0$ and $|\vartheta_j| < \pi/16$. These configurations form a nonempty open set. If $\zeta = t + is$, choose $\upsilon \in (\pi/2)\mathbb{Z}$ with $|t - \upsilon| \le \pi/4$. In the light-cone coordinates of the tube,

$$\operatorname{Re}\big(\mathsf{R}_{\zeta-\upsilon}(y_{j+1} - y_j)\big)^{\pm} = r_j e^{\mp s} \cos(\vartheta_j + t - \upsilon) > 0.$$

Thus $\mathsf{R}_\zeta X \in \mathcal{Z}_n$ for every complex ζ. For a fixed tuple of weight labels, write $\kappa = \sum_j k(\lambda_j)$. The function

$$h_X(\zeta) = e^{i\kappa\zeta} \mathcal{K}_n(\mathsf{R}_\zeta X; \underline{\lambda})$$

is entire and, by quarter-turn covariance, has period $\pi/2$.

For $|t| \le \pi/4$, cut $\mathsf{R}_t X$ between its $\lfloor n/2 \rfloor$-th and next points, at their midpoint. The points after the cut and the reflected points before it are fans. Their angles have modulus less than $5\pi/16$, and as t varies they range over compact sets of fans. The Gram formula in Lemma 5.25(c), the growth assumption and Schwarz's inequality give

$$|h_X(t + is)| \le C_X e^{\mathsf{A}_n |s|}.$$

Here $|\kappa| \le 2n$ accounts for the last term in A_n. The Fourier coefficients may be computed on any horizontal line. Shifting that line to imaginary height tending to either infinity shows that the coefficients with $4|m| > \mathsf{A}_n$ vanish. Hence $h_X(\zeta) = \sum_{4|m| \le \mathsf{A}_n} \mathsf{c}_m(X) e^{4im\zeta}$.

This expansion extends from pencils to every tube by a finite interpolation. Let $\mathcal{M}_n = \{m \in \mathbb{Z} : 4|m| \le \mathsf{A}_n\}$ and $\mu = |\mathcal{M}_n|$. The matrix $(e^{-4m\ell})_{0 \le \ell < \mu,\, m \in \mathcal{M}_n}$ is a Vandermonde matrix. Applying its inverse to $e^{-\kappa\ell} \mathcal{K}_n(\mathsf{R}_{i\ell} Z; \underline{\lambda})$ defines holomorphic functions c_m on $\mathcal{Z}_n$, since each imaginary rotation preserves each tube. On pencils they are the preceding coefficients. Every tube contains an open set of real configurations that a permutation and a quarter turn carry to pencils. The identity theorem on that tube therefore gives

$$e^{-\kappa s} \mathcal{K}_n(\mathsf{R}_{is} Z; \underline{\lambda}) = \sum_{m \in \mathcal{M}_n} \mathsf{c}_m(Z; \underline{\lambda}) e^{-4ms} \qquad (Z \in \mathcal{Z}_n,\ s \in \mathbb{R}). \tag{12}$$

The coefficients are invariant under joint permutations of points and labels and under translations.

Exact phases on the real tube union. Let $\mathcal{O}_n = \mathcal{Z}_n \cap (\mathbb{R}^2)^n$. Suppose that X belongs to the real part of the tube indexed by $(\mathfrak{s}, \upsilon)$. Write

$$\mathsf{R}_{-\upsilon}(y_{\mathfrak{s}(j+1)} - y_{\mathfrak{s}(j)}) = r_j n_{\vartheta_j}, \qquad r_j > 0, \quad |\vartheta_j| < \pi/2,$$

and put

$$I_X = \bigcap_j (-\pi/2 - \vartheta_j, \pi/2 - \vartheta_j).$$

This is an open interval containing zero. The preceding light-cone computation shows that $\mathsf{R}_{t+is} X$ stays in this same tube for $t \in I_X$ and every real s. The two sides of (12), with s replaced by w, are

holomorphic on the connected strip $-\operatorname{Im} w \in I_X$ and agree for real w. At $w = s - it$, coefficient comparison in their finite exponential sums gives

$$\mathsf{c}_m(\mathsf{R}_t X; \underline{\lambda}) = e^{i(4m-\kappa)t}\mathsf{c}_m(X; \underline{\lambda}) \qquad (t \in I_X). \tag{13}$$

We need this identity when both endpoints belong to $\mathcal{O}_n$, even if the intervening real orbit leaves a particular tube. Consider the configurations with distinct points and with no two distinct difference vectors perpendicular. They are rotation invariant and dense. Indeed their complement is the zero set of the polynomial

$$Q(X) = \prod_{a<b} |y_a - y_b|^2 \prod_{\{a,b\}\neq\{c,d\}} (y_a - y_b)\cdot(y_c - y_d),$$

where each unordered pair occurs once in the second product. This polynomial is not zero: at $y_a = (a, a^2)$, every scalar product in the second product is $(a-b)(c-d)[1+(a+b)(c+d)] \neq 0$. For such a configuration, every real rotation belongs to $\mathcal{O}_n$. Otherwise one pair would have equal times and another equal abscissae; those difference vectors would be perpendicular, or the coincident pair would consist of equal points. By (13), $t \mapsto e^{-i(4m-\kappa)t}\mathsf{c}_m(\mathsf{R}_t X)$ is locally constant on the whole real line, and is therefore constant. Approximating any X with $X, \mathsf{R}_t X \in \mathcal{O}_n$ by this dense set proves (13) for those two endpoints.

Extension to all distinct real configurations. For a configuration X of pairwise different points, choose t so that $\mathsf{R}_t X$ has pairwise different time coordinates. Such an angle exists: each difference forbids only one angle modulo π. Define

$$\widetilde{\mathsf{c}}_m(X; \underline{\lambda}) = e^{-i(4m-\kappa)t}\mathsf{c}_m(\mathsf{R}_t X; \underline{\lambda}). \tag{14}$$

The endpoint phase identity makes this independent of the choice of t. A single choice works in a neighborhood of any given X, where the right-hand side is the restriction of a holomorphic function. Thus the extension is real analytic on the entire collision-free real configuration space. It agrees with c_m on $\mathcal{O}_n$, is invariant under translations and joint permutations, and has phase $e^{i(4m-\kappa)t}$ under rotation by t about any centre. In particular this extension includes polygons, configurations with ties in both coordinates, and configurations with some points fixed. We now omit the tilde.

The extreme coefficient and Schwarz's inequality. Let $\bar{m}(n)$ be the largest $|m|$ for which a coefficient at some tuple of n labels is nonzero, taking $\bar{m}(n) = 0$ when all such coefficients vanish, and put $\bar{m}(0) = \bar{m}(1) = 0$. Reality and conjugation of the labels exchange the extreme positive and negative frequencies. For $a \geq 1$, put $\nu(a) = \bar{m}(2a)$ and let $\mathsf{t}_a = \mathsf{c}_{-\nu(a)}$ at $2a$ points. The Gram formula, after multiplying each vector by its factor $e^{-\kappa(S)s}$, reads

$$\left\langle e^{-\kappa(S)s}\Psi(\mathsf{R}_{is}S), e^{-\kappa(T)s}\Psi(\mathsf{R}_{is}T)\right\rangle = \sum_m \mathsf{c}_m(\theta S \cup T)e^{-4ms}.$$

Here reflection carries the reflected conjugate labels. Multiplication by $e^{-4\nu(a)s}$ and passage to $s \to +\infty$ make $\mathsf{G}_a(S,T) = \mathsf{t}_a(\theta S \cup T)$ a positive Hermitian kernel on the configurations of a points in the positive half plane. Continuity allows ties in time. At any other line L, the exact phase formula identifies the corresponding values with those at the coordinate line, up to factors of modulus one. Consequently

$$|\mathsf{t}_a(\theta_{\mathsf{L}} S \cup T)|^2 \leq |\mathsf{t}_a(\theta_{\mathsf{L}} S \cup S)|\,|\mathsf{t}_a(\theta_{\mathsf{L}} T \cup T)|. \tag{15}$$

We use this modulus inequality, without asserting positivity after discarding the phases at a tilted line. Each reflected conjugate weight label is a nonzero scalar multiple of the original weight label; those scalar factors can be removed in every vanishing assertion below by multilinearity.

Schwarz's inequality before taking the extreme coefficient also gives

$$2\bar{m}(a+b) \leq \bar{m}(2a) + \bar{m}(2b). \tag{16}$$

Indeed a nonzero coefficient of frequency $-\bar{m}(a+b)$ grows as $e^{4\bar{m}(a+b)s}$, whereas the two squared norms on the right of Schwarz have growth at most $e^{4\bar{m}(2a)s}$ and $e^{4\bar{m}(2b)s}$. In particular $\nu(0) = 0$ and $2\nu(a) \le \nu(a-1) + \nu(a+1)$.

Halving a prescribed subconfiguration. For a labelled configuration S with at most $2a$ points, let $\mathcal{N}_a(S)$ mean that t_a vanishes on every collision-free configuration of $2a$ labelled points containing S. Let S' consist of $j' \le a$ points on one open side of a line L. If $S \subset \theta_{\mathsf{L}} S' \cup S'$ and $\mathcal{N}_a(S)$ holds, we claim that both $\mathcal{N}_a(S')$ and $\mathcal{N}_a(\theta_{\mathsf{L}} S')$ hold.

Fix the reflected points $P = \theta_{\mathsf{L}} S'$. Add $a - j'$ variable points y and a variable points z, with arbitrary fixed weight labels. Their collision-free parameter space D is open and connected: its complement is a finite union of affine subspaces of real codimension two. On D the function

$$(y, z) \longmapsto \mathsf{t}_a(P \cup y \cup z)$$

is real analytic by (14). On the nonempty open subset where y is on the side of P and z is on the opposite side, set $T = S' \cup \theta_{\mathsf{L}} y$. The configuration $\theta_{\mathsf{L}} T \cup T$ contains S, so its top coefficient is zero. Applying (15) to T and z gives $\mathsf{t}_a(P \cup y \cup z) = 0$ on this open subset. The real-analytic identity theorem gives zero on all of D. Since the added labels were arbitrary, this proves $\mathcal{N}_a(P)$. Exchanging the two sides proves $\mathcal{N}_a(S')$. This argument uses the extension on the full collision-free domain; analyticity only on the original tube union would not suffice.

Polygons and divisibility. Suppose, towards a contradiction, that a does not divide $2\nu(a)$, and fix any weight label λ of weight k. On a regular polygon of $2a$ vertices carrying this label, rotation by π/a fixes the labelled configuration. Since its total weight is $2ak$, the phase of the extreme coefficient under this rotation is

$$\exp\bigl(i(-4\nu(a) - 2ak)\pi/a\bigr) = \exp\bigl(-4\pi i \nu(a)/a\bigr) \ne 1.$$

The coefficient therefore vanishes on every such polygon.

Write its vertices as $P_j = p + r n_{\omega + j\pi/a}$. Suppose that $\mathcal{N}_a$ holds for every arc of j consecutive vertices and put $j' = \lceil j/2 \rceil$. An arbitrary arc $S' = \{P_{k_0+1}, \dots, P_{k_0+j'}\}$ lies on one side of the line through p with direction $n_{\omega + (k_0 + 1/2)\pi/a}$. Reflection in that line sends P_{k_0+q} to P_{k_0+1-q}. Thus $\theta_{\mathsf{L}} S' \cup S'$ is an arc of $2j' \ge j$ vertices containing an arc for which $\mathcal{N}_a$ holds. The halving argument proves $\mathcal{N}_a(S')$. Starting at $j = 2a$ and iterating proves $\mathcal{N}_a$ for every one-vertex arc. Every point is such an arc for a suitable polygon. Hence t_a vanishes on every configuration containing the label λ. Since λ was arbitrary, it vanishes identically, contrary to the choice of the extreme frequency. We have proved

$$a \mid 2\nu(a) \qquad (a \ge 1). \tag{17}$$

The integer sequence and the growth threshold. Set $\mu(a) = 2\nu(a)/a$ for $a \ge 1$. These are nonnegative integers by (17). Convexity of ν, with $\nu(0) = 0$, makes μ nondecreasing. If $\Delta_a = \mu(a+1) - \mu(a)$, the same convexity is

$$(a+1)\Delta_a \ge (a-1)\Delta_{a-1} \qquad (a \ge 2).$$

If μ is not constant, let a' be its first index of increase. From that index on, every Δ_a is a positive integer, and therefore at least one. It follows that

$$\nu(a) \ge a\nu(1) + \tfrac{1}{2}a(a - a') \qquad (a \ge a').$$

But (12) gives $\nu(a) \le A_a/2 + a$. The nonlinear alternative would imply

$$\frac{A_a - a^2}{a} \ge 2\nu(1) - a' - 2 \qquad (a \ge a'),$$

contradicting $\liminf_a (A_a - a^2)/a = -\infty$. Under that growth hypothesis, therefore, $\nu(a) = a\nu(1)$.

For the weaker hypothesis $\liminf_a A_a/a^2 < 2$, use (D3) at the diagonal plane for tuples of every length. At the diagonal mirror, the angular expansion has the additional factor $(-1)^m$, apart from

label factors of modulus one attached to each configuration. Positivity there therefore makes the kernel

$$\sum_m (-1)^m \mathsf{c}_m(\theta S \cup T)$$

positive. This positivity continues to the complex points used in the boosts. To see the continuation, use light-cone coordinates, in which the domain is a product of right half planes. Every finite set of points in a right half plane lies in a disc centred at a positive real point and contained in that half plane. The Taylor expansion about such a real point expresses the continued Gram matrices as limits of quadratic forms in derivative Gram matrices. The latter are limits of finite-difference Gram matrices at real points and are positive. Applying this in all coordinates gives positivity of

$$\left(\sum_m (-1)^m e^{-4ms} \mathsf{c}_m(\theta S_i \cup S_{i'})\right)_{i,i'} \qquad (s \in \mathbb{R}).$$

The same positive normalisations of the vectors as above do not affect the conclusion. Its extreme limit is $(-1)^{\nu(a)}\mathsf{G}_a$. If $\nu(a) > 0$, the kernel G_a is nonzero: otherwise the extreme coefficient would vanish on the open set of configurations split into a points on each side, hence identically by real analyticity. Since both G_a and $(-1)^{\nu(a)}\mathsf{G}_a$ are positive, $\nu(a)$ is even. This is also true when $\nu(a) = 0$.

In the nonlinear alternative, $\mu(a)$ is consequently a multiple of four at odd a: indeed $a\mu(a) = 2\nu(a)$ is then a multiple of four and a is odd. Its increments are positive integers from a' on. Between consecutive odd indices it therefore increases by at least four. The possible first and last single steps cost at most three in this lower bound, giving

$$\nu(a) \geq a\nu(1) + a(a - a' - \tfrac{3}{2}) \qquad (a > a').$$

Combining this with $\nu(a) \leq A_a/2 + a$ gives $A_a \geq 2a^2 - (2a' + 5)a$ and hence $\liminf_a A_a/a^2 \geq 2$, a contradiction. Thus in both cases

$$\bar{m}(2a) = a\bar{m}(2), \qquad \bar{m}(n) \leq \tfrac{n}{2}\bar{m}(2),$$

the second inequality following from (16) with $a = \lfloor n/2 \rfloor$ and $b = \lceil n/2 \rceil$.

Two points and arbitrary tuples. By the assumed covariance at pairs, the twisted two-point kernel is constant on a real interval of rotation angles. Holomorphy continues this identity to the corresponding angular strip. Coefficient comparison in (12) gives $\bar{m}(2) = 0$. Therefore every $\bar{m}(n)$ is zero. The coefficients with $m \neq 0$ vanish on the real tube union, hence on each complex tube, and (12) gives

$$\mathcal{K}_n(\mathsf{R}_{is} Z; \underline{\lambda}) = e^{\kappa s} \mathcal{K}_n(Z; \underline{\lambda}).$$

For real time-ordered configurations, the exact phase formula with $m = 0$ gives covariance under small real rotations. Integrating against plate profiles proves covariance at time-ordered plates. Finite sums of plates approximate weights in pairwise disjoint slabs by Weierstrass's theorem; (D1) passes the identity to their limits. Lemma 5.30(b) then gives covariance for all tuples. The invariance group contains W_3 and the rotations R_t. Conjugation by W_3 supplies rotations about all three axes, which generate SO(3), and $-\mathbf{1} \in W_3$ supplies the remaining component of O(3).

The argument may also be restricted to a set Λ of weight labels closed under $\lambda \mapsto -\lambda$, $\lambda \mapsto \lambda^\dagger$ and $\lambda \mapsto \bar{\lambda}$. Define the largest frequencies using labels in Λ only. The Gram argument uses the reflected conjugate labels, the polygon argument uses one label at a time, and all vanishing assertions are unchanged by the reflection phases. Thus the same conclusion holds with the exponents A_j^Λ. For a finite set Φ of real transverse profiles, this applies to $\Lambda_\Phi = \{(\varphi, \pm b) : \varphi \in \Phi,\ b \text{ in the weight basis}\}$. Each finite plate approximation uses only one such set, so these restricted conclusions suffice for the assertion about all tuples. □

Corollary 5.35. Let σ be labelled data with (S) that is covariant at all pairs under the R_t.

(a) The following are equivalent: σ is O(3)-covariant; the twisted plate vectors are bounded along the boosts, $\sup_{s,\,z\in\mathcal{C}} e^{-\kappa(\underline{\lambda})s}\|\Psi(\mathsf{R}_{is}z;\underline{\lambda})\| < \infty$ on compact sets $\mathcal{C}$ of fans; the growth hypothesis of Proposition 5.34 holds for some exponents with $\liminf A_j/j^2 < 1$; it holds with $A_j = 2j$; the point operators grow at most exponentially along the boosts, $\sup_s \sup_{\mathcal{K}} e^{-\gamma|s|}\|\mathsf{B}_\lambda(\mathsf{R}_{is}\xi, \mathsf{R}_{is}\xi')|_{\mathcal{H}_{\rm pl}}\| < \infty$ on compact sets $\mathcal{K}$ of pairs of real points rn_α, $|\alpha| < \frac{5\pi}{16}$, for some $\gamma < \infty$; it holds with $\gamma = 2$. The same follows from (P) with any $p < \infty$, and from a growth $\gamma_\lambda < \infty$ of its own at every label.

(b) If σ is not covariant and the growth hypothesis holds with some exponents, there is $a' \geq 1$ with $\bar{m}(2a) \geq \frac{1}{2}a(a-a')$, so $A_a \geq a(a-a'-2)$, for all $a \geq a'$; if $\bar{m}(4) \geq 1$, then $a' = 1$ and $\bar{m}(2a) \geq \binom{a}{2}$: the defect grows at least quadratically.

■□

Proof. By Lemma 5.32 (b), covariance gives the twisted bound with equality and the operator bound with $\gamma = 2$, as $|k| \leq 2$; the twisted bound gives the growth with $A_j = 2j$, as $|\kappa| \leq 2j$; such a growth gives covariance by Proposition 5.34; an exponential growth γ of the point operators gives $A_j = \gamma j$, a product of j point operators making up a plate vector; and (P) gives $\gamma = p$ by Lemma 5.25 (d). A growth $\gamma_\lambda < \infty$ of its own at every label gives covariance through Proposition 5.34 relative to a set of labels: for a finite set Φ the set Λ_Φ is finite, a plate vector with j labels in Λ_Φ is a product of j point operators applied to Ω, at pairs of arguments in a compact set of pairs of real points rn_α, $|\alpha| < \frac{5\pi}{16}$, when its fan ranges over a compact set; so the growth hypothesis holds at the tuples of labels in Λ_Φ with $A_j^\Phi = j\gamma_\Phi$, $\gamma_\Phi = \max_{\lambda\in\Lambda_\Phi}\gamma_\lambda$, and $(A_j^\Phi - j^2)/j \to -\infty$; covariance at pairs gives $\bar{m}_{\Lambda_\Phi}(2) = 0$; so the identity for $\mathcal{K}_n$ holds at all tuples of labels in Λ_Φ, for every finite Φ, and σ is O(3)-covariant. (b) is the second case of the integer argument in the proof of Proposition 5.34, with $\nu(1) = \bar{m}(2) = 0$; if $\nu(2) \geq 1$, then $\mu(2) = \nu(2) > \mu(1) = 0$, the differences Δ_a are ≥ 1 from $a = 1$ on, and $\nu(a) \geq \binom{a}{2}$. □

Remark 5.36. Of the hypotheses of Theorem T, neither (N), nor (O), nor positivity at the diagonal planes can be dropped, and covariance under W_3, reflection positivity and bounds do not suffice; the instances below are data, built from free fields with the standard properties of Wick polynomials (reflection positivity at every plane, Euclidean covariance, bounds at non-coinciding points), and they say nothing about the theory. (1) Let $T^{\rm W}$ be the tensor of three free photon fields and χ an independent free scalar field of mass 1; $T^{\rm W} + 2\epsilon\,\delta_{\lambda\lambda'}\partial_\lambda^2\chi$ gives labelled data with (S), (O), the properties of the scalar part, growth and an insertion bound with a power, and even the short-distance value of Theorem S (i) with the error $c\epsilon^2 b^2 \mathsf{d}$; but not (N), since $\|[(H_{he_3})]\|^2 = \epsilon^2 \int |\tilde{h}|^2 E^2(2E^2-1)^2 d\rho_\chi > 0$, and it is not covariant: the top harmonic 2 sits at the labels of weight -2.

So the statement on two points for scalar plates, the two-point conclusion in the proof of Theorem YMM1:AK, does not carry over to labelled data: covariance under W_3, reflection positivity, the bounds and even the short-distance value do not give covariance at pairs; in Proposition 5.31 conservation takes its place. With a massless χ conservation among scalar members and covariance with one tensor member among scalars hold, while (N) and covariance at pairs fail. (2) A covariant base with decay plus a constant random tensor that is diagonal, traceless and invariant in law under W_3 has all the hypotheses but positivity at the diagonal mirror, and is not covariant (the top harmonic is 1): the diagonal mirror is really needed. (3) Let $\Theta(p) = \sum_\beta \mu_\beta(p)(p\times e_\beta)(p\times e_\beta)^{\rm T}$, $\mu_\beta(p) = 2p^2p_\beta^2 - (p^4 - \sum_\lambda p_\lambda^4)$: symmetric, homogeneous of the order 6, with $\sum_\nu p_\nu\Theta_{\nu\rho} = 0$, $\operatorname{tr}\Theta = 0$, covariant under W_3 and not under SO(3).

Then $T^{\rm W} + \epsilon\,\Theta(-i\partial)\chi$ gives labelled data with (D1)–(D4), (N), a covariant scalar part and a point bound with a power, but not (O): $\sigma(\theta h, h)$ grows like $\mathsf{d}^{-7}|h|_\infty^2$ at off-diagonal h of the scale d, as the leading part at short distance of the kernel at the off-diagonal label of the plane of e_1, e_2 has the transform $\Theta_{12}(p)^2/p^2$, which is no polynomial. Nor is it covariant at pairs: covariance under R

would make the difference of two kernels a distribution carried by the origin, so that $N(p)/(p^2+1)$ would be a polynomial for $N = \Theta\otimes\Theta - \Theta^{\mathsf{R}}\otimes\Theta^{\mathsf{R}}$, homogeneous of the order 12, $\Theta^{\mathsf{R}} = \mathsf{R}^{\mathrm{T}}\Theta(\mathsf{R}\,\cdot)\mathsf{R}$; comparing the lowest and the highest homogeneous parts gives $N = 0$, so $\Theta^{\mathsf{R}} = \pm\Theta$, and as $\mathrm{SO}(3)$ is connected Θ would be covariant under it.

So the bound on the off-diagonal members cannot be dropped. The threshold $a < 4$ of Proposition 5.31 (b) is sharp up to the interval $4 \le a < 5$. Let $S(p)$ be the symmetric matrix with $S_{\beta\beta} = 0$, $S_{12} = p_3(p_1^2 - p_2^2)$, $S_{23} = p_1(p_2^2 - p_3^2)$, $S_{31} = p_2(p_3^2 - p_1^2)$, let $[p]_\times$ be the matrix of $v \mapsto p\times v$, and $\Theta_5 = [p]_\times S[p]_\times^{\mathrm{T}}$. It is symmetric and homogeneous of the order 5; $\sum_\nu p_\nu(\Theta_5)_{\nu\rho} = 0$, as $p^{\mathrm{T}}[p]_\times = 0$; $\operatorname{tr}\Theta_5 = |p|^2\operatorname{tr} S - p^{\mathrm{T}}Sp = 0$, as $\operatorname{tr} S = 0$ and $p^{\mathrm{T}}Sp = 2p_1p_2p_3\sum_{\mathrm{cyc}}(p_1^2 - p_2^2) = 0$; on the generators of W_3 one checks $S(\mathsf{w}p) = \det\mathsf{w}\,\rho(\mathsf{w})S(p)$, and with $[\mathsf{w}p]_\times = \det\mathsf{w}\,\mathsf{w}[p]_\times\mathsf{w}^{\mathrm{T}}$ this gives $\Theta_5(\mathsf{w}p) = \det\mathsf{w}\,\rho(\mathsf{w})\Theta_5(p)$ for $\mathsf{w}\in W_3$; and Θ_5 is not covariant under the R_t.

Put $c_e(p) = -\frac12\operatorname{Tr}(e\,\Theta_5(p))$. The two-point kernel $c_e(\partial)c_{e'}(\partial)(4\pi|u|)^{-1}$ is, up to the sign $(-1)^5$ of the odd order, the covariance of the derivatives $c_e(\partial)\chi$ of a massless free field χ; under an element w of W_3 the two members bring the factor $(\det\mathsf{w})^2 = 1$, and at a mirror the factor $\det\theta = -1$ that the reflection puts on the reflected member compensates that sign, so that the kernel gives pair data with covariance under $\mathbb{R}^3\rtimes W_3$ and positivity at every coordinate and diagonal mirror; it has (N) at pairs, as Θ_5 is conserved and traceless; its scalar entries vanish, so (I_0) holds at pairs; and the kernel is homogeneous of the order -11, so that $\sigma(\theta(h\,o), h\,o) \le C\mathsf{d}^{-5}|h|_\infty^2$ at the scale d, the bound (O_a) with $a = 5$.

Its harmonics $m = \pm1, \pm2$ do not vanish. So the conclusion of Proposition 5.31 (b) holds for every $a < 4$ and fails at $a = 5$. (4) $\partial_i\partial_j\phi$, ϕ a free field of mass $m > 0$, is covariant and not conserved: (N) is not necessary.

5.7. **Proofs of the theorems.**

Proof of Theorem T. Step 1 (conservation). Lemma 5.30 (c) gives (ii), and in particular $\sigma(H_\eta, H') = 0$ at disjoint supports. *Step 2 (two points).* Proposition 5.31 (a) gives $\sigma(\mathsf{R}H, \mathsf{R}H') = \sigma(H, H')$ for all $\mathsf{R}\in\mathrm{O}(3)$; under (O_a) and (I_0) at pairs, Proposition 5.31 (b). *Step 3 (growth).* Lemma 5.25 (d) gives the growth of the plate vectors with $A_j = pj$, and $(A_j - j^2)/j = p - j \to -\infty$. *Step 4 (all points).* Proposition 5.34 gives (i) and (iii), under (P) or under any of the growths named after the theorem. *Step 5 (unitary boosts).* By (i), σ is invariant under the R_t at all tuples of plates, and Lemma 5.32 (b) gives the unitary group $U(s)$ and the norm identity of (iv). □

Proof of Theorem U. Step 1 (one member). By Proposition 5.31 (a), σ is covariant at pairs; by Lemma 5.32 (a), $\langle\Psi(\mathsf{R}_{is}\xi;\lambda), \Psi(\mathsf{R}_{is}\xi';\lambda')\rangle = e^{(k(\lambda)+k(\lambda'))s}\langle\Psi(\xi;\lambda), \Psi(\xi';\lambda')\rangle$ at weight labels, and at scalar labels by linearity, as $\mathbf{1} = \varepsilon_0 + \varepsilon_0'$. For the second assertion of the theorem only this step changes: covariance at pairs is assumed. *Step 2 (a bound free of the boost).* Let $\underline{\lambda} = (\lambda, \varphi_1, \dots, \varphi_n, \lambda')$, two weight labels and n scalar ones, $w = k(\lambda) + k(\lambda')$, and let $\mathcal{K}$ be the kernel of these labels, continuous on the real points of $\mathcal{Z}_{n+2}$. Near a fixed configuration in which the two tensor points lie far apart on the time axis and the scalar points on a short segment between them at the angle $\frac{\pi}{4}$, every rotated configuration R_tY is time-ordered after a quarter turn, with consecutive differences in a compact set $\mathcal{V}_0$ of $\mathbb{R}^2_+$; so $g_Y(\zeta) = e^{iw\zeta}\mathcal{K}(\mathsf{R}_\zeta Y)$ is entire of period $\frac{\pi}{2}$, and

$$|g_Y(t+is)| = e^{-ws}\big|\big\langle\Psi(\tfrac12\xi_0^*;\lambda^\dagger),\ \mathsf{A}_{\underline{\varphi}}(\tfrac12\xi_0, \xi_1, \dots, \xi_{n-1}, \tfrac12\xi_n)\,\Psi(\tfrac12\xi_n;\lambda')\big\rangle\big|, \qquad \xi_j = \mathsf{R}_{is}v_j,\ v_j\in\mathcal{V}_0.$$

By Lemma 5.33 and Step 1 this is bounded uniformly in t and s. *Step 3 (the kernel is covariant).* By Liouville's theorem g_Y is constant; so the real-analytic function $\frac{d}{dt}|_{t=0}e^{iwt}\mathcal{K}(\mathsf{R}_tY)$ vanishes on an open set of real configurations, hence on the connected set of the real points of $\mathcal{Z}_{n+2}$, the complement of finitely many subspaces of codimension 2; across the gaps of the set of t with R_tY in it one passes by the density of the configurations at which no two differences are orthogonal. So $\mathcal{K}(\mathsf{R}_tY) = e^{-iwt}\mathcal{K}(Y)$ whenever Y and R_tY are real points of the tubes. *Step 4 (all configurations).* $\mathcal{K}$ extends to exactly one real-analytic function $\tilde{\mathcal{K}}$ on all configurations of pairwise different points

with the same law under rotations, and σ at plates with pairwise disjoint supports is the integral of $\tilde{\mathcal{K}}$: the difference of the two is real-analytic in a slide along e_1 of the plates above a level in y^0 (Lemma 5.30 (a)), and vanishes once the abscissae are parted. *Step 5 (tuples).* Hence $\sigma(\mathsf{R}_t X) = \sigma(X)$ at tuples of plates of the class; tent partitions of unity make the members limits of sums of plates in the sup norm, with (D1), which gives the tuples whose planar projections are pairwise disjoint. For the other tuples of the class, cut the members into small pieces, so that two pieces whose planar projections meet have disjoint x_2-ranges, and argue by induction on the number of such pairs. For one such pair take a level $x_2 = c$ between their x_2-ranges and outside those of all pieces, write $X = X_I \cdot X_J$ with the pieces of X_I below and those of X_J above the level, and put

$$F(s) = \sigma\big(\mathsf{R}_t(X_I \cdot \tau_{se_1} X_J)\big) - \sigma(X_I \cdot \tau_{se_1} X_J).$$

As R_t keeps x_2, $\mathsf{R}_t(X_I \cdot \tau_{se_1} X_J) = \mathsf{R}_t X_I \cdot \tau_{s\mathsf{R}_t e_1} \mathsf{R}_t X_J$, with the unit vector $\mathsf{R}_t e_1 \perp e_2$; so Lemma 5.30 (a) at $\mu = 2$, at the unit vectors $\mathsf{R}_t e_1$ and e_1, makes both terms real-analytic in s. For large s fewer pairs have meeting planar projections, so $F(s) = 0$ by the induction; hence $F(0) = 0$, which gives all tuples of the class. *Step 6 (the group).* The tuples $(H_1, H_2, f_1\mathbf{1}, \dots, f_n\mathbf{1})$ are carried into such tuples by every $\mathsf{R} \in \mathrm{O}(3)$, as $\rho(\mathsf{R})\mathbf{1} = \mathbf{1}$; the group of the R that keep σ at them holds W_3 and the R_t, hence $\mathrm{O}(3)$. □

Lemma 5.37. Let $0 < g \le \gamma$, let σ be a tensor limit at g along (K_j, β_j, ρ_j) with label b_*, let $z \ge 1$ be an integer with $L^z g^{-2} > 2\max\{(\gamma_W^{\mathrm{sd}})^{-2}, |\bar{B}|\}$, and $g' = (L^z b_*/2)^{-1/2}$. Then $g' < g$, $g' < \gamma_W^{\mathrm{sd}}$, $(K_j - z, \beta_j) \in \mathfrak{d}(g')$ for large j, the images ρ_j' of the ρ_j under $x \mapsto L^z x$ are periodic Gibbs states, and $\sigma'(X) = \lim_j \rho_j'(A^{\rho_j'}_{K_j - z}(X))$ is a tensor limit at g' with label $L^z b_*$ and

$$\sigma(X) = L^{nz}\sigma'(X^{(z)}), \qquad X^{(z)} = \big(H_1(L^{-z}\cdot), \dots, H_n(L^{-z}\cdot)\big).$$

■

Proof. As $b_* \ge g^{-2}$, $g'^{-2} = L^z b_*/2 \ge L^z g^{-2}/2$ exceeds g^{-2}, $(\gamma_W^{\mathrm{sd}})^{-2}$ and $|\bar{B}|$. The labels $L^z a_{K_j}\beta_j$ tend to $2g'^{-2}$, which lies inside $(g'^{-2} + \bar{B}, X_{g'} - \bar{B}]$, because $X_{g'} - \bar{B} - 2g'^{-2} = (L-2)(g'^{-2} + \bar{B}) > 0$; so $(K_j - z, \beta_j) \in \mathfrak{d}(g')$ for large j. The dilation carries $\mathbb{L}_{K_j}$ onto $\mathbb{L}_{K_j - z}$, bonds to bonds and plaquettes to plaquettes; the Wilson weight does not depend on the spacing, so Gibbs states and invariance under lattice translations go over; and as $a_K^{-1} = L^z a_{K-z}^{-1}$, $\mathcal{T}_K(H)$ goes over into $L^z \mathcal{T}_{K-z}(H(L^{-z}\cdot))$. Hence $\rho_j(A^{\rho_j}_{K_j}(X)) = L^{nz}\rho_j'(A^{\rho_j'}_{K_j - z}(X^{(z)}))$, and $X \mapsto X^{(z)}$ is a bijection of $\mathfrak{S}_V(\mathbb{R}^3)$. □

Proof of Theorem R. Step 1 (two members, at g). Let $0 < g \le \gamma$ and $\delta_0 = \min\{\mathsf{d}, \frac{1}{2}\ell'\}$. Cut η and H_2 by partitions of unity into pieces of sup diameter $\le \frac{1}{8}\delta_0$; $H_\eta = \sum_k H_{\chi_k \eta}$, as H_η is linear in η, $\|\chi_k \eta\|_{C^2} \le C\|\eta\|_{C^2}$, and the number of pairs of pieces depends on d, R and ℓ' alone. Two pieces at sup distance $\ge \mathsf{d}$ are $\ge \delta_0$ apart in one coordinate, and counting the offsets in $a_{K-t_0}\mathbb{Z}^3$, t_0 as in Proposition 5.24, gives a board of $\mathbb{L}_K$ with cells of side $\frac{1}{2}\ell'$ on which they lie in two different cells, each at distance $\ge \frac{1}{16}\delta_0$ from the walls.

By Lemma 5.3 (c), with $Q = e^{G_g(\ell'/2)^3}$, $|\nu(A^\nu[F_1]A^\nu[F_2])| \le 2Q^2 \|F_1 - c_1\|_{\mathrm{ch},\ell'} \|F_2 - c_2\|_{\mathrm{ch},\ell'}$ for functions F_i of the two cells and real c_i. For $F_1 = \mathcal{T}_K(H_{\chi\eta})$ Proposition 5.24 (d) at $c = \frac{1}{15}$ gives the seminorm $CK^p L^{-K/15}\|\eta\|_{C^2}$, and for $F_2 = \mathcal{T}_K(\chi' H_2)$ Proposition 5.24 (c) gives $CK^{2\mathsf{p}_0} L^{K/100}|H_2|_\infty$. As $\frac{1}{15} - \frac{1}{100} > \frac{1}{60}$, $|\nu(A^\nu_K(H_\eta, H_2))| \le CK^p L^{-K/60}\|\eta\|_{C^2}|H_2|_\infty$, the case $q = 2$ of (a) at a weaker rate; and for $H_2 = H_{\eta'}$ both factors are of the first kind, and $\frac{2}{15} > \frac{1}{20}$. *Step 2 (any number of members).* Let z be the least integer ≥ 1 such that the couplings g_1', g_2' with $g_1'^{-2} = L^z g^{-2}/2$ and $g_2'^{-2} = L^{z+1} g^{-2}/4$ are $\le \gamma_W^{\mathrm{sd}}$ and their least sides $\ell'(g_\iota')$ are $\le \frac{1}{2}L^z\mathsf{d}$; the least sides grow like a power of z, so z exists. By the windows of first passage (Corollary YMM1:74.2) the dilation $x \mapsto L^z x$ carries $\mathfrak{d}(g)$ into $\mathfrak{d}(g_1') \cup \mathfrak{d}(g_2')$, and it carries members, states, tori, boards and seminorms exactly: the lattice, the Gibbs states and the members by Lemma 5.37, the tori, the boards and the chessboard seminorms as in the step *Dilation* of the proof of Proposition 5.8 and in Proposition 5.18 (d).

Let g' be the one of g'_1, g'_2 at which the dilated datum (K', β), $K' = K - z$, lies. Pieces of the dilated members of sup diameter $\le \ell'(g')/(8q)$ get, by an offset in $a_{K'-t'_0}\mathbb{Z}^3$, $t'_0 = K' - \lceil K'/400 \rceil$, distinct cells of side $\frac{1}{2}\ell'(g')$, at distance $\ge \ell'(g')/(16q)$ from the walls; Lemma 5.3 (c) at g' bounds a mean of centred pieces by $e^{qG_{g'}(\ell'(g')/2)^3}$ times their seminorms: $CK^pL^{-K/15}\|\eta\|_{C^2}$ for the conserved piece (Proposition 5.24 (d) at g'), and a number free of K for each other piece. For the latter, cut the piece further, by a partition of unity, into small pieces of sup diameter $\le \frac{1}{4}$, whose number depends on $\ell'(g')$, q, d and R alone; the chessboard seminorm is subadditive, so the seminorm of the piece less its mean is at most the sum of the seminorms of the small pieces less their means.

Fix a small piece, a member H_a of which it is a piece, and a direction μ, and let $c + \frac{1}{2}\ell'(g')\mathbb{Z}$, $c \in a_{K'}(\mathbb{Z} + \frac{1}{2})$, be the walls of the board of side $\frac{1}{2}\ell'(g')$ normal to e_μ. Of the two families of planes $c + \mathbb{Z}$ and $c + \frac{1}{2} + \mathbb{Z}$ one keeps a sup distance $\ge \frac{1}{8}$ from the projection of the small piece to the axis of e_μ, an interval of length $\le \frac{1}{4}$. If it is $c + \mathbb{Z}$, take $c + \mathbb{Z}$ as the walls normal to e_μ: the reflections in the walls of the coarse board keep this family, so that all the eight mirror copies of the small piece keep the distance $\ge \frac{1}{8}$ from it. Otherwise the projection lies within $\frac{3}{8}$ of a point of $c + \mathbb{Z}$, and so do those of all the copies; then take $c + \frac{1}{2}(1 - a_{K'}) + \mathbb{Z}$ as the walls normal to e_μ, which lie in $a_{K'}(\mathbb{Z} + \frac{1}{2})$, as walls must, while the planes $c + \frac{1}{2} + \mathbb{Z}$ lie in $a_{K'}\mathbb{Z}$, $L^{K'}$ being odd: all the copies keep a distance $\ge \frac{1}{8} - \frac{1}{2}a_{K'}$ from them.

This gives one board of $T_{\ell'(g')}$ with cells of side 1 in which the corners of the plaquettes of each copy lie in the interior of one cell, at a distance $\ge \frac{1}{8} - \frac{3}{2}a_{K'}$ from its walls; two copies may lie in one cell. Two different copies differ in a direction in which the projection of the small piece lies at a distance $\ge \ell'(g')/(16q)$ from both walls of its cell of side $\frac{1}{2}\ell'(g')$; so on the circle of length $\ell'(g')$ the reflected copy is at a distance $\ge \ell'(g')/(8q)$, and the corners of the plaquettes of different copies are at least $\ell'(g')/(8q) - 2a_{K'} \ge \ell'(g')/(16q)$ apart once $a_{K'} \le \ell'(g')/(32q)$. Let s be the least integer $s \ge 1$ with $(\ell'(g')/(16q))L^s \ge Mu_*(8)$, a number of g, d and q, and let K be so large that $K' \ge s + 2$ and $a_{K'} \le \min\{\frac{1}{16}, \ell'(g')/(32q)\}$: then $K' \ge 3$ and $1 \le s \le K' - 2$, as Lemma 5.6 asks at (K', β), and the corners of the plaquettes of different copies, at least $\ell'(g')/(16q)$ apart, are at least $(\ell'(g')/(16q))L^s \ge Mu_*(8)$ units of the level $K' - s$ apart.

The least torus at $g' \le \gamma_W^{\mathrm{sd}} \le \gamma_W^{\mathrm{ref}}$ is small over the run of (K', β) (Lemma YMM1:126.3), and on it the eight copies are the first members of an admissible system of real sources under the majorants $(60|H_a|_\infty, S_\kappa)$, S_κ the set of their plaquettes (Definition 5.4, Lemma 5.5 (a), (b)); as $8 \le \ell'(g')^3$, Lemma 5.6 at (K', β), $n = 8$ and the depth s gives numbers c_κ, the constants of the progression at the level $K' - s$, with $|\langle \prod_{\kappa \in B}(F_\kappa - c_\kappa)\rangle_{K', \ell'(g'), \beta}| \le (16\mathsf{C}_1 L^{4s} \cdot 60|H_a|_\infty)^{\#B}$ for every set B of copies; with m the common mean of the copies, $|c_\kappa - m| \le 16\mathsf{C}_1 L^{4s} \cdot 60|H_a|_\infty$, and expanding $\prod_\kappa (F_\kappa - m)$ as in the step *The copies* of the proof of Proposition 5.8 bounds the seminorm on $T_{\ell'(g')}$ of the small piece less its mean by $32\mathsf{C}_1 L^{4s} \cdot 60|H_a|_\infty$, a number free of K.

Centred products and joint cumulants are sums of products of such means with the conserved piece in one factor, and $\frac{1}{15} > \frac{1}{36}$, the shift of the cutoff by z costing a constant. On T_ℓ: $L^z\ell \in \mathfrak{L}(g')$, Lemma 5.3 (a), and the chessboard estimate on the torus itself, with numbers that depend on ℓ. This is (a). *Step 3 (the mirror form).* For η as in (a′), cut η by a partition of unity into pieces $\chi_k\eta$ of sup diameter $\le \frac{1}{8}\min\{h_0, \ell'\}$; the covariance in (a′) is the sum over the pairs (k, k') of the covariances of $\theta_K\mathcal{T}_K(H^K_{\chi_k\eta})$ and $\mathcal{T}_K(H^K_{\chi_{k'}\eta})$, and the number of pairs depends on h_0, R_0 and ℓ' alone. The two members of a pair lie on the two sides of the plane $x_3 = \frac{1}{2}a_K$, at distance $\ge 2h_0 - a_K$ from each other, and counting the offsets gives a board of $\mathbb{L}_K$ with cells of side $\frac{1}{2}\ell'$ on which they lie in distinct cells, at a distance from the walls fixed by h_0 and ℓ'. By (11), which is linear in η, the null property and Proposition 5.24 (a), (b), the eight-copy seminorm of $b\,\mathcal{T}_K(H^K_{\chi_k\eta})$ less its mean is $\le CK^pL^{-cK}\|\eta\|_{C^2}$ for every $c < \frac{1}{10}$, and so is that of its image under the lattice isometry θ_K; Lemma 5.3 (c) bounds each covariance by $2e^{2G_g(\ell'/2)^3}$ times the product of the two seminorms, which gives the upper

bound. The covariance is $\nu(\theta_K F\cdot F)$ with $F=\mathcal{T}_K(H_\eta^K)-\nu(\mathcal{T}_K(H_\eta^K))$, as ν is invariant under θ_K, and reflection positivity at the bond mirror $x_3=\frac12 a_K$ (Per) gives the lower bound. *Step 4 (the four properties).* Let $g\le\gamma_W^{\mathrm{sd}}$. By Propositions 5.10, 5.13, 5.15 a tensor limit σ at g is labelled data with (S), (O) and (P) for every $p>\frac{17}{2}$. For $\eta\in C_c^2(\mathbb{E}_+;\mathbb{R}^3)$ the supports of $\theta H_\eta=H_{\theta\eta}$ and H_η are at positive distance, and (a) at $q=2$ gives (N): $\sigma(\theta H_\eta,H_\eta)=\lim_j\rho_j(A_{K_j}^{\rho_j}(\theta H_\eta,H_\eta))=0$. *Step 5 ((b), (c) at $g\le\gamma_W^{\mathrm{sd}}$).* Theorem T (i), (ii). *Step 6 (all reference couplings).* Let $g\le\gamma$ and σ', g', z as in Lemma 5.37. Rotations commute with the dilation, $(\mathsf{R}X)^{(z)}=\mathsf{R}X^{(z)}$, and $H_\eta(L^{-z}\cdot)=H_{\eta^{[z]}}$ with $\eta^{[z]}(x)=L^z\eta(L^{-z}x)$; by Step 5 at g',

$$\sigma(\mathsf{R}X)=L^{nz}\sigma'(\mathsf{R}X^{(z)})=L^{nz}\sigma'(X^{(z)})=\sigma(X),\qquad \sigma((H_\eta)\cdot X)=L^{(n+1)z}\sigma'((H_{\eta^{[z]}})\cdot X^{(z)})=0.$$

□

5.8. **The limits are not zero.** Theorem S shows that the tensor limits at $0<g\le\gamma_W^{\mathrm{sd}}$, to which Theorems R, T and U and Corollary 5.2 apply, are not zero, and that each of the six fields, and every real combination of them, survives in every such limit. By Lemma 5.37 the same holds for every tensor limit at every reference coupling $0<g\le\gamma$, where Theorem R applies. Let σ be one at g, with the label b_*; let z, $g'=(L^zb_*/2)^{-1/2}<\gamma_W^{\mathrm{sd}}$ and σ', a tensor limit at g' with the label L^zb_*, be as in Lemma 5.37; choose $0<\mathsf{d}'<\mathsf{d}_0(g')$ with $e_{g'}(\mathsf{d}')<w_0$, the bump φ' of Theorem S (iii) at d', and $E\in V$, $E\ne0$; and put $H=(\varphi'E)(L^z\,\cdot)$, a member carried by $\mathbb{E}_+$ with $H^{(z)}=\varphi'E$. As θ commutes with the dilation, $(\theta H)^{(z)}=\theta(\varphi'E)$, and Theorem S (iii) at g' gives

$$\|[(H)]\|^2=\sigma(\theta H,H)=L^{2z}\sigma'(\theta(\varphi'E),\varphi'E)\ge L^{2z}(w_0-e_{g'}(\mathsf{d}'))(L^zb_*)^{-2}\operatorname{tr}E^2=(w_0-e_{g'}(\mathsf{d}'))b_*^{-2}\operatorname{tr}E^2>0;$$

here g' and d' depend on b_*.

Proof of Theorem S. (i) Let $s_{16}(g)$, an integer formed with the constants and g, be the least depth from which on the thresholds of the factorisation at sixteen copies (below), that of Lemma 5.12 at eight pairs with the copies centred at their means, hold, and let $\mathsf{d}_0(g)=L^{-s_{16}(g)}$; for $0<\mathsf{d}<\mathsf{d}_0(g)$ the depth $s=s(\mathsf{d})$ fitted to d exceeds $s_{16}(g)$. Let ℓ' be the least side at g and $\mathsf{l}=\ell'/2$. We work first at a cutoff: let $(K,\beta)\in\mathfrak{d}(g)$ with $K\ge s+2$ and $4a_K\le\mathsf{d}-\mathsf{d}_-$, and $b=a_K\beta$. The working level is $\mathsf{k}=K-s$ (equation YMM1:(2322)), and $\upsilon=(a_sx_{K-s}(\beta))^{-1}$, the number υ of Lemma 5.7 at g and d, with $s_{\mathsf{k}}=s$ as $K\ge s+2$, is the coupling of the working level in the physical scale, the natural size there of a source of unit majorant; by Lemmas YMM1:126.1 and 5.7, $|\upsilon^{-1}-b|\le\bar Ba_s$, $\upsilon^2\le\frac98b^{-2}$, $|\upsilon^2-b^{-2}|\le3\bar Bg^2L^{2-s}b^{-2}$, $8a_K\le\mathsf{d}$, $a_s\le\mathsf{d}$, $20\mathsf{d}\le\ell'$ and $Y_s\ge s\log L\ge\log\frac1{\mathsf{d}}$.

Put $F_\iota=\mathcal{T}_K(H_\iota)$, and on the least torus $c_\iota=\langle F_\iota\rangle_{K,\ell',\beta}$, $\tilde F_\iota=F_\iota-c_\iota$, and the *pair value* $m=\langle\tilde F_1\tilde F_2\rangle_{K,\ell',\beta}=\langle F_1;F_2\rangle_{K,\ell',\beta}$. *The sixteen copies.* Consider the board of the least torus with eight cells of side l and an offset within $\frac12a_K$ of the midpoint of x_0 and y_0: the two members lie in the middle of one cell, every corner of a plaquette on which F_ι depends lying within $3\mathsf{d}<\frac12\mathsf{l}$ of its centre, and their sixteen mirror copies $F_{(\kappa,\iota)}$, $\kappa\in\{0,1\}^3$, with the majorants $(60|H_\iota|_\infty,S_{H_\iota})$ of Lemma 5.5, are eight close pairs $\tau=\kappa$: the two copies of one pair are $3\mathsf{d}$ to $4\mathsf{d}$ apart, and the corners of the plaquettes of different pairs are at sup distances $\ge\mathsf{l}-6\mathsf{d}\ge11M$. By the invariance of the torus measure under the reflections every copy of F_ι has the mean c_ι, and every pair the value m. *Quadratic sources; the Gaussian value.* For real H let $\mathsf{t}_H=\mathsf{t}[w_H]+\mathsf{t}[\mathsf{w}_H]$, the kernel of Lemma 5.5 (c), a real symmetric kernel on the pairs of bare plaquettes, where

$$\mathsf{t}[w](p,p')=\tfrac12w(p)\delta_{pp'},\qquad \mathsf{t}[\mathsf{w}](p,p')=-\tfrac12\sum_b\mathsf{w}(b)\big[c_{b,\lambda_b}(p)c_{b,\lambda_b'}(p')+c_{b,\lambda_b}(p')c_{b,\lambda_b'}(p)\big],$$

$c_{b,\lambda}(p)\in\{0,\pm\frac12\}$ being the coefficients of $\mathbf{u}_{b,\lambda}$, to the first order, as a linear form in the vector parts of the plaquettes; they are carried by the two plaquettes of the plane of λ and μ_b that contain b. The kernel vanishes off $S_H\times S_H$, and $2\sum_{p'}|\mathsf{t}_H(p,p')|\le3|H|_\infty$. With this kernel $\mathcal{T}_K(H)$ is a

quadratic source under $(60|H|_\infty, S_H)$ (Definition 5.4 (5), Lemma 5.5 (c)): besides the properties of a source under a majorant that Lemma 5.5 names, at a small point of the chart of every step its second order is the quadratic form $\sum_{p,p'} \mathsf{t}_H(p,p')\langle \mathsf{ang}_p, \mathsf{ang}_{p'}\rangle$ in the angles of the plaquettes, up to a remainder of a higher order in the radius times $(\#S_H)\,60|H|_\infty$.

For $\mathcal{O}(w)$ this is the expansion of a_p to the second order; for $Y[\mathsf{w}]$, $q_b = \langle \mathbf{u}_{b,\lambda_b}, \mathbf{u}_{b,\lambda'_b}\rangle$ is, to the second order, the product of the two linear forms. The carried family at the flat top (Proposition YMM1:125.1) is worded for the plaquette sources, with the kernels $\frac{1}{2}w(p)\delta_{pp'}$, and its proof reads a source only through this quadratic form and the row sums of its kernel; so it holds for kernels with two indices, with the same constants and the same errors, read at the majorants. With it the law of two points (Proposition YMM1:126.4) holds for two real quadratic sources under majorants $(\mathsf{s}_\iota, S_\iota)$ whose plaquettes lie within $\mathsf{d} - a_K$ of x_0 and of y_0: $|\langle F_1; F_2\rangle_{K,\ell,\beta} - G| \le \epsilon^\natural_g(s)\, \upsilon^2 \mathsf{s}_1\mathsf{s}_2$ on every side ℓ that is small over the run, with a function $\epsilon^\natural_g$ of the constants, g and s that tends to 0, where

$$G = 6\upsilon^2 \sum_{p,p',q,q'} \mathsf{t}_1(p,p')\,\mathsf{t}_2(q,q')\,C(p,q)\,C(p',q')$$

is the *Gaussian value* of the two sources with the kernels t_1, t_2. Here $6 = 2(N^2-1)$ at $N=2$, and $C = C^{\mathrm{free}}_K - C^{\mathrm{fl}}_{K,s}$, the background kernel $C^{\mathrm{bg}}_{K,s}$ of the depth s of the working level (Section YMM1:120, Lemma 5.11), is the covariance of the background of the chain at the depth s, on pairs of bare plaquettes and in the bare units: with the orientation signs $\epsilon_p = \pm 1$ of the plaquettes and $u = x(p) - x(q)$, the free part differs from $a_K^3 K_3(u)_{\lambda(p)\lambda(q)}$, after the signs $\epsilon_p\epsilon_q$, by at most $C_{\mathrm{lat}} a_K^3 [a_K^2|u|^{-5} + \ell'^{-3}]$, and the part of the fluctuations is at most $C^{\mathrm{fl}}_* a_K^3 a_s^{-3} e^{-\delta_{\mathrm{tp}} L|u|/(\sqrt{3}a_s)}$, with numbers C_{lat}, C^{fl}_*, δ_{tp} of the constants. At the plaquettes of our two members $|C(p,q)| \le C_{\mathsf{k}}(a_K/\mathsf{d})^3$, C_{k} a number of the constants, that of Lemma 5.11, and $\#S_{H_\iota} \le 81(\mathsf{d}/a_K)^3$; so the Gaussian value G_τ of every pair τ has $|G_\tau| \le \mathsf{g}'_0 \hat{m}$, with $\mathsf{g}'_0 = \frac{3}{2}\,81^2 C_{\mathsf{k}}^2$ and $\hat{m} = 3600\upsilon^2 |H_1|_\infty |H_2|_\infty$; the pair of the members themselves has $G_0 = G$ at $\mathsf{t}_\iota = \mathsf{t}_{H_\iota}$. *Factorisation, centred at the means.* For a pair τ let $\tilde{P}_\tau = \tilde{F}_{(\tau,1)}\tilde{F}_{(\tau,2)}$, and for a set J of pairs $\tilde{P}_J = \prod_{\tau\in J} \tilde{P}_\tau$. The mean on the least torus of a product of centred copies is, as in the proof of Lemma 5.12, a sum over the level of the first creation of a large field (equation (314)); along the histories without large fields the conditional density at the upper level is a sum over the partitions of the copies, the blocks of one element being the conditional means less the true means, those of the two copies of one pair their conditional covariance, and those that link two pairs terms of the exponent on polymers joining them, exponentially small in their distance in units of the working level; a block of two or more elements reads no centring constant.

In the place of a vanishing mean one reads: the conditional mean of F_ι at the upper level is the constant c'_ι of the progression up to a small number, and the sum over the level of the first large field, read for $F_\iota - c'_\iota$, puts the true mean c_ι within the same small number of c'_ι; so a block of one element is at most $\mathsf{e}^{\mathrm{c}}_g(s)\,60\upsilon|H_\iota|_\infty$, with $\mathsf{e}^{\mathrm{c}}_g(s) \to 0$. A block of a close pair is its Gaussian value up to a small multiple of $\hat{m}$, by the flat top for kernels with two indices. On the least side, which is small over the run (Lemma YMM1:126.3), the large fields are rare (Lemma YMM1:125.3) and pay for the levels below the upper one.

So, for every set J of pairs,

$$\Big|\langle \tilde{P}_J\rangle_{K,\ell',\beta} - \prod_{\tau\in J} G_\tau\Big| \le \omega'_{g,16}(s)\,\hat{m}^{\#J}, \qquad \big|\langle \tilde{P}_J\rangle_{K,\ell',\beta} - m^{\#J}\big| \le \omega'^{\sharp}_{g,16}(s)\,\hat{m}^{\#J},$$

the second because every pair has the value m; and for the eight copies of one member, one of each pair, $|\langle \prod_\kappa \tilde{F}_{(\kappa,\iota)}\rangle_{K,\ell',\beta}| \le (\mathsf{mn}_g(s)\,60\upsilon|H_\iota|_\infty)^8$. The numbers $\omega'_{g,16}(s) \le \omega'^{\sharp}_{g,16}(s)$ and $\mathsf{mn}_g(s)$ are formed with the constants, g and $s \ge s_{16}(g)$; they tend to 0 as $s\to\infty$, and $Y_s^{2\mathfrak{p}_0}\omega'^{\sharp}_{g,16}(s)$ is bounded. *The*

lattice sum. As C is K_3 up to the lattice and volume corrections, and $a_K^3\sum_{p,p'}|\mathsf{t}_H(p,p')|\le 45\mathsf{d}^3|H|_\infty$,

$$\Big|6\sum_{p,p',q,q'}\mathsf{t}_{H_1}(p,p')\mathsf{t}_{H_2}(q,q')C(p,q)C(p',q')-\mathcal{W}(H_1,H_2)\Big|\le\Big[12150E_1\big(\tfrac{1}{\pi}+E_1\big)+7400\frac{a_K}{\mathsf{d}}\Big]|H_1|_\infty|H_2|_\infty+\mathsf{Ri}_K,$$

with $E_1=C_{\mathrm{lat}}[(a_K/\mathsf{d})^2+(\mathsf{d}/\ell')^3]+C_*^{\mathrm{fl}}\check{\mathsf{d}}^3e^{-\delta_{\mathrm{tp}}L\check{\mathsf{d}}/\sqrt{3}}$, $\check{\mathsf{d}}=L^s\mathsf{d}$, and the Riemann remainder $\mathsf{Ri}_K\le 310[\omega_1(a_K)|H_2|_\infty+|H_1|_\infty\omega_2(a_K)]+12800\frac{a_K}{\mathsf{d}}|H_1|_\infty|H_2|_\infty$, ω_ι the modulus of continuity of H_ι; and $|\mathcal{W}(H_1,H_2)|\le 24|H_1|_\infty|H_2|_\infty$. *All states and sides.* Let $\mathfrak{s}$ be any $\nu\in\mathcal{G}^{\mathrm{per}}_{K,\beta}$, or the torus measure of any side $\ell\in\mathfrak{L}(g)$. For every real function D of the cell, $|\mathfrak{s}(D)|\le e^{G_g|^3}\|D\|_{\mathrm{ch},\ell'}$ (Lemma 5.3 (b), (c)), and $\|D\|^8_{\mathrm{ch},\ell'}$ is the mean on the least torus of the eight mirror copies of D. At $D=F_\iota-c_\iota$ these are the eight centred copies of one member, one of each pair: $|\mathfrak{s}(F_\iota)-c_\iota|\le e^{G_g|^3}\mathsf{mn}_g(s)\,60\upsilon|H_\iota|_\infty$. At $D=(F_1-c_1)(F_2-c_2)-m$: $\|D\|^8_{\mathrm{ch},\ell'}=\sum_J(-m)^{8-\#J}\langle\tilde P_J\rangle_{K,\ell',\beta}$, the sum over the sets J of pairs; with $\langle\tilde P_J\rangle_{K,\ell',\beta}=m^{\#J}+r_J$, $|r_J|\le\omega'^\sharp_{g,16}(s)\hat m^{\#J}$, the terms $m^8\sum_J(-1)^{8-\#J}=m^8(1-1)^8$ cancel, and $|m|\le(\mathsf{g}'_0+\omega'_{g,16}(s))\hat m$ bounds the rest by $\omega'^\sharp_{g,16}(s)(1+\mathsf{g}'_0+\omega'_{g,16}(s))^8\hat m^8$; the eighth root gives $|\mathfrak{s}((F_1-c_1)(F_2-c_2))-m|\le\mathsf{Df}'_g(s)\,\hat m$ with $\mathsf{Df}'_g(s)=e^{G_g|^3}\omega'^\sharp_{g,16}(s)^{1/8}(1+\mathsf{g}'_0+\omega'_{g,16}(s))$. As $\mathfrak{s}(F_1;F_2)=\mathfrak{s}((F_1-c_1)(F_2-c_2))-\mathfrak{s}(F_1-c_1)\,\mathfrak{s}(F_2-c_2)$,

$$|\mathfrak{s}(F_1;F_2)-m|\le\big[\mathsf{Df}'_g(s)+e^{2G_g|^3}\mathsf{mn}_g(s)^2\big]\hat m.$$

The law at a cutoff. With $|m-\upsilon^2X|\le\omega'_{g,16}(s)\hat m$ for the sum $X=6\sum\mathsf{t}_{H_1}\mathsf{t}_{H_2}CC$ (the case $J=\{0\}$), the lattice sum, $\upsilon^2\le\frac98 b^{-2}$, $|\upsilon^2-b^{-2}|\le 3\bar Bg^2L^{2-s}b^{-2}$ and $|\mathcal{W}|\le 24|H_1|_\infty|H_2|_\infty$:

$$|\mathfrak{s}(F_1;F_2)-b^{-2}\mathcal{W}(H_1,H_2)|\le b^{-2}\Big\{e_g(\mathsf{d})+\tfrac98\Big[12150\Big(E_1\big(\tfrac{1}{\pi}+E_1\big)-E_1^\infty\big(\tfrac{1}{\pi}+E_1^\infty\big)\Big)+7400\frac{a_K}{\mathsf{d}}\Big]\Big\}|H_1|_\infty|H_2|_\infty+\tfrac98 b^{-2}\mathsf{Ri}_K,$$

where $E_1^\infty=E_1-C_{\mathrm{lat}}(a_K/\mathsf{d})^2$ and

$$e_g(\mathsf{d})=\tfrac98\Big\{3600\big[\omega'_{g,16}(s)+\mathsf{Df}'_g(s)+e^{2G_g|^3}\mathsf{mn}_g(s)^2\big]+12150E_1^\infty\big(\tfrac{1}{\pi}+E_1^\infty\big)\Big\}+72\,\bar Bg^2L^{2-s},\qquad s=s(\mathsf{d}).$$

The function e_g is formed with the constants and g alone: it reads none of K, β, the state, the side and the members. The other terms read K and the members, and they tend to 0 as $K\to\infty$ at continuous members. *The rate.* As $Y_s^{2\mathfrak{p}_0}\omega'^\sharp_{g,16}(s)$ is bounded, $\omega'_{g,16}(s)\le\omega'^\sharp_{g,16}(s)\le cY_s^{-2\mathfrak{p}_0}$, and the eighth root gives $\mathsf{Df}'_g(s)\le c'Y_s^{-\mathfrak{p}_0/4}$; $\mathsf{mn}_g(s)^2$ decays faster in Y_s, and so do L^{2-s} and E_1^∞, as $\mathsf{d}<LC_W(s)L^{-s}$ and $\check{\mathsf{d}}\ge C_W(s)\to\infty$. With $Y_s\ge\log\frac{1}{\mathsf{d}}$ this gives $\sup_{\mathsf{d}}(\log\frac{1}{\mathsf{d}})^{\mathfrak{p}_0/4}e_g(\mathsf{d})<\infty$, and $e_g(\mathsf{d})\to 0$ as $\mathsf{d}\to 0$, the depth $s(\mathsf{d})$ tending to infinity. *The limit.* Let σ be a tensor limit along (K_j,β_j,ρ_j), with the label b_*. For large j, $K_j\ge s+2$ and $4a_{K_j}\le\mathsf{d}-\mathsf{d}_-$, and the bound at $\mathfrak{s}=\rho_j$ bounds $\rho_j(A^{\rho_j}_{K_j}(H_1,H_2))=\rho_j(F_1;F_2)$; as $j\to\infty$, $a_{K_j}\beta_j\to b_*$, $E_1\to E_1^\infty$, $a_{K_j}/\mathsf{d}\to 0$ and $\mathsf{Ri}_{K_j}\to 0$, and the definition of a tensor limit gives (i). (ii) $\mathcal{W}$ is invariant under the dilations of the members; so for fixed H_1,H_2 with $\mathcal{W}(H_1,H_2)\ne 0$, (i) at the dilated members $H_\iota(\cdot/\epsilon)$ gives $b_*^{-2}=\lim_{\epsilon\to0}\sigma(H_1(\cdot/\epsilon),H_2(\cdot/\epsilon))/\mathcal{W}(H_1,H_2)$. (iii) A direct computation gives $\mathcal{W}(\theta(\varphi E),\varphi E)\ge w_0\,\mathrm{tr}\,E^2$ for the bump φ and the mirror image at the distance $3\mathsf{d}$; (i) at $H_1=\theta(\varphi E)$, $H_2=\varphi E$, with $|E|^2_\infty\le\mathrm{tr}\,E^2$, gives the bound, and the left side is $\|[(\varphi E)]\|^2$. (iv) The same argument on T_ℓ, with the torus functionals of Proposition 5.18, at every label $\mathsf{b}\in(g^{-2}+\bar B,X_g-\bar B]$, for which $(K,L^K\mathsf{b})\in\mathfrak{d}(g)$ at every K. □

5.9. **The fields in real time.**

Proof of Corollary 5.2. (A) Invariance under all isometries: Theorem R (c), (D2), and Lemma 5.26, which also identifies $\mathcal{H}(\sigma^1)$ with $\mathcal{H}(\sigma)$. A rotation S about e_3 keeps $\mathbb{E}_+$ and commutes with θ,

so $[F] \mapsto [\mathsf{S}F]$ is unitary on $\mathcal{H}(\sigma)$ and turns $e^{-tH}e^{iv\cdot P}$ into $e^{-tH}e^{i(\mathsf{S}v)\cdot P}$; so, with $U_{\mathsf{S}}[F] = [\mathsf{S}F]$ and $\hat{\mathsf{S}}(E,q) = (E,\mathsf{S}q)$, $U_{\mathsf{S}}\mathcal{P}(B)U_{\mathsf{S}}^{-1} = \mathcal{P}(\hat{\mathsf{S}}B)$ for every Borel set B. $\mathcal{P}$ is carried by the square cone (D4), hence by its images under all the $\hat{\mathsf{S}}$, and so by their intersection, the cone $\{E \geq |q|\}$, as in Proposition 5.31 (c). The insertion bound is the equivalent form of Proposition 5.15, with $b_* \geq g^{-2}$. (B) The construction of Lemma 5.25 (a) in three variables, with the semigroup $\mathsf{T}_3(\mathfrak{z}) = \int e^{-\mathfrak{z}_3 E + i(\mathfrak{z}_1 q_1 + \mathfrak{z}_2 q_2)} d\mathcal{P}$ on the tube $\mathsf{Tb}^{\square} = \{\operatorname{Re}\mathfrak{z}_3 > |\operatorname{Im}\mathfrak{z}_1| + |\operatorname{Im}\mathfrak{z}_2|\}$ of the proof of Proposition 5.31 (b) and the mean value property on a polydisc of $\mathbb{C}^3$, gives point operators of the members $e\,\delta_x$, which (P) bounds by $C|e|\min\{1,\cdot\}^{-p}$ as in Lemma 5.25 (d); so at time-ordered configurations with consecutive time differences $\geq 2\eta$ the kernel $\mathbf{W}_n$ of σ is continuous and $|\mathbf{W}_n| \leq (C_V\eta^{-p})^n \prod |e_k|$.

For n pairwise different points the directions $u \in S^2$ with $|u\cdot(x_i - x_j)| \geq n^{-2}|x_i - x_j|$ for all $i \neq j$ fill more than half of the sphere; a rotation that turns such a u into e_3 makes the configuration time-ordered with gaps $\geq n^{-2}\delta(x)$, and by (A) the value $\mathsf{s}_n(x;e) = \mathbf{W}_n$ at the rotated configuration does not depend on the rotation chosen. This gives the bound; real-analyticity comes from the holomorphy of the kernels in the tubes, and the representation of σ at all tuples from the slides alone: Lemma 5.30 (a), with the induction on the pairs of pieces with overlapping heights of the proof of Lemma 5.30 (b), as in Step 4 of the proof of Theorem U.

For φ with components in $\mathcal{S}_{\neq}(\mathbb{R}^{3n})$, flat on the coincidence set, Taylor's formula at that set pays for the factor $\max\{1, 2n^2/\delta(x)\}^{pn}$, at the cost of $(n!)^{2p}$ and of $\lceil p\rceil n$ derivatives; this is the growth condition with the constants $(\lceil p\rceil, 1, \mathsf{C}_E, 2p)$, $\mathsf{C}_E = 6\pi^2 2^p e^{2p} 3^{\lceil p\rceil}\mathsf{c}\,C_V$. (C) The reconstruction theorem among the construction results, Theorem YMM1:AO, is used in its form for members with values in V: the labelled form stated, with the full list of its changes, at the end of Subsection 5.3. It is applied to σ^1, which has the data (Rec1)–(Rec4) by (A). Its data are a real symmetric functional σ^1 on the tuples of members in $C_c^1(\mathbb{R}^3;V)$ with pairwise disjoint supports, $\sigma^1(\varnothing) = 1$, n-linear on the products of the spaces $C_c^1(O_a;V)$ for open sets with pairwise disjoint closures, with $(\text{Rec1})_V$ $\sigma^1(\mathsf{r}X) = \sigma^1(X)$ for every isometry r of $\mathbb{R}^3$, acting on points and values; $(\text{Rec2})_V$ positivity at $x_3 = 0$, a separable space $\mathcal{H}(\sigma^1)$, and $H \geq 0$, the translations $e^{iv\cdot P}$ and the joint spectral measure $\mathcal{P}$ as in (D4); $(\text{Rec3})_V$ $\mathcal{P}(\{E < |q|\}) = 0$; $(\text{Rec4})_V$ the insertion bound $|\sigma^1(\theta\bar{F}\cdot(h)\cdot F')| \leq C_V\eta^{-p_V}\|h\|_{L^1}\|[\tau_{-\eta e_3}F]\|\,\|[\tau_{-\eta e_3}F']\|$ for $\eta \in (0,1]$, F, F' over $\{x_3 > \eta\}$ and $h \in C_c^1(\{|x_3| < c_0\eta\};V)$, the norm $\|h\|_{L^1}$ being formed with a norm of V that ρ keeps.

For such data the theorem gives: a strongly continuous unitary representation U of the proper orthochronous Poincaré group of $\mathbb{R}^{1+2}$ with $U(x,1) = e^{itH}e^{i\vec{x}\cdot P}$, $U\Omega = \Omega$ and spectrum in the closed forward cone; fields $T(f)$, $f \in \mathcal{S}(\mathbb{R}^{1+2};V_{\mathbb{C}})$, linear in f, on the span $\mathcal{D}_0$ of Ω and of the vectors $T(f_1)\cdots T(f_n)\Omega$, tempered, with $\langle\psi, T(f)\psi'\rangle = \langle T(f^*)\psi, \psi'\rangle$, $f^* = \rho(\theta)\bar{f}$; $U(a,\Lambda)T(f)U(a,\Lambda)^{-1} = T(D(\Lambda)f(\Lambda^{-1}(\cdot - a)))$ on $\mathcal{D}_0$; locality of all components with all components; $\mathcal{D}_0$ dense; and functions $\mathbf{W}_n(\mathfrak{z};e)$, holomorphic on the tubes and n-linear in $e \in V_{\mathbb{C}}^n$, bounded by $(C_V\eta^{-p_V})^n\prod|e_k|$ where the consecutive differences have the margin 2η, $0 < \eta \leq 1$, whose boundary values are the Wightman functions and which at real configurations ordered in x_3 are the density of σ^1.

Here $D(\Lambda)A = \hat{\Lambda}A\hat{\Lambda}^{\mathrm{T}}$, $A \in V_{\mathbb{C}}$, $\hat{\Lambda} = \iota\Lambda\iota^{-1}$: $\hat{\Lambda}^{\mathrm{T}}\hat{\Lambda} = \mathbf{1}$, $\det\hat{\Lambda} = 1$ and $\widehat{\Lambda\Lambda'} = \hat{\Lambda}\hat{\Lambda}'$, so that D is a continuous homomorphism of the Lorentz group into $\mathrm{GL}(V_{\mathbb{C}})$; $D(1\oplus\mathsf{R}) = \rho(\mathsf{R}\oplus 1)$ for $\mathsf{R} \in \mathrm{SO}(2)$; $D(B(s)) = \exp(is\,d\rho(\omega_1))$ for the boost $B(s)$ in the plane of x^0 and x^1, $\omega_1 = e_1e_3^{\mathrm{T}} - e_3e_1^{\mathrm{T}}$, $d\rho(\omega)A = \omega A + A\omega^{\mathrm{T}}$; and $D(\Lambda)e^* = (D(\Lambda)e)^*$ with $e^* = \rho(\theta)\bar{e}$, as $\theta\omega_1\theta^{-1} = -\omega_1$. The proof is that among the construction results, index by index: the point operators become linear in a value e, with $\mathsf{B}(s,s';e)^* = \mathsf{B}(s',s;e^*)$, and the rotations R about e_3 act on them by $e \mapsto \rho(\mathsf{R})e$; the kernels are permuted together with their values, and $\mathsf{s}_n(\mathsf{r}x;\rho(\mathsf{R})e) = \mathsf{s}_n(x;e)$ for $\mathsf{r}x = \mathsf{R}x + v$; the bounds keep their constants because $\rho(\mathsf{R})$ is orthogonal for the norm of V that ρ keeps; the kernels satisfy $\mathbf{W}_n(\hat{\Lambda}\mathfrak{z};D(\Lambda)e) = \mathbf{W}_n(\mathfrak{z};e)$, at real rotations by the covariance of s_n and at the boosts by holomorphic continuation, no bound of $D(\Lambda)$ being read; in the Lorentz covariance of the

fields $f \circ \Lambda^{-1}$ becomes $D(\Lambda) f \circ \Lambda^{-1}$ and $\bar{f}$ becomes f^*, and the one new fact is $(\Lambda f)^* = \Lambda(f^*)$ for $(\Lambda f)(x) = D(\Lambda) f(\Lambda^{-1} x)$; locality is proved index by index.

The theorem is used in its form without (Rec5), that is, except the uniqueness of the vacuum. Its hypotheses are (A), with $p_V = p$, $c_0 = \frac{1}{2}$ and the number C_V of (A); the norm $|h(x)|_\infty$ in the bound of (A) is at most the norm $(\operatorname{tr} h(x)^2)^{1/2}$, which ρ keeps. It gives the fields $T(f)$ on the smooth vectors, with the kernels of (B) as Euclidean Green's functions; the boosts are the analytic continuation of the rotations R_t, which on the plate vectors is the unitary group of Lemma 5.32 (b); the spectral condition comes from the cone; locality from the symmetry of the kernels of (B) at all configurations of pairwise different points; and the density of $\mathcal{D}_0$ from Lemma 5.29.

Before invoking rotation covariance, the construction already gives the semigroup on the tube, the point operators, the functions $\mathbf{W}_n$ and the vectors, the forms and the operators $T(f)$, and the boundary values. These steps use no rotations and apply with the square cone: with $d_\square(\mathfrak{z}) = \operatorname{Re}\mathfrak{z}_3 - |\operatorname{Im}\mathfrak{z}_1| - |\operatorname{Im}\mathfrak{z}_2|$ in the place of $\operatorname{Re}\mathfrak{z}_3 - |\operatorname{Im}\vec{\mathfrak{z}}|$, the tube $\mathsf{Tb}^\square = \{d_\square > 0\}$, and $V_+^\square = \{\alpha^0 > |\alpha^1| + |\alpha^2|\}$ in the place of the forward cone; the required spectral estimate is (on $\{E \geq \max(|q_1|, |q_2|)\}$, $|e^{-\mathfrak{z}_3 E + i(\mathfrak{z}_1 q_1 + \mathfrak{z}_2 q_2)}| \leq e^{-d_\square(\mathfrak{z}) E}$ and $|q_k| \leq E$), and the symmetries used are translations, θ and the eight elements of W_3 that fix e_3.

With the inputs (D1)–(D4), (S) and (P) of Propositions 5.10 and 5.15 they give fields $T(f)$ on the smooth vectors, tempered, with $f^* = \rho(\theta)\bar{f}$, covariant under the translations and under the eight elements of W_3 that fix e_3, with Wightman functions on the tubes of the square cone bounded by $(C\eta^{-p})^n$, $0 < \eta \leq 1$, and with spectrum in $\{E \geq \max(|q_1|, |q_2|)\}$. □

5.10. **Scope of the conclusions.** The theorems are statements on tuples with continuous members and pairwise disjoint supports. Each tensor limit is treated by itself, with its own label. The rates of Theorem R (a) are rates in the cutoff at fixed d and R, not in the distance of the supports; neither covariance nor conservation is a statement on the decay of correlations, and at large distances the argument needs only the boundedness of the two-point kernels. Theorem S is not used in the proofs of Theorems R, T, U and of Corollary 5.2. The rotation theorem for the action density, Theorem YMM1:AK, is not used in the proof of Theorem R (c). Of the positivity (D3), Theorem T under (P) and Proposition 5.31 (b) need only the plane $x_3 = 0$ and, at tuples of one member, the plane Σ.

6. Reflection positivity, spectral cones and reconstruction

Reflections act both on the arguments and on the tensor labels. We compare the Hilbert spaces reconstructed in the different lattice pictures and obtain the forward spectral cone before using full rotation covariance. This also makes precise which positivity statements survive for growing tori.

The lattice-source admission argument below treats bond bilinears directly. It supplies the tensor input that cannot be obtained merely by applying a scalar-source theorem by name. The remaining results concern the passage to components, their tensor lifts and the labelled reconstruction in real time.

6.1. **Notation and hypotheses.** *Constants and lattice notions.* The constants and the data are those of the main theorems; a number depends on the constants if it is formed from them alone. $L \geq 13$ is the odd block factor, $a_K = L^{-K}$, and $a_i = L^{-i}$ for every integer i. Recall the reference coupling g and its ceilings $\gamma_W^{\mathrm{sd}} \leq \gamma_W^{\mathrm{ref}} \leq \gamma$; the first-passage data (K, β) at g, whose labels $a_K\beta$ lie in the window $(g^{-2}, L(g^{-2} + \bar{B})]$, $\bar{B}$ a constant, so that limits of labels lie in the closed interval $[g^{-2}, L(g^{-2} + \bar{B})]$, and the interval $I(g) = (g^{-2} + \bar{B}, L(g^{-2} + \bar{B}) - 2\bar{B}]$, which is sufficient for first passage: for $\mathsf{b} \in I(g)$ and every K the pair $(K, L^K \mathsf{b})$ is a first-passage datum at g (Proposition YMM1:74.1, Corollary YMM1:74.2); the sets $\mathcal{G}_{K,\beta}^{\mathrm{per}}$ of periodic Gibbs states on $a_K\mathbb{Z}^3$ (Section YMM1:91); the sides ℓ admissible at g, the least of them ℓ', the tori T_ℓ and their Wilson measures $\tilde{\mu}_{K,\ell,\beta}$; boards of cells of side a_i with offsets in $a_K\mathbb{Z}^3$, the mirror copies $F^{[\mathbf{k}']}$ of a function

F of the bonds of one cell, and the chessboard seminorms: $\|F\|^N_{\mathrm{ch},\ell}$ is the mean under $\tilde\mu_{K,\ell,\beta}$ of the product of the $N=(\ell/a_i)^3$ mirror copies of F; the pressures $p_\ell=\ell^{-3}\log Z_{K,\ell,\beta}$ (Section YMM1:86) and the pressure gap $|p_\ell-p_{\ell_1}|\le G_g$ for admissible sides, G_g a number depending on the constants and g (Lemma N.1); and the exponent $\mathfrak{p}_0\ge 1$ of the logarithms in the small-field bounds. W_3 is the group of the 48 signed permutation matrices, e_1,e_2,e_3 the standard basis, $|x|$ the Euclidean norm and $|x|_\infty=\max_\mu|x_\mu|$; sup diameters and sup distances are formed with $|\cdot|_\infty$. R_t is the rotation about e_2 with $\mathsf{R}_t e_3=\cos t\,e_3+\sin t\,e_1$.

Labels, weights and tuples. $V=\mathrm{Sym}_3(\mathbb{R})$, $V_{\mathbb{C}}=\mathrm{Sym}_3(\mathbb{C})$, with $\rho(R)E=RER^{\mathrm{t}}$ for $R\in\mathrm{O}(3)$ and $|E|_\infty=\max_{\lambda\lambda'}|E_{\lambda\lambda'}|$; $E_{\lambda\lambda'}$ denotes also a matrix unit, and $o_{\mu\nu}=E_{\mu\nu}+E_{\nu\mu}$ for $\mu\ne\nu$. As $F_{\mu\nu}=\varepsilon_{\mu\nu\lambda}B_\lambda$, the array $\mathrm{tr}\,F_{ij}F_{kl}$ is the tensor $T_{\lambda\lambda'}=\langle B_\lambda,B_{\lambda'}\rangle$, $\langle X,Y\rangle=\frac12\mathrm{tr}\,XY$, whose components are indexed by V. The decomposition $V=V_A\oplus V_E\oplus V_T$ into the multiples of $\mathbf{1}$, the traceless diagonal matrices and the matrices with zero diagonal is invariant under $\rho(W_3)$, with projections P_A,P_E,P_T, and $Z_z=P_A+P_E+zP_T$, z real, multiplies the off-diagonal labels by z.

A weight is an $H\in C^1_c(\mathbb{R}^3;V)$; where continuous weights $H\in C_c(\mathbb{R}^3;V)$ are admitted we say so. $|H|_\infty=\sup_x|H(x)|_\infty$, $\|H\|_{L^1}=\int|H(x)|_\infty\,dx$, $H^{(z)}(x)=H(L^{-z}x)$ for $z\in\mathbb{N}$. An isometry $\iota x=Rx+v$ acts by $(\iota H)(x)=\rho(R)H(\iota^{-1}x)$, and on vector fields by $(\iota\eta)(x)=R\eta(\iota^{-1}x)$; τ_v is the translation by v. For open $O\subset\mathbb{R}^3$, $\mathfrak{S}_V(O)$ is the set of the unordered tuples $X=(H_1,\dots,H_n)$, $n\ge0$, of weights with pairwise disjoint supports in O; $X\cdot Y$ is the concatenation of two tuples with disjoint supports, $\mathbb{C}\mathfrak{S}_V(O)$ the space of the complex combinations $F=\sum c_iX_i$, and $\bar F=\sum\bar c_iX_i$.

Isometries and linear maps of V, applied pointwise, act on tuples entry by entry and on combinations linearly. An entry with values in $V_{\mathbb{C}}$ stands for the expansion of $H=\mathrm{Re}\,H+i\,\mathrm{Im}\,H$ in that entry. For a vector field $\eta\in C^1(\mathbb{R}^3;\mathbb{R}^3)$, with $(\nabla\eta)_{ij}=\partial_i\eta_j$,

$$H^{\mathrm{cons}}[\eta]=(\nabla\cdot\eta)\mathbf{1}-\nabla\eta-(\nabla\eta)^{\mathrm{t}},\qquad \iota H^{\mathrm{cons}}[\eta]=H^{\mathrm{cons}}[\iota\eta];$$

formally $\frac12\int\mathrm{tr}(H^{\mathrm{cons}}[\eta]T)=-\int\eta_\nu\partial_\mu\Theta_{\mu\nu}$ with the stress tensor $\Theta=\frac12(\mathrm{tr}\,T)\mathbf{1}-T$, $\Theta_{\mu\nu}=F_{\mu\alpha}F_{\nu\alpha}-\frac14\delta_{\mu\nu}F_{\alpha\beta}F_{\alpha\beta}$.

Lattice observables and limits. A configuration on $a_K\mathbb{Z}^3$, or on a torus T_ℓ, assigns to every oriented bond b a matrix $U(b)\in\mathrm{SU}(2)$, with $U(\bar b)=U(b)^{-1}$ at the reversed bond. For a plaquette p, its plaquette variable $\partial U(p)$ is the product of U around p, defined up to a conjugation that the functions below do not see; $x(p)$ is its centre, $\lambda(p)$ its normal direction, and $a_p=1-\frac12\mathrm{tr}\,\partial U(p)\in[0,2]$ its plaquette square. With $e_{-\mu}=-e_\mu$, for $\alpha,\alpha'\in\{\pm1,\pm2,\pm3\}$ with $|\alpha|\ne|\alpha'|$ let $W_x(\alpha,\alpha')$ be the product of U along the loop $x\to x+a_Ke_\alpha\to x+a_Ke_\alpha+a_Ke_{\alpha'}\to x+a_Ke_{\alpha'}\to x$, and $\mathbf{w}(V)=(V-V^{-1})/(2i)$. For a positively oriented bond $b=\langle x,x+a_Ke_\mu\rangle$ with midpoint x_b, and $\lambda_b<\lambda_b'$ the two directions other than μ, put

$$u_{b,\alpha}=-\tfrac12\big[\mathbf{w}(W_x(\mu,\alpha))-\mathbf{w}(W_x(\mu,-\alpha))\big]\quad(\alpha\in\{\lambda_b,\lambda_b'\}),\qquad q_b=\langle u_{b,\lambda_b},u_{b,\lambda_b'}\rangle:$$

$u_{b,\alpha}$ is formed from the two plaquettes of the plane of e_μ,e_α that contain b, read from x, and q_b is the bond form of b. A weight w of the plaquettes, or w of the bonds, is a bounded complex function on the plaquettes, or on the positively oriented bonds, and

$$O(w)=a_K^{-1}\sum_p w(p)a_p,\qquad Y[\mathsf{w}]=-a_K^{-1}\sum_b\mathsf{w}(b)q_b.$$

A bounded weight is a bounded Borel function $H:\mathbb{R}^3\to V$, or $V_{\mathbb{C}}$, of bounded support; weights are bounded weights. For a bounded weight H

$$O_K^T(H)=O(w_H)+Y[\mathsf{w}_H],\qquad w_H(p)=H_{\lambda(p)\lambda(p)}(x(p)),\quad \mathsf{w}_H(b)=H_{\lambda_b\lambda_b'}(x_b),$$

and the same formulas define $O_K^T(H)$ on a torus, for H on T_ℓ or for H on $\mathbb{R}^3$ with support in a period box. So $O_K^T(H)$ weights the square of each plaquette with $H_{\lambda\lambda}$ at its centre, λ normal to the plaquette, and the bond form of the directions $\lambda\ne\lambda'$ with $H_{\lambda\lambda'}$ at the midpoint of the bond, and $O_K^T(f\mathbf{1})=O(f)$ is the action density weighted with f. The plaquette squares and the

bond forms enter with one normalisation: for the configuration $U(b) = e^{ia_K A_\mu(x_b)}$ of a smooth field A with curvature F, $F_{\mu\nu} = \varepsilon_{\mu\nu\lambda}B_\lambda$, one has $a_p = \frac12 a_K^4\langle F_{\mu\nu}, F_{\mu\nu}\rangle + o(a_K^4)$ at a plaquette of the plane of e_μ, e_ν, and $q_b = a_K^4\langle F_{\mu\lambda_b}, F_{\mu\lambda_b'}\rangle + o(a_K^4) = -a_K^4\langle B_{\lambda_b}, B_{\lambda_b'}\rangle + o(a_K^4)$; so formally $O_K^T(H) = \frac12\int \operatorname{tr}(H(x)T(x))\,dx$, the minus sign in Y compensating that of $\langle F_{\mu\lambda}, F_{\mu\lambda'}\rangle = -\langle B_\lambda, B_{\lambda'}\rangle$. A Gibbs sequence at g is a sequence (K_j, β_j, ν_j) of first-passage data at g with $K_j \to \infty$ and of states $\nu_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$. A tensor limit at g is a functional on $\mathfrak{S}_V(\mathbb{R}^3)$ given, for some Gibbs sequence at g, by

$$\sigma(X) = \lim_j \nu_j\Big(\prod_{a=1}^{n}\big(O^T_{K_j}(H_a) - \nu_j(O^T_{K_j}(H_a))\big)\Big), \qquad X = (H_1, \dots, H_n), \tag{18}$$

the limit existing for every X; a limit at continuous weights is the same at all tuples of continuous weights. The label of the sequence is $b = \lim_j a_{K_j}\beta_j$ when this limit exists; the trace part of σ is $\sigma_0(f_1, \dots, f_n) = \sigma(f_1\mathbf{1}, \dots, f_n\mathbf{1})$. Let ξ be a component of the canonical decomposition of the scalar limit of the sequence and $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$ its approximants, the states ν_j conditioned on translation-invariant events, as in the theorem on the scalar limit among the construction results (Theorems YMM1:AL and YMM1:AP). A lift $\sigma^\sharp_\xi$ is a limit (18) with the outer state ν_j replaced by ρ_j, along a subsequence; its re-centred functional σ^c_ξ is the limit with ρ_j in both places.

Mirrors and pictures. A mirror is a pair $(n, c) \in S^2 \times \mathbb{R}$, with the reflection $\theta_{n,c}x = x - 2(n\cdot x - c)n$, $\Theta_n = 1 - 2nn^{\mathrm{t}}$, $\theta_n = \theta_{n,0}$; it acts on weights by $(\theta_{n,c}H)(x) = \Theta_n H(\theta_{n,c}x)\Theta_n$. We put $\mathcal{D}_{n,c} = \mathbb{C}\mathfrak{S}_V(\{n\cdot x > c\})$ and $\mathcal{D}_n = \mathcal{D}_{n,0}$. A functional σ is positive at (n, c) if $\sigma(\theta_{n,c}\bar F \cdot F) \ge 0$ for all $F \in \mathcal{D}_{n,c}$. $\mathfrak{N}_{18}$ is the set of the vectors $\pm e_\mu$, $(\pm e_\mu \pm e_\lambda)/\sqrt2$, $\mu \ne \lambda$, the normals of the nine families of lattice planes. For an orthonormal frame (u, u', u'') the cubic group of the frame consists of the 48 orthogonal maps that permute u, u', u'' up to signs; its 18 normals are $\pm u, \pm u', \pm u''$ and $(\pm v \pm v')/\sqrt2$, $v \ne v'$ in the frame.

If σ satisfies (D0)–(D2) of Definition 6.1 and is positive at $(u, 0)$, the picture u (Lemma 6.3) consists of the Hilbert space $\mathcal{H}_u$ of the form $\sigma(\theta_u\bar F' \cdot F)$ on $\mathcal{D}_u$ with the classes $[F]_u$, the vacuum $\Omega_u = [\emptyset]_u$, the energy $H_u \ge 0$ with $e^{-tH_u}[F]_u = [\tau_{tu}F]_u$, the momenta P_u generating $[F]_u \mapsto [\tau_v F]_u$, $v \perp u$, and the joint spectral measure $\mathcal{P}_u$ of (H_u, P_u) on $[0,\infty)\times u^\perp$; for $G, G' \in \mathcal{D}_u$, $m^u_{G',G} = \langle [G']_u, \mathcal{P}_u(\cdot)[G]_u\rangle$. At $u = e_3$ we write $\mathcal{H}(\sigma)$, $[F]$, Ω, H, $P = (P_1, P_2)$, $\mathcal{P}$, $\theta = \theta_{e_3}$, and $U(t, \vec x) = e^{itH}e^{i(x_1P_1 + x_2P_2)}$, $\vec x = (x_1, x_2)$.

The forward cone is $\{(E, q) : E \ge |q|\}$, $|q|$ Euclidean, and the square cone $\{E \ge \max(|q_1|, |q_2|)\}$; the circular tube is $\mathsf{Tb} = \{\zeta \in \mathbb{C}^3 : \operatorname{Re}\zeta_3 > |(\operatorname{Im}\zeta_1, \operatorname{Im}\zeta_2)|\}$, the square tube $\mathsf{Tb}^\square = \{\zeta : \operatorname{Re}\zeta_3 > |\operatorname{Im}\zeta_1| + |\operatorname{Im}\zeta_2|\}$, and $\mathsf{E}(\zeta) = \int e^{-\zeta_3 E + i(\zeta_1 q_1 + \zeta_2 q_2)}\,d\mathcal{P}(E, q)$. $\Lambda^{(1)}_\varsigma(E, q_1, q_2) = (E\cosh\varsigma + q_1\sinh\varsigma,\ q_1\cosh\varsigma + E\sinh\varsigma,\ q_2)$ is the boost in the plane (E, q_1), and $\Lambda^{(2)}_\varsigma$ the same in (E, q_2).

Definition 6.1. For $\sigma : \mathfrak{S}_V(\mathbb{R}^3) \to \mathbb{R}$ we consider the conditions:

- (D0) $\sigma(\emptyset) = 1$; σ is symmetric and n-linear on $\prod_a C^1_c(O_a; V)$ for open sets O_a with pairwise disjoint closures, and it is extended linearly to combinations;
- (D1) for $n \ge 1$ and $\delta, \varrho_0 > 0$ there is $C_n(\delta, \varrho_0)$ with $|\sigma(H_1, \dots, H_n)| \le C_n(\delta, \varrho_0)\prod_a |H_a|_\infty$ whenever the supports have sup diameters at most ϱ_0 and pairwise sup distances at least 2δ; the bound does not depend on the position of the supports, and for complex entries it holds with the factor 2^n;
- (D2) $\sigma\circ\tau_v = \sigma$ for $v \in \mathbb{R}^3$; (D3) $\sigma\circ w = \sigma$ for $w \in W_3$;
- (D4) σ is positive at (n, c) for all $n \in \mathfrak{N}_{18}$ and $c \in \mathbb{R}$.

We put $G_\sigma = \{R \in \mathrm{O}(3) : \sigma(RX) = \sigma(X) \text{ for all } X\}$; σ is covariant under $\mathrm{O}(3)$ if $G_\sigma = \mathrm{O}(3)$. A set $\mathfrak{K}$ of tuples is full if $\iota X \in \mathfrak{K}$ for every $X \in \mathfrak{K}$ and every isometry ι, and then $G_\sigma[\mathfrak{K}] = \{R \in \mathrm{O}(3) : \sigma(RX) = \sigma(X) \text{ for all } X \in \mathfrak{K}\}$. $\mathfrak{K}_N$ is the set of the tuples with at most N entries and $\mathfrak{T}_k$ that of the tuples with at most k entries not of the form $f\mathbf{1}$; both are full, as $\rho(R)\mathbf{1} = \mathbf{1}$. σ is covariant at order N if $G_\sigma[\mathfrak{K}_N] = \mathrm{O}(3)$. For $m \in \mathbb{N}\cup\{\infty\}$, $\mathfrak{M}^{(m)}(\sigma)$ is the set of the $u \in S^2$ with $\sigma(\theta_u\bar F\cdot F) \ge 0$

for every $F \in \mathcal{D}_u$ that combines tuples with at most m entries, and $\mathfrak{M}(\sigma) = \mathfrak{M}^{(\infty)}(\sigma)$. Positivity is meant with complex coefficients throughout. ■

6.2. **Principal results.**

Theorem V (Mirrors and the forward cone for labelled functionals)**.** Let $\sigma : \mathfrak{S}_V(\mathbb{R}^3) \to \mathbb{R}$.

(a) *The mirror on the labels.* For every mirror (n, c) and every $E \in V$,

$$(\Theta_n E \Theta_n)_{\lambda\lambda'} = E_{\lambda\lambda'} - 2n_\lambda (En)_{\lambda'} - 2(En)_\lambda n_{\lambda'} + 4(n \cdot En)\, n_\lambda n_{\lambda'};$$

$\rho(\Theta_n)$ is $+1$ on $\mathbb{R}nn^{\mathrm{t}} \oplus \{E : En = 0\}$, of dimension $1 + 3$, and -1 on $V_n^- = \{nm^{\mathrm{t}} + mn^{\mathrm{t}} : m \perp n\}$, of dimension 2; at $n = e_\mu$ a component with k indices equal to μ acquires the factor $(-1)^k$; on the four indices of $\operatorname{tr} F_{ij}F_{kl}$ the mirror acts as $\Theta_n^{\otimes 4}$. $\Theta_n \in W_3$ if and only if $n \in \mathfrak{N}_{18}$, and for $n \notin \mathfrak{N}_{18}$ the map $\rho(\Theta_n)$ mixes $V_A \oplus V_E$ with V_T; at $n = (1, 1, 1)/\sqrt{3}$, for instance, $(\Theta_n E \Theta_n)_{\lambda\lambda'} = E_{\lambda\lambda'} - \frac{2}{3}(r_\lambda + r_{\lambda'}) + \frac{4}{9}s$, with the row sums r_λ and the sum s of the entries of E. Under (D0), positivity at (n, c) and at $(-n, -c)$ are equivalent; under (D0), (D2) both are equivalent to positivity at $(n, 0)$. The action on the labels is forced: if σ satisfies (D0)–(D2) and is positive at $(u, 0)$, and if $A : V \to V$ commutes with $\rho(\Theta_u)$ and $\sigma((A\theta_u\bar{F}) \cdot F) \geq 0$ for all $F \in \mathcal{D}_u$, then $[AF]_u = [F]_u$ for all F; in particular, for the reflection applied to the arguments alone, $A = \rho(\Theta_u)$, one gets $[(h)]_u = 0$ for every weight h with values in V_u^-.

(b) *A positive mirror is a symmetry; nine families or all planes.* If σ satisfies (D0), (D2) and $u \in \mathfrak{M}(\sigma)$, then $\Theta_u \in G_\sigma$; it suffices that the numbers $\sigma(\theta_u\bar{F} \cdot F)$, $F \in \mathcal{D}_u$, be real. If σ satisfies (D0), (D2), $m \in \mathfrak{M}(\sigma)$, $R \in G_\sigma$ and $Rm = n$, then σ is positive at (n, c) for every c. If σ satisfies (D0)–(D4), then G_σ is a closed subgroup of O(3) containing W_3, and the following are equivalent: (i) σ is covariant under O(3); (ii) G_σ contains an element outside W_3; (iii) σ is positive at one plane whose normal is not in $\mathfrak{N}_{18}$; (iv) σ is positive at every plane. In (ii) one reflection Θ_n, $n \notin \mathfrak{N}_{18}$, may be taken, and (iii) may be weakened to: the numbers $\sigma(\theta_n\bar{F} \cdot F)$, $F \in \mathcal{D}_n$, are real for one $n \notin \mathfrak{N}_{18}$. Hence $\mathfrak{M}(\sigma) = \mathfrak{N}_{18}$ or $\mathfrak{M}(\sigma) = S^2$.

(c) *How much covariance one plane uses.* Let σ satisfy (D0)–(D4). For every full set $\mathfrak{K}$, $G_\sigma[\mathfrak{K}]$ is W_3 or O(3). If $\mathfrak{F}$ and $\mathfrak{K}$ are full, $X \cdot Y \in \mathfrak{K}$ for all $X, Y \in \mathfrak{F}$ with disjoint supports, and $G_\sigma[\mathfrak{K}] = \mathrm{O}(3)$, then $\sigma(\theta_{n,c}\bar{F} \cdot F) \geq 0$ at every mirror for every combination F of tuples of $\mathfrak{F}$ on the side of the mirror; this applies to $(\mathfrak{F}, \mathfrak{K}) = (\mathfrak{K}_m, \mathfrak{K}_{2m})$, $(\mathfrak{T}_k, \mathfrak{T}_{2k})$ and $(\mathfrak{T}_0 \cup \mathfrak{K}_1, \mathfrak{T}_1 \cup \mathfrak{K}_2)$. For $m \in \mathbb{N} \cup \{\infty\}$: covariance at order $2m$ implies $\mathfrak{M}^{(m)}(\sigma) = S^2$, which implies $\mathfrak{M}^{(m)}(\sigma) \neq \mathfrak{N}_{18}$, which implies covariance at order m; for $m = \infty$ the four statements are equivalent.

Covariance at order 1 holds always: $\sigma((H)) = c_\sigma \int \operatorname{tr} H$ with a number c_σ. If $\sigma(H, H') = \iint \langle H(x) \otimes H'(y), s(y - x)\rangle\, dx\, dy$ with a continuous $s : \mathbb{R}^3 \setminus \{0\} \to V \otimes V$, then covariance at order 2, $\mathfrak{M}^{(1)}(\sigma) = S^2$ and $\mathfrak{M}^{(1)}(\sigma) \neq \mathfrak{N}_{18}$ are equivalent; if s is real analytic, covariance at order 2 follows from $\sigma(RH, RH') = \sigma(H, H')$ for one $R \notin W_3$ and all H, H' supported in two fixed balls with disjoint closures.

(d) *The forward cone from three mirrors.* Let σ satisfy (D0)–(D2), let (u, u', u'') be an orthonormal frame, and let σ be positive at $(u, 0)$, $((u + u')/\sqrt{2}, 0)$ and $((u + u'')/\sqrt{2}, 0)$. Then σ is invariant under the cubic group of the frame and positive at (n, c) for its 18 normals n and all c, and

$$\mathcal{P}_n(\{(E, q) : E < |q|\}) = 0 \qquad \text{for each of the 18 normals } n.$$

In the picture u, $\mathsf{E}(\zeta)$ is a contraction for $\zeta \in \overline{\mathsf{Tb}}$, holomorphic in norm on Tb, with $\mathsf{E}(\zeta)\mathsf{E}(\zeta') = \mathsf{E}(\zeta + \zeta')$ and $\mathsf{E}((v, t)) = e^{-tH_u}e^{iv \cdot P_u}$ at real points. In the coordinates $e_3 = u$, $e_1 = -u'$, $e_2 = u''$ there is a positive self-adjoint injective operator D on $\mathcal{H}_u$ with $D\Omega_u = \Omega_u$, $D^{is}(H_u \pm P_1)D^{-is} = e^{\pm\pi s/2}(H_u \pm P_1)$ and $D^{is}\mathcal{P}_u(B)D^{-is} = \mathcal{P}_u(\Lambda^{(1)}_{-\pi s/2}B)$; for every $\Lambda \in \mathrm{SO}_0(1, 2)$ there is a unitary V_Λ with $V_\Lambda\Omega_u = \Omega_u$ and $V_\Lambda\mathcal{P}_u(B)V_\Lambda^{-1} = \mathcal{P}_u(\Lambda B)$.

So the null sets and the support of $\mathcal{P}_u$ are invariant under $\mathrm{SO}_0(1,2)$, and the support is the union of $\{0\}$ with some of the orbits $\{E = |q| > 0\}$ and $\{E^2 - |q|^2 = M^2,\ E > 0\}$, $M > 0$. Between the pictures of any two of the 18 normals there is a unitary map that carries vacuum, energy, momenta and spectral measure into one another; so the set of the masses M that occur is the same in the 18 pictures. For the vectors of the wedge $\{x \cdot u > |x \cdot u'|\}$ the pictures u and $(u + u')/\sqrt{2}$ give one law to the pair (mass squared in the plane of the two mirrors, momentum along u''), in the sense of Lemma 6.9. All this holds with V replaced by any finite-dimensional real representation of O(3).

The two diagonal mirrors may be replaced by square cones: if σ satisfies (D0)–(D2), $u, u' \in \mathfrak{M}(\sigma)$ and $\mathcal{P}_u(\{E < |q \cdot u'|\}) = \mathcal{P}_{u'}(\{E < |q \cdot u|\}) = \mathcal{P}_u(\{E < |q \cdot u''|\}) = 0$, then the forward cone holds in the pictures $\pm u$, $\pm u'$.

(e) *From rotations.* If σ satisfies (D0)–(D2), $e_3 \in \mathfrak{M}(\sigma)$, $H \geq |P_1|$, and G_σ contains the rotations about e_3 by a dense set of angles, then $\mathcal{P}(\{E < |q|\}) = 0$. If σ satisfies (D0)–(D2), $e_3 \in \mathfrak{M}(\sigma)$ and $G_\sigma = \mathrm{O}(3)$, then $\mathfrak{M}(\sigma) = S^2$; for $Re_3 = u$ the map $[F] \mapsto [RF]_u$ is unitary from $\mathcal{H}(\sigma)$ onto $\mathcal{H}_u$ and carries $(H, P, \mathcal{P})$ to $(H_u, P_u, \mathcal{P}_u)$, the momenta turned by R; $\mathcal{P}_u(\{E < |q|\}) = 0$ for every u; and the maps $[F] \mapsto [RF]$, $Re_3 = e_3$, form a strongly continuous unitary representation of O(2) on $\mathcal{H}(\sigma)$.

(f) *Examples.* (i) Let $\sigma^{\mathrm{fr}}(H_1, \dots, H_n)$ be the correlation of the Wick products

$$\frac{1}{2} \int \sum_{\lambda\lambda'} H_a(x)_{\lambda\lambda'} {:}\langle B_\lambda, B_{\lambda'}\rangle(x){:}\, dx$$

for three independent Gaussian fields $B^{\mathsf{a}} = (B^{\mathsf{a}}_\alpha)_{\alpha \leq 3}$, $\mathsf{a} \in \{1,2,3\}$, with covariance $\delta^{\mathsf{ab}} K_3(x - y)_{\alpha\gamma}$ at $x \neq y$,

$$K_3(u) = \partial\partial(4\pi|u|)^{-1} = (4\pi|u|^3)^{-1}(3\hat{u}\hat{u}^{\mathrm{t}} - \mathbf{1})$$

for $u \neq 0$, $\hat{u} = u/|u|$, taken at tuples with disjoint supports and without self-contraction, so that K_3 is read off 0 alone. Then σ^{fr} satisfies (D0)–(D4) and is covariant under O(3), while $\sigma^{\mathrm{fr}} \circ Z_2$ satisfies (D0)–(D4), has the forward cone in the nine pictures, and $\mathfrak{M}(\sigma^{\mathrm{fr}} \circ Z_2) = \mathfrak{N}_{18}$. (ii) The diagonal mirrors cannot be omitted in (d): for $m, \lambda > 0$ the Gaussian functional σ_D of the traces $\operatorname{tr} H_a$ with the pair covariance

$$\hat{S}_D(p) = [m^2 + |p|^2 + \lambda(p_1^2 p_2^2 + p_1^2 p_3^2 + p_2^2 p_3^2)]^{-1}$$

satisfies (D0)–(D3), is positive at every coordinate mirror, and $\mathcal{P}(\{E < c|q_1|\}) \neq 0$ for every $c > 0$; it is positive at no diagonal mirror. (iii) The third mirror cannot be omitted in (d): for $0 < c < 1$ and $m > 0$ the Gaussian functional σ_c of the traces with $\hat{S}_c(p) = [p_1^2 + c^2 p_2^2 + p_3^2 + m^2]^{-1}$ satisfies (D0)–(D2) and is positive at $(u, 0)$ for every unit vector $u \perp e_2$, so at $(e_3, 0)$ and $((e_3 + e_1)/\sqrt{2}, 0)$; on the vectors of one entry its spectral measure is carried by $\{E^2 = q_1^2 + c^2 q_2^2 + m^2\}$, and $\mathcal{P}(\{E < |q|\}) \neq 0$.

■□

Theorem W (The tensor limits)**.** Let $0 < g \leq \gamma_W^{\mathrm{ref}}$.

(1) *The limits are data.* Every Gibbs sequence at g has a subsequence with a tensor limit. If a Gibbs sequence has a tensor limit σ, its label b exists, $g^{-2} \leq b \leq L(g^{-2} + \bar{B})$, and σ determines it: $b^{-2} = \lim_{d \downarrow 0} \sigma(\varphi_1^d E, \varphi_2^d E)/\mathcal{W}(\varphi_1^d E, \varphi_2^d E)$ for $E = o_{12}$ and the bumps of Proposition 6.15. The trace part of σ is the scalar limit of the sequence. Every tensor limit at g and every lift satisfies (D0)–(D4), the number $C_n(\delta, \varrho_0)$ of (D1) being the number C_n^{lc} of Proposition 6.13, which depends on the constants, g, n, δ and ϱ_0 alone; tensor limits have $\sigma((H)) = 0$, lifts $\sigma_\xi^\sharp((H)) = \frac{c_\xi}{3} \int \operatorname{tr} H$ with a real number c_ξ. The re-centred functional σ_ξ^c is

a tensor limit at g, that of (K_j, β_j, ρ_j), and

$$\sigma^\sharp_\xi(X) = \sum_{S\subset\{1,\dots,n\}} \prod_{a\notin S} \Big(\frac{c_\xi}{3}\int \operatorname{tr} H_a\Big)\, \sigma^c_\xi(X_S), \qquad \sigma^c_\xi(X) = \sum_{S\subset\{1,\dots,n\}} \prod_{a\notin S} \Big(-\frac{c_\xi}{3}\int \operatorname{tr} H_a\Big)\, \sigma^\sharp_\xi(X_S),$$

$X_S = (H_a)_{a\in S}$.

(2) *The forward cone.* For every tensor limit and every lift, $\mathcal{P}_n(\{E < |q|\}) = 0$ in the picture of each $n \in \mathfrak{N}_{18}$, together with the contractions $\mathsf{E}(\zeta)$ on $\overline{\mathsf{Tb}}$, the boosts D^{is}, the unitaries V_Λ, the invariance of the support under $\mathrm{SO}_0(1,2)$ and the unitary maps between the pictures of Theorem V(d).

(3) *Covariance.* For every tensor limit at every $0 < g \le \gamma$, and for every lift, $\sigma(RX) = \sigma(X)$ for all $R \in \mathrm{O}(3)$ and all $X \in \mathfrak{S}_V(\mathbb{R}^3)$. At two entries the covariance follows from conservation, the diagonal mirror, the invariance of the scalar pair and the scale-free bound on the off-diagonal fields alone (Proposition 6.20), with no bound by a power of the distance.

(4) *Positivity at every plane.* Every tensor limit at every $0 < g \le \gamma$, and every lift, is positive at every mirror $(n, c) \in S^2 \times \mathbb{R}$:

$$\sigma(\theta_{n,c}\bar F \cdot F) \ge 0 \quad (F \in \mathcal{D}_{n,c}), \qquad (\theta_{n,c}H)(x) = \Theta_n H(x - 2(n\cdot x - c)n)\Theta_n.$$

So $\mathfrak{M}(\sigma) = S^2$ at every $0 < g \le \gamma$. For $0 < g \le \gamma^{\mathrm{ref}}_W$, for every tensor limit and every lift, every $u \in S^2$ has its picture, unitarily equivalent to the picture e_3 and with the forward cone, and the rotations about e_3 act by a strongly continuous unitary representation of $\mathrm{O}(2)$ on $\mathcal{H}(\sigma)$. Turning the labels is necessary: for a tensor limit at $0 < g \le \gamma^{\mathrm{ref}}_W$, every $E \in V$ and the bumps $\varphi \ge 0$ of Proposition 6.15(b), $\|[(\varphi E)]\|^2 = \sigma(\theta(\varphi E), \varphi E) \ge (w_0 - \epsilon_g(d))\, b^{-2} \operatorname{tr} E^2$, by the two-point law of Proposition 6.15, which is carried from $g \le \gamma^{\mathrm{sd}}_W$ to $\gamma^{\mathrm{sd}}_W < g \le \gamma^{\mathrm{ref}}_W$ by the dilation, with $d_0(g) = L^{-z} \min_s d_0(g'_s)$; so no nonzero real combination of the six fields vanishes in $\mathcal{H}(\sigma)$; at $0 \ne E \in V^-_{e_3}$ the form $\sigma((\varphi\circ\theta)E, \varphi E)$ of the reflection acting on the points alone is negative, and by the covariance the same holds at every plane.

(5) *The hypotheses of the reconstruction.* Every tensor limit σ at g satisfies (R1)–(R4) of Proposition 6.24 for every $p > 17/2$, with C_V depending on the constants, g and p; for $g \le \gamma^{\mathrm{sd}}_W$ one may take $C_V = 2^p C_p b^{-1} \le 2^p C_p g^2$, C_p the number of Proposition 6.17, and for $\gamma^{\mathrm{sd}}_W < g \le \gamma^{\mathrm{ref}}_W$ the same with one further factor L^{4z}, z the dilation of Lemma 6.16. The kernels $\mathbf{W}_n$ of the product formula are holomorphic on Tb^{n-1} (for every lift too) and

$$|\mathbf{W}_n(\zeta; e)| \le (C_V \eta^{-p})^n \prod_k |e_k|_\infty \quad \text{if } \operatorname{Re}\zeta^k_3 - |(\operatorname{Im}\zeta^k_1, \operatorname{Im}\zeta^k_2)| \ge 2\eta \text{ for all } k,\ 0 < \eta \le 1.$$

(6) *Wightman fields.* Every tensor limit σ at g has the conclusions (i)–(iv) of Proposition 6.24 with $p = 9$: for each $n \ge 2$ one continuous kernel s_n on the configurations of n different points, real analytic, symmetric and covariant under the isometries acting on points and labels, which integrates to σ at every tuple of C^1 or of continuous weights, with $|s_n(x; e)| \le (cC_V)^n \max\{1, 2n^2/\delta(x)\}^{9n} \prod_k |e_k|_\infty$, $|\sigma(X)| \le (cC_V)^n (2n^2/d)^{9n} \prod_a \|H_a\|_{L^1}$ for tuples at mutual distances $\ge d$, $0 < d \le 1$, and $|S_n(\varphi)| \le C^n (n!)^{18} |\varphi|_{9n}$ on test functions flat at the coincidences; the truncated functions have the kernels that the formula of the cumulants writes in the s_m; six tempered fields $T(f)$ with $T(f)^* \supset T(\rho(\Theta_{e_3})\bar f)$, so that T_{33} and T_{jk}, $j, k \le 2$, are Hermitian and T_{3j} is Hermitian after the factor i; a strongly continuous unitary representation of the Poincaré group of $\mathbb{R}^{1+2}$ under which the fields are covariant, the vacuum is invariant and the spectrum lies in the closed forward cone; locality; cyclicity of the vacuum; the Wightman functions are tempered boundary values of the $\mathbf{W}_n$ from every direction of the forward cone.

Every lift $\sigma^\sharp_\xi$ has such kernels, with $2\max\{1, |c_\xi|\}\max\{1, cC_V\}$ in the place of cC_V and $S_1(\varphi) = \frac{c_\xi}{3}\int \operatorname{tr}\varphi$.

(7) *Components.* Every tensor limit σ at g has a decomposition $(\mathsf{X}, \lambda, (\sigma_\chi)_{\chi\in\mathsf{X}})$ with labels, the canonical decomposition among the construction results (Theorem YMM1:AL) applied to labelled tuples: X compact metrisable, λ a Borel probability measure of support X, $\chi \mapsto \sigma_\chi$ injective and continuous at each tuple, and $\int \prod_i \sigma_\chi(X^i)\,\lambda(d\chi)$ the iterated plateau of σ at $(X^1, \dots, X^q)$ for every $q \geq 1$ and all tuples $X^1, \dots, X^q$. The iterated plateau is that of Definition 2.2(5), read at labelled tuples: $G^{(1)}(v_2, \dots, v_q) = \sigma(X^1 \cdot \tau_{v_2} X^2 \cdots \tau_{v_q} X^q)$ where the supports of $X^1, \tau_{v_2}X^2, \dots, \tau_{v_q}X^q$ are pairwise disjoint, $G^{(p)}(v_{p+1}, \dots, v_q) = \lim_{|v_p|\to\infty} G^{(p-1)}(v_p, v_{p+1}, \dots, v_q)$ for $p = 2, \dots, q$, the limits taken one after the other, and the iterated plateau is the number $G^{(q)}$; for $q = 2$ it is the plateau $\lim_{|v|\to\infty} \sigma(X^1 \cdot \tau_v X^2)$ of σ at (X^1, X^2).

That all these limits exist is part of the assertion, and along the sequence of σ one has $G^{(q)} = \lim_j \nu_j(\prod_i E_{\nu_j}[A_j(X^i) \mid \mathcal{I}])$, $A_j(X)$ the product of the entries of X centred in ν_j and $\mathcal{I}$ the translation-invariant events. Let $(\mathsf{X}_0, \lambda_0, (\sigma_{0,\zeta}))$ be the canonical decomposition of the trace part. Exactly one map $\pi : \mathsf{X} \to \mathsf{X}_0$ has $\pi(\chi)$ the trace part of σ_χ; it is continuous and onto, and $\pi_*\lambda = \lambda_0$. Each σ_χ is the lift of $\pi(\chi)$ formed with its own approximants along the full sequence, with $\sigma_\chi((H)) = \frac{c_{\pi(\chi)}}{3} \int \operatorname{tr} H$, and it clusters: $\sigma_\chi(X \cdot \tau_v Y) \to \sigma_\chi(X)\sigma_\chi(Y)$ as $|v| \to \infty$. $\ker H = \mathbb{C}\Omega$ on $\mathcal{H}(\sigma_\chi)$ and on $\mathcal{H}(\sigma_\chi^c)$; so the six fields of σ_χ^c satisfy all the Wightman axioms, uniqueness of the vacuum included.

(8) *A functional with exactly nine families.* Let $0 < g \leq \gamma_W^{\mathrm{sd}}$ and σ be a tensor limit at g. Then $\sigma \circ Z_2$ satisfies (D0)–(D4), with $2^n C_n(\delta, \varrho_0)$ in (D1), has the trace part of σ, the operators, the slab and point operators, the product formula and the fields of σ up to a unitary map, with Z_2 applied to the labels, and the forward cone; and $\mathfrak{M}(\sigma \circ Z_2) = \mathfrak{N}_{18}$. Among the functionals $\sigma \circ Z_z$, $z \neq 0$, the two-point law of Proposition 6.15, at all pairs of weights and with some label $b' > 0$ in the place of b, holds for $z = 1$ alone; at the pairs of off-diagonal weights alone, with the label b of σ, it holds if and only if $z^2 = 1$.

At the pairs $(\varphi_1^d\mathbf{1}, \varphi_2^d\mathbf{1})$ of diagonal weights, with the bumps of Proposition 6.15(a), where $\sigma \circ Z_z = \sigma$ and the kernel of $\mathcal{W}$ at $u = x - y$ is $\frac{3}{2}\operatorname{tr} K_3(u)^2 = 9(4\pi|u|^3)^{-2} > 0$, the law forces $b' = b$; at the pairs $(\varphi_1^d o_{12}, \varphi_2^d o_{12})$ of Proposition 6.15(a), placed along e_3, where $\sigma \circ Z_z = z^2\sigma$, it then forces $z^2 = 1$; at the mixed pairs $(\varphi_1^d\mathbf{1}, \varphi_2^d o_{12})$ with the same bumps placed along $(e_1 + e_2)/\sqrt{2}$, where $\sigma \circ Z_z = z\sigma$ and the kernel of $\mathcal{W}$ is $\frac{3}{2}\operatorname{tr}[K_3(u)o_{12}K_3(u)] = 9\hat{u}_1\hat{u}_2(4\pi|u|^3)^{-2} > 0$, so that $\mathcal{W}$ is a positive number independent of d, it forces $z = 1$.

And $\sigma' \circ Z_2$, σ' the limit at continuous weights of Lemma 6.16(d) that agrees with σ at the tuples of weights, has every hypothesis of Proposition 6.22 except conservation at two points.

■□

6.3. **Construction estimates.**

(S1) Theorems YMM1:D, YMM1:AJ and YMM1:AD among the construction results, and the following statements among the construction results built on them: the small-field renormalisation progression with plaquette weights as sources (Proposition B.12, including its zero-source specialization), with its block maps and its small-field sets of each level (Theorem YMM1:D); the never-large histories, that is the histories without large-field regions, and the decomposition of a mean by the scale at which a large field is first created, an exact sum rule (Section YMM1:123, equation (314)); the rarity of large fields (Proposition M.2, Proposition L.6); the sides of the torus that are small over the run of a first-passage datum, its canonical sequence of running couplings, the least admissible side among them when $g \leq \gamma_W^{\mathrm{sd}}$, and the weights of the first creation of a large field on such a side (equation YMM1:(2312), Lemmas YMM1:126.3 and YMM1:125.3); the working level of a depth (equation YMM1:(2322))

and the carried family at the flat top of the second order, with its Gaussian value (Proposition YMM1:125.1); the chessboard estimates (Proposition YMM1:86.3), the domination of every periodic Gibbs state by the tori (Proposition YMM1:91.9) and that of every larger torus by the least admissible torus (Corollary YMM1:86.6); the pressure gap (Lemma N.1); the invariance of the periodic Gibbs states under the lattice isometries and their reflection positivity at the nine families of lattice planes (Proposition YMM1:103.4); the lattice steps to the cone, that is the energy-momentum inequality and the five-point inequality of the periodic Gibbs states (Proposition YMM1:99.3 and Lemma F.5); the dilation of lattices, Gibbs states, tori, boards and chessboard seminorms (Proposition YMM1:119.1 and Lemma K.1), with the windows of labels of first-passage data (Proposition YMM1:74.1, Corollary YMM1:74.2); the existence of Gibbs sequences at every reference coupling, obtained from a label in $I(g)$, its first-passage line and the periodic torus states, as in the proof of Theorem Q.

(S2) The theorem on the scalar limit (Theorem YMM1:AP): the canonical decomposition of a scalar limit (the specification preceding Theorem YMM1:AL), with approximants obtained by conditioning on translation-invariant events, and the scalar lifts (Theorems YMM1:AL and YMM1:AP); the invariance of a scalar limit under all isometries, its reflection positivity, its forward cone, its Wightman theory (Theorem YMM1:AP), and its bound $\sigma_0(f\circ\theta,f)\le C_\varphi t^{-a_\Gamma}$, the plate growth YMM1:(1896) of property (R7) of Definition YMM1:95.1, which the scalar limit has by Proposition YMM1:105.2, with $a_\Gamma=3<4$, for $t\in(0,1]$ and $f(x)=\alpha(x_3,x_1)\varphi(x_2)$, $\varphi\in C^1_c(\mathbb{R})$ real, α real with support in $[t,2t]\times[-t,t]$, $|\alpha|\le 3$, $\operatorname{Lip}\alpha\le 12/t$.

Three statements among the construction results beneath it are used through their proofs, which run unchanged at labelled tuples: the existence of a canonical decomposition of the limit of a frame (Theorem YMM1:AL), with the iterated plateaux of Definition 2.2(5), in Proposition 6.27; the reconstruction of a Wightman theory from data (Theorem YMM1:AO) in Proposition 6.24; and the extension of multilinear forms bounded at separated tuples (Proposition YMM1:93.3), with the growth hypothesis in Proposition YMM1:93.5, in Proposition 6.25(c).

(S3) The following abstract facts will also be used. *Reconstruction:* the operator argument in the proof of Proposition YMM1:94.1 gives the following statement: let the complex vector space $\mathcal{D}$ carry a positive semidefinite Hermitian form and a unit vector $\mathbf{1}$, and let $(T_t)_{t\ge0}$, $(U(v))_{v\in\mathbb{R}^N}$ be a semigroup and a group of commuting linear maps fixing $\mathbf{1}$, T_t symmetric, $U(v)$ isometric, weakly continuous at 0, with $c_F=\sup_t|\langle F,T_tF\rangle|<\infty$; then $\|T_tF\|\le\|F\|^{1-2^{-k}}c_F^{2^{-k-1}}$ for all k, the T_t give a strongly continuous semigroup of self-adjoint contractions with zero kernel, the $U(v)$ a unitary group, and one projection-valued measure $\mathcal{P}$ on $[0,\infty)\times\mathbb{R}^N$ has $T_tU(v)=\int e^{-tE+iv\cdot q}\,d\mathcal{P}$. *One measure in two pictures* (Lemma YMM1:94.3): if $\mu\ge0$ is finite on $[0,\infty)\times\mathbb{R}$, $w=(E-iq)/\sqrt{2}$, and $\int e^{-sw-s'\bar w}d\mu=\langle a,e^{-sH_+}e^{-is'Q}b\rangle$ for $s,s'\ge0$, with $H_+\ge0$ and Q self-adjoint, not necessarily commuting, then $\int_{w\ne0}e^{2\kappa\arg w}d\mu\le\|a\|\|b\|e^{|\kappa|\pi/2}$ for real κ, so $\mu(\{|q|>E\})=0$. *Uniqueness:* finite complex Borel measures on $[0,\infty)\times\mathbb{R}^N$ with the same integrals of all $e^{-tE+iv\cdot q}$ are equal. Indeed, for their difference ν, polynomial approximation in e^{-E} shows that $\int\varphi(E)e^{iv\cdot q}\,d\nu=0$ for every continuous φ on the compactification $[0,\infty]$. Fourier uniqueness in $\mathbb{R}^N$ then gives $\int\varphi(E)\psi(q)\,d\nu=0$ for every bounded continuous ψ, hence $\nu=0$. This is the measure-uniqueness argument in the proof of Proposition YMM1:96.1, with $q\in\mathbb{R}^N$. *Subgroups:* a subgroup of O(3) containing W_3 and a nontrivial one-parameter group of rotations is O(3) (Lemma YMM1:112.4).

From the books we use the identity theorem, the theorems of Morera, Weierstrass, Stone–Weierstrass and Liouville, the maximum principle for subharmonic functions, the spectral theorem, von Neumann's theorem on A^*A and the polar decomposition, the generation of $\mathrm{SO}_0(1,2)$ by two boosts,

the reflection positivity of the free massless field at every plane and its passage to Wick polynomials. The statements on the six lattice fields that the argument needs beyond (S1)–(S3) (the admission of the bond forms, in any number, as sources of the progression of (S1), Lemma 6.12; the passage to $\mathbb{R}^3$, the reconstructed operators, the two-point law, the power bound, conservation and covariance) are proved below.

6.4. **Mirrors, pictures and the forward cone.**

Lemma 6.2 (Mirrors and labels)**.** (a) Isometries act as a group on weights, tuples and combinations. If $R \in \mathrm{O}(3)$, $Rm = n$, $c \in \mathbb{R}$ and $\iota x = Rx + cn$, then $\iota\{m \cdot x > 0\} = \{n \cdot x > c\}$ and $\theta_{n,c} = \iota\theta_m\iota^{-1}$ on points, weights and combinations. The formula for $\Theta_n E \Theta_n$, its eigenspaces, the action $\Theta_n^{\otimes 4}$, the characterisation of $\Theta_n \in W_3$, the mixing off $\mathfrak{N}_{18}$ and the equivalences of positivity in Theorem V(a) hold.

(b) If σ satisfies (D0), (D2) and the numbers $\sigma(\theta_u \bar{F} \cdot F)$, $F \in \mathcal{D}_u$, are real, then $\Theta_u \in G_\sigma$.

(c) If σ satisfies (D0), (D2), $m \in \mathfrak{M}(\sigma)$, $R \in G_\sigma$ and $Rm = n$, then σ is positive at (n, c) for every c.

(d) Let σ satisfy (D0)–(D2) and be positive at $(u, 0)$, and let $A : V \to V$ commute with $\rho(\Theta_u)$ and satisfy $\sigma((A\theta_u\bar{F}) \cdot F) \geq 0$ for $F \in \mathcal{D}_u$. Then $[AF]_u = [F]_u$.

(e) If σ satisfies (D0), (D1), then G_σ is closed, and so is $G_\sigma[\mathfrak{K}]$ for every full $\mathfrak{K}$. A closed subgroup of O(3) that contains W_3 and one element more is O(3).

■

Proof. (a) ρ is a homomorphism; $n \cdot \iota x - c = m \cdot x$ and $\theta_{n,c}(\iota x) = R(x - 2(m \cdot x)m) + cn = \iota(\theta_m x)$. Expanding $(1 - 2nn^{\mathrm{t}})E(1 - 2nn^{\mathrm{t}})$ with $(nn^{\mathrm{t}}E)_{\lambda\lambda'} = n_\lambda (En)_{\lambda'}$ gives the formula, and $\Theta_n n = -n$, $\Theta_n m = m$ for $m \perp n$ give the eigenspaces; at $n = (1,1,1)/\sqrt{3}$ one has $(En)_\lambda = r_\lambda/\sqrt{3}$ and $n \cdot En = s/3$. From $\varepsilon_{abc} R_{ia} R_{jb} R_{\lambda c} = \det R \, \varepsilon_{ij\lambda}$ the array $\varepsilon_{ij\lambda}\varepsilon_{kl\lambda'} E_{\lambda\lambda'}$ turns with $R^{\otimes 4}$, the two determinants cancelling. The entries of Θ_n are $\delta_{\lambda\lambda'} - 2n_\lambda n_{\lambda'}$, while a signed permutation matrix has one nonzero entry in each row: this excludes three nonzero coordinates of n and forces $n_\mu^2 = n_\lambda^2 = \frac{1}{2}$ if two are nonzero. Off $\mathfrak{N}_{18}$, $\Theta_n E_{\mu\mu} \Theta_n$ has the entry $-2(1 - 2n_\mu^2) n_\mu n_\lambda$ at (μ, λ), or $4n_\mu^2 n_\lambda n_\nu$ at (λ, ν), which is not zero. For the equivalences put $G = \theta\bar{F}$, so that $\theta\bar{G} \cdot G = \theta\bar{F} \cdot F$, and use $\theta_{n,c} = \tau_{cn}\theta_n\tau_{-cn}$ with (D2).

(b) A sesquilinear form on a complex space with real diagonal is Hermitian; for real tuples X', X on the side of u this gives $\sigma(\theta_u X' \cdot X) = \sigma(\theta_u X \cdot X') = \sigma(\theta_u(\theta_u X' \cdot X))$. At $X' = \emptyset$ we get $\sigma(\theta_u X) = \sigma(X)$; a translation along u carries every tuple to the side of u, and $\theta_u \tau_{su} = \tau_{-su}\theta_u$ with (D2) gives the identity for all X; and θ_u is Θ_u as a linear isometry.

(c) With ι as in (a), $\sigma \circ \iota = \sigma$ by (D2) and $R \in G_\sigma$, and for $F \in \mathcal{D}_{n,c}$ and $G = \iota^{-1}F \in \mathcal{D}_m$,

$$\sigma(\theta_{n,c}\bar{F} \cdot F) = \sigma(\iota(\theta_m \bar{G} \cdot G)) = \sigma(\theta_m \bar{G} \cdot G) \geq 0.$$

(d) As in (b), $\sigma(AY) = \sigma(Y)$ for all Y; so $[F]_u \mapsto [AF]_u$ extends to an isometry A with $\langle \mathsf{A}\psi, \psi\rangle \geq 0$, which is self-adjoint with $\mathsf{A}^2 = 1$ and spectrum in $\{1\}$: $\mathsf{A} = 1$. For $A = \rho(\Theta_u)$ and h with values in V_u^- it gives $[(h)]_u = [(-h)]_u = -[(h)]_u$.

(e) If $R_j \to R$, the supports of the $R_j H_a$ stay in fixed disjoint neighbourhoods and $|R_j H_a - R H_a|_\infty \to 0$; (D0), (D1) give $\sigma(R_j X) \to \sigma(RX)$, and for full $\mathfrak{K}$ the set $G_\sigma[\mathfrak{K}]$ is a group because $\mathfrak{K}$ is stable under O(3). Let G be the subgroup; $G_+ = G \cap \mathrm{SO}(3)$ properly contains the 24 cubic rotations. If G_+ is infinite, it has elements $g_j \neq 1$, $g_j \to 1$, rotations by angles $t_j \to 0$ about axes $n_j \to n$, and $g_j^{\lfloor t/t_j \rfloor}$ tends to the rotation by t about n; so G contains a one-parameter group, and the lemma on subgroups (S3) applies. If G_+ is finite of order $N > 24$, the count of the poles of its rotations, $2 - 2/N = \sum_i (1 - 1/r_i)$ over three orbits with $1/r_1 + 1/r_2 + 1/r_3 > 1$, the stabilisers at $\pm e_\mu$ being of order divisible by 4, has the only solution $(4, 2, 3)$, with $N = 24$. □

Lemma 6.3 (The picture of a positive normal)**.** Let σ satisfy (D0)–(D2) and $u \in \mathfrak{M}(\sigma)$. Then the picture u exists: the classes $[F]_u$ are dense, e^{-tH_u} is a strongly continuous semigroup of self-adjoint

contractions with zero kernel, $[F]_u \mapsto [\tau_v F]_u$, $v \perp u$, a strongly continuous unitary group, and $\mathcal{P}_u$ is the unique projection-valued measure on $[0,\infty)\times u^\perp$ with

$$\sigma(\theta_u \bar G' \cdot \tau_w G) = \int e^{-(w\cdot u)E + iw\cdot q}\, dm^u_{G',G}(E,q) \qquad (w\cdot u \ge 0); \tag{19}$$

$m^u_{G,G} \ge 0$ and $|m^u_{G',G}|(B) \le \|\mathcal{P}_u(B)[G']_u\|\,\|\mathcal{P}_u(B)[G]_u\|$. For $R \in G_\sigma$, $Ru \in \mathfrak{M}(\sigma)$ and $[F]_u \mapsto [RF]_{Ru}$ is unitary; it carries Ω_u and H_u to Ω_{Ru} and H_{Ru}, the translation by v to that by Rv, and $\mathcal{P}_u$ to $\mathcal{P}_{Ru}$ with q turned by R. ■

Proof. Apply the reconstruction lemma of (S3) to the form on $\mathcal{D}_u$ with $T_t = \tau_{tu}$ and $U(v) = \tau_v$. T_t is symmetric because $\theta_u \tau_{tu} = \tau_{-tu}\theta_u$ and (D2). In $\theta_u X_i \cdot \tau_{tu} X_k$ the supports keep their diameters and stay at distance at least $\min\{d_1, 2d_0\}$, d_0 the distance of the supports from the plane and d_1 their mutual distance, and $|\Theta_u E \Theta_u|_\infty \le 3|E|_\infty$; as (D1) does not depend on the position of the supports, $c_F < \infty$ at every mirror, and the iterated inequality of Schwarz, $\|T_t F\| \le \|F\|^{1-2^{-k}} c_F^{2^{-k-1}}$, gives the contractions as $k \to \infty$. Continuity follows from $|\tau_w H - H|_\infty \le |w|\,\mathrm{Lip}\, H$ with (D0), (D1); uniqueness of $\mathcal{P}_u$ is the uniqueness statement of (S3); the bound on $|m^u_{G',G}|$ is the inequality of Schwarz for the positive form $\langle \cdot, \mathcal{P}_u(B)\cdot\rangle$. For the transport, $\theta_{Ru} R = R\theta_u$. □

Lemma 6.4 (Two mirrors at the angle $\pi/4$)**.** Let σ satisfy (D0)–(D2), $u \perp u'$, and $u, (u+u')/\sqrt{2} \in \mathfrak{M}(\sigma)$. Then $\mathcal{P}_u(\{(E,q) : E < |q\cdot u'|\}) = 0$. ■

Proof. Let $e_\pm = (u \pm u')/\sqrt{2}$, $\theta_+ = \theta_{e_+}$, and let F be supported in the wedge $\{x\cdot u > |x\cdot u'|\}$; then $F \in \mathcal{D}_u \cap \mathcal{D}_{e_+}$, $\theta_+\theta_u F \in \mathcal{D}_{e_+}$ and $\theta_+(\theta_+\theta_u \bar F) = \theta_u \bar F$. As $se_+ + s'e_- = \frac{s+s'}{\sqrt2}u + \frac{s-s'}{\sqrt2}u'$, (19) in the pictures u and e_+ gives for $s, s' \ge 0$

$$\int e^{-sw - s'\bar w}\, d\mu = \sigma(\theta_u \bar F \cdot \tau_{se_+ + s'e_-} F) = \langle [\theta_+\theta_u F]_{e_+}, e^{-sH_{e_+}} e^{-is'Q} [F]_{e_+}\rangle,$$

where $w = (E - iq)/\sqrt2$, $\mu \ge 0$ is the image of $m^u_{F,F}$ under $(E,q) \mapsto (E, q\cdot u')$, and $Q = -e_- \cdot P_{e_+}$. The lemma on one measure in two pictures (S3) gives $\int_{w\ne 0} e^{2\kappa \arg w} d\mu \le C e^{|\kappa|\pi/2}$ for all real κ; letting $\kappa \to \pm\infty$ gives $|\arg w| \le \pi/4$ μ-almost everywhere, that is $\mu(\{|q| > E\}) = 0$. Every $F' \in \mathcal{D}_u$ is carried into the wedge by some τ_{ru}, and e^{-rH_u} has zero kernel. □

Lemma 6.5 (A lemma on a cylinder)**.** Let $r, \kappa > 0$, $C < \infty$, and let B be a finite set of angles containing 0 and β_1 such that every real t lies at a distance less than $\pi/2$ from $B + 2\pi\mathbb{Z}$; for instance $B_8 = \frac{\pi}{4}\{0,\dots,7\}$ or $B_4 = \frac{\pi}{2}\{0,1,2,3\}$. For $\beta \in B$ let m_β be complex measures on $\{(E,q) \in \mathbb{R}^2 : E \ge |q|\}$ of total variation at most C, and

$$f_\beta(c;\rho) = \int \exp\bigl(2rE - \rho[E\cos(c-\beta) - iq\sin(c-\beta)]\bigr)\, dm_\beta(E,q)$$

where the integrand is bounded. Suppose (i) $f_\beta(t;\rho) = f_{\beta'}(t;\rho)$ for $\beta, \beta' \in B$, $\rho > 0$ and real t with $\rho\cos(t-\beta) > 2r$ and $\rho\cos(t-\beta') > 2r$; (ii) $\mu = e^{2rE} m_0$ is a finite positive measure; (iii) m_{β_1} is carried by $\{E \ge \kappa\}$. Then $\mu(\{E^2 - q^2 < \kappa^2\}) = 0$. ■

Proof. Fix $\gamma_0 \ne 0$ and $0 < \delta < \min\{1/4, |\gamma_0|/2\}$. For $c = t + i\gamma$ the real part of $E\cos(c-\beta) - iq\sin(c-\beta)$ is $\cos(t-\beta)(E\cosh\gamma + q\sinh\gamma) \ge \cos(t-\beta)Ee^{-|\gamma|}$ on the cone; so f_β is holomorphic and bounded by C where $\rho\cos(t-\beta)e^{-|\gamma|} > 2r$. By (i) and the identity theorem the f_β are restrictions of one bounded 2π-periodic holomorphic function f on a band $|\operatorname{Im} c| < \Gamma(\rho)$, $\Gamma(\rho) = \log(\rho\cos\vartheta_B/2r)$, $\vartheta_B < \pi/2$ the largest distance of a real t from B. By (iii), $|f| \le Ce^{-\kappa\rho(e^{-\delta}\cos\delta - 2r/\rho)}$ on the disc of radius δ about β_1. With $N(c) = \log|2\sin\frac{c-\beta_1}{2}|$, harmonic off $\beta_1 + 2\pi\mathbb{Z}$ with $e^{2N(c)} = 2\cosh\gamma - 2\cos(t-\beta_1)$, $\Gamma' = \Gamma(\rho) - 1$, $M = \log(2\sinh(\Gamma'/2))$ and $h = (M-N)/(M + \log(2/\delta))$, one has $h \le 0$ on $|\gamma| = \Gamma'$ and $h \le 1$ on the boundary of the disc, and $h(i\gamma_0) \to 1$ as $\rho \to \infty$; the

maximum principle for the subharmonic function $\log|f| - \log C + \kappa\rho(e^{-\delta}\cos\delta - 2r/\rho)h$ on the band less the discs about $\beta_1 + 2\pi\mathbb{Z}$ gives

$$\int e^{-\rho(E\cosh\gamma_0 + q\sinh\gamma_0)}\,d\mu = f(i\gamma_0;\rho) \le Ce^{-\kappa\rho(e^{-\delta}\cos\delta - o(1))} \qquad (\rho\to\infty).$$

For fixed $\gamma_0 \neq 0$, first let $\rho\to\infty$ and then $\delta\downarrow 0$. Positivity of μ gives $E\cosh\gamma_0 + q\sinh\gamma_0 \ge \kappa$ almost everywhere. Apply this on a countable dense subset of $\mathbb{R}\setminus\{0\}$; continuity in γ_0 then gives the inequality for every real γ_0 on one set of full measure. Its infimum over γ_0 is $(E^2-q^2)^{1/2}$ for $E > |q|$ and 0 for $E = |q|$, proving the assertion. □

Proposition 6.6 (The forward cone from three mirrors)**.** (a) Let σ satisfy (D0)–(D2), let (u, u', u'') be an orthonormal frame, and let σ be positive at $(u, 0)$, $((u+u')/\sqrt{2}, 0)$ and $((u+u'')/\sqrt{2}, 0)$. Then σ is invariant under the cubic group of the frame, positive at (n, c) for its 18 normals and all c, and $\mathcal{P}_n(\{E < |q|\}) = 0$ at each of them.

(b) Let σ satisfy (D0)–(D2), let (u, u', u'') be an orthonormal frame, let $u, u' \in \mathfrak{M}(\sigma)$, and $\mathcal{P}_u(\{E < |q\cdot u'|\}) = \mathcal{P}_{u'}(\{E < |q\cdot u|\}) = \mathcal{P}_u(\{E < |q\cdot u''|\}) = 0$. Then $\mathcal{P}_{\pm u}(\{E < |q|\}) = \mathcal{P}_{\pm u'}(\{E < |q|\}) = 0$; no diagonal mirror is used.

■

Proof. Symmetries. By Lemma 6.2(b) the three reflections lie in G_σ. With $\mathsf{p} = \Theta_{(u+u')/\sqrt{2}}$, $\mathsf{p}' = \Theta_{(u+u'')/\sqrt{2}}$ one has $\mathsf{p}\Theta_u\mathsf{p} = \Theta_{u'}$, $\mathsf{p}'\Theta_u\mathsf{p}' = \Theta_{u''}$, and $\Theta_u\Theta_{u'}\mathsf{p}$, $\Theta_u\Theta_{u''}\mathsf{p}'$ exchange u with u', resp. with u''. These elements generate the cubic group of the frame, which carries the three normals to all 18; Lemma 6.2(c) gives positivity there, Lemma 6.2(a) at every c.

Eight pictures. Let $n_\beta = \cos\beta\,u + \sin\beta\,u'$, $n'_\beta = n_{\beta+\pi/2}$, $\beta \in B_8$. Since $(n_\beta + n'_\beta)/\sqrt{2} = n_{\beta+\pi/4}$ is a positive normal, Lemma 6.4 gives $E \ge |q\cdot n'_\beta|$ on the carrier of $\mathcal{P}_{n_\beta}$; at (u, u'') it gives $E \ge |q\cdot u''|$ in the picture u.

One number in eight pictures. Let $F \in \mathcal{D}_u$ have its supports in $\{|x| < r\}$, and put $\mathsf{U}(x) = \sigma(\theta_u\bar{F}\cdot\tau_x F)$ for $|x| \ge 2r$. With $G'_\beta = \theta_{n_\beta}\tau_{-rn_\beta}\theta_u F$ and $G_\beta = \tau_{rn_\beta}F$, both in $\mathcal{D}_{n_\beta}$, (D2) and (19) give, whenever $x\cdot n_\beta \ge 2r$,

$$\mathsf{U}(x) = \int e^{-(x\cdot n_\beta - 2r)E + ix\cdot q}\,dm^\beta(E,q), \qquad m^\beta = m^{n_\beta}_{G'_\beta,G_\beta}, \quad m^0 = e^{-2rE}m^u_{F,F}. \tag{20}$$

The left side does not depend on β: σ is symmetric and the tuple $\theta_u\bar{F}\cdot\tau_x F$ is unordered, also when x has gone around the support of F. This symmetry takes the place of the rotations.

The cut. The momentum $q\cdot u''$ is common to the eight pictures. Let $\kappa > 0$; restrict m^β to $\{|q\cdot u''| \ge \kappa\}$ and carry it to the variables $(E, q\cdot n'_\beta)$. At $x = \rho n_t + su''$ the uniqueness of the Fourier transform in s turns (20) into (i) of Lemma 6.5; (ii) comes from m^0, and (iii), with $\beta_1 = 0$, from $E \ge |q\cdot u''| \ge \kappa$. The lemma gives $m^u_{F,F}(\{|q\cdot u''| \ge \kappa,\ E^2 - (q\cdot u')^2 < \kappa^2\}) = 0$ for every $\kappa > 0$; if $E \ge |q\cdot u'|$ and $E^2 < (q\cdot u')^2 + (q\cdot u'')^2$ there is a rational κ with $(E^2 - (q\cdot u')^2)^{1/2} < \kappa \le |q\cdot u''|$; so $m^u_{F,F}(\{E < |q|\}) = 0$. The classes are dense.

All 18 normals. The hypotheses (eight positive normals n_β, the cone $E \ge |q\cdot n'_\beta|$ in each picture n_β, the cone $E \ge |q\cdot u''|$ in one of them) do not change if (u, u') is replaced by $(n_{\beta_0}, n_{\beta_0+\pi/2})$, $\beta_0 \in B_8$; then the picture u, which carries $E \ge |q\cdot u''|$, sits at the angle $\beta_1 = -\beta_0$, which Lemma 6.5 admits. So the cone holds in the eight pictures n_β; the frames (u, u'', u') and (u', u'', u) give the remaining normals.

(b) By Lemma 6.2(a), $-u, -u' \in \mathfrak{M}(\sigma)$. $\Theta_u \in G_\sigma$ (Lemma 6.2(b)), and Lemma 6.3 at $R = \Theta_u$ gives a unitary map $\mathcal{H}_u \to \mathcal{H}_{-u}$ that carries $\mathcal{P}_u(B)$ to $\mathcal{P}_{-u}(B)$, as $\Theta_u q = q$ on $u^\perp$; so the square cones hold in the pictures $-u$, $-u'$ too, for the four angles of B_4. The parts *one number*, *the cut* of the proof of (a) use nothing else of the pictures; Lemma 6.5 holds with B_4; for $\pm u'$ replace the frame as there, with $\beta_0 \in B_4$. □

Remark 6.7. The proof uses all real translations, through (20) at every x with $x\cdot n_\beta \geq 2r$. Discrete translations would not do: on a lattice of unit spacing the free field has the joint spectrum $\cosh E = 1+\sum_k(1-\cos q_k)$, which meets $\{E<|q|\}$, e.g. at $q=(\pi,0)$, where $E=\operatorname{arccosh}3<\pi$.

Proposition 6.8 (Boosts and the identification of pictures)**.** Let σ satisfy (D0)–(D2), be invariant under the quarter turn q about e_2 with $\mathsf{q}e_3=e_1$, and be positive at $(e_3,0)$ and at $(n_-,0)$, $n_\pm=(e_3\pm e_1)/\sqrt{2}$, with $\mathcal{P}(\{E<|q_1|\})=0$. These hypotheses hold if σ is positive at the three mirrors $(e_3,0)$, $(n_-,0)$, $((e_3+e_2)/\sqrt{2},0)$; then also $\mathcal{P}(\{E<|q_2|\})=0$. Let $T(x)=e^{-x_3H+ix_1P_1}$ for $x=(x_1,0,x_3)$, $x_3\geq 0$.

(a) The classes of the tuples in the quadrant $\{x_1<0<x_3\}$ are dense, and so are those of $\{x_1>0, x_3>0\}$. $I_0:[F]\mapsto[F]_{n_-}$, F supported in the quadrant $\{x_1<0<x_3\}$, is a well defined closable operator from $\mathcal{H}(\sigma)$ into $\mathcal{H}_{n_-}$, with closure $\bar I$; $D=\bar I^*\bar I$ is positive, self-adjoint and injective, $D[F]=[\mathsf{q}F]$ and $\langle[F],D[F]\rangle=\sigma(\theta_{n_-}\bar F\cdot F)$ for these F, and $D\Omega=\Omega$.

(b) $DT(x)=T(\mathsf{q}x)D$ on $\operatorname{dom}D$ for $x_1\leq 0\leq x_3$; D commutes with the translations along e_2; and for real s

$$D^{is}(H\pm P_1)D^{-is}=e^{\pm\pi s/2}(H\pm P_1),\qquad D^{is}\mathcal{P}(B)D^{-is}=\mathcal{P}(\Lambda^{(1)}_{-\pi s/2}B).$$

(c) If besides $\mathcal{P}(\{E<|q_2|\})=0$, then $\mathcal{P}(\{E<|q|\})=0$. If σ is invariant under the exchange of e_1 and e_2, then for every $\Lambda\in\mathrm{SO}_0(1,2)$ there is a unitary V_Λ with $V_\Lambda\Omega=\Omega$ and $V_\Lambda\mathcal{P}(B)V_\Lambda^{-1}=\mathcal{P}(\Lambda B)$; the null sets and the support of $\mathcal{P}$ are invariant under $\mathrm{SO}_0(1,2)$.

(d) $\bar I=WD^{1/2}$ with a unitary $W:\mathcal{H}(\sigma)\to\mathcal{H}_{n_-}$ that carries Ω, e^{-tH}, the translation by $v_1e_1+v_2e_2$ and $\mathcal{P}$ to Ω_{n_-}, $e^{-tH_{n_-}}$, the translation by $v_1n_++v_2e_2$ and $\mathcal{P}_{n_-}$, the momenta of the picture n_- being taken in the basis (n_+,e_2).

■

Proof. Under the three mirrors the reflections lie in G_σ, $\mathsf{q}^{-1}=\Theta_{n_-}\Theta_{e_3}$, and Lemma 6.4 gives $E\geq|q_1|$ and $E\geq|q_2|$ on the carrier of $\mathcal{P}$. As $\theta_{n_-}=\theta_{e_3}\mathsf{q}=\mathsf{q}^{-1}\theta_{e_3}$, for F,G in the quadrant

$$\langle[G]_{n_-},[F]_{n_-}\rangle=\sigma(\theta_{n_-}\bar G\cdot F)=\langle[\mathsf{q}G],[F]\rangle=\langle[G],[\mathsf{q}F]\rangle,$$

which gives (a) by von Neumann's theorem on $\bar I^*\bar I$: if $[F]=0$, then $\|[F]_{n_-}\|^2=\langle[\mathsf{q}F],[F]\rangle=0$; a limit point of I_0 at 0 is orthogonal to the range, in whose closure it lies; for $\eta\in\operatorname{dom}\bar I$ the identity, extended by closure, reads $\langle\bar I\eta,I_0[F]\rangle=\langle\eta,[\mathsf{q}F]\rangle$, so $I_0[F]\in\operatorname{dom}\bar I^*$ and $D[F]=[\mathsf{q}F]$; and injectivity follows from the density of the classes of $\{x_1>0,x_3>0\}=\mathsf{q}\{x_1<0<x_3\}$. The quadrant classes are dense because $v\mapsto\langle\psi,e^{ivP_1}e^{-\eta H}[F]\rangle$ is holomorphic in the strip $|\operatorname{Im}v|<\eta$, by $E\geq|q_1|$, and vanishes for large v of one sign if ψ is orthogonal to them.

(b) Write $x=(x_1,0,x_3)=an_-+bn_+$. The closed quadrant $\{x_1\leq 0\leq x_3\}$ is $\{|b|\leq a\}$, so it holds $x^\dagger=\Theta_{n_+}x=an_--bn_+$ with x; and $\Theta_{e_1}x^\dagger=\mathsf{q}x$. In the picture n_-, with its momenta in the basis (n_+,e_2), $T^-(x)=e^{-aH_{n_-}}e^{ib\,n_+\cdot P_{n_-}}$, $a\geq 0$, is a contraction with $T^-(x)[F]_{n_-}=[\tau_xF]_{n_-}$ (Lemma 6.3 at n_-) and $T^-(x)^*=T^-(x^\dagger)$; likewise $T(y)^*=T(\Theta_{e_1}y)$. Let x lie in the closed quadrant. (α) The quadrant is stable under τ_x, so $I_0T(x)=T^-(x)I_0$ on the quadrant classes; both operators being bounded and $\bar I$ closed, $T(x)\operatorname{dom}\bar I\subset\operatorname{dom}\bar I$ and $\bar IT(x)=T^-(x)\bar I$ there. (β) For $\xi\in\operatorname{dom}D$ and $\eta\in\operatorname{dom}\bar I$, by ($\alpha$) at x and at $x^\dagger$,

$$\langle\bar I\eta,\bar IT(x)\xi\rangle=\langle T^-(x^\dagger)\bar I\eta,\bar I\xi\rangle=\langle\bar IT(x^\dagger)\eta,\bar I\xi\rangle=\langle T(x^\dagger)\eta,D\xi\rangle=\langle\eta,T(\mathsf{q}x)D\xi\rangle;$$

so $\bar IT(x)\xi\in\operatorname{dom}\bar I^*$, that is $T(x)\xi\in\operatorname{dom}D$, and $DT(x)\xi=T(\mathsf{q}x)D\xi$. ($\gamma$) The translations U, U^- by ve_2 in the two pictures are unitary, keep the quadrant and satisfy $I_0\mathsf{U}=\mathsf{U}^-I_0$; so $\bar I\mathsf{U}=\mathsf{U}^-\bar I$, and $\mathsf{U}^{-1}D\mathsf{U}=\bar I^*(\mathsf{U}^-)^{-1}\mathsf{U}^-\bar I=D$: D commutes with the translations along e_2. Put $T(w,w')=\int\exp(-[w(E-q_1)+w'(E+q_1)]/2)\,d\mathcal{P}$ for $\operatorname{Re}w,\operatorname{Re}w'\geq 0$, a contraction by $E\geq|q_1|$; then $T(x)=T(w_x,\bar w_x)$ with $w_x=x_3+ix_1$, and $T(\mathsf{q}x)=T(iw_x,-i\bar w_x)$. For $\xi,\eta\in\operatorname{dom}D$ the

functions $\langle D\eta, T(w,w')\xi\rangle$ and $\langle \eta, T(iw,-iw')D\xi\rangle$ are holomorphic on the sector $-\pi/2 < \arg w < 0 < \arg w' < \pi/2$; by (β) they agree at its points $(w_x, \bar w_x)$, $x_1 < 0 < x_3$, which form an open set of the real plane of the coordinates $(\frac12(w+w'), \frac{1}{2i}(w-w'))$; so they agree on the sector, and, D being self-adjoint, $T(w,w')\operatorname{dom} D \subset \operatorname{dom} D$ and $DT(w,w') = T(iw,-iw')D$ on $\operatorname{dom} D$ for (w,w') in the sector.

For such (w,w') and for φ,ψ in spectral subspaces of $\log D$ for bounded intervals, $G(z) = \langle D^{i\bar z}\varphi, T(e^{-\pi z/2}w, e^{\pi z/2}w')D^{iz}\psi\rangle$ is bounded and holomorphic on a neighbourhood of $-1 \le \operatorname{Im} z \le 0$; at $z = r - i$, r real, one has $D^{iz}\psi = D(D^{ir}\psi)$ with $D^{ir}\psi \in \operatorname{dom} D$, the arguments of T are $(iw(r), -iw'(r))$ with $(w(r), w'(r)) = (e^{-\pi r/2}w, e^{\pi r/2}w')$ in the sector, and the last identity gives $G(r-i) = G(r)$. So G extends to a bounded entire function, constant by Liouville's theorem:

$$D^{is}T(w,w')D^{-is} = T(e^{-\pi s/2}w, e^{\pi s/2}w'),$$

on the sector and then, by continuity, for $\operatorname{Re} w, \operatorname{Re} w' \ge 0$. The uniqueness statement (S3) turns this, with (γ), into the formulas of (b), $E \mp q_1$ being multiplied by $e^{\mp\pi s/2}$. (c) $\{E < |q|\} \subset \{E < |q_1|\} \cup \bigcup_{\varsigma\in\mathbb{Q}} \Lambda^{(1)}_\varsigma\{E < |q_2|\}$: if $E \ge |q_1|$ and $(E-q_1)(E+q_1) < q_2^2$, the energy $\frac12((E+q_1)e^{-\varsigma} + (E-q_1)e^{\varsigma})$ of $\Lambda^{(1)}_{-\varsigma}(E,q)$ falls below $|q_2|$ for some rational ς. The exchange of e_1 and e_2 yields, through Lemma 6.3, a second group that boosts in (E,q_2); the two generate $\mathrm{SO}_0(1,2)$. (d) is the polar decomposition $\bar I = WD^{1/2}$: W is unitary as $\ker D = 0$ and the range of I_0 is dense in $\mathcal{H}_{n_-}$ (translate along n_- into the quadrant).

For $x_1 < 0 < x_3$ the identity of (b), continued to $s = -i/2$ on the spectral subspaces of $\log D$ for bounded intervals, which form a core of $D^{1/2}$, gives $D^{1/2}T(x) = T(x^\flat)D^{1/2}$ on $\operatorname{dom} D^{1/2} = \operatorname{dom}\bar I$, $w_{x^\flat} = e^{i\pi/4}w_x$. With (α), $T^-(x)WD^{1/2} = \bar I T(x) = WD^{1/2}T(x) = WT(x^\flat)D^{1/2}$, and the range of $D^{1/2}$ is dense; so $T^-(x)W = WT(x^\flat)$. For $x = an_- + bn_+$, $|b| < a$, one has $x^\flat = ae_3 + be_1$, hence $We^{-aH}e^{ibP_1}W^{-1} = e^{-aH_{n_-}}e^{ib\,n_+\cdot P_{n_-}}$; at $b = 0$ this is $We^{-aH}W^{-1} = e^{-aH_{n_-}}$, and as $e^{-aH_{n_-}}$ has zero kernel, $We^{ibP_1}W^{-1} = e^{ib\,n_+\cdot P_{n_-}}$ for $|b| < a$, so for all b.

By (γ) and the functional calculus $D^{1/2}$ commutes with the translations along e_2, and $\bar I\mathsf{U} = \mathsf{U}^-\bar I$ gives $W\mathsf{U} = \mathsf{U}^-W$; the spectral measures correspond by uniqueness. □

Lemma 6.9 (One correlation in two pictures)**.** Let σ satisfy (D0)–(D2), let $u, n \in \mathfrak{M}(\sigma)$ with $u\cdot n = \cos\gamma$, $0 < \gamma < \pi/2$, $u' = (n - \cos\gamma\, u)/\sin\gamma$, $m = \sin\gamma\, u - \cos\gamma\, u'$, $u'' \perp u, u'$; take the momenta of the picture u in the basis (u', u'') and those of the picture n in (m, u''), $q = (q_1, q_2)$, and suppose $\mathcal{P}_u(\{E < |q_1|\}) = \mathcal{P}_n(\{E < |q_1|\}) = 0$. Let F be supported in $W_\gamma = \{x : u\cdot x > \tan\gamma\,|u'\cdot x|\}$, $\mathsf{m} = m^u_{F,F} \ge 0$ and $\mathsf{n} = m^n_{\theta_n\theta_u F, F}$.

(a) For real $w = w_0u + w_1u' + w_2u''$ with $w_0 \ge 0$ and $w\cdot n \ge 0$: $\int e^{-w_0E + i(w_1q_1 + w_2q_2)}d\mathsf{m} = \sigma(\theta_u\bar F\cdot\tau_w F) = \int e^{-(w\cdot n)E + i((w\cdot m)q_1 + w_2q_2)}d\mathsf{n}$.

(b) For a bounded Borel $g \ge 0$ let μ_g be the image of $g(q_2)\mathsf{m}$ under $(E,q) \mapsto (E - q_1, E + q_1)$ and ν_g that of $g(q_2)\mathsf{n}$ under $(E,q) \mapsto (E + q_1, E - q_1)$, measures on $[0,\infty)^2$. Then for $\gamma - \pi/2 < \arg z < \pi/2$ and $-\pi/2 < \arg z' < \pi/2 - \gamma$

$$\int e^{-(za + z'b)/2}\,d\mu_g(a,b) = \int e^{-(e^{-i\gamma}za + e^{i\gamma}z'b)/2}\,d\nu_g(a,b).$$

(c) For real κ_1, κ_2: $\int_{(0,\infty)^2} a^{-i\kappa_1}b^{-i\kappa_2}\,d\mu_g = e^{-(\kappa_1-\kappa_2)\gamma}\int_{(0,\infty)^2} a^{-i\kappa_1}b^{-i\kappa_2}\,d\nu_g$, with the like identities on the two half axes and $\mu_g(\{(0,0)\}) = \nu_g(\{(0,0)\})$: at a fixed value of $ab = E^2 - q_1^2$ and of q_2, ν_g is the continuation of μ_g in the rapidity $\frac12\log(b/a)$ by $i\gamma$.

(d) $\int \Phi(E^2 - q_1^2, q_2)\,d\mathsf{m} = \int \Phi(E^2 - q_1^2, q_2)\,d\mathsf{n}$ for every bounded Borel Φ. So, with $\mathsf{T}(E,q) = (E^2 - q_1^2, q_2)$, $\mathcal{P}_u(\mathsf{T}^{-1}B) = 0$ if and only if $\mathcal{P}_n(\mathsf{T}^{-1}B) = 0$, for every Borel $B \subset [0,\infty)\times\mathbb{R}$; in particular the forward cone holds in the picture u if and only if it holds in the picture n.

■

Proof. (a) On W_γ, $n\cdot x \ge \cos\gamma(u\cdot x - \tan\gamma|u'\cdot x|) > 0$ and $n\cdot\theta_u x < 0$; so F and $\theta_n\theta_u F$ lie in $\mathcal{D}_n$, and $\theta_n(\theta_n\theta_u\bar F) = \theta_u\bar F$; (19) in the two pictures. (b) Both outer members of (a) are, as functions of w_2, Fourier transforms of measures in q_2; their equality lets one insert $g(q_2)$. With $z = w_0 + iw_1$, $z' = w_0 - iw_1$ one has $-w_0E + iw_1q_1 = -[z(E-q_1) + z'(E+q_1)]/2$ and $-(w\cdot n)E + i(w\cdot m)q_1 = -[e^{-i\gamma}z(E+q_1) + e^{i\gamma}z'(E-q_1)]/2$; so the identity holds at $z' = \bar z$, $\gamma - \pi/2 \le \arg z \le \pi/2$. Both members are holomorphic on the product of the two sectors (the cones in q_1 make the integrands bounded), and agree on a non-empty open set of its real points: they agree. (c) Integrate (b) at $(z,z') = (2\varrho, 2\varrho')$ against $d_{\eta,\mathsf{z}}(\varrho)d_{\eta,\mathsf{z}'}(\varrho')$, where $d_{\eta,\mathsf{z}} = c_{\eta,\mathsf{z}} - \eta c_{\eta,\mathsf{z}+1}$, $c_{\eta,\mathsf{z}}(\varrho) = \Gamma(\mathsf{z})^{-1}\varrho^{\mathsf{z}-1}e^{-\eta\varrho}$, whose Laplace transform $\zeta(\zeta+\eta)^{-\mathsf{z}-1}$ vanishes at $\zeta = 0$ and is bounded by $\max\{1,\eta^{-1}\}e^{|\operatorname{Im}\mathsf{z}|\gamma}$ on $|\arg\zeta| \le \gamma$; let $\operatorname{Re}\mathsf{z}\downarrow 0$, then $\eta\downarrow 0$, by dominated convergence, and use $(e^{\mp i\gamma}x)^{-i\kappa} = x^{-i\kappa}e^{\mp\kappa\gamma}$; the half axes come from $\varrho\to\infty$ in one variable. (d) At $\kappa_1 = \kappa_2$ the images of the two measures under $\log ab$ have one Fourier transform, and the masses on $\{ab = 0\}$ agree; rectangles generate the Borel sets.

If $\mathcal{P}_n(\mathsf{T}^{-1}B) = 0$, then $\mathsf{m}(\mathsf{T}^{-1}B) = \|\mathcal{P}_u(\mathsf{T}^{-1}B)[F]_u\|^2 = 0$ for all F in W_γ, whose classes are dense in $\mathcal{H}_u$. Conversely, (a) holds by polarisation for pairs F', F in W_γ, and the classes $[\theta_n\theta_u F']_n$ and $[F]_n$, F, F' in W_γ, are total in $\mathcal{H}_n$: the translations along $u = \cos\gamma\, n + \sin\gamma\, m$ and along $\theta_n\theta_u u = \cos\gamma\, n - \sin\gamma\, m$, which in the picture n are $e^{-s\cos\gamma H_n}$ times unitaries, carry every compact set into W_γ, resp. into $\theta_n\theta_u W_\gamma$, for large s, and for $\psi\in\mathcal{H}_n$, $G\in\mathcal{D}_n$ the function $s\mapsto\langle\psi, e^{-s\cos\gamma H_n}e^{\pm is\sin\gamma\, m\cdot P_n}[G]_n\rangle$ is holomorphic on the sector $|\arg s| < \pi/2 - \gamma$ by the cone in q_1; if it vanishes for large real s, it vanishes at $s\downarrow 0$. □

Lemma 6.10 (How much covariance one plane uses)**.** Let σ satisfy (D0)–(D4).

(a) For a full $\mathfrak{K}$, $G_\sigma[\mathfrak{K}]$ is a closed subgroup of O(3) containing W_3, so it is W_3 or O(3): covariance on $\mathfrak{K}$ under one $R\notin W_3$ is covariance on $\mathfrak{K}$ under O(3).

(b) Let $\mathfrak{F}$, $\mathfrak{K}$ be full, with $X\cdot Y\in\mathfrak{K}$ for all $X, Y\in\mathfrak{F}$ with disjoint supports, and $G_\sigma[\mathfrak{K}] = \mathrm{O}(3)$. Then $\sigma(\theta_{n,c}\bar F\cdot F)\ge 0$ for every mirror and every combination F of tuples of $\mathfrak{F}$ on its side. For one mirror (u,c) and one $F = \sum\zeta_i X_i$ the proof uses $\sigma(gY) = \sigma(Y)$ at one isometry $gx = Rx + cu$, $Rn = u$, $n\in\mathfrak{N}_{18}$, and at the tuples $Y = g^{-1}(\theta_{u,c}X_i\cdot X_k)$ alone.

(c) Instances of (b) are $(\mathfrak{F},\mathfrak{K}) = (\mathfrak{K}_m, \mathfrak{K}_{2m})$, $(\mathfrak{T}_k, \mathfrak{T}_{2k})$, $(\mathfrak{T}_0\cup\mathfrak{K}_1, \mathfrak{T}_1\cup\mathfrak{K}_2)$. In particular covariance at order 2 gives positivity at every mirror on the vectors of at most one entry, and covariance at order 2 together with $G_\sigma[\mathfrak{T}_1] = \mathrm{O}(3)$ gives positivity at every mirror on the combinations of scalar tuples and of single tensor entries; $G_\sigma[\mathfrak{T}_0] = \mathrm{O}(3)$ is the invariance of the trace part.

(d) Let $\mathfrak{F}$ be full with $\emptyset\in\mathfrak{F}$, $u\in S^2$, and let $\sigma(\theta_{u,c}\bar F\cdot F)\ge 0$ for all real c and all combinations F of tuples of $\mathfrak{F}$ on the side of the plane. Then $\sigma(\Theta_u X) = \sigma(X)$ for $X\in\mathfrak{F}$, and for $X = X'\cdot X''$ with $X', X''\in\mathfrak{F}$ on the two sides of a plane normal to u.

(e) $\sigma((H)) = c_\sigma\int\operatorname{tr}H$ with a number c_σ. If $\sigma(H,H') = \iint s(y-x; H(x), H'(y))\,dx\,dy$ with s continuous on $(\mathbb{R}^3\setminus\{0\})\times V\times V$, then positivity of the two-point form at the planes normal to one $u\notin\mathfrak{N}_{18}$ gives covariance at order 2; if s is real analytic and $\sigma(RH, RH') = \sigma(H,H')$ for one $R\notin W_3$ and all $H\in C^1_c(B;V)$, $H'\in C^1_c(B';V)$, B, B' open balls with disjoint closures, then σ is covariant at order 2.

■

Proof. (a) Lemma 6.2(e) and (D3). (b) As in Lemma 6.2(c): $Y_i = g^{-1}X_i\in\mathfrak{F}$ lies on the side of n, $Z_{ik} = \theta_n Y_i\cdot Y_k\in\mathfrak{K}$, $\theta_{u,c}X_i\cdot X_k = gZ_{ik}$, $\sigma(gZ_{ik}) = \sigma(Z_{ik})$, and $\sum\bar\zeta_i\zeta_k\sigma(Z_{ik})\ge 0$ by (D4). (c) A concatenation of two tuples with at most m entries has at most $2m$, and the same for the entries outside $\mathbb{R}\mathbf{1}$; at most one non-scalar entry in each of two tuples gives at most two. (d) As in Lemma 6.2(b), with $F' = \emptyset$, and with $F' = \theta X'$, $F = X''$. (e) $\ell(H) = \sigma((H))$ is linear, invariant under the translations and bounded in sup norm for supports in a fixed ball; so $f\mapsto\ell(fE)$ is a translation-invariant Radon measure, a multiple of Lebesgue measure, and $\ell(H) = \int\operatorname{tr}(\mathsf{c}H)$ with

$\rho(w)\mathsf{c} = \mathsf{c}$ for $w \in W_3$: the sign changes kill the entries of c off the diagonal and the permutations make the diagonal constant.

For the second assertion, (d) at $\mathfrak{F} = \mathfrak{K}_1$ says $s(\Theta_u v; \rho(\Theta_u)e, \rho(\Theta_u)e') = s(v; e, e')$ for $u \cdot v \neq 0$, by continuity for all $v \neq 0$; so $\Theta_u \in G_\sigma[\mathfrak{K}_2]$, as two continuous kernels of one bilinear form agree, and $\Theta_u \notin W_3$; (a). If s is real analytic, $s(Rv; \rho(R)e, \rho(R)e') - s(v; e, e')$ is real analytic on the connected set $\mathbb{R}^3 \setminus \{0\}$ and vanishes on the open set $B' - B$; for a general pair cut both entries by partitions of unity into pieces so small that a coordinate plane parts any two of them. □

6.5. **Examples.**

Proposition 6.11 (Functionals with exactly nine families, and the inputs of the cone)**.** (a) The functional σ^{fr} of Theorem V(f)(i) satisfies (D0)–(D4) and is covariant under O(3); at two entries it is

$$\sigma^{\mathrm{fr}}(H_1, H_2) = \mathcal{W}(H_1, H_2) = \frac{3}{2} \iint \mathrm{tr}[H_1(x) K_3(x-y) H_2(y) K_3(x-y)]\, dx\, dy$$

. The functional $\sigma^{\mathrm{fr}} \circ Z_2$ satisfies (D0)–(D4), with 2^n times the numbers of (D1), is not covariant at order 2, has the forward cone in the nine pictures, and $\mathfrak{M}(\sigma^{\mathrm{fr}} \circ Z_2) = \mathfrak{N}_{18}$.

(b) The functional

$$\sigma_D(H_1, \dots, H_n) = \sum_{\text{pairings}} \prod_{\{a,b\}} S_D(\mathrm{tr}\, H_a, \mathrm{tr}\, H_b),$$

$S_D(f, f') = (2\pi)^{-3} \int \overline{\hat{f}(p)} \hat{f}'(p) \hat{S}_D(p)\, dp$, with $\hat{S}_D$ of Theorem V(f)(ii), has (D0)–(D3) and is positive at every coordinate mirror; on the vectors $[(h)]$ the joint spectrum of (H, P_1, P_2) is the surface $E = \omega(q)$, $\omega(q)^2 = (m^2 + |q|^2 + \lambda q_1^2 q_2^2)/(1 + \lambda|q|^2)$, with $\omega(q_1, 0)^2 \leq \max\{m^2, 1/\lambda\}$; so $\mathcal{P}(\{E < c|q_1|\}) \neq 0$ for every $c > 0$, and σ_D is positive at no diagonal mirror.

(c) The functional σ_c formed in the same way with $\hat{S}_c(p) = [p_1^2 + c^2 p_2^2 + p_3^2 + m^2]^{-1}$, $0 < c < 1$, $m > 0$, has (D0)–(D2), is positive at $(u, 0)$ for every unit $u \perp e_2$, and on the vectors $[(h)]$ its spectral measure is carried by $\{E^2 = q_1^2 + c^2 q_2^2 + m^2\}$ and charges $\{E < |q|\}$.

■

Proof. (a) (D0) is Wick's rule: at disjoint supports σ^{fr} is a finite sum over the pairings without self-contraction of integrals of products of n kernels K_3; $|K_3(u)|_\infty \leq (2\pi|u|^3)^{-1}$ gives (D1), and $K_3(Ru) = RK_3(u)R^{\mathrm{t}}$ gives (D2), (D3) and the covariance. Off 0, $-K_3$ is the covariance of the gradient of the free massless scalar field ϕ: $\langle \partial_\alpha \phi(x)\, \partial_\gamma \phi(y) \rangle = \partial_\alpha^x \partial_\gamma^y (4\pi|x-y|)^{-1} = -K_3(x-y)_{\alpha\gamma}$ for $x \neq y$. The free field is reflection positive at every plane; so for every $n \in S^2$ the reflected covariance of the gradient, a vector field that turns with Θ_n, is the positive kernel $-\Theta_n K_3(\theta_n x - y)$ on $\{n \cdot x > 0\}$.

The field B, of covariance $+K_3$ off 0, is a pseudovector: it turns with $-\Theta_n$, so its reflected covariance is the same positive kernel $-\Theta_n K_3(\theta_n x - y)$, and in $\langle B_\lambda, B_{\lambda'} \rangle$ the two signs cancel, so that the labels turn by $\rho(\Theta_n)$. Equivalently, the Wick squares of the gradient give $(-1)^n \sigma^{\mathrm{fr}}$ at n entries, each term having n kernels, and $F = \sum c_i X_i \mapsto \sum c_i (-1)^{|X_i|} X_i$ keeps positivity. Positivity passes from a Gaussian field to its Wick polynomials, after a mollification that is removed at separated supports. For $E = o_{12}$ and u parallel to e_3, $\frac{3}{2}\mathrm{tr}[EK_3(u)EK_3(u)] = 3K_{11}K_{22} = 3(4\pi|u|^3)^{-2} > 0$, so $\sigma^{\mathrm{fr}}(\varphi_1 E, \varphi_2 E) \neq 0$ for nonnegative bumps φ_1, φ_2 about two points on a vertical line.

Proposition 6.26 makes $\sigma^{\mathrm{fr}} \circ Z_2$ a functional with (D0)–(D4) that is not covariant at order 2; Theorem V(b) gives $\mathfrak{M} = \mathfrak{N}_{18}$, and Proposition 6.6 the cone.

(b) $\hat{S}_D$ is invariant under the signed permutations of p, and $\mathrm{tr}(\rho(R)E) = \mathrm{tr}\, E$: (D0), (D2), (D3). With $q = (p_1, p_2)$, $A = m^2 + |q|^2 + \lambda q_1^2 q_2^2$, $B' = 1 + \lambda|q|^2$ and $\omega = (A/B')^{1/2}$, the integral over p_3 gives

$$S_D(z) = (2\pi)^{-2} \int e^{iq\cdot\vec{z} - \omega(q)|z_3|} \big(2(AB')^{1/2}\big)^{-1} d^2q \qquad (z_3 \neq 0),$$

which converges uniformly for $|z_3| \geq 2\delta$. Indeed, on $|q_1| \geq \max\{1, |q_2|\}$ one has $(AB')^{-1/2} \leq [\sqrt{\lambda}\, q_1^2 \sqrt{1+\lambda q_2^2}]^{-1}$; integration in q_1 leaves an integrable multiple of $[\max\{1,|q_2|\}\sqrt{1+\lambda q_2^2}]^{-1}$. The other unbounded wedge follows by symmetry, and the compact part is bounded since $m > 0$. Thus the kernel is bounded for $|z|_\infty \geq 2\delta$ by (D3): (D1). For h, h' in $\{x_3 > 0\}$, $f = \operatorname{tr} h$, $\tilde f(q) = \int f(x) e^{-iq\cdot\vec x - \omega(q)x_3} dx$: $\sigma_D(\theta h', \tau_{(v,t)} h) = (2\pi)^{-2} \int \overline{\tilde f'(q)} \tilde f(q) e^{-iq\cdot v - \omega(q)t} (2(AB')^{1/2})^{-1} d^2q$; at $h' = h$, $v = 0$, $t = 0$ it is ≥ 0. A Gaussian functional is positive at a mirror if its two-point form is: sorting the pairings of $\theta X' \cdot X$ by the pairs that cross the mirror, $\sigma_D(\theta X' \cdot X) = \langle \Phi(X'), \Phi(X)\rangle$ with $\Phi(X) = \sum_{A \subset X} c(X \setminus A)(|A|!)^{1/2} \mathrm{Sym} \bigotimes_{a\in A} [f_a]$ in the symmetric Fock space over the one-entry space, $c(Y)$ the sum over the pairings of Y; so $\sigma_D(\theta \bar F \cdot F) = \| \sum \zeta_i \Phi(X_i)\|^2$; (D3) gives the other coordinate mirrors. By uniqueness of the transform the spectral measure of $[(h)]$ is the image of $|\tilde f|^2 (8\pi^2 (AB')^{1/2})^{-1} d^2q$ under $q \mapsto (\omega(q), -q)$; $\tilde f$ is real analytic and not 0 for $f \geq 0$, $f \neq 0$, and the open set $\{\omega(q) < c|q_1|\}$ is not empty. By Lemma 6.4 with (D3), positivity at one diagonal mirror would give $E \geq |q_1|$.

(c) With $\mathsf{s}_c(x) = (x_1, x_2/c, x_3)$, σ_c is, up to the factor c^n, the Gaussian functional of the free field of mass m evaluated at $f_a \circ \mathsf{s}_c^{-1}$; s_c commutes with θ_u for $u \perp e_2$, so positivity passes from the free field; the transform in p_3 is $(2E)^{-1} e^{-|x_3|E}$, $E = (q_1^2 + c^2 q_2^2 + m^2)^{1/2}$, which is $< |q|$ where $(1-c^2)q_2^2 > m^2$. □

6.6. **The lattice input: bond forms as sources, passage, operators, the two-point law, dilation and a power bound.**

Lemma 6.12 (The bond forms as sources)**.** Let $0 < g \leq \gamma_W^{\mathrm{ref}}$, let (K, β) be a first-passage datum at g and ℓ an admissible side; plaquettes and bonds are those of T_ℓ at the spacing a_K. For a weight w of the bonds let $S[\mathsf{w}]$ be the set of the plaquettes that contain a bond b with $\mathsf{w}(b) \neq 0$. A majorant is a pair (s, S) of a number $s \geq 0$ and a set S of plaquettes; with the constants $\mathsf{c}^\flat$, $M = L^{m'}$ and α_0 of the progression of (S1) put $\mathsf{m}_j = 12 M^3 \alpha_0^2 L^{K-j} s$ for $j \geq 0$. A continuous gauge-invariant function F of the configuration is a source under (s, S) if: (i) $|F| \leq a_K^{-1} s \sum_{p\in S} a_p$; (ii) at height 0 a family represents the variation of F from its zero-fluctuation background value in the first chart integral; at each level $j \geq 1$, F is the total of a family of local terms without base point, with the same sum rule as for a plaquette weight; these families vanish at the regions that hold no plaquette of S, and their sizes are at most those that the progression grants to the plaquette weight $s\mathbf{1}_S$: $\mathsf{c}^\flat \mathsf{m}_0$ at the height 0 and $\frac12 \mathsf{m}_j$ at the level j; (iii) if F is real: at the small points of the chart of each level, $a_K F$ differs from a quadratic form $\sum_{p,p'} t(p,p') \langle \Phi_p, \Phi_{p'}\rangle$ in the plaquette angles, $\partial U(p) = e^{i\Phi_p}$, by at most the error that the progression admits there for $s\mathbf{1}_S$, with a real symmetric kernel t that vanishes off $S \times S$ and has $2\sum_{p'} |t(p,p')| \leq s$ for every p.

(a) q_b is a polynomial in the entries of the bond variables of the four plaquettes that contain b and of their inverses; it is gauge invariant, real on SU(2), and $|q_b| \leq \frac12 \sum_{p\ni b} a_p$. So $Y[\mathsf{w}]$ is gauge invariant and $|Y[\mathsf{w}]| \leq 2a_K^{-1} \sup|\mathsf{w}| \sum_{p\in S[\mathsf{w}]} a_p$. For a weight w of the plaquettes, $O(w)$ is a source under $(|w|_\infty, \operatorname{supp} w)$, with $t(p,p') = \frac12 w(p)\delta_{pp'}$ if w is real; for a weight w of the bonds, $Y[\mathsf{w}]$ is a source under $(59 \sup|\mathsf{w}|, S[\mathsf{w}])$, with

$$t(p,p') = -\tfrac12 \sum_b \mathsf{w}(b) \big[c_{b,\lambda_b}(p) c_{b,\lambda_b'}(p') + c_{b,\lambda_b}(p') c_{b,\lambda_b'}(p) \big]$$

if w is real, $c_{b,\alpha}(p) \in \{0, \pm\frac12\}$ the coefficients of $u_{b,\alpha} = \sum_p c_{b,\alpha}(p)\Phi_p + \dots$ to the first order in the angles; if F, F' are sources under (s,S), (s',S') and $c \in \mathbb{C}$ (c real for (iii)), then $F + F'$ is one under $(s+s', S \cup S')$ and cF one under $(|c|s, S)$. So $O_K^T(H)$ is a source under $(60|H|_\infty, S_H)$, S_H the set of the plaquettes that carry a weight of H or contain a bond that carries one; for real H its kernel t_H, the sum of the kernels of $O(w_H)$ and of $Y[\mathsf{w}_H]$, has $2\sum_{p'} |t_H(p,p')| \leq 3|H|_\infty$.

(b) Let $F_1, \dots, F_{n'}$ be sources under majorants (s_a, S_a), in any finite number n' and mixed with plaquette weights. The progression of Theorem YMM1:D with the source $\sum_a \lambda_a F_a$, λ in a polydisc about 0 in $\mathbb{C}^{n'}$, is formed, with all its numbers taken at the plaquette weights $s_a \mathbf{1}_{S_a}$, and it has the finite-source properties of Proposition B.8: its families are holomorphic and Lipschitz in λ; they are local, a family on a region reading only the sources whose sets meet the region; the density of a never-large history up to the level t is $e^{D_t^\lambda}$ times that at $\lambda = 0$, with D_t^λ holomorphic in λ and $D_t^0 = 0$; the first derivatives in the λ_a at $\lambda = 0$, read at a small-field configuration of the level t and less their values at the trivial one, are bounded, summed over the polymers of the levels up to t, by a number of the constants times $L^{K-t} s_a$, times the number of the cubes of the level t that meet S_a, times the radius of the small fields of the level t; and the mixed derivatives at $\lambda = 0$ in $r \geq 2$ different parameters vanish on the polymers that do not meet the r sets, and are bounded by a number of r and the constants times the product of the r sizes, the number being a constant times $(4r)^r$ when the sets lie far apart in the units of the level.

The decomposition of a mean by the level at which a large field is first created and the quotients of products at the never-large histories hold as in (S1), with all their numbers formed at the plaquette weights $s_a \mathbf{1}_{S_a}$: the quotient of $e^{\sum_a \lambda_a F_a}$ at the never-large history up to the level t is $e^{D_t^\lambda}$, and that of a product $\prod_a (F_a - c_a)$ of centred sources is the sum, over the partitions of the sources, of the products over the blocks of the derivatives of $D_t^\lambda - \sum_a c_a \lambda_a$ at $\lambda = 0$ in the parameters of the block.

(c) Consequently, for $n \geq 2$ and $\delta > 0$ there are $K_n(g, \delta)$ and $k_n(g, \ell, \delta)$, depending on the constants, g, n, ℓ and δ alone, such that for $K \geq K_n(g, \delta)$ with $3a_K \leq \delta$ and for closed sets $\Sigma_1, \dots, \Sigma_n$ at pairwise sup distances $\geq 2\delta$ the following holds. Let each F_a be one of $O_K^T(H_a)$, $O(w_a)$, $Y[\mathsf{w}_a]$, or a sum of two of these, with a bounded weight H_a that vanishes off Σ_a and weights w_a, w_a that vanish at the plaquettes and bonds whose centres and midpoints lie off Σ_a, and let s_a be $60|H_a|_\infty$, $|w_a|_\infty$, $59 \sup |\mathsf{w}_a|$, or the sum of the two numbers: so F_a is a source under (s_a, S_a) with the corners of the plaquettes of S_a within the sup distance a_K of Σ_a. Then the joint cumulant under the Wilson measure of T_ℓ satisfies

$$|\langle F_1; \dots; F_n \rangle_{K,\ell,\beta}| \leq k_n(g, \ell, \delta) \prod_a s_a.$$

If ℓ is small over the run of (K, β), its canonical sequence of running couplings (equation YMM1:(2312)), as the least admissible side is when $g \leq \gamma_W^{\mathrm{sd}}$ (Lemma YMM1:126.3), then for $K \geq K_n^\circ(g, \delta)$ the bound holds in the form $k_n^\circ(g, \delta)(a_K \beta)^{-n} \prod_a s_a$, with numbers that depend on the constants, g, n and δ alone and read neither the side nor the datum. On such a side, for $0 < d < d_2^\circ(g)$ and $K \geq K_2'(g, d)$, numbers formed with the constants, g and d, two real sources F_1, F_2 under majorants (s_1, S_1), (s_2, S_2), with the kernels t_1, t_2 of (iii) and with the centres of the plaquettes of S_1 and of S_2 within the distance $d - a_K$ of two points at a distance between $3d$ and $4d$, satisfy

$$\Big| \langle F_1; F_2 \rangle_{K,\ell,\beta} - 6\upsilon^2 \sum_{p_1, p_1', p_2, p_2'} t_1(p_1, p_1')\, t_2(p_2, p_2')\, C^{\mathrm{bg}}(p_1, p_2)\, C^{\mathrm{bg}}(p_1', p_2') \Big| \leq \epsilon_g'(d)(a_K \beta)^{-2} s_1 s_2,$$

with $\epsilon_g'(d)$ formed with the constants, g and d and tending to 0 as $d \to 0$; here C^{bg} is the covariance of the background field at the working level of the depth of d (equation YMM1:(2322)) and $\upsilon \leq (\frac{9}{8})^{1/2} (a_K \beta)^{-1}$ the running coupling of that level. This gives the two-point law of Proposition 6.15 and the bound of its clause (e).

■

Proof. (a) Under a gauge transformation the loops $W_x(\mu, \pm\alpha)$, read from x, are conjugated by its value at x, and $\langle \cdot, \cdot \rangle$ is invariant under conjugation. For $V \in \mathrm{SU}(2)$ with $\operatorname{tr} V = 2 \cos \vartheta$, $\mathbf{w}(V)$ is

Hermitian and $\langle \mathbf{w}(V), \mathbf{w}(V)\rangle = \sin^2\vartheta \le 2(1-\cos\vartheta)$; so $\langle u_{b,\alpha}, u_{b,\alpha}\rangle \le a_p + a_{p'}$ for the two plaquettes p, p' of the plane of e_μ, e_α at b, and $|q_b| \le \frac{1}{2}(\langle u_{b,\lambda_b}, u_{b,\lambda_b}\rangle + \langle u_{b,\lambda'_b}, u_{b,\lambda'_b}\rangle)$. A plaquette has four bonds.

For $O(w)$ the three properties are those of the plaquette weights in the progression of (S1), and (iii) is the expansion $a_p = \frac{1}{2}\langle \Phi_p, \Phi_p\rangle + \dots$. For $Y[\mathsf{w}]$, (i) is the bound just shown. At the height 0 the member of the family at a region is the change of $-a_K^{-1}\sum_b \mathsf{w}(b) q_b$, over the bonds b whose four plaquettes have their corners in the region, under the fluctuation field of the first block step; the region of a bond consists of at most six blocks of the level 0 with a common corner and holds its four plaquettes, and at most $18M^3$ bonds have one and the same region. At configurations with $|U(b')^{\pm 1}| \le e^{1/13}$ whose plaquette variables lie within ζ of $\mathbf{1}$, $e^{2/13}\zeta \le 1$, a fluctuation $e^{iB'}$ with $\max|B'| = \rho \le \frac{1}{128}$ changes q_b by at most $784\rho^2 + 132\rho\zeta$, by the expansion of $\mathbf{w}$ to the second order.

At the radii of the first block step this, with the count of the bonds that have a given region, bounds the size of the family of the height 0 by $18 \cdot 3138 = 56484$ units of a quantity proportional to $\sup|\mathsf{w}|$, of which $\mathsf{c}^\flat \mathsf{m}_0$ at $s = 59\sup|\mathsf{w}|$ is $81 \cdot 12 \cdot 59 = 57348$ units; so the family of the height 0 stays below the bound for the plaquette weight $59\sup|\mathsf{w}|\,\mathbf{1}_S$, $S = S[\mathsf{w}]$, and this is the origin of the number 59. At the levels $j \ge 1$ the bond forms of the bonds whose blocks of the level j lie in a region, read on the analyticity cores of that level, form a family of local terms without base point whose sizes stay below the bounds for $59\sup|\mathsf{w}|\,\mathbf{1}_S$: at most $98M^3\alpha_0^2 L^{K-j}\sup|\mathsf{w}|$, against $\frac{1}{2}\mathsf{m}_j = 354M^3\alpha_0^2 L^{K-j}\sup|\mathsf{w}|$ at $s = 59\sup|\mathsf{w}|$.

To the first order $u_{b,\alpha}$ is $\frac{1}{2}$ times the sum, with signs, of the angles of the two plaquettes of the plane of e_μ, e_α at b, so the second order of q_b is the form of the kernel t; two different plaquettes share at most one bond, so $|t(p,p')| \le \frac{1}{8}\sup|\mathsf{w}|$, and a plaquette has four bonds with two partners at each, so $2\sum_{p'}|t(p,p')| \le 2\sup|\mathsf{w}|$. The three properties are additive or subadditive in the source and monotone in (s,S), and $|w_H|_\infty + 59\sup|\mathsf{w}_H| \le 60|H|_\infty$; for real H, $2\sum_{p'}|t_H(p,p')| \le |w_H(p)| + 2\sup|\mathsf{w}_H| \le 3|H|_\infty$.

(b) The proofs of the progression with sources, of the decomposition of a mean by the level of the first large field and of the quotients read a source through (i)–(iii) alone; every other step of them is worded for every family of local terms or every bounded Borel function of the configuration, or concerns numbers formed from s and S. So they hold for sources under majorants, in any number and mixed with plaquette weights, with the numbers formed at the majorants. The derivatives of all orders in the parameters come from the chain rule for the step of the progression in any number of variables. A family on a region reads the parameters of the sources whose sets meet the region alone, so a mixed derivative vanishes on the polymers that do not meet all its sets; on the polydisc of the radii $1/(4r)$, in the units in which the sizes are measured against the room of the progression, the step stays within that room, and Cauchy's estimate gives the factor $(4r)^r$, the decay of the families in the size of the polymers that join sets far apart paying the combinatorial factor. D_t^λ is the difference of the actions of the never-large history at λ and at 0, the source and the families of the progression up to the level t being read at its configuration; so the quotient of $e^{\sum_a \lambda_a F_a}$ is $e^{D_t^\lambda}$, that of $\prod_a (F_a - c_a)$ is the derivative $\partial_{\lambda_1}\cdots\partial_{\lambda_n}$ at $\lambda = 0$ of $e^{D_t^\lambda - \sum_a c_a\lambda_a}$, and this derivative of the exponential of a function that vanishes at 0 is the sum over the partitions of the products of its derivatives in the blocks.

(c) The mean of a product of centred sources is the sum over the level of the first creation of a large field of integrals, along the never-large history, of the quotients of the product; by (b) these are sums over the partitions of the sources of products of mixed derivative families of the progression, and a family of a block of at least two sources lives on regions that meet every S_a of the block, so it is small in the separation; the large fields are paid by their rarity. A joint cumulant is a polynomial in such means; this gives the first bound. On a small side, the least side at $g \le \gamma_W^{\mathrm{sd}}$ among them, the progression is run to the working level of the depth fixed by δ, the bound comes in the units υs_a, υ the running coupling of that level, with $\upsilon^2 \le \frac{9}{8}(a_K\beta)^{-2}$, and the weights of the

first creation of a large field (Lemma YMM1:125.3) are summable against the sizes of the deeper levels; a small side is at most a number formed with the constants and g, by the fourth inequality of equation YMM1:(2312) and the bound of the last coupling of the run, so these numbers read no side.

For two real sources the second cumulant at the never-large history is the second order of the progression: there the two sources are the quadratic forms of their kernels (iii) in the plaquette angles, whose covariance at the working level is the Gaussian term $6v^2\sum t_1t_2C^{\mathrm{bg}}C^{\mathrm{bg}}$ displayed in (c), compared with the value of the free field as for plaquette weights; the bound of the carried family at the flat top (Proposition YMM1:125.1), which reads a source only through its kernel and its majorant, carries over with its constants and errors, and the rest is small with the depth of d. At the kernels of the bond forms this is the law of Proposition 6.15 at the off-diagonal labels, and the bound of its clause (e) with a number that does not depend on the distance. □

Proposition 6.13 (The passage to $\mathbb{R}^3$)**.** Let $0<g\le\gamma_W^{\mathrm{ref}}$.

(a) Let $n\ge1$, $\delta,\varrho_0>0$ and $\delta'=\min\{\delta,1/(8n)\}$. For $r\le n$ let $C_r^\flat$ be a number with $\|D\|_{\mathrm{ch},\ell'}\le C_r^\flat\prod_a|H_a|_\infty$ for every product $D=\prod_{a\le r}(O_K^T(H_a)-c_a)$, $c_a=c(H_a)$, of centred entries carried by one cell of side 1, at sup distances $\ge\delta'$ from its walls and $\ge2\delta'$ from one another, on the least admissible torus, uniformly in the first-passage data at g with $K\ge K^G$. Here $c(H)=e_{\ell'}a_K^{-1}\sum_p H_{\lambda(p)\lambda(p)}(x(p))$ for a bounded weight H, $e_{\ell'}$ the mean of a plaquette square a_p under the Wilson measure of the least admissible torus, which is the same at every plaquette; c is linear in H, and for an entry carried by one cell $c(H)$ is the mean of $O_K^T(H)$ under that measure, the bond forms having mean 0. $K^G=K^G(n,\delta')$, depending on the constants, g, n and δ' alone, is a cutoff with $3a_K\le\delta'$ for $K\ge K^G$ beyond which the joint cumulants of at most $n\ell'^3$ centred entries of this kind on the least admissible torus are bounded uniformly in the cutoff (Lemma 6.12(c) on the least side, with $s_a=60|H_a|_\infty$); and put

$$C_m^{\mathrm{loc}}=(4n\varrho_0+2)^{3m}\Big(\max_{1\le r\le n}\max\{1,e^{G_g}C_r^\flat\}\Big)^m,\qquad C_n^{\mathrm{lc}}=\sum_{k=0}^{n}\tbinom{n}{k}(C_1^{\mathrm{loc}})^{n-k}C_k^{\mathrm{loc}}.$$

Such numbers exist and depend on the constants, g, n, δ, ϱ_0 alone, and for every first-passage datum (K,β) at g with $K\ge K^G$, all $\nu,\nu'\in\mathcal{G}_{K,\beta}^{\mathrm{per}}$ and all bounded weights $H_1,\dots,H_n$ that vanish off closed sets of sup diameters $\le\varrho_0$ at pairwise sup distances $\ge2\delta$:

$$\Big|\nu\Big(\prod_a(O_K^T(H_a)-\nu'(O_K^T(H_a)))\Big)\Big|\le C_n^{\mathrm{lc}}\prod_a|H_a|_\infty;$$

the same holds under the Wilson measures of the admissible tori whose period boxes hold the supports with room. No position, cutoff, volume or state enters the numbers.

(b) Every Gibbs sequence at g has a subsequence along which (18) exists at every tuple of C^1 weights and at every tuple of continuous weights, and along which the labels converge, to $b\in[g^{-2},L(g^{-2}+\bar B)]$.

(c) Such a limit σ is real, symmetric, $\sigma((H))=0$, and has (D0)–(D4) with $C_n=C_n^{\mathrm{lc}}$; for every $d>0$, $|\sigma(X\cdot\tau_vY)|$ is bounded uniformly over translations v for which all supports in $X\cdot\tau_vY$ remain at pairwise sup distance at least d; its truncated functions are the limits of the lattice ones; its trace part is the scalar limit of the subsequence; and if $X_j\to X$ entry by entry in the sup norm, with supports in a fixed compact set at pairwise distances $\ge d>0$, the lattice correlations at X_j tend to $\sigma(X)$.

(d) For every component ξ of the decomposition of the scalar limit, with approximants ρ_j, a further subsequence has a lift $\sigma_\xi^\sharp$; it has (D0)–(D4) with the numbers of (a), its trace part is the component $\sigma_{0,\xi}$, and $\sigma_\xi^\sharp((H))=\frac{c_\xi}{3}\int\operatorname{tr}H$, c_ξ the number with $\rho_j(O_{K_j}^T(f\mathbf{1}))-\nu_j(O_{K_j}^T(f\mathbf{1}))\to c_\xi\int f$ of the theorem on the scalar limit (Theorem YMM1:AP).

(e) Along growing tori, with the Wilson measures of admissible sides $\ell_j \to \infty$ in the place of the ν_j, (b) and (c) hold, except that of (D4) only the three coordinate families of mirrors are asserted.

■

Proof. (a) Put $E_a = O_K^T(H_a)$. The Wilson measure of the least torus is invariant under the lattice isometries $\hat r$, which act transitively on the plaquettes and satisfy $\hat r O_K^T(H) = O_K^T(\hat r H)$, $(\hat r H)(x) = RH(\hat r^{-1}x)R^{\mathrm t}$ with R the linear part of $\hat r$; so a_p has one mean $e_{\ell'}$, and the reflection in the plane through b normal to e_{λ_b} keeps b and changes the sign of q_b, so q_b has mean 0: $c(H)$ is the mean of $O_K^T(H)$ for an entry carried by one cell, and $c(\hat r H) = c(H)$. For a product D of r entries $E_a - c(H_a)$ in one cell of a board of side l, $\|D\|_{\mathrm{ch},\ell'}^N$, $N = (\ell'/l)^3$, is the mean on the least torus of the N mirror copies of D; a copy is $\prod_a (O_K^T(\hat r H_a) - c(\hat r H_a))$ with a lattice isometry $\hat r$ and $|\hat r H_a|_\infty = |H_a|_\infty$, so the copies are centred entries of the same kind at pairwise sup distances $\ge 2\delta'$.

The mean of a product of centred variables is the sum over the partitions without singletons of the products of their joint cumulants, each bounded uniformly in the cutoff on the least torus by Lemma 6.12(c), with $s_a = 60|H_a|_\infty$; the N-th root gives $C_r^\flat$. In a torus of side $\ell \ge \ell'$ the chessboard estimates give $|\tilde\mu_{K,\ell,\beta}(D)| \le \|D\|_{\mathrm{ch},\ell} \le e^{l^3(p_{\ell'} - p_\ell)}\|D\|_{\mathrm{ch},\ell'} \le e^{G_g l^3}\|D\|_{\mathrm{ch},\ell'}$, and the domination of every periodic Gibbs state by the tori gives the same bound in ν; products over several cells are bounded by the products of the bounds, whatever the positions of the cells. For entries of any extent cut $\mathbb{R}^3$ into the half-open cubes P of side $l/(4n)$ of one grid.

As $H \mapsto O_K^T(H) - c(H)$ is linear, $\prod_a (E_a - c(H_a))$ is the sum, over the choices of one cube P_a for each entry, of the products $\prod_a (O_K^T(H_a \mathbf{1}_{P_a}) - c(H_a \mathbf{1}_{P_a}))$, whose pieces $H_a \mathbf{1}_{P_a}$ are bounded weights; at most $(4n\varrho_0/l + 2)^{3n}$ of these products are not 0. For each, in every coordinate the offsets of the board that put a wall within δ' of one of the n pieces have a measure at most $l/2$ in a period, so an offset in $a_K\mathbb{Z}^3$ puts every piece into one cell at distance $\ge \delta'$ from the walls, and two pieces of different entries lie $\ge 2\delta'$ apart; the bounds above, in the occupied cells, give $C_n^{\mathrm{loc}} \prod_a |H_a|_\infty$ for the mean of $\prod_a (E_a - c(H_a))$ under ν.

At $l = 1$, with $c_a = c(H_a)$, $\prod_a (E_a - \nu'(E_a)) = \sum_J \prod_{a\notin J}(c_a - \nu'(E_a)) \prod_{a\in J}(E_a - c_a)$ and $|c_a - \nu'(E_a)| = |\nu'(E_a - c_a)| \le C_1^{\mathrm{loc}}|H_a|_\infty$, this gives C_n^{lc}. (b) Let $\mathfrak O$ be the finite unions of open cubes with rational corners, and for $O \in \mathfrak O$ let $\mathfrak D_O$ be a countable sup-dense subset of $C_c^1(O; V)$. A diagonal subsequence converges at every tuple with entries in the $\mathfrak D_{O_a}$, $O_a \in \mathfrak O$ with disjoint closures, and has convergent labels, which lie in the bounded window and converge in its closure; by (a) and multilinearity the lattice correlations at any tuple are Cauchy. The same for continuous weights. (c) Symmetry, multilinearity, $\sigma(\emptyset) = 1$, $\sigma((H)) = 0$ and the bound pass to the limit. ν_j is invariant under $a_{K_j}\mathbb{Z}^3 \rtimes W_3$, and real translations are reached by moving the entries, $|\tau_v H - \tau_{v_j} H|_\infty \le \operatorname{Lip} H |v - v_j|$. ν_j is reflection positive at the lattice planes $\{n \cdot x = c'\}$ of the nine families with $c' \in n \cdot (a_{K_j}\mathbb{Z}^3)$, that is $c' \in a_{K_j}\mathbb{Z}$ at the coordinate normals and $c' \in a_{K_j}\mathbb{Z}/\sqrt{2}$ at the diagonal ones, and at the bond mirrors $\{x_\mu = c'\}$, $c' \in a_{K_j}(\mathbb{Z} + \frac12)$, among them the plane $x_3 = \frac12 a_{K_j}$ (Proposition YMM1:103.4); the lattice observables turn with the reflection as the weights do; taking $c_j \to c$ in $n \cdot (a_{K_j}\mathbb{Z}^3)$ gives positivity at every c. $O_K^T(f\mathbf{1})$ is the action density, so the trace part is the scalar limit. (d) The proofs of (a)–(c) use of ν_j only that it is a periodic Gibbs state, and of the centring constants only that they are invariant under the lattice isometries and bounded as in (a); so they hold for ρ_j. The one-point function is $\rho_j(O_K^T(H)) - \nu_j(O_K^T(H)) = (e_{\rho_j} - e_{\nu_j}) a_K^{-1} \sum_p H_{\lambda(p)\lambda(p)}(x(p))$, e the means of the plaquette squares a_p, the bond forms having mean 0; at $H = f\mathbf{1}$ it tends to $c_\xi \int f$, and $a_K^3 \sum_{p:\lambda(p)=\lambda} H_{\lambda\lambda}(x(p)) \to \int H_{\lambda\lambda}$. (e) The bounds hold on the tori with $\ell \ge \ell'$, whose Wilson measures are invariant under the lattice isometries and reflection positive at the coordinate planes of the torus. □

Proposition 6.14 (The reconstructed operators)**.** Let σ be a tensor limit at $0 < g \le \gamma_W^{\mathrm{ref}}$.

(a) $\mathcal{H}(\sigma)$ is separable; e^{-tH}, $e^{iv\cdot P}$ and $\mathcal{P}$ are as in Lemma 6.3, $H\Omega = 0$; and $\mathcal{P}(\{E < \max(|q_1|,|q_2|)\}) = 0$.

(b) The eight $w \in W_3$ with $we_3 = e_3$ act by unitaries $[F] \mapsto [wF]$, a representation of the dihedral group of order eight that commutes with H, fixes Ω and turns the translations. The closed span $\mathcal{H}_0$ of the classes of scalar tuples is $\mathcal{H}(\sigma_0)$ through $[F]_0 \mapsto [F\mathbf{1}]$; it reduces H, P, $\mathcal{P}$ and the dihedral group, and on it the forward cone and the Poincaré representation of the scalar theory hold.

(c) *Slab operators of tuples.* Let $i \in \mathbb{Z}$, $l = a_i$, $v \in \mathbb{R}^2$, $Q = (v,0) + (-\frac{l}{2},\frac{l}{2})^2 \times (0,l)$, and $X = (h_1,\dots,h_n) \in \mathfrak{S}_V(Q)$ with supports at sup distances $\geq \delta$ from ∂Q and $\geq 2\delta$ from one another. Then $B_l(X)[F] = [X \cdot \tau_{le_3}F]$ is bounded, $\|B_l(X)\| \leq C_n^{\mathrm{sl}}(g;l,\delta)\prod_a |h_a|_\infty$, where

$$C_n^{\mathrm{sl}}(g;l,\delta) = \sum_{k=0}^{n} \tbinom{n}{k} (e^{G_g l^3} C_1^\flat)^{n-k} e^{G_g l^3} C_k^\flat, \qquad C_0^\flat = 1,$$

and, for $1 \leq r \leq n$, $C_r^\flat = C_r^\flat(g;l,\delta)$ is a number with $\|D\|_{\mathrm{ch},\ell_l} \leq C_r^\flat \prod_a |H_a|_\infty$ for every product D of r entries $O_K^T(H_a)$ centred at their means on T_{ℓ_l} and carried by one cell of side l, at sup distances $\geq \frac{1}{2}\delta$ from its walls and $\geq \delta$ from one another, uniformly in the first-passage data at g beyond a cutoff; here ℓ_l is the least admissible side with $\ell_l \geq 2l$ (the least admissible side ℓ' if $l \leq \frac{1}{2}\ell'$), and $C_r^\flat$ is formed as the number $C_r^\flat$ of Proposition 6.13(a), with l, $\frac{1}{2}\delta$, ℓ_l in the places of 1, δ', ℓ'. In particular $C_1^{\mathrm{sl}}(g;l,\delta) = (e^{2G_g l^3} + e^{G_g l^3})C_1^\flat \leq 2e^{2G_g l^3} C_1^\flat$. Moreover $B_l(X)\Omega = [X]$, $B_l(X)^* = B_l(\theta_{e_3,l/2}X)$, and $e^{iv'\cdot P}B_l(X)e^{-iv'\cdot P} = B_l(\tau_{(v',0)}X)$.

(d) *Slab operators of one entry.* For every $l > 0$ and $h \in C_c(\{0 < x_3 < l\}; V_{\mathbb{C}})$ (a complex entry taken by its expansion; a continuous one through the limit at continuous weights of Lemma 6.16(d) and the unitary map there, or, what is the same, as the norm limit of the operators of C^1 entries that tend to it in sup norm with supports in a fixed compact set), $B_l(h)[F] = [(h)\cdot\tau_{le_3}F]$ is bounded, $\|B_l(h)\| \leq C^{\mathrm{sl}}(\mathcal{K},l)\, b^{-1}|h|_\infty$ for $\operatorname{supp} h \subset \mathcal{K}$ compact, with a number $C^{\mathrm{sl}}(\mathcal{K},l)$ depending on the constants, g, $\mathcal{K}$ and l; $\langle [F'], B_{l_1}(h_1)\cdots B_{l_n}(h_n)[F]\rangle = \sigma(\theta\bar{F}'\cdot(h_1)\cdot(\tau_{l_1 e_3}h_2)\cdots(\tau_{(l_1+\cdots+l_{n-1})e_3}h_n)\cdot\tau_{(l_1+\cdots+l_n)e_3}F)$; $e^{-tH}B_l(h)e^{-t'H} = B_{l+t+t'}(\tau_{te_3}h)$; $B_l(h)^* = B_l(h^\star)$, $h^\star(x) = \rho(\Theta_{e_3})\overline{h(x_1,x_2,l-x_3)}$, so that a component with r indices equal to 3 acquires the sign $(-1)^r$; $B_l(h)$ turns with the translations along e_1, e_2 and with the dihedral group.

(e) *Point operators.* For $s, s' > 0$ and $e \in V$ there is exactly one bounded operator $B(s,s';e)$, linear in e, with

$$\sigma(\theta(\tau_{se_3}\bar{G}')\cdot(h)\cdot\tau_{s'e_3}G) = \int \langle [G'], e^{i\vec{x}\cdot P}B(s+x_3, s'-x_3; h(x))e^{-i\vec{x}\cdot P}[G]\rangle\, dx$$

for $G, G' \in \mathcal{D}_{e_3}$ and $h \in C_c^1(\{-s < x_3 < s'\}; V)$; $\|B(s,s';e)\| \leq C_{\mathrm{pt}}(\min\{s,s'\})|e|_\infty$ with $C_{\mathrm{pt}}(\eta) = 6(80/l_\eta)^3 C_1^{\mathrm{sl}}(g; l_\eta, l_\eta/16)$, l_η the largest power L^{-i} with $\frac{9}{16}L^{-i} \leq \eta$; $e^{-tH}B(s,s';e)e^{-t'H} = B(s+t, s'+t'; e)$, $B(s,s';e)^* = B(s',s;\rho(\Theta_{e_3})e)$, $(s,s') \mapsto B(s,s';e)$ is norm continuous, and the dihedral group turns e by $\rho(w)$. So $|\sigma(\theta\bar{F}\cdot(h)\cdot F')| \leq C_{\mathrm{pt}}(\eta/2)\|h\|_{L^1}\|[\tau_{-\eta e_3}F]\|\|[\tau_{-\eta e_3}F']\|$ for $\eta \in (0,1]$, $F, F' \in \mathcal{D}_{e_3,\eta}$, $h \in C_c^1(\{|x_3| < \eta/2\}; V)$.

(f) *The product formula.* For $n \geq 1$, $e \in V^n$, $\zeta \in (\mathsf{Tb}^\square)^{n-1}$ and $\varepsilon > 0$ with $\zeta^k - 2\varepsilon e_3 \in \mathsf{Tb}^\square$ for all k,

$$\mathbf{W}_n(\zeta;e) = \langle \Omega, B(\varepsilon,\varepsilon;e_1)\mathsf{E}(\zeta^1 - 2\varepsilon e_3)B(\varepsilon,\varepsilon;e_2)\cdots\mathsf{E}(\zeta^{n-1} - 2\varepsilon e_3)B(\varepsilon,\varepsilon;e_n)\Omega\rangle$$

does not depend on ε; it is holomorphic in ζ, n-linear in e, $|\mathbf{W}_n(\zeta;e)| \leq \prod_k C_{\mathrm{pt}}(\varepsilon)|e_k|_\infty$, and $\sigma(h_1,\dots,h_n) = \int \mathbf{W}_n(x^2 - x^1, \dots, x^n - x^{n-1}; h_1(x^1), \dots, h_n(x^n))\, dx$ for every tuple whose supports are ordered in the third coordinate.

The lifts have (a)–(c), (e), (f) with the same numbers, and (d) with the bound $\|B_l(h)\| \leq C^{\mathrm{sl}}(\mathcal{K},l)\, b^{-1}|h|_\infty + \frac{|c_\xi|}{3}\left|\int \operatorname{tr} h\right|$, c_ξ the number of Theorem W(1). ∎

Proof. (a) The form is positive by (D4) and Hermitian; separability comes from the countable dense family of the proof of Proposition 6.13(b). Lemma 6.3 gives the operators. For the square cone, the lattice steps to the cone, here the five-point inequality of Lemma F.5, give, for ν_j, $t_j \in a_{K_j}\mathbb{N}$ and $k \in \{1,2\}$, $u(0) - 4u(t_j e_3) + u(2t_j e_3) + u(t_j e_3 + t_j e_k) + u(t_j e_3 - t_j e_k) \geq 0$ with $u(w) = \sigma_j(\theta \bar{F} \cdot \tau_w F)$; in the limit $\int f_t \, d\langle \psi, \mathcal{P}\psi\rangle \geq 0$ with $f_t(E,q) = 4e^{-tE}(\sinh^2(tE/2) - \sin^2(tq_k/2))$, first for $\psi = [F]$ and by density for all ψ; at $\psi = \mathcal{P}(\Delta)\psi'$ this gives $f_t \geq 0$ $\mathcal{P}$-almost everywhere for all rational $t > 0$ at once, and $t \downarrow 0$ gives $E \geq |q_k|$. (b) (D3) and $w\theta = \theta w$; $\rho(\Theta_{e_3})\mathbf{1} = \mathbf{1}$ makes the map isometric, and a closed subspace invariant under a self-adjoint semigroup and a unitary group reduces them. (c) The number $C_r^\flat$ exists: the mean on T_{ℓ_l} of the $N = (\ell_l/l)^3$ mirror copies of D is the sum over the partitions without singletons of the products of joint cumulants of centred entries of the same kind, at sup distances $\geq \delta$ from one another, and these are bounded uniformly in the cutoff on every admissible torus by Lemma 6.12(c), with $\frac{1}{2}\delta$ in the place of its δ, $s_a = 60|H_a|_\infty$ and a number that reads the side; on the least torus this is the bound of the proof of Proposition 6.13(a).

Let $\sigma_j(X) = \nu_j(\prod_a (O^T_{K_j}(H_a) - \nu_j(O^T_{K_j}(H_a))))$ be the functional under the limit (18), extended linearly to combinations. In ν_j the multiple reflections in the walls of a board of cells of side l with a wall in the plane $x_3 = \frac{1}{2}a_{K_j}$, one cell of which is $(v_j, 0) + (-\frac{l}{2}, \frac{l}{2})^2 \times (\frac{1}{2}a_{K_j}, \frac{1}{2}a_{K_j} + l)$, $v_j \in a_{K_j}\mathbb{Z}^2$, $v_j \to v$, and holds the entries of X at sup distances $\geq \frac{1}{2}\delta$ from its walls for large j, give

$$|\sigma_j(\theta_{e_3, a_{K_j}/2} \bar{F}' \cdot X \cdot \tau_{l e_3} F)| \leq \|D_j\|_{\mathrm{ch}} \, \sigma_j(\theta_{e_3, a_{K_j}/2} \bar{F}' \cdot F')^{1/2} \sigma_j(\theta_{e_3, a_{K_j}/2} \bar{F} \cdot F)^{1/2},$$

D_j the product of the entries $E_a = O^T_{K_j}(h_a)$ of X centred in ν_j, and $\|D_j\|_{\mathrm{ch}}$ the lower limit of its chessboard seminorms along admissible sides that tend to infinity (the domination of the periodic Gibbs states by the tori, Proposition YMM1:91.9). With c_a the mean of E_a on T_{ℓ_l},

$$D_j = \sum_{J \subset \{1,\dots,n\}} \prod_{a \notin J} (c_a - \nu_j(E_a)) \prod_{a \in J} (E_a - c_a);$$

the chessboard seminorm is subadditive, homogeneous, and equal to $|c|$ at a constant c; on every admissible side $\ell \geq \ell_l$ the chessboard estimates with the pressure gap give $\|\prod_{a\in J}(E_a - c_a)\|_{\mathrm{ch},\ell} \leq e^{G_g l^3} C^\flat_{\#J} \prod_{a\in J} |h_a|_\infty$, and the domination gives $|c_a - \nu_j(E_a)| \leq e^{G_g l^3} C_1^\flat |h_a|_\infty$. So $\|D_j\|_{\mathrm{ch}} \leq C_n^{\mathrm{sl}} \prod_a |h_a|_\infty$. In the limit (Proposition 6.13(c)) the moving mirror $\theta_{e_3, a_{K_j}/2}$ becomes θ, and the lattice correlations become the values of σ; the adjoint follows from $\theta_{e_3, l/2} = \tau_{l e_3}\theta$. (d) A compact $\mathcal{K}$ in the slab is covered by at most $27(\mathrm{diam}_\infty \mathcal{K}/a_i + 2)^3$ cubes $\{|x - z|_\infty \leq \frac{1}{2}a_i - \delta\}$, $\delta = \frac{1}{8}a_i$, at the least i with $a_i \leq \min\{l, \ell'/2, 8\,\mathrm{dist}(\mathcal{K}, \{x_3 \in \{0, l\}\})\}$; a partition of unity cuts h into pieces carried by these cubes, of sup norms at most $|h|_\infty$, and the translations and the semigroup move each cube to the height $z_3 = \frac{1}{2}a_i$.

For one piece: if $g \leq \gamma_W^{\mathrm{sd}}$, the reflections of (c) with one cell give the basic inequality $|\sigma(\theta \bar{F}' \cdot (h) \cdot \tau_{a_i e_3} F)| \leq c(i,\delta) b^{-1} |h|_\infty \|[F']\| \|[F]\|$, where $c(i,\delta)$ is $236 e^{G_g a_i^3}$ times the N-th root, $N = (\ell'/a_i)^3$, of the sum over the partitions of the N mirror copies of the products of the bounds $2^r 60^r k_r^\circ(g,\delta)$, $k_r^\circ(g,\delta)(a_K \beta)^{-r} \prod_a s_a$ with $s_a = 60|h|_\infty$ being the bound of the joint cumulants of r such copies on the least torus, in the form of Lemma 6.12(c) on a small side, which the least side is for $g \leq \gamma_W^{\mathrm{sd}}$; so $C^{\mathrm{sl}}(\mathcal{K}, l) = 27(\mathrm{diam}_\infty \mathcal{K}/a_i + 2)^3 c(i, \frac{1}{8}a_i)$.

If $\gamma_W^{\mathrm{sd}} < g \leq \gamma_W^{\mathrm{ref}}$, (c) at $n = 1$ on the box of side a_i about the cube, with the factor 2 of the real and the imaginary part and $1 \leq L(g^{-2} + \bar{B})b^{-1}$, gives the same with $C^{\mathrm{sl}}(\mathcal{K}, l) = 54(\mathrm{diam}_\infty \mathcal{K}/a_i + 2)^3 C_1^{\mathrm{sl}}(g; a_i, \frac{1}{8}a_i) L(g^{-2} + \bar{B})$. The bound is in the sup norm, so it passes to continuous entries; the rules are identities between values of σ, at continuous entries values of the limit of Lemma 6.16(d), which agrees with σ at the tuples of weights. (e) Fix $l = a_i$, $\delta = l/16$, $Q = (-\frac{l}{2}, \frac{l}{2})^2 \times (0, l)$ and $\omega, \omega' \in \mathcal{H}(\sigma)$; $\mu(h) = \langle e^{-\delta H}\omega', B_l((h)) e^{-\delta H}\omega\rangle$ is a bounded linear form of h in the sup norm, and $\mu(\tau_y h) = \langle e^{-(\delta + y_3)H} e^{-i\vec{y}\cdot P}\omega', B_l((h)) e^{-(\delta - y_3)H} e^{-i\vec{y}\cdot P}\omega\rangle$, which by the

square cone continues holomorphically to $y \in \mathbb{C}^3$ with $|\operatorname{Re} y_3| + |\operatorname{Im} y_1| + |\operatorname{Im} y_2| < \delta$, bounded by $C = C_1^{\mathrm{sl}} \|\omega'\| \|\omega\|$.

Cauchy's estimates bound $\mu(\partial_S h)$ by $(3/\delta)^{|S|} C |h|_\infty$, and the identity

$$\chi \partial_1 \partial_2 \partial_3 f = \sum_S (-1)^{3-|S|} \partial_S [(\partial_{S^c} \chi) f]$$

for a cut-off χ shows that $\partial_1 \partial_2 \partial_3 (\chi \mu)$ is a measure: μ has a bounded Lipschitz density near the centre of Q, and $|\mu(h)| \le 6(5/\delta)^3 C \int |h|_\infty$. Its value at the centre, transported by the translations and the semigroup, defines $B(s, s'; e)$; the formula, the bound and the relations follow. The L^1 bound is the formula at $s = s' = \eta$ with

$$\|B(\eta \pm x_3, \eta \mp x_3; e)\| \le \|B(\eta/2, \eta/2; e)\|.$$

(f) For $h \in C_c^1(\{0 < x_3 < c\}; V)$ the formula gives $[(h) \cdot \tau_{ce_3} G] = \mathsf{A}_c(h)[G]$ with

$$\mathsf{A}_c(h) = \int e^{i\vec{x}\cdot P} B(x_3, c - x_3; h(x)) e^{-i\vec{x}\cdot P} dx;$$

by induction $[X]$ is a product of such operators applied to Ω, and $\sigma(X) = \langle \Omega, [X] \rangle$; $B(s, s'; e) = e^{-(s-\varepsilon)H} B(\varepsilon, \varepsilon; e) e^{-(s'-\varepsilon)H}$ collects the factors into $\mathsf{E}(x^{k+1} - x^k - 2\varepsilon e_3)$, and $\|\mathsf{E}\| \le 1$ on the square tube by the square cone. *Lifts.* For a lift the proofs of (a)–(c), (e), (f) run in its approximants ρ_j, which are periodic Gibbs states, with the entries centred in ν_j, the bounds used being those of every periodic Gibbs state. For (d): by the identity of Theorem W(1), $\sigma_\xi^\sharp = \sigma_\xi^c \circ \mathsf{S}_\xi$ with $\mathsf{S}_\xi(X) = \sum_J \prod_{a \notin J} s_\xi(H_a) X_J$, $s_\xi(H) = \frac{c_\xi}{3} \int \operatorname{tr} H$, and σ_ξ^c is a tensor limit at g; S_ξ is multiplicative and commutes with the bar and with the isometries, so $[F] \mapsto [\mathsf{S}_\xi F]$ is a unitary map of $\mathcal{H}(\sigma_\xi^\sharp)$ onto $\mathcal{H}(\sigma_\xi^c)$ that intertwines e^{-tH}, the translations and the dihedral group, and it carries $B_l(h)$ to $B_l^c(h) + s_\xi(h) e^{-lH}$, as

$$\mathsf{S}_\xi((h) \cdot \tau_{le_3} F) = (h) \cdot \tau_{le_3} \mathsf{S}_\xi F + s_\xi(h)\, \tau_{le_3} \mathsf{S}_\xi F;$$

(d) for σ_ξ^c gives the bound. At the components of the decomposition this algebra is Proposition 6.27(d). □

Proposition 6.15 (The two-point law at short distance)**.** Let $0 < g \le \gamma_W^{\mathrm{ref}}$. There are $d_0(g) > 0$ and a function $\epsilon_g(d) \to 0$ as $d \to 0$, with $\sup_{0<d<d_0(g)} (\log \frac{1}{d})^{\mathfrak{p}_0/4} \epsilon_g(d) < \infty$, depending on the constants and g alone, such that for every tensor limit σ at g with label b, every $0 < d < d_0(g)$, all x_0, y_0 with $3d \le |x_0 - y_0| \le 4d$ and all weights H_1, H_2 supported in closed balls of radius less than d about x_0, y_0:

$$|\sigma(H_1, H_2) - b^{-2} \mathcal{W}(H_1, H_2)| \le \epsilon_g(d)\, b^{-2} |H_1|_\infty |H_2|_\infty, \qquad \mathcal{W}(H_1, H_2) = \tfrac{3}{2} \iint \operatorname{tr}[H_1(x) K_3(x - y) H_2(y) K_3(x - y)]\, dx\, dy,$$

$K_3(u) = \partial\partial(4\pi|u|)^{-1} = (4\pi|u|^3)^{-1}(3\hat{u}\hat{u}^{\mathrm{t}} - \mathbf{1})$ for $u \neq 0$, $\hat{u} = u/|u|$, read off 0 alone as in Theorem V(f)(i). The same holds at a finite cutoff with two further errors, one for all the volumes: for every first-passage datum (K, β) at g with $K \ge K_0(g, d)$, $b = a_K \beta$, in every periodic Gibbs state and under the Wilson measure of every admissible torus T_ℓ (the weights read on T_ℓ, and $\mathcal{W}$ formed at their lifts to balls about lifts of x_0, y_0 at the distance $|x_0 - y_0|$), and for continuous H_1, H_2 carried by closed balls of a radius $d_- < d$ with $4a_K \le d - d_-$,

$$\big|\langle O_K^T(H_1); O_K^T(H_2) \rangle - b^{-2} \mathcal{W}(H_1, H_2)\big| \le b^{-2} \big[(\epsilon_g(d) + C_g (a_K/d)^2) |H_1|_\infty |H_2|_\infty + r_K(H_1, H_2)\big],$$

with a number C_g depending on the constants and g, and a number $r_K(H_1, H_2) \ge 0$ that reads K, d and the moduli of continuity of H_1, H_2 alone and tends to 0 as $K \to \infty$; none of the errors reads β, the side or the state. Consequently:

(a) The label exists along every Gibbs sequence with a tensor limit, and σ determines it: with a fixed bump $\varphi \geq 0$ supported in the ball of radius $\frac{1}{2}$ about 0, $\varphi_i^d(x) = \varphi((x - x_i)/d)$ and $x_2 - x_1 = \frac{7}{2} d e_3$, $\mathcal{W}(\varphi_1^d o_{12}, \varphi_2^d o_{12})$ is a positive number independent of d ($\mathcal{W}$ is invariant under dilations), and $b^{-2} = \lim_{d \downarrow 0} \sigma(\varphi_1^d o_{12}, \varphi_2^d o_{12}) / \mathcal{W}(\varphi_1^d o_{12}, \varphi_2^d o_{12})$.

(b) With $w_0 = \frac{1}{12} 388^{-6}$, for d with $\epsilon_g(d) < w_0$, the reflection θ' in a plane $\{x_\mu = c\}$ with $|c - x_{0,\mu}| = \frac{3}{2} d$, and $\varphi \in C_c^1$, $0 \leq \varphi \leq 1$, equal to 1 on $B(x_0, d/128)$ and to 0 off $B(x_0, d/64)$: $\sigma(\theta'(\varphi E), \varphi E) \geq (w_0 - \epsilon_g(d)) b^{-2} \operatorname{tr} E^2$ for every $E \in V$.

(c) $|\sigma(rH_1, rH_2) - \sigma(H_1, H_2)| \leq 10\, \epsilon_g(d) b^{-2} |H_1|_\infty |H_2|_\infty$ for every rotation r about x_0.

(d) If $Z = a P_A + e P_E + z P_T$ and $\sigma(ZH_1, ZH_2)$ obeys the same law with the same b and an error $\epsilon'(d) \to 0$, then $a = e = z \in \{1, -1\}$.

Moreover, for $0 < g \leq \gamma_W^{\mathrm{sd}}$:

(e) for $0 < d < 1$ and real off-diagonal $h = h_0 o_{\mu\nu}$ with h_0 supported in $B(x_0, d)$, $x_{0,3} \in [\frac{3}{2} d, 2d]$: $\|[(h)]\|^2 = \sigma(\theta h, h) \leq C_\infty(g) b^{-2} |h|_\infty^2$, $C_\infty(g)$ depending on the constants and g alone;

(f) for every weight h supported in a ball of radius d at height at least $\frac{3}{2} d$: $\|[(h)]\|^2 \leq C(g) d^{-2} (\log \frac{1}{d})^{20 \mathfrak{p}_0} b^{-2} |h|_\infty^2$ for small d.

■

Proof. Let first $g \leq \gamma_W^{\mathrm{sd}}$, so that the least admissible side is small. On the least admissible torus, Theorem YMM1:D gives the moments of several close pairs of quadratic observables (plaquette squares and bond forms with bounded coefficients, the bond forms entering the progression as sources, Lemma 6.12(a), (b)), centred at their means, that are far from one another: the renormalisation progression shows that the conditional mean given the block field is a constant plus something small, and the sum rule among the construction results, the exact decomposition of a mean by the level at which a large-field region is first created (equation (314)), shows that the true mean is as close to that constant; the value on the least torus is the Gaussian term of Lemma 6.12(c) at the kernels t_{H_1}, t_{H_2} of Lemma 6.12(a), the plaquettes of S_{H_1} and of S_{H_2} lying within the distance $d - 2a_K$ of x_0 and of y_0 once $4a_K \leq d - d_-$, $d_- < d$ the radius of the balls that carry the weights, and comparing the lattice Gaussian term with $\mathcal{W}$ gives $b^{-2}\mathcal{W}$ up to errors that tend to 0 with d, besides two errors of a finite cutoff, $C_g(a_K/d)^2$ from the lattice kernel and r_K from the moduli of continuity of the weights at the scale a_K, which tend to 0 as $K \to \infty$ and read neither β nor the side.

The chessboard estimate then bounds, in any periodic Gibbs state or larger torus, the mean of a function of one cell of the board of eight cells of side $l = \frac{1}{2}\ell'$ by $e^{G_g l^3}$ times the eighth root of the mean, on the least torus, of the product of its eight mirror images; applied to the centred product minus its mean, the products of means cancel and what is left tends to 0 with d, at the rate of the eighth root, $(\log \frac{1}{d})^{-\mathfrak{p}_0/4}$; the difference of the means between volumes is small by the same estimate applied to one centred field (Theorems YMM1:AJ and YMM1:AD enter through G_g). This gives the law for $g \leq \gamma_W^{\mathrm{sd}}$, at a finite cutoff in every volume and, as $K \to \infty$, for σ, with $d_0(g)$ a negative power of L fixed by the depth at which the progression is stopped; above, the dilation of Lemma 6.16(c) carries it over with $d_0(g) = L^{-z} \min_s d_0(g'_s)$, as $\mathcal{W}(H_1^{(z)}, H_2^{(z)}) = \mathcal{W}(H_1, H_2)$ and $\sigma(X) = L^{2z} \sigma_z(X^{(z)})$ at two entries; at a finite cutoff it carries (K, β) to $(K - z, \beta)$, T_ℓ to the admissible torus $T_{L^z \ell}$ and the periodic Gibbs states to periodic Gibbs states, with $a_{K-z}/(L^z d) = a_K/d$. (a) Two limit points of the bounded labels give two laws for one σ; at $E = o_{12}$ and $x_2 - x_1 \parallel e_3$ the kernel of $\mathcal{W}$ is $3(4\pi|x - y|^3)^{-2} > 0$. (b) is the law with the computation $\mathcal{W}(\theta'(\varphi E), \varphi E) \geq w_0 \operatorname{tr} E^2$. (c) $\mathcal{W}$ is invariant under O(3), and two applications of the law. (d) Compare the two laws on pairs within each of the three blocks and across them. (e) is the two-point bound at short distance in every periodic Gibbs state at off-diagonal labels, whose means vanish, carried to the limit: at the off-diagonal weights the bond forms enter the small-field progression and the term of the never-large histories as sources under the majorant $(59 \sup|\mathsf{w}|, S[\mathsf{w}])$, $S[\mathsf{w}]$ the plaquettes that contain a bond where $\mathsf{w} \neq 0$, and their second order at small fields as a quadratic form in the plaquette angles of

$S[\mathsf{w}]$ with a kernel whose row sums lie under the same majorant (Lemma 6.12(a), (b)); the second cumulant of Lemma 6.12(c) gives the bound with a number that does not depend on d. (f) follows from the law.

Let $d < d_0(g)$, and cut h by a partition of unity into a fixed number m_0 of pieces carried by balls of radius $\frac14 d$ with centres in the ball of radius d that carries h; the centres are at heights $y_3 \geq \frac12 d$. As e^{-tH} is a contraction, the norm of the class of a piece is at most that of the class of the same piece moved down to the height $y_3' = \min\{y_3, d\} \in [\frac12 d, d]$. There the law applies to the piece k and its mirror image θk, at the parameter $d'' = \frac47 y_3' < d_0(g)$: the radius $\frac14 d$ is less than d'', and the centres are $2y_3' = \frac72 d''$ apart. For weights carried by balls of radius less than d'' whose centres are at least $3d''$ apart, $|K_3(u)_{\lambda\lambda'}| \leq (2\pi|u|^3)^{-1}$ gives $|\mathcal{W}(H_1, H_2)| \leq \frac32 \cdot 81(2\pi d''^3)^{-2}(\frac43 \pi d''^3)^2 |H_1|_\infty |H_2|_\infty = 54|H_1|_\infty|H_2|_\infty$.

So $\|[(k)]\|^2 = \sigma(\theta k, k) \leq (54 + \bar\epsilon_g) b^{-2}|h|_\infty^2$, $\bar\epsilon_g = \sup_{0<d<d_0(g)} \epsilon_g(d)$, and $\|[(h)]\|^2 \leq m_0^2(54 + \bar\epsilon_g) b^{-2}|h|_\infty^2$, at all six labels, which is below the bound of (f) for small d. □

Lemma 6.16 (Exact dilation)**.** Let $z \in \mathbb{N}$.

(a) For $K \geq z+1$ and bounded H of bounded support, $O_K^T(H)(U) = L^z O_{K-z}^T(H^{(z)})(U^{(z)})$, $U^{(z)}$ the configuration carried to $a_{K-z}\mathbb{Z}^3$ by $x \mapsto L^z x$. The map $X \mapsto X^{(z)}$ is a bijection of $\mathfrak{S}_V(O)$ onto $\mathfrak{S}_V(L^z O)$, keeps sup norms, commutes with O(3), and $(\tau_v H)^{(z)} = \tau_{L^z v} H^{(z)}$, $(\theta_{n,c} H)^{(z)} = \theta_{n,L^z c} H^{(z)}$, $\|H^{(z)}\|_{L^1} = L^{3z}\|H\|_{L^1}$, $(H^{\mathrm{cons}}[\eta])^{(z)} = H^{\mathrm{cons}}[\eta^{[z]}]$ with $\eta^{[z]}(x) = L^z \eta(L^{-z}x)$; on tori the cumulants of n entries scale by L^{nz}, the side by L^z.

(b) Let $0 < g \leq \gamma$ and σ be a tensor limit at g with label b. Then $g_z = (L^z b/2)^{-1/2} < g$; along a subsequence the dilated sequence $(K_j - z, \beta_j, \nu_j^{(z)})$ is a Gibbs sequence at g_z with a tensor limit σ_z of label $L^z b$, and

$$\sigma(X) = L^{nz}\sigma_z(X^{(z)}) \qquad (X \text{ with } n \text{ entries});$$

$[F]_\sigma \mapsto [S_z F]_{\sigma_z}$, with S_z multiplying every entry by L^z after dilating it, is unitary and carries e^{-tH} to $e^{-L^z t H_z}$. Moreover $g_z \leq \gamma_W^{\mathrm{sd}}$ once z exceeds a number depending on the constants and g. The same holds at continuous weights.

(c) Let $0 < g \leq \gamma_W^{\mathrm{ref}}$, $t_1 = L^z g^{-2} - \bar B$, $t_2 = L^{z+1} g^{-2} - 3\bar B$ and $g_s' = t_s^{-1/2}$. For every first-passage datum (K, β) at g with $K \geq z+1$, $(K - z, \beta)$ is a first-passage datum at g_1' or at g_2'; $L^z \ell$ is admissible at g_s' for every side ℓ admissible at g; and $g_s' \leq \gamma_W^{\mathrm{sd}}$ once z exceeds a number depending on the constants and g.

(d) Let $0 < g \leq \gamma_W^{\mathrm{sd}}$. If the limit (18) of a Gibbs sequence at g exists at all tuples of weights, a subsequence has a label and a limit σ' at all tuples of continuous weights, which agrees with the first limit at the tuples of weights, with the same label; the restriction of a limit at continuous weights to the tuples of weights is a tensor limit; and $[F]_\sigma \mapsto [F]_{\sigma'}$ extends to a unitary map of the two Hilbert spaces that carries Ω, H, the translations and $\mathcal{P}$ into one another. Above γ_W^{sd} the same holds through (c).

■

Proof. (a) The dilation carries $a_K\mathbb{Z}^3$ onto $a_{K-z}\mathbb{Z}^3$, plaquettes, bonds, Haar measure and action onto themselves, and the normalisation a_K^{-1} to $L^z a_{K-z}^{-1}$; the rest is the chain rule: $\nabla\eta^{[z]}(x) = (\nabla\eta)(L^{-z}x)$. (b) By the dilation statements (Propositions YMM1:119.1 and K.1), periodic Gibbs states go to periodic Gibbs states; the datum $(K_j - z, \beta_j)$ passes first at g_z for large j, because its label $L^z a_{K_j}\beta_j$ tends to $L^z b$, which is an inner point of the interval $I(g_z) = (g_z^{-2} + \bar B, L(g_z^{-2} + \bar B) - 2\bar B]$, $g_z^{-2} = L^z b/2$, sufficient for first passage at g_z (Corollary YMM1:74.2 and Lemma G.4); and $b \geq g^{-2}$ gives $g_z^{-2} \geq L^z g^{-2}/2 > g^{-2}$, that is $g_z < g$.

The formula follows from (a), every entry carrying the factor L^z, and the unitarity from $(\theta H)^{(z)} = \theta H^{(z)}$. (c) A pair whose label lies in $I(g')$ is a first-passage datum at g' (Corollary YMM1:74.2). Here $I(g_1') = (L^z g^{-2}, L^{z+1} g^{-2} - 2\bar B]$ and $I(g_2') = (L^{z+1} g^{-2} - 2\bar B, L^{z+2} g^{-2} - (2L+2)\bar B]$, and their

union holds $L^z\mathfrak{b}$ for every $\mathfrak{b}$ in the window $(g^{-2}, L(g^{-2}+\bar{B})]$, as $(L^{z+1}+2L+2)\bar{B} \le L^{z+1}(L-1)g^{-2}$ by $g^{-2} \ge 4\bar{B}$, which holds for $g \le \gamma_W^{\mathrm{ref}}$; the label of $(K-z,\beta)$ is $L^z a_K \beta$. For the sides: $\ell = 2L^m$ is admissible at g if and only if $m \ge m_{\mathfrak{L}}(g) = 1+m'+\max\{\log_L R(L(g^{-2}+\bar{B})), \lceil \log_L C_{\mathrm{s}} \rceil\}$, where $R(x)$ is the least power of L that is $\ge (\log x)^r$ and m', C_{s}, $r \ge 1$ are constants (equation YMM1:(1528)); and $L^z\ell$ is admissible at g' if and only if $m+z \ge m_{\mathfrak{L}}(g')$ (equation YMM1:(1528)).

So it suffices that $R(L(t_s+\bar{B})) \le L^z R(L(g^{-2}+\bar{B}))$. Now $L(t_1+\bar{B}) = L^{z+1}g^{-2}$ and $L(t_2+\bar{B}) = L^{z+2}g^{-2} - 2L\bar{B}$ are at most $L^{z+1}\cdot L(g^{-2}+\bar{B})$; with $y_g = \log(L(g^{-2}+\bar{B}))$,

$$\big((z+1)\log L + y_g\big)^r \le y_g^r\, L^{r(z+1)/y_g} \le y_g^r\, L^z,$$

because $r(z+1) \le 2rz \le y_g z$: at $g \le \gamma_W^{\mathrm{ref}}$ one has $y_g \ge \log g^{-2} \ge 2\mathfrak{p}_0 > 3r+2$, by the logarithmic lower bounds in the reference choice preceding equation YMM1:(2326) and the exponent choice $r \ge 2$, $\mathfrak{p}_0 \ge 6r+1$ in Theorem YMM1:D. So $L^z R(L(g^{-2}+\bar{B}))$ is a power of L that is $\ge (\log L(t_s+\bar{B}))^r$, and it is $\ge R(L(t_s+\bar{B}))$. The least side grows like a power of $\log g^{-2}$, the dilation like L^z. Finally $t_2 > t_1 \ge (L^z-1)g^{-2}$ gives $g_2' < g_1' < g$ and the last assertion. (d) The bound of Proposition 6.13(a) holds for bounded weights uniformly in the cutoff; a diagonal extraction over a countable family of continuous tuples, dense in sup norm with controlled supports, gives the subsequence, and at the tuples of weights the full sequence converges already; identities and inequalities between values pass, and so do the Hilbert spaces. □

Proposition 6.17 (A power bound for one tensor entry)**.** Let $0 < g \le \gamma_W^{\mathrm{ref}}$, $p_T > 11/2$ and $0 < \delta \le \frac{1}{4}$. There are i_0, $K_0(i)$ and C_T, depending on the constants, g, p_T and δ, such that for every integer $i \ge i_0$, every first-passage datum (K,β) at g with $K \ge K_0(i)$, every board of cells of side a_i, every cell $\square$, every side ℓ admissible at g, and every bounded $H : \mathbb{R}^3 \to V_{\mathbb{C}}$ vanishing at the points within sup distance δa_i of the complement of $\square$,

$$\|O_K^T(H) - c\|_{\mathrm{ch},\ell} \le C_T L^{p_T i} |H|_\infty,$$

c the mean of $O_K^T(H)$ on an admissible torus or in a periodic Gibbs state. For $g \le \gamma_W^{\mathrm{sd}}$ this holds for every $i \ge 1$ and $K \ge K_E(i)$ in the form $\|O_K^T(H) - c\|_{\mathrm{ch},\ell} \le 2C_E \mathsf{Y}_i^{q_E} L^{(11/2)i} b^{-1} |H|_\infty$, $b = a_K\beta$, $\mathsf{Y}_i = 2(c_E + i\log L)$, where $c_E = \log(2L(g^{-2}+\bar{B}))$ and q_E, the latter formed from the constants alone, do not depend on δ, C_E is δ^{-4} times a number depending on the constants and g, of the order $\delta^{-4}e^{G_g}$, and besides that δ enters only $K_E(i)$, which depends on the constants, g and δ. Consequently, for $g \le \gamma_W^{\mathrm{sd}}$:

(i) for entries H_a carried by different cells of one board of side a_i, at the margin δa_i, and $\nu, \nu' \in \mathcal{G}_{K,\beta}^{\mathrm{per}}$: $|\nu(\prod_a (O_K^T(H_a) - \nu'(O_K^T(H_a))))| \le \prod_a 2e^{G_g} C_E \mathsf{Y}_i^{q_E} L^{(11/2)i} b^{-1} |H_a|_\infty$, with no factorial and no order of the cells;

(ii) every tensor limit at g has $\|B_{a_i}(h)\| \le c_E(i) b^{-1} |h|_\infty$ for h supported in $\{|x-z|_\infty \le \frac{3}{8}a_i\}$, $z_3 = \frac{1}{2}a_i$, with $c_E(i) = 2C_E \mathsf{Y}_i^{q_E} a_i^{-11/2}$ at $\delta = \frac{1}{16}$;

(iii) every tensor limit at g has, for every $p > 17/2$, $0 \le d' < d$ and $h \in C_c(\mathbb{R}^3; V_{\mathbb{C}})$ supported in $\{|x_3| \le d'\}$ (a complex entry taken by its expansion, a continuous one through Lemma 6.16(d)),

$$\|B_{2d}(\tau_{de_3} h)\| \le C_p \min\{1, d-d'\}^{-p}\, b^{-1} \|h\|_{L^1},$$

C_p depending on the constants, g and p alone; so (R4) of Proposition 6.24 holds with $C_V = 2^p C_p b^{-1} \le 2^p C_p g^2$; and for $0 < \eta \le 1$, $C_{\mathrm{pt}}(\eta) \le 12 \cdot 80^3 e^{2G_g} C_T' (9L/16)^{3+p_T} \eta^{-3-p_T}$, where C_T' is the larger of the number C_T of the first display at $\delta = \frac{1}{32}$ and of the finitely many numbers $L^{-ip_T} C_1^{\flat}(g; a_i, \frac{1}{16}a_i)$, $0 \le i < i_0$, of Proposition 6.14(c).

For $\gamma_W^{\mathrm{sd}} < g \le \gamma_W^{\mathrm{ref}}$, (iii) holds with C_p depending on the constants, g and p, which includes the factor L^{4z} of the dilation. ■

Proof. Let first $g \le \gamma_W^{\mathrm{sd}}$ and $i \ge 1$. Let $x_\bullet$ be the run of (K,β), $K' = K - i$, and let $g_{(i)}$ be the stopped coupling, $g_{(i)}^{-2} = L^{-1}x_{K'} - B_\sharp$ (equation YMM1:(1536)): then $g_{(i)} < g$, (K',β) is a first-passage datum at $g_{(i)}$, $L^i\ell$ is admissible at $g_{(i)}$ for every side ℓ admissible at g, and $G_{g_{(i)}} \le G_g + \frac{9}{2} i \log L + \frac{1}{8}$, one constant alone of the pressure gap reading the coupling (Corollary YMM1:74.3 and Lemma G.3). The exact dilation by L^i (Lemma 6.16(a)) carries the board of side a_i at (K,β) to a board of side 1 at (K',β), the entry $O_K^T(H)$ to $L^i O_{K'}^T(H')$ with H' vanishing within δ of the complement of its unit cell, and the chessboard seminorm on T_ℓ at (K,β) to that on $T_{L^i\ell}$ at (K',β).

Let F' be one of the four real pieces of $O_{K'}^T(H')$ (the plaquette and the bond part of the real and of the imaginary part of H'), a source under a majorant (s, S) with $\mathsf{s} \le 59|H|_\infty$ (Lemma 6.12(a)). Let ℓ'' be the least admissible side at $g_{(i)}$; it is small over the run of (K',β) (Lemma YMM1:126.3, as $g_{(i)} < g \le \gamma_W^{\mathrm{sd}}$), and it has $N = \ell''^3$ cells of side 1, with $N \le C(\log \frac{1}{a_i})^{2\mathfrak{p}_0 - 1}$ by the condition (Sd.4) of a small side. The chessboard seminorm of $F' - m_0$ on $T_{\ell''}$, m_0 the mean of F' there, is the N-th root of the mean of the product of the N mirror copies $F_\kappa - m_0$, and the copies F_κ are sources under majorants (s, S_κ) whose sets lie in N different cells, at sup distances $\ge \delta$ from one another. *The moments.* For every set B of copies,

$$\Big|\Big\langle \prod_{\kappa\in B} (F_\kappa - c_\kappa)\Big\rangle_{K',\ell'',\beta}\Big| \le (\mathsf{As})^{\#B}, \qquad \mathsf{A} = 2N\mathsf{C}_1 L^{4s},$$

with numbers c_κ, a number C_1 depending on the constants alone, and s the depth below K' of the level $\mathsf{k} = K' - s$ at which two different sets are $M\mathsf{u}(N)$ units of the level apart, $\mathsf{u}(N)$ a number of the constants and N that grows like $N \log N$; so L^s is at most a power of $\log \frac{1}{a_i}$ divided by δ. Indeed, by the sum rule of the first creation (equation (314)) the mean is the term of the never-large history up to the level k plus the sum, over the level $t \le \mathsf{k}$ of the first creation of a large field, of its weight w_t times an integral along the never-large history of the quotient of the product, the conditional mean given the block field; by Lemma 6.12(b) the quotient of $e^{\sum \lambda_\kappa F_\kappa}$ is $e^{D_t^\lambda}$, so that of the centred product is a sum over the partitions of B of products of derivatives of D_t^λ at $\lambda = 0$; a block of one element is at most the size of one source at the level t, $\mathsf{C}_1 L^{4(K'-t)}\mathsf{s}$, a block of $m \ge 2$ elements is a sum of mixed derivative families on polymers that join m different cells, which the separation of the cells makes small enough to pay the factor $(4m)^m$, and a set of r elements has at most r^r partitions.

The large fields are paid by their rarity on the small side: $\mathsf{w}_t \le 2M^{-3}\ell''^3 L^{3(K'-t)} e^{-\frac{1}{2}c' p_0(g_t)^2}$ (Lemma YMM1:125.3, which rests on the rarity of large fields, Proposition M.2 and Proposition L.6), $p_0(g_t)$ the large-field threshold at the running coupling g_t of the level t, and the condition $(\frac{9}{2}\log x_{K'} + 2)\ell''^3 \le \frac{1}{2}c' p_0(g_{K'})^2$ of a small side gives $\sum_{t\le K'} L^{4(K'-t+1)r}\mathsf{w}_t \le 1$ for every $r \le \ell''^3$: the rarity pays the sizes of as many sources as the side has unit cells. This is Theorem YMM1:D; Theorems YMM1:AJ and YMM1:AD do not enter the moments. *The seminorm.* At B of one element $|m_0 - c_\kappa| \le \mathsf{As}$, and the expansion of $\prod_\kappa (F_\kappa - m_0)$ about the c_κ gives $\|F' - m_0\|_{\mathrm{ch},\ell''} \le 2\mathsf{As}$: the moment contributes a power of $\log \frac{1}{a_i}$ alone. Back to every admissible side $L^i\ell$ at $g_{(i)}$ the chessboard estimate pays the pressure gap of one unit cell at the stopped coupling, $e^{G_{g_{(i)}}} \le e^{G_g + \frac{1}{8}} L^{\frac{9}{2}i}$ (Theorems YMM1:AJ and YMM1:AD, at zero source); the dilation pays L^i; the re-centring at the mean of the entry on an admissible torus or in a periodic Gibbs state pays 2 (the domination of the periodic Gibbs states by the tori); and $1 \le L(g^{-2} + \bar{B})b^{-1}$.

So the exponent is $\frac{11}{2} = 1 + \frac{9}{2}$, 1 from the dilation and $\frac{9}{2}$ from the pressure gap, and the four pieces, of sizes at most 1, 59, 1, 59 times $|H|_\infty$, give the factor $480 = 4(1 + 59 + 1 + 59)$ in C_E, which with $\mathsf{A} \le c\mathsf{Y}_i^{q_E}\delta^{-4}$ is of the order $\delta^{-4}e^{G_g}$. (i) The domination of the periodic Gibbs states by the tori bounds a product over several cells by the product of the seminorms. (ii) The multiple reflections of Proposition 6.14(c) with one cell. (iii) Let $\vartheta = d - d'$ and $i(\vartheta)$ the least $i \ge i_0$ with $a_i \le \vartheta$. A sup bound becomes an L^1 bound on a cube $Q = \{|x - z|_\infty \le \varrho\}$: if b maps $C_c(Q)$ linearly into bounded operators with $\|\mathsf{b}(g)\| \le c \sup|g|$, $\varepsilon \ge 12\varrho$, and $\mathsf{B}^\varepsilon(g) = e^{-\varepsilon H}\mathsf{b}(g)e^{-\varepsilon H}$ turns with the

translations by $|u|_\infty \le 2\varrho$ as the point operators do, then writing h as an integral of translates of pieces $\chi(\cdot)h(\cdot+u)$ and using the square cone to control the factors $e^{\pm u_3 H}$ against the margin $e^{-\varepsilon H}$ gives $\|\mathsf{B}^\varepsilon(h)\| \le 4c\varrho^{-3}\|h\|_{L^1}$.

For $\vartheta < a_{i_0}$ the minimality gives $a_{i(\vartheta)} > \vartheta/L$; otherwise $i(\vartheta) = i_0$. Thus the preceding estimate gives $\|B_{2d}(\tau_{de_3}h)\| \le 4\cdot 32^3 a_{i(\vartheta)}^{-3} c_E(i(\vartheta))b^{-1}\|h\|_{L^1}$, and $a_{i(\vartheta)}^{-3-11/2}\mathsf{Y}^{q_E} \le C_p \min\{1,\vartheta\}^{-p}$ for every $p > 17/2 = \frac{11}{2}+3$; with $d=\eta$, $d'=\eta/2$ this is (R4). The bound of C_{pt}: for $0<\eta\le 1$, $l_\eta = a_i$ with $i \ge 0$, so $e^{G_g l_\eta^3} \le e^{G_g}$ and $C_1^{\mathrm{sl}}(g; l_\eta, \frac{1}{16}l_\eta) \le 2e^{2G_g} C_1^\flat(g; l_\eta, \frac{1}{16}l_\eta)$, the number $C_1^\flat$ being formed at the margin $\frac{1}{32}l_\eta$; the first display at $\delta = \frac{1}{32}$ for $i \ge i_0$, and the finitely many numbers of Proposition 6.14(c) for $0 \le i < i_0$, give $C_1^\flat(g; a_i, \frac{1}{16}a_i) \le C_T' L^{p_T i}$; and $l_\eta^{-1} < 9L/(16\eta)$, as $\frac{9}{16}Ll_\eta > \eta$.

For $\gamma_W^{\mathrm{sd}} < g \le \gamma_W^{\mathrm{ref}}$, Lemma 6.16(c) carries data, boards and seminorms at g to the couplings g_1', g_2', and the dilation of an entry costs L^z and of the L^1 norm L^{3z}. □

6.7. **Conservation and covariance.**

Lemma 6.18 (The cubic remainder after the small scales)**.** Let $0 < g \le \gamma_W^{\mathrm{sd}}$, $0 < \tau \le \frac14$, $0 < \phi < \frac{1}{42}$ and $c' = \min\{\frac{1}{14} - \frac{\tau}{7}, \frac{1}{14} - 3\phi\}$; for $\phi < \frac{1}{30}$ one may take $c' = \min\{\frac{1}{10} - \frac{\tau}{5}, \frac{1}{10} - 3\phi\}$. Fix an admissible torus, let $K \ge K_0$, let b' lie in the window of labels at g, $\beta = L^K b'$, and $t = K - \lceil \phi K \rceil$. Let $S[\Xi] = \sum_p L^{2K} \Xi^{\rho(p)}(x(p))\, \mathfrak{r}^\sharp_{\rho(p)}(p)$ be the cubic lattice entry of a field $\Xi = (\Xi^1, \Xi^2, \Xi^3)$ of directions on the torus, three real functions of the centres of the plaquettes, and $\mathsf{H}(\Xi) = \max\sup|\Xi| + \max \mathrm{Lip}\,\Xi$. Here $\mathfrak{r}^\sharp$ is defined by (294). By Proposition H.1, it is a gauge invariant polynomial on the two adjacent cubes, is cubic in the plaquette defects on the complex bond domain, and satisfies $|\mathfrak{r}^\sharp_\rho(p)| \le c_{\mathrm{orb}}\mu^3$ on real configurations whose eleven plaquette matrices are within μ of the identity.

A *box* is a set $Q = \{x + a_K \sum_\mu n_\mu e_\mu : 0 \le n_\mu \le r_\mu\}$ of bare sites with $r \in \{0,1,2\}^3$ and two $r_\mu \ge 1$; a *density* on Q is a polynomial j in the entries of the bond variables of Q, read also at $SL(2,\mathbb{C})$-valued configurations and invariant under the gauge transformations on Q; it has the *height* $\hat c$ if $|\mathsf{j}| \le \hat c$ where the bond variables of Q have operator norms ≤ 2, and the *order* m with the constant c if besides $|\mathsf{j}| \le c\,\varrho^m$ where $|\partial U(q) - \mathbf{1}| \le \varrho \le 1$ at the plaquettes q of Q. A *local entry* of the type $(m, c, \hat c, N)$, of the order m, is a finite family $\mathfrak{J} = (Q_\iota, \mathsf{j}_\iota, \varkappa_\iota)_\iota$ of boxes, densities on them of the height $\hat c$ and the order m with the constant c, and complex coefficients, at most N boxes having one lowest site; it is read as $\mathfrak{J}(U) = \sum_\iota \varkappa_\iota \mathsf{j}_\iota(U|_{Q_\iota})$, and $|\varkappa|_\infty = \max_\iota |\varkappa_\iota|$.

Small $|s|$ means $|s| < r_{\mathfrak{J}}$, a number formed with the type, $|\varkappa|_\infty$ and the first coupling $x_0 = \beta$ of the run, of the order $1/|\varkappa|_\infty$, for which $s\mathfrak{J}$ stays within the room of the progression. So $S[\Xi]$ is a local entry of the order three, the boxes being the pairs of cubes with a common face. There are K_0, C and p, depending on the constants, g, τ, ϕ and the side, such that:

(a) for every local entry $\mathfrak{J}$ of order at least two and small $|s|$, the image under the block maps of level $k \le t$ of the Wilson measure, restricted to the small-field histories and weighted with $e^{s\mathfrak{J}}$, has on the small-field set of level k the density $\exp[\sum_{i\le k} c_i(s)]\, e^{\Phi_k^s}$, with numbers $c_i(s)$ and a bounded function Φ_k^s: the entry enters the renormalisation progression of Theorem YMM1:D as a source;

(b) for every Ξ there is a number $\mathsf{a}(\Xi)$ with $|(\mathsf{Q}_{t\leftarrow 0}S[\Xi])(V) - \mathsf{a}(\Xi)| \le C\,\mathsf{H}(\Xi)K^p L^{-c'K}$ for ν_t-almost every small-field configuration V of level t, $\mathsf{Q}_{t\leftarrow 0}$ the conditional expectation onto the block field of level t along the small-field progression.

■

Proof. (a) The progression of Theorem YMM1:D is set up with sources. A local entry of order at least two is a sum of local terms on the regions of level zero that hold its boxes, and it enters the first step as a further family of local terms at the height 0, as the bond forms do in Lemma 6.12(a): the first block step makes it into its value at the background and one pointed family of level 1, that is, a family of local terms $E(X, \cdot, z)$ on the polymers X of the level, each with a marked site $z \in X$,

measured in a norm with the weight $e^{\kappa d_1(X)}$, $d_1(X)$ the size of X in the units of the level; every further step carries the pointed families of the chain, the families $E^{(i)}$ of the small-field progression, with the families of the entry among them; its order makes these families small at small fields, and for $|s| < r_{\mathfrak{J}}$ they stay within the room of the progression.

The normalisations $c_i(s)$ are the constants that the steps produce, and the image of the measure is the displayed density. (b) Let $\mathsf{Q}_k h = \mathsf{I}[hF_k]/\mathsf{I}[F_k]$ on the small-field set of level $k+1$, F_k the density of the progression at the level k and I the integral over the fluctuation field of the step: the conditional expectation of one step; the tower is $\mathsf{Q}_{n\leftarrow k} = \mathsf{Q}_{n-1}\cdots\mathsf{Q}_k$, and each Q_k is a contraction in the sup norm on the small-field set that carries constants to themselves. Put $\varkappa(p) = L^{2K}\Xi^{\rho(p)}(x(p))$, so that $S[\Xi] = \sum_p \varkappa(p)\mathfrak{r}^{\sharp}_{\rho(p)}(p)$, and let s_n be $S[\Xi]$ read at the background of level n on the small-field set.

To the first order in the source the tower is linear in the weight: $\mathsf{Q}_k\mathsf{s}_k = \mathsf{s}_{k+1} + \Sigma_{k+1}[\mathsf{D}^{(k+1)}[\varkappa]]$, where $\mathsf{D}^{(k+1)}[\varkappa]$ is the pointed family born at the step, linear in $\varkappa$, its member on X reading $\varkappa$ on the plaquettes of X alone, and Σ_{k+1} is the sum of a pointed family over the polymers and their sites, read at the background. Fix a middle level $n_0 = K - \lceil \psi K\rceil$, $\phi < \psi < 1$, and a Hölder exponent $0 \le \beta_{\mathrm{H}} < 1$. Then

$$\mathsf{Q}_{t\leftarrow 0}S[\Xi] = \mathsf{Q}_{t\leftarrow n_0}\mathsf{s}_{n_0} + \sum_{j\le n_0}\mathsf{Q}_{t\leftarrow j}\Sigma_j\big[\mathsf{D}^{(j)}[\varkappa]\big].$$

The entry at n_0. The density is of the order three, and at a background of level n_0 the plaquette variables are within $\varepsilon_{n_0}L^{-2n_0}$ of $\mathbf{1}$, ε_n the small-field radius of the level n; so $\sup|\mathsf{s}_{n_0}|$ is at most a power of K times $L^{-(1-\frac{9}{2}\psi)K}\mathsf{H}(\Xi)$. *The norm of a birth.* The Gaussian integral over the fluctuation field of a step is invariant under $B \mapsto -B$; split into its even and its odd part in B, the birth has an even part of the second order in the fluctuation, of the size g_k^2, and an odd part that meets only the odd part of the base family, of the size $g_k(\log x_k)^{\mathfrak{p}_0}$; so $\|\mathsf{D}^{(k+1)}[\varkappa]\| \le C(\log x_k)^{\mathfrak{p}_0}g_k^2L^{-3k}\max|\varkappa|$, g_k the running coupling and $x_k = g_k^{-2}$. *A family at a background.* The differential of a local term at the trivial configuration vanishes, by its invariance under the constant gauge transformations; so a pointed family of level j, read at a background of level $n \ge j$, differs from its value at the trivial configuration by at most $\varepsilon_n^2L^{-4(n-j)}$ times its norm at each of its sites. With the norm of a birth this leaves, for the level j, $L^{3(K-n)-j}$ up to logarithms, which is not small at $n = t$; the smallness comes from the inversions. *The inversions.* The progression is covariant under the lattice isometries of the levels, and the inversion r_z through a site z of level j changes the sign of the cubic density, so that the birth of the weight $\varkappa$, read at r_zU, is the birth of $-\varkappa\circ\mathsf{r}_z$ read at U. Cut $\varkappa$ into the pieces $\theta_z\varkappa$ about the sites z of level j, with $\sum_z\theta_z = 1$ and $\theta_z\circ\mathsf{r}_z = \theta_z$, and let $\Sigma_z[\varkappa]$ be the sum of the birth of $\theta_z\varkappa$; this gives the exact split

$$\Sigma_z[\varkappa](U) = \tfrac{1}{2}\big(\Sigma_z[\varkappa](U) - \Sigma_z[\varkappa](\mathsf{r}_zU)\big) + \tfrac{1}{2}\Sigma_z[\varkappa - \varkappa\circ\mathsf{r}_z](U).$$

In the first part a background of level n_0 is compared with its mirror image: in a Hölder gauge of exponent β_{H} about z their difference is of the relative order $\vartheta^{\beta_{\mathrm{H}}}$, $\vartheta = L^{-(n_0-j)}$, and the family moves by $\varepsilon_{n_0}^2\vartheta^{4+\beta_{\mathrm{H}}}$ times its norm. In the second part the weight $\varkappa - \varkappa\circ\mathsf{r}_z$ is at most L^{2K} times the Lipschitz constant of Ξ times L^{j-K}, and its family at the background is bounded as above, its value at the trivial configuration being kept in the constant. Together, the births of the levels $j < n_0$, read at n_0 and less the values of their second parts at the trivial configuration, are at most a power of K times $\mathsf{H}(\Xi)L^{3(K-n_0)-j-\beta_{\mathrm{H}}(n_0-j)}$, of the rate $\beta_{\mathrm{H}} - (3+\beta_{\mathrm{H}})\psi$, the second parts alone of the rate $1-3\psi$; and the birth of the level n_0 has the rate $1-4\psi$. *From n_0 to t.* The tower is a contraction in the sup norm, but every step feeds parts of the families that it carries into the families of the chain, each feeding at a level k smaller by $L^{-(K-k)/2}$ up to logarithms. The fed parts are followed along chains of levels $k_1 < \cdots < k_m$, and each chain is stopped at the level $\lceil K - \frac{1}{3}\tau Y\rceil$, $Y = \sum_l(K-k_l)$, where its family is replaced by its value at the trivial configuration and the error of a family at a background; the chains that live have at most a number of τ members, and their errors

have the rates $(\frac{1}{2}-\tau)\psi$ and $\frac{1}{2}\psi-3\phi$. *The constant and the rate.* $\mathsf{a}(\Xi)$ is the sum of the values at the trivial configuration of the second parts of the births of the levels $j<n_0$, of the families of the stopped chains and of the birth of the level n_0; it is real linear in Ξ and reads no configuration. The error is a power of K times $\mathsf{H}(\Xi)L^{-c'K}$, c' the least of the six rates $1-\frac{9}{2}\psi$, $1-4\psi$, $\beta_{\mathrm{H}}-(3+\beta_{\mathrm{H}})\psi$, $1-3\psi$, $(\frac{1}{2}-\tau)\psi$, $\frac{1}{2}\psi-3\phi$. At $(\psi,\beta_{\mathrm{H}})=(\frac{1}{7},\frac{3}{4})$ they are $\frac{5}{14}$, $\frac{3}{7}$, $\frac{3}{14}$, $\frac{4}{7}$, $\frac{1}{14}-\frac{\tau}{7}$, $\frac{1}{14}-3\phi$, and the least is $\min\{\frac{1}{14}-\frac{\tau}{7},\frac{1}{14}-3\phi\}$; at $(\frac{1}{5},\frac{9}{10})$ and $\phi<\frac{1}{30}$ they are $\frac{1}{10}$, $\frac{1}{5}$, $\frac{3}{25}$, $\frac{2}{5}$, $\frac{1}{10}-\frac{\tau}{5}$, $\frac{1}{10}-3\phi$, and the least is $\min\{\frac{1}{10}-\frac{\tau}{5},\frac{1}{10}-3\phi\}$: the two numbers c' of the statement. Theorems YMM1:AJ and YMM1:AD are not used. □

Proposition 6.19 (Conservation of the tensor)**.** (a) Let $0<g\le\gamma_W^{\mathrm{sd}}$, $h_0,R_0>0$ and $c<\frac{1}{10}$. There are C, p, K_0, depending on the constants, g, h_0, R_0 and c, such that for every first-passage datum (K,β) at g with $K\ge K_0$, $b=a_K\beta$, every $\rho\in\mathcal{G}^{\mathrm{per}}_{K,\beta}$ and every $\eta\in C^2(\mathbb{R}^3;\mathbb{R}^3)$ with support in $\{x_3\ge h_0,|x|_\infty\le R_0\}$:

$$0\le\rho(\theta_K\mathcal{T}_K^{\mathrm{lat}}(\eta);\mathcal{T}_K^{\mathrm{lat}}(\eta))\le b^{-2}\big(CK^pL^{-cK}\|\eta\|_{C^2}\big)^2,$$

and $|\rho(\mathcal{T}_K^{\mathrm{lat}}(\eta);Y)|\le b^{-1}CK^pL^{-cK}\|\eta\|_{C^2}\,\rho(\theta_KY;Y)^{1/2}$ for every real bounded local function Y of the bonds in $\{x_3<\frac{1}{2}a_K\}$. Moreover, for every $r>0$ there are C, p, K_0, depending on the constants, g, c and r, such that for every first-passage datum (K,β) at g with $K\ge K_0$, on the least admissible torus with the board of eight cells of side $\frac{1}{2}\ell'$ and any offset in $a_K\mathbb{Z}^3$, and for every C^2 vector field η on $T_{\ell'}$ carried by the points of one cell at sup distances $\ge r$ from its walls,

$$\big\|O_K^T(H^{\mathrm{cons}}[\eta])-m_\eta\big\|_{\mathrm{ch},\ell'}\le CK^pL^{-cK}\|\eta\|_{C^2},\qquad m_\eta\text{ the mean on }T_{\ell'}.$$

Here θ_K is the reflection in the plane $x_3=\frac{1}{2}a_K$, $\rho(F;G)=\rho(FG)-\rho(F)\rho(G)$, and $\mathcal{T}_K^{\mathrm{lat}}(\eta)=O_K^T(H^{\mathrm{cons}}[\eta]+H_K'')$ is the conservation observable formed with the symmetric lattice differences $(\nabla^{\mathrm{s}}_\rho\varphi)(y)=(2a_K)^{-1}[\varphi(y+a_Ke_\rho)-\varphi(y-a_Ke_\rho)]$ and $(\nabla^{\mathrm{c}}_\rho\varphi)(y)=a_K^{-1}[\varphi(y+\frac{1}{2}a_Ke_\rho)-\varphi(y-\frac{1}{2}a_Ke_\rho)]$, $\nabla^{\mathrm{s}}\cdot\eta=\sum_\rho\nabla^{\mathrm{s}}_\rho\eta^\rho$: its plaquette weights are $(\nabla^{\mathrm{s}}\cdot\eta)(x(p))-2(\nabla^{\mathrm{s}}_{\lambda(p)}\eta^{\lambda(p)})(x(p))$ at the centres and its bond weights $-(\nabla^{\mathrm{c}}_{\lambda'}\eta^\lambda+\nabla^{\mathrm{c}}_\lambda\eta^{\lambda'})(x_b)$ at the midpoints, $\lambda<\lambda'$ the two directions other than that of the bond b, the lattice forms of the entries $\nabla\cdot\eta-2\partial_\lambda\eta^\lambda$ and $-(\partial_\lambda\eta^{\lambda'}+\partial_{\lambda'}\eta^\lambda)$ of $H^{\mathrm{cons}}[\eta]$; they differ from these entries by at most $\frac{3}{2}a_K\|\nabla^2\eta\|_\infty$ at the plaquettes and $\frac{1}{2}a_K\|\nabla^2\eta\|_\infty$ at the bonds, so that $|H_K''|_\infty\le\frac{3}{2}a_K\|\nabla^2\eta\|_\infty$.

(b) Let $0<g\le\gamma$, $q\ge2$, $d>0$ and $R>0$. There are C, p, K_0, depending on the constants, g, q, d and R, such that for every first-passage datum (K,β) at g with $K\ge K_0$, every $\nu\in\mathcal{G}^{\mathrm{per}}_{K,\beta}$, every $\eta\in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and all bounded weights $H_2,\dots,H_q$ such that the q supports of $\eta,H_2,\dots,H_q$ lie in a cube of side $2R$ at pairwise sup distances $\ge d$,

$$\Big|\nu\Big(A^\nu[O_K^T(H^{\mathrm{cons}}[\eta])]\prod_{a\ge2}A^\nu[O_K^T(H_a)]\Big)\Big|\le CK^pL^{-K/36}\|\eta\|_{C^2}\prod_{a\ge2}|H_a|_\infty,\qquad A^\nu[F]=F-\nu(F),$$

and the joint cumulant $\langle O_K^T(H^{\mathrm{cons}}[\eta]);O_K^T(H_2);\dots;O_K^T(H_q)\rangle$ under ν obeys the same bound. On a torus T_ℓ of an admissible side ℓ at g, the joint cumulant under its Wilson measure obeys the same bound for $K\ge K_0$, for every C^2 vector field η and all bounded weights on T_ℓ whose supports have pairwise sup distances $\ge d$ on T_ℓ, with C, p, K_0 depending on the constants, g, q, d and ℓ.

(c) Every tensor limit σ at every $0<g\le\gamma$ has $\sigma(\theta H^{\mathrm{cons}}[\eta],H^{\mathrm{cons}}[\eta])=0$ for $\eta\in C^2_c(\{x_3>0\};\mathbb{R}^3)$, that is $[(H^{\mathrm{cons}}[\eta])]=0$ in $\mathcal{H}(\sigma)$, and $\sigma((H^{\mathrm{cons}}[\eta])\cdot X)=0$ for every $\eta\in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and every tuple X whose supports do not meet $\operatorname{supp}\eta$: the stress tensor Θ is conserved, $\partial_\mu\Theta_{\mu\nu}=0$, against every tuple.

■

Proof. (a) Let $\mathfrak{v}_\eta$ be the derivation of the functions of the configuration along the left translations of the bond variables by the field of directions that η induces on the bonds, and $A = \sum_p a_p$ the Wilson action. Computing the variation $\beta\mathfrak{v}_\eta A$ of the action and the divergence $\operatorname{div}\mathfrak{v}_\eta$, ordering the sums by the bonds and by the plaquettes, and using the parallelogram law $\frac{1}{4}|\mathbf{w}_+ - \mathbf{w}_-|^2 = \frac{1}{2}(|\mathbf{w}_+|^2 + |\mathbf{w}_-|^2) - \frac{1}{4}|\mathbf{w}_+ + \mathbf{w}_-|^2$ for the $\mathbf{w}$ of the plaquette variables of the two plaquettes of a plane at a bond, and $|\mathbf{w}(W)|^2 = 2a_q - a_q^2$ for the plaquette variable W of a plaquette q, one obtains, identically in the configuration, as an identity between polynomials in the bond variables at finitely many bonds, the lattice Ward identity

$$b\,\mathcal{T}_K^{\mathrm{lat}}(\eta) = \mathcal{N}_\eta - \tfrac{1}{4}\mathfrak{N}[\mathsf{k}_\eta] + X''[\eta] + \mathfrak{Y}[\eta] - \tfrac{1}{4}c_\eta. \tag{21}$$

Here $\mathcal{N}_\eta = \beta\mathfrak{v}_\eta A - \operatorname{div}\mathfrak{v}_\eta$, and $\mathfrak{N}[\mathsf{k}_\eta]$ is formed in the same way with the field of the lattice derivative k_η of η; they are carried by the bonds at which η, resp. k_η, does not vanish. They are null terms: the Haar measure of one bond is invariant under the left translations of its variable, so an integration by parts over the finitely many bonds at which the field does not vanish, the other bonds being fixed, shows that the conditional mean of $\mathcal{N}_\eta Y$, resp. $\mathfrak{N}[\mathsf{k}_\eta]Y$, given the other bonds, vanishes for every polynomial Y in the bonds at which the field vanishes; with the equations of a Gibbs state, $\nu(\mathcal{N}_\eta Y) = \nu(\mathfrak{N}[\mathsf{k}_\eta]Y) = 0$ for every Gibbs state ν, and the same holds under the Wilson measure of every torus. $X''[\eta]$ is a sum of nine local entries, linear in η: the cubic entry $-S[b\eta]$ of Lemma 6.18, of order three, with weights at most $L^{2K}b\|\eta\|_\infty$; five entries formed with the lattice derivative k_η, $\mathsf{k}_\eta^\rho(y) = a_K^{-1}[\eta^\rho(y + a_K e_\rho) - \eta^\rho(y)]$, of the orders two, two, two, three and four, the one of order three with weights at most $\frac{1}{4}L^K b\|\nabla\eta\|_\infty$; the entry $-\frac{3}{2}\sum_p w_\eta(p)a_p$ of order two, $w_\eta(p)$ the sum of $(\nabla_\rho^{\mathrm{c}}\eta^\rho)(x(p))$ over the two directions ρ of the plane of p; an entry of order two formed with the second lattice differences of η; and an entry of order four formed with the a_p^2. $\mathfrak{Y}[\eta]$ is a form in the squares of the in-plane differences of plaquette variables at the bonds, with the coefficients $\nabla_\nu^{\mathrm{c}}\eta^\nu$, and c_η is a number.

The plaquette squares and the bond forms enter (21) with one normalisation, that of O_K^T: this is what makes the left member the lattice form of $H^{\mathrm{cons}}[\eta]$. With θ_K, $\langle F, G\rangle_\rho = \rho(\theta_K F; G)$ is a positive semidefinite form on the real local functions of the bonds above the mirror, by the reflection positivity of ρ; the null terms are null in it, because θ_K of a function above the mirror is a polynomial in bonds below it, where η vanishes. So $\|b\,\mathcal{T}_K^{\mathrm{lat}}(\eta)\|_\rho \le \|X''[\eta]\|_\rho + \|\mathfrak{Y}[\eta]\|_\rho$. Cut η by a partition of unity into at most $(2R_0/\delta + 3)^3$ pieces η_i in cubes of side $\frac{1}{8}\mathsf{l}'$, $\mathsf{l}' = \frac{1}{2}\ell'$, $\delta = \frac{1}{16}\mathsf{l}'$; for each piece there is a board of the least torus with an offset in $a_K\mathbb{Z}^3$ in which the piece and its mirror image lie in two cells, at distance $\ge r = \min\{\frac{1}{4}h_0, \frac{1}{32}\mathsf{l}'\}$ from the walls.

By the domination of ρ (the chessboard estimate with the pressure gap) $\|F_1\|_\rho^2 \le e^{2G_g\mathsf{l}'^3}\bar{\mathsf{m}}^2$, where $\bar{\mathsf{m}}^8$ bounds the mean on the least torus of the eight mirror copies of the centred piece F_1. For $F_1 = X''[\eta_i]$ the copies are entries carried by different cells at distance $\ge r$; by Lemma 6.18(a) they enter the progression as sources, a joint cumulant of entries that, integrated over the scales up to t, are constant up to ϵ_a on the small-field set is at most a number times $\prod\epsilon_a$, and the large fields are negligible at the depth t; the eight entries other than $-S[b\eta]$ are small by power counting, with the exponent $\frac{1}{2} - 4\phi$, which exceeds $\frac{11}{30} > \frac{1}{10} > c'$ as $\phi < \frac{1}{30}$, and $-S[b\eta]$ is small by the estimate on the cubic remainder, Lemma 6.18(b), with the rate $c' = \min\{\frac{1}{10} - \frac{\tau}{5}, \frac{1}{10} - 3\phi\}$ that the Lemma admits for $\phi < \frac{1}{30}$; so $\bar{\mathsf{m}} \le CK^p L^{-c'K}\|\eta_i\|_{C^2}$.

For $F_1 = \mathfrak{Y}[\eta_i]$ a pointwise bound at the background, where the in-plane differences of the plaquette variables are Hölder small, gives the mean of the eight copies $\le (CK^{2\mathfrak{p}_0}L^{-c_{\mathrm{Y}}K}\|\nabla\eta_i\|_\infty)^8$, with

$$c_{\mathrm{Y}} = \min\{\tfrac{1}{2}\psi - 4\phi',\ \tfrac{1}{2} - 4\phi',\ 2\beta_{\mathrm{H}} - (3 + 2\beta_{\mathrm{H}})\psi\}$$

for any $0 < \beta_{\mathrm{H}} < 1$ and $0 < \phi' < \psi < 1$ with $\phi' \le \frac{1}{4}$ and $c_{\mathrm{Y}} > 0$, the number C depending on them besides: β_{H} is the Hölder exponent of the backgrounds from a plaquette to its neighbour,

the pointwise bound is taken at the level $K-\lceil\psi K\rceil$, and the progression is stopped at the level $K-\lceil\phi' K\rceil$. At $(\beta_{\mathrm H},\psi,\phi')=(\frac12,\frac16,\frac{1}{336})$ one has $c_{\mathrm Y}=\frac{1}{14}$, at $(\frac34,\frac14,\frac{1}{160})$ one has $c_{\mathrm Y}=\frac{1}{10}$, and $\sup c_{\mathrm Y}=\frac{2}{11}$, not reached. The seminorm is subadditive; summing the pieces gives the first display with the rate $\min\{c',c_{\mathrm Y}\}$. At the choice $c_{\mathrm Y}=\frac{1}{10}>c'$ this rate is $c'=\min\{\frac{1}{10}-\frac{\tau}{5},\frac{1}{10}-3\phi\}$, and every $c<\frac{1}{10}$ is reached by the choice of τ and ϕ.

The second display is the inequality of Schwarz for the form. For the chessboard bound: by (21), $b\,\mathcal T_K^{\mathrm{lat}}(\eta)-\bar c=Z+R$, $\bar c$ its mean on $T_{\ell'}$, with $Z=\mathcal N_\eta-\frac14\mathfrak N[\mathsf k_\eta]$, of mean 0, and $R=X''[\eta]+\mathfrak Y[\eta]-\bar c'$, $\bar c'$ the mean of $X''[\eta]+\mathfrak Y[\eta]$. In the mean on $T_{\ell'}$ of the product of the eight mirror copies of $Z+R$, every term with a factor $Z^{[\kappa]}$ vanishes: by the invariance of the Wilson measure under the reflections in the walls it is the mean of Z times a polynomial in the bonds of the other cells, where η and $\mathsf k_\eta$ vanish, and the null terms are null under the Wilson measure of the torus.

So $\|b\,\mathcal T_K^{\mathrm{lat}}(\eta)-\bar c\|_{\mathrm{ch},\ell'}=\|R\|_{\mathrm{ch},\ell'}\le\|X''[\eta]-c_1\|_{\mathrm{ch},\ell'}+\|\mathfrak Y[\eta]-c_2\|_{\mathrm{ch},\ell'}$, c_1, c_2 the means, the seminorm being subadditive; these are the two numbers $\bar{\mathsf m}$ bounded above, at the rates c' and $c_{\mathrm Y}$, the copies being entries in different cells, at sup distances $\ge r$ from their walls; $b^{-1}\le g^2$; and $O_K^T(H^{\mathrm{cons}}[\eta])=\mathcal T_K^{\mathrm{lat}}(\eta)-O_K^T(H_K'')$ with $\|O_K^T(H_K'')-c_3\|_{\mathrm{ch},\ell'}\le\frac32 C_1^\flat(g;\frac12\ell',r)a_K\|\nabla^2\eta\|_\infty$, the bound of one centred entry of Proposition 6.14(c). The rate is again every $c<\frac{1}{10}$. (b) Let $\Lambda=L^z$, $z\ge1$ an integer, and let g_1',g_2' be the couplings with $g_1'^{-2}=\Lambda g^{-2}/2$ and $g_2'^{-2}=L\Lambda g^{-2}/4$. As $g_2'^{-2}>g_1'^{-2}>g^{-2}$, they are reference couplings for every $0<g\le\gamma$, and they read g alone, not the label. Put $x=g^{-2}$. The labels of the first-passage data at g lie in the window $(x,L(x+\bar B)]$, which the dilation carries to $(\Lambda x,L\Lambda(x+\bar B)]$, and $I(g_1')=(\frac12\Lambda x+\bar B,\frac12 L\Lambda x+(L-2)\bar B]$, $I(g_2')=(\frac14 L\Lambda x+\bar B,\frac14 L^2\Lambda x+(L-2)\bar B]$. Here $\bar B<\gamma^{-2}\le x$: the constants in Section YMM1:74 satisfy $B_\sharp\le\gamma^{-2}/2$ and $\bar B=LB_\sharp/(L-1)<\gamma^{-2}$. So $\bar B\le\frac{L-4}{4}x$, as $L\ge13$, and the three comparisons of ends

$$\tfrac12\Lambda x+\bar B\le\Lambda x,\qquad \tfrac14 L\Lambda x+\bar B\le\tfrac12 L\Lambda x+(L-2)\bar B,\qquad L\Lambda(x+\bar B)\le\tfrac14 L^2\Lambda x+(L-2)\bar B$$

show that $I(g_1')\cup I(g_2')$ holds the dilated window, at every $z\ge1$. By the windows of labels (Corollary YMM1:74.2) every first-passage datum (K,β) at g with $K\ge z+1$ thus dilates to a first-passage datum $(K-z,\beta)$ at g_1' or at g_2', of label $\Lambda a_K\beta$. Let $2\mathsf l_\iota$ be the least admissible side at g_ι', and let z be the least integer $z\ge1$ with $\Lambda g^{-2}/2\ge(\gamma_W^{\mathrm{sd}})^{-2}$, so that $g_2'<g_1'\le\gamma_W^{\mathrm{sd}}$, and with $\mathsf l_2\le\Lambda d/2$; such integers exist, the least side at g_ι' growing like a power of $\log g_\iota'^{-2}$, that is of z, and Λd like L^z. The dilation of Lemma 6.16(a) carries entries, states and tori at g to those at g_ι', and the supports to sets at pairwise sup distances $\ge\Lambda d\ge2\mathsf l_2$.

Use the board of cells of side $\mathsf l_\iota$ on the dilated lattice. Cutting each entry into small pieces and choosing the offset as in the proof of Theorem R, the selected pieces occupy distinct cells, each with margin $\mathsf l_\iota/(8q)$. Evaluate each cell's eight-copy seminorm separately on the least torus at g_ι'. The cell of η carries the chessboard bound of (a) on the least torus at $g_\iota'\le\gamma_W^{\mathrm{sd}}$, at the margin $\mathsf l_\iota/(8q)$: $\|O^T(H^{\mathrm{cons}}[\eta'])-\langle\cdot\rangle\|_{\mathrm{ch}}\le CK^pL^{-cK}\|\eta'\|_{C^2}$ for every $c<\frac{1}{10}$, in particular at $c=\frac{1}{36}$, η' the dilated piece of η; every other cell carries the eighth root of the mean of the eight mirror copies of its centred entry, which the cumulant bounds of the orders $2,\dots,8$ on the least torus bound, as in the proof of Proposition 6.13(a): the least side at $g_\iota'\le\gamma_W^{\mathrm{sd}}$ is small, and the entries, bond forms included, are sources (Lemma 6.12(a), (c)).

The chessboard estimates, the pressure gap and the domination of the periodic Gibbs states and of the larger tori by the least torus bound the mean of the product of the centred entries by the product of these numbers; the joint cumulant is a polynomial in such means, each monomial with one factor that holds a piece of η. The powers of Λ that the dilation brings to the entries and to $\|\eta\|_{C^2}$, $(H^{\mathrm{cons}}[\eta])^{(z)}=H^{\mathrm{cons}}[\eta^{[z]}]$ with $\|\eta^{[z]}\|_{C^2}\le\Lambda\|\eta\|_{C^2}$, and the factor $L^{z/36}$ of the shift of the cutoff enter C; on a torus T_ℓ the same argument runs on $T_{\Lambda\ell}$, with numbers that depend on ℓ. (c) Let first $g\le\gamma_W^{\mathrm{sd}}$ and $\eta\in C_c^2(\{x_3>0\};\mathbb R^3)$. By (a) in $\rho=\nu_j$, with $b_j^{-1}\le g^2$, $\|\mathcal T_{K_j}^{\mathrm{lat}}(\eta)\|_{\nu_j}\to0$; by Proposition 6.13(a) the part $O_K^T(H_K'')$ contributes $O(a_K)$, and by Proposition 6.13(c) with the moving mirror $\theta_{K_j}H\to$

θH, $\nu_j(\theta_{K_j} O^T(H); O^T(H)) \to \sigma(\theta H, H)$ for $H = H^{\mathrm{cons}}[\eta]$. So $\sigma(\theta H^{\mathrm{cons}}[\eta], H^{\mathrm{cons}}[\eta]) = 0$. The second assertion follows from (b) in the limit, or from the first by Proposition 6.22(c). Above γ_W^{sd} use Lemma 6.16(b) and $(H^{\mathrm{cons}}[\eta])^{(z)} = H^{\mathrm{cons}}[\eta^{[z]}]$. □

Proposition 6.20 (Covariance at two points, for labelled functionals)**.** Let σ_2 be real, symmetric and bilinear on the pairs of continuous weights with disjoint supports, bilinear on $C_c(O;V) \times C_c(O';V)$ for open O, O' with disjoint closures and extended bilinearly to $V_{\mathbb{C}}$, with:

- (h1) $\sigma_2(\iota H, \iota H') = \sigma_2(H, H')$ for $\iota \in \mathbb{R}^3 \rtimes W_3$;
- (h2) for every compact $\mathcal{K} \subset \{x_3 > 0\}$ a number $c(\mathcal{K})$ with $|\sigma_2(\theta\bar{h}, h')| \le c(\mathcal{K})|h|_\infty |h'|_\infty$ for $h, h' \in C_c(\{x_3 > 0\}; V_{\mathbb{C}})$ supported in $\mathcal{K}$;
- (h3) a Hilbert space with a linear map v from $C_c(\{x_3 > 0\}; V_{\mathbb{C}})$, $\langle v(h), v(h')\rangle = \sigma_2(\theta\bar{h}, h')$, and a projection-valued measure $\mathcal{P}$ on $[0,\infty) \times \mathbb{R}^2$ carried by the square cone, with $\int e^{-a_3 E + i(a_1 q_1 + a_2 q_2)} d\mathcal{P}\, v(h) = v(\tau_a h)$ for $a_3 \ge 0$;
- (h4) $\sigma_2(\theta_\Sigma \bar{H}, H) \ge 0$ for $H \in C_c(\{x_1 + x_3 > 0\}; V_{\mathbb{C}})$, θ_Σ the reflection in $\{x_1 + x_3 = 0\}$;
- (h5) $\sigma_2(H^{\mathrm{cons}}[\eta], H') = 0$ for $\eta \in C_c^2(\mathbb{R}^3; \mathbb{R}^3)$ and H' with support disjoint from $\operatorname{supp}\eta$;
- (h6) $\sigma_2((f \circ \mathsf{R}_{-t})\mathbf{1}, (f' \circ \mathsf{R}_{-t})\mathbf{1}) = \sigma_2(f\mathbf{1}, f'\mathbf{1})$ for real t and f, f' with disjoint supports;
- (h7) there are $a < 4$, C_{od} and $1 > d_n \downarrow 0$ with $\sigma_2(\theta h, h) \le C_{\mathrm{od}} d_n^{-a} |h|_\infty^2$ for all n, $\mu \ne \nu$ and $h = h_0 o_{\mu\nu}$, $h_0 \in C_c(B(2d_n e_3, d_n))$ real.

Then the kernel $G(u)(e, e')$ of σ_2 is real analytic on $\mathbb{R}^3 \setminus \{0\}$ with $G(Ru)(\rho(R)e, \rho(R)e') = G(u)(e, e')$, and $\sigma_2(RH, RH') = \sigma_2(H, H')$ for all $R \in \mathrm{O}(3)$ and all pairs with disjoint supports. ■

Proof. The measure of one entry. Write $p = (E, q_1, q_2)$, $p_\pm = E \pm q_1$, $\pi(p) = (iq_1, iq_2, -E)$ and $\langle u, p\rangle = u_3 E - i(u_1 q_1 + u_2 q_2)$ for $u \in \mathbb{C}^3$, so that $\partial_{u_k} e^{-\langle u,p\rangle} = \pi_k e^{-\langle u,p\rangle}$. Modulating an entry, $h \mapsto h e^{-i\kappa\cdot x}$, does not change its sup norm; from (h2), (h3) one obtains one family of complex Radon measures $M(e, e')$ on the square cone, antilinear in e, linear in e', positive at $e = e'$, with $\langle v(ke), \mathcal{P}(B) v(k'e')\rangle = \int_B \bar{F}_k F_{k'} dM(e, e')$, $F_k(p) = \int k(x) e^{-\langle x,p\rangle} dx = \int k(x) e^{-x_3 E + i(x_1 q_1 + x_2 q_2)} dx$, and $\int e^{-tE} dM(e,e) < \infty$ for $t > 0$. For the last, fix a continuous $g_1 : \mathbb{R} \to [0,1]$ with support in $(-\frac{1}{2}, \frac{1}{2})$ and $\max g_1 = 1$, put $c_1 = \int g_1$, $\hat{g}_1(\kappa) = \int g_1(x) e^{ix\kappa} dx$ and $c_g = \int_{\mathbb{R}} |\hat{g}_1(\kappa)|^2 e^{-|\kappa|} d\kappa$, and for $d > 0$ and $\kappa \in \mathbb{R}^2$ let $h_\kappa^d(x) = g_1(x_1/d) g_1(x_2/d) g_1(x_3/d - 2) e^{-i(\kappa_1 x_1 + \kappa_2 x_2)}$ be the modulated bumps of size d: $|h_\kappa^d| \le 1$, their supports lie in $\mathcal{K}_d = B(2de_3, d)$, and $F_{h_\kappa^d}(p) = \mathsf{L}(E)\, d\hat{g}_1(d(q_1 - \kappa_1))\, d\hat{g}_1(d(q_2 - \kappa_2))$ with $\mathsf{L}(E) = \int g_1(x_3/d - 2) e^{-x_3 E} dx_3 \ge c_1 d\, e^{-5dE/2}$.

If $\mu \ge 0$ is carried by the square cone and $\int |F_{h_\kappa^d}|^2 d\mu \le A$ for all $\kappa \in \mathbb{R}^2$, then integrating over the modulation against $e^{-d(|\kappa_1| + |\kappa_2|)} d\kappa$, with $|q_1| + |q_2| \le 2E$ on the cone, gives $\int e^{-7dE} d\mu \le 4A(c_1 c_g)^{-2} d^{-6}$; at $\mu = M(e,e)$, (h2) gives this with $A = c(\mathcal{K}_d)|e|_\infty^2$. *The kernel.* $G(u)(e,e') = \int e^{-\langle u,p\rangle} dM(e^\theta, e')$, $e^\theta = \rho(\Theta_{e_3})\bar{e}$, is holomorphic on the square tube and represents σ_2 on pairs parted by a plane $x_3 = c$; by (h1) the kernels of the frames of W_3 agree on overlaps and give one function on the union of the rotated square tubes, whose real points are $\mathbb{R}^3 \setminus \{0\}$; for a real u with $(u_3, u_1) \ne 0$, $\zeta \mapsto G(\mathsf{R}_\zeta u)$ is entire and 2π-periodic, and an imaginary rotation $\mathsf{R}_{i\tau}$ is the boost $\beta_\tau(E, q_1, q_2) = (E\cosh\tau + q_1 \sinh\tau, q_1 \cosh\tau + E \sinh\tau, q_2)$ of (E, q_1) acting on M: $\langle \mathsf{R}_{i\tau} u, p\rangle = \langle u, \beta_\tau p\rangle$ and $p_\pm \circ \beta_\tau = e^{\pm\tau} p_\pm$.

Conservation is algebra. With $v \vee w = \frac{1}{2}(vw^{\mathrm{t}} + wv^{\mathrm{t}})$ for $v, w \in \mathbb{C}^3$ one has $H^{\mathrm{cons}}[\eta] = (\nabla\cdot\eta)\mathbf{1} - 2\sum_{k,l} \partial_k \eta_l\, e_k \vee e_l$, and (h5) gives, as measures, $2\sum_k \pi_k M(e, e_k \vee e_l) = \pi_l M(e, \mathbf{1})$; in the helicity basis $E_{\pm 2} = \varepsilon_\pm \vee \varepsilon_\pm$, $E_{\pm 1} = e_2 \vee \varepsilon_\pm$, $E_0 = e_2 e_2^{\mathrm{t}}$, $\mathbf{1}$, $\varepsilon_\pm = e_3 \pm i e_1$, whose helicities $h_s = 2, 1, 0, 0, -1, -2$ for $E_2, E_1, E_0, \mathbf{1}, E_{-1}, E_{-2}$ are fixed by $\rho(\mathsf{R}_t) E_s = e^{-ih_s t} E_s$ (so h_s is minus the helicity k of a label of the plates below, which is fixed by $\rho(\mathsf{R}_t)\varepsilon_k = e^{ikt}\varepsilon_k$): $-p_- M(e, E_2) + 2iq_2 M(e, E_1) + p_+ M(e, E_0) = 0$, $-p_+ M(e, E_{-2}) + 2iq_2 M(e, E_{-1}) + p_- M(e, E_0) = 0$, $2iq_2 M(e, E_0) - p_- M(e, E_1) - p_+ M(e, E_{-1}) = iq_2 M(e, \mathbf{1})$.

The trace. (h6) makes $M(\mathbf{1}, \mathbf{1})$ invariant under the boosts. *Growth.* By (h7), through the modulation bound with $A = 4C_{\mathrm{od}} d_n^{-a}$ (the factor 4 for the real and imaginary parts of $h_\kappa^{d_n}$),

$\int e^{-7d_nE}dM(o,o) \le 16C_{\mathrm{od}}(c_1c_g)^{-2}d_n^{-6-a}$ at the off-diagonal labels $o = o_{\mu\nu}$, and the boosted off-diagonal measures grow at most like $e^{(6+a)|\tau|}$ along $\tau_n = \log(t/7d_n)$; conservation passes this growth to the diagonal labels, except near $q_1 \approx 0$, where a boost does not lower the energy below its half. So only the harmonics $|\nu| \le 6+a$ occur: $(\beta_\tau)_*M(e,e') = \sum_\nu e^{-\nu\tau}M_\nu(e,e')$, and by the quarter turn $M_\nu(E_s, E_{s'}) = 0$ unless $\nu \equiv h_s + h_{s'}$ modulo 4, h_s the helicities.

The extreme wrong harmonic $M^{(m)}$, $m \neq 0$, is itself a positive matrix of measures, conserved, and it scales under the boosts. *Odd and even.* If its index m is odd, positivity at the diagonal mirror (h4) says that it is also negative: it vanishes. If m is even, $|m| \ge 2$, the entries at the helicities ∓1, ∓2 have the frequencies $\mp(2+4|m|)$, $\mp(4+4|m|)$, beyond $6+a<10$, so vanish, and with the trace three of the six rows are empty; conservation then empties the rest outside $\{p_\mp = 0\}$, puts the helicity-0 entry at $p=0$, where the scaling under boosts kills it, and on $\{p_\mp = 0\}$ a measure whose mass on a smaller set is $e^{|\nu|\tau}$ times its mass on the larger one is not finite on bounded sets unless it vanishes.

So all harmonics but $\nu = h_s + h_{s'}$ vanish, $G(\mathsf{R}_t u)(\rho(\mathsf{R}_t)e, \rho(\mathsf{R}_t)e') = G(u)(e,e')$, and the group generated by W_3 and the R_t is O(3). □

Remark 6.21. The exponent enters through $10 > 6+a$; $a<4$ cannot be replaced by $a=5$. Let $S(p)$ be the symmetric matrix with zero diagonal and $S_{12} = p_3(p_1^2 - p_2^2)$, $S_{23} = p_1(p_2^2 - p_3^2)$, $S_{31} = p_2(p_3^2 - p_1^2)$, $[p]_\times$ the matrix of $q \mapsto p \times q$, and $\Upsilon(p) = [p]_\times S(p)[p]_\times^{\mathrm{t}}$: it is symmetric, traceless, conserved ($p^{\mathrm{t}}\Upsilon(p) = 0$), homogeneous of order five, $\Upsilon(wp) = \det w\, \rho(w)\Upsilon(p)$ for $w \in W_3$, and not covariant under the R_t. The pair functional with the kernel $G(u)(e,e') = c_e(\partial)c_{e'}(\partial)(4\pi|u|)^{-1}$, $c_e(p) = -\frac{1}{2}\operatorname{tr}(e\Upsilon(p))$, built on a free massless field and positive at the planes of the nine families by the positivity of that field, has (h1)–(h6) and (h7) with $a=5$, and it is not covariant.

Plates and boosts. For Proposition 6.22 write $y = (x_3, x_1)$ for the coordinates of the plane of the rotations R_t and $x = (y, x_2)$. With $u_\pm = e_3 \pm ie_1$, the matrices $\varepsilon_{\mp2} = u_\pm u_\pm^{\mathrm{t}}$, $\varepsilon_{\mp1} = u_\pm e_2^{\mathrm{t}} + e_2 u_\pm^{\mathrm{t}}$, $\varepsilon_0 = e_3e_3^{\mathrm{t}} + e_1e_1^{\mathrm{t}}$, $\varepsilon_0' = e_2e_2^{\mathrm{t}}$ form a basis of $V_{\mathbb{C}}$ with $\rho(\mathsf{R}_t)\varepsilon_k = e^{ikt}\varepsilon_k$, $\rho(\mathsf{R}_t)\varepsilon_0' = \varepsilon_0'$; k is the helicity of the label, the opposite of the helicity h of the proof of Proposition 6.20: the matrix $u_+u_+^{\mathrm{t}} = \varepsilon_{-2}$ is the E_2 of that proof, of helicity $h=2$.

A plate is a weight $\alpha(y)\varphi(x_2)\epsilon$ with $\alpha \in C_c(\mathbb{R}^2)$, $\varphi \in C_c^1(\mathbb{R})$ real and ϵ in this basis; $\lambda = (\varphi, \epsilon)$ is its label, $k(\lambda)$ its helicity, $\lambda^\dagger = (\varphi, \rho(\Theta_{e_3})\bar\epsilon)$ its reflected label, and $\kappa(\lambda_1, \dots, \lambda_n) = \sum k(\lambda_a)$; for $\xi \in \mathbb{C}^2$, $\xi^* = (\bar\xi^0, -\bar\xi^1)$. In the coordinates $\xi^\pm = \xi^0 \pm i\xi^1$ of $\mathbb{C}^2$ an imaginary rotation acts by $(\mathsf{R}_{is}\xi)^\pm = e^{\mp s}\xi^\pm$: it is a boost of the plane. For data with bounded slab operators the slab operator of a plate has a density in the point of the plane, the point plate $B_\lambda(\xi, \xi')$, holomorphic in norm for ξ, ξ' in $\{\operatorname{Re}\xi^\pm > 0\}$; the plate vectors $\Psi(x; \lambda_1, \dots, \lambda_n)$ are the products of point plates applied to Ω, and the kernels $\mathcal{K}_n(Z; \lambda_1, \dots, \lambda_n)$ of the plates are their scalar products, continued to one holomorphic function on the union $\mathcal{Z}_n$ of the tubes $\{Z = (z_1, \dots, z_n) : \operatorname{Re}(\mathsf{R}_{-\upsilon}(z_{\mathfrak{s}(c+1)} - z_{\mathfrak{s}(c)}))^\pm > 0,\ 1 \le c < n\}$ of the frames $\upsilon \in \frac{\pi}{2}\mathbb{Z}$ and the permutations $\mathfrak{s}$ of the points.

With $n_\alpha = (\cos\alpha, \sin\alpha)$, a real configuration $X = (y_1, \dots, y_n)$ lies in the tube of $(\mathfrak{s}, \upsilon)$ if and only if $n_\upsilon \cdot y_{\mathfrak{s}(1)} < \dots < n_\upsilon \cdot y_{\mathfrak{s}(n)}$; so the real points of $\mathcal{Z}_n$ are the configurations whose times, or whose abscissae, are pairwise different. A fan of j points is a real z with $z_1 = r_0 n_{\alpha_0}$, $z_{i+1} - z_i = r_i n_{\alpha_i}$, $r_i > 0$, $|\alpha_i| < \frac{5\pi}{16}$. $\mathcal{H}_{\mathrm{pl}}$ is the closed span of Ω and of the plate vectors.

Proposition 6.22 (Conservation and a power bound give covariance)**.** Let σ be a real functional on the tuples of continuous weights with:

- (C1) $\sigma(\emptyset) = 1$, $\sigma((H)) = 0$, σ symmetric and n-linear on $\prod C_c(O_a; V)$ for open O_a with disjoint closures, with sup-norm bounds as in (D1) that do not depend on the position; invariance under $\mathbb{R}^3 \rtimes W_3$; positivity at the nine families; the square cone $\mathcal{P}(\{E < \max(|q_1|, |q_2|)\}) = 0$;
- (C2) bounded slab operators of one entry: for $l > 0$ and $h \in C_c(\{0 < x_3 < l\}; V_{\mathbb{C}})$, $B_l(h)[F] = [(h) \cdot \tau_{le_3}F]$ is bounded by $C(\mathcal{K}, l)|h|_\infty$ for $\operatorname{supp} h \subset \mathcal{K}$ compact, with no condition on the growth of $C(\mathcal{K}, l)$;

(C3) the scale-free bound $\sigma(\theta h, h) \le C_{\mathrm{od}}|h|_\infty^2$ for $0 < d < 1$ and real $h = h_0 o_{\mu\nu}$, $h_0 \in C_c(B(x_0, d))$, $x_{0,3} \in [\frac{3}{2}d, 2d]$;
(C4) the bound $\sigma(\theta(f\mathbf{1}), f\mathbf{1}) \le C_\varphi t^{-a_\Gamma}$, $a_\Gamma < 4$, of (S2) at the plates f of scale $t \in (0, 1]$;
(C5) conservation at two points: $\sigma(\theta H^{\mathrm{cons}}[\eta], H^{\mathrm{cons}}[\eta]) = 0$ for $\eta \in C_c^2(\{x_3 > 0\}; \mathbb{R}^3)$;
(C6) for one $p < \infty$, $\|B_{2d}(\tau_{de_3} h)\| \le C \min\{1, d - d'\}^{-p} \|h\|_{L^1}$ for $0 \le d' < d$ and $h \in C_c(\mathbb{R}^3; V_{\mathbb{C}})$ supported in $\{|x_3| \le d'\}$.

Then:

(a) $\sigma(RX) = \sigma(X)$ for all $R \in \mathrm{O}(3)$ and all tuples;
(b) $\mathcal{K}_n(\mathsf{R}_{is} Z; \underline{\lambda}) = e^{\kappa(\underline{\lambda})s} \mathcal{K}_n(Z; \underline{\lambda})$ for all $n \ge 2$, all weight labels $\underline{\lambda}$ of plates and all real s, and $e^{-\kappa(\underline{\lambda})s} \|\Psi(\mathsf{R}_{is} z; \underline{\lambda})\| = \|\Psi(z; \underline{\lambda})\|$ at real z;
(c) $\sigma((H^{\mathrm{cons}}[\eta]) \cdot X) = 0$ for every $\eta \in C_c^2(\mathbb{R}^3; \mathbb{R}^3)$ and every tuple X whose supports do not meet $\operatorname{supp} \eta$.

A growth with the sequence $A_\bullet = (A_j)_{j \ge 1}$, $A_j \ge 0$, is the bound $\|\Psi(\mathsf{R}_{is} z; \underline{\lambda})\| \le C e^{A_j |s|}$ for all real s, all labels $\underline{\lambda}$ of j plates and all z in a compact set of fans of j points, C depending on the labels and the compact set, for every $j \ge 1$. The same holds if (C6) is replaced by a growth with $\liminf_j (A_j - j^2)/j = -\infty$, or, the diagonal mirror being used at all tuples, with $\liminf_j A_j/j^2 < 2$. If σ has (C1), (C2) and is covariant at two entries under the rotations R_t, the following are equivalent: covariance under $\mathrm{O}(3)$; the growth with $A_j = 2j$; a growth with $\liminf_j A_j/j^2 < 1$; a bound $\sup_{s \in \mathbb{R}} \sup_{(\xi, \xi') \in \mathcal{C}} e^{-\gamma|s|} \|B_\lambda(\mathsf{R}_{is}\xi, \mathsf{R}_{is}\xi')|_{\mathcal{H}_{\mathrm{pl}}}\| < \infty$ of the boosted point plates on $\mathcal{H}_{\mathrm{pl}}$, with one $\gamma < \infty$, for every label λ and every compact set $\mathcal{C}$ of pairs of real $\xi = r n_\alpha$, $\xi' = r' n_{\alpha'}$, $r, r' > 0$, $|\alpha|, |\alpha'| < \frac{5\pi}{16}$; and (C6) with any $p < \infty$ implies them.

If σ has (C1), (C2), the covariance at two entries under the R_t and a growth with some sequence $A_\bullet$, of any size, then the top frequency $\bar{m}(n)$ of the kernels of n plates is finite, $\bar{m}(n) \le \frac{1}{4}(A_{\lfloor n/2 \rfloor} + A_{\lceil n/2 \rceil} + 2n)$, and if covariance fails, there is an $a' \ge 1$ with $\bar{m}(2a) \ge \frac{1}{2} a(a - a')$, so $A_a \ge a(a - a' - 2)$, for all $a \ge a'$. ■

Proof. Conditions (C1)–(C3), (C5) and (C6) are (D1)–(D4), (S), (O), (N) and (P) of Definition 5.1. Theorem T gives (a)–(c). Under the alternative growth hypotheses, Proposition 5.31(a) gives covariance at two points and Proposition 5.34 gives it at all orders. Its proof includes the coefficient continuation, the modulus Schwarz inequality at tilted lines and the polygon-halving argument. Lemma 5.32 gives the exact norm formula for the plate vectors.

The equivalences: under covariance at two points about one axis $\bar{m}(2) = 0$ as soon as a growth is had, the kernels of two points being then constant along the boosts; a growth with $\liminf_j A_j/j^2 < 1$ gives covariance by the convexity; covariance gives unitary boosts $U(s)$ on $\mathcal{H}_{\mathrm{pl}}$, $U(s)\Psi(w; \underline{\lambda}) = e^{-\kappa(\underline{\lambda})s} \Psi(\mathsf{R}_{is} w; \underline{\lambda})$, $U(s) B_\lambda(\xi, \xi') U(-s) = e^{-k(\lambda)s} B_\lambda(\mathsf{R}_{is}\xi, \mathsf{R}_{is}\xi')$ on $\mathcal{H}_{\mathrm{pl}}$, so the growth $A_j = 2j$ and the bound of the boosted point plates with $\gamma = 2$; that bound with any γ gives, by the product of the point plates, the growth $A_j = \gamma j$, so covariance; and under a growth with any sequence, if covariance fails, the second case of the integer sequences holds with $\nu(1) = 0$ and $\nu(a) \le \frac{1}{2} A_a + a$.

□

Remark 6.23. Conservation cannot be omitted from Proposition 6.22. For a tensor limit σ at $g \le \gamma_W^{\mathrm{sd}}$ let σ' be the limit at continuous weights of Lemma 6.16(d). Then $\sigma' \circ Z_2$ has (C1)–(C4) and (C6): Z_2 commutes with $\rho(W_3)$, is the identity on $V_A \oplus V_E$, keeps the operators up to a unitary map, multiplies the bound of (C3) by 4 and the L^1 norm in (C6) by at most 2. It is not covariant (Proposition 6.26 with Proposition 6.15(a) and Theorem W(3)). So it violates (C5): conservation, in which the plaquette squares and the bond forms enter with one normalisation, is the property of the theory that its rescaled forms $\sigma \circ Z_z$, $z \ne 1$, do not have: for $z^2 \ne 1$ by the argument above, and at $z = -1$ because, with R the rotation by $\pi/4$ about e_3, $\rho(R) o_{12}$ lies in V_E, where Z_{-1} is the identity, so that covariance of $\sigma' \circ Z_{-1}$ would give $-\sigma = \sigma$ at the mixed pairs $(\varphi_1^d \mathbf{1}, \varphi_2^d o_{12})$ of

Proposition 6.26, against the law of Proposition 6.15 with $\mathcal{W} \neq 0$ there; and $\sigma' \circ Z_{-1}$ has (C1)–(C4) and (C6) as $\sigma' \circ Z_2$ does.

6.8. **Reconstruction, rescaling and components.**

Proposition 6.24 (Wightman fields from labelled functionals)**.** Let σ be a real functional on $\mathfrak{S}_V(\mathbb{R}^3)$ with (D0), (D1) and $\sigma((H)) = 0$, and suppose:

(R1) $\sigma \circ \iota = \sigma$ for every isometry ι of $\mathbb{R}^3$;
(R2) σ is positive at $(e_3, 0)$, and $\mathcal{H}(\sigma)$ is separable;
(R3) $\mathcal{P}(\{E < |q|\}) = 0$;
(R4) there are C_V and p with $|\sigma(\theta \bar{F} \cdot (h) \cdot F')| \leq C_V \eta^{-p} \|h\|_{L^1} \|[\tau_{-\eta e_3} F]\| \|[\tau_{-\eta e_3} F']\|$ for $\eta \in (0,1]$, $F, F' \in \mathcal{D}_{e_3,\eta}$ and $h \in C^1_c(\{|x_3| < \eta/2\}; V)$.

Then:

(i) for $n \geq 2$ there is exactly one continuous function s_n on $\{x \in (\mathbb{R}^3)^n : x_i \neq x_j \ (i \neq j)\} \times V^n$, n-linear in e, with $\sigma(H_1, \dots, H_n) = \int s_n(x; H_1(x_1), \dots, H_n(x_n))\, dx$ for all tuples, and for the tuples of continuous weights if σ is given there; it is real analytic, symmetric, invariant under the isometries acting on points and labels, and

$$|s_n(x;e)| \leq (cC_V)^n \max\{1, 2n^2/\delta(x)\}^{pn} \prod_k |e_k|_\infty, \qquad \delta(x) = \min_{i \neq j} |x_i - x_j|,$$

c a number depending on (V, ρ) and its norm; so $|\sigma(X)| \leq (cC_V)^n (2n^2/d)^{pn} \prod_a \|H_a\|_{L^1}$ if the supports are at mutual distances $\geq d$, $0 < d \leq 1$. For $\varphi : \mathbb{R}^{3n} \to V_{\mathbb{C}}^{\otimes n}$ whose 6^n components are Schwartz functions vanishing with all their derivatives where two of the n points coincide, $S_n(\varphi) = \int s_n \varphi$ converges absolutely and

$$|S_n(\varphi)| \leq (c' C_V)^n (n!)^{2p} |\varphi|_{k_E n}, \qquad k_E = \max\{\lceil p \rceil, 4\}, \quad c' = 6\pi^2 2^p e^{2p} 3^{k_E} c,$$

$|\varphi|_k$ the greatest of the norms $\sup(1+|x|^2)^{k/2} |\partial^\alpha \varphi_\iota|$, $|\alpha| \leq k$, over the components; $S_n(H_1 \otimes \cdots \otimes H_n) = \sigma(H_1, \dots, H_n)$ at smooth entries with compact disjoint supports, and S_n is the only linear functional bounded for one of the norms with these values. The truncated functions have the kernels that the formula of the cumulants writes in the s_m, $m \leq n$.

(ii) Ω and the classes of the tuples whose entries lie in pairwise disjoint slabs $\{t < x_3 < t'\}$ are total in $\mathcal{H}(\sigma)$.

(iii) On $\mathcal{D}_\infty = \bigcap_k \operatorname{dom} H^k$ there are operators $T(f)$, $f \in \mathcal{S}(\mathbb{R}^{1+2}; V_{\mathbb{C}})$, linear in f, with $\langle \psi, T(f)\psi' \rangle = \int \lim_{s \downarrow 0} \langle U(x)^{-1}\psi, B(s, s; f(x)) U(x)^{-1}\psi' \rangle\, dx$, B the point operators that (R4) provides, and $\langle \psi, T(f)\psi' \rangle = \langle T(\rho(\Theta_{e_3})\bar{f})\psi, \psi' \rangle$, so that a component with r indices equal to 3 is Hermitian after the factor i^r; and there is a strongly continuous unitary representation U of the Poincaré group of $\mathbb{R}^{1+2}$ extending $x \mapsto U(x)$, with $U\Omega = \Omega$, the spectrum of the translations in the closed forward cone, and $U(a,\Lambda) T(f) U(a,\Lambda)^{-1} = T(\rho_{\mathbb{C}}(\hat{\Lambda}) f(\Lambda^{-1}(\cdot - a)))$ on the span $\mathcal{D}_0$ of Ω and of the vectors $T(f_1) \cdots T(f_n)\Omega$.

Here $\hat{\Lambda} = \iota \Lambda \iota^{-1} \in \mathrm{SO}(3, \mathbb{C})$ for $\Lambda \in \mathrm{SO}_0(1,2)$, with $\iota(t, \vec{x}) = (\vec{x}, -it)$: a time t sits at the Euclidean height $x_3 = -it$, as $U(t, \vec{x}) = \mathsf{E}((\vec{x}, -it))$; the boost of (t, x_1) by s goes to R_{is}, and a rotation $1 \oplus R$, $R \in \mathrm{SO}(2)$ acting on $\vec{x}$, to $R \oplus 1$; and $\rho_{\mathbb{C}}(\hat{\Lambda}) E = \hat{\Lambda} E \hat{\Lambda}^{\mathrm{t}}$, so that $\rho_{\mathbb{C}}(\mathsf{R}_{is}) = \exp(is\, d\rho(E_{13} - E_{31}))$, $d\rho(\omega) E = \omega E + E\omega^{\mathrm{t}}$.

(iv) $T(f)T(f') = T(f')T(f)$ on $\mathcal{D}_0$ when the supports of f and f' are spacelike separated, all six components with all six; $\mathcal{D}_0$ is dense; the Wightman functions $\langle \Omega, T(f_1) \cdots T(f_n)\Omega \rangle$ are tempered and equal $\lim_{\epsilon \downarrow 0} \int \mathbf{W}_n(\iota(x_2 - x_1 + i\epsilon\alpha_1), \dots; f_1(x_1), \dots)\, dx$ for all α_k in the forward cone, with the ι of (iii).

(v) The kernels $\mathbf{W}_n$ of the product formula are holomorphic on Tb^{n-1}, with $|\mathbf{W}_n(\zeta; e)| \leq (C_V \eta^{-p})^n \prod_k |e_k|_\infty$ for $e \in V^n$ where $\operatorname{Re} \zeta_3^k - |(\operatorname{Im} \zeta_1^k, \operatorname{Im} \zeta_2^k)| \geq 2\eta$ for all k, $0 < \eta \leq 1$; $\hat{\Lambda}$ of (iii) maps $\mathsf{Tb} = \iota(\mathbb{R}^{1+2} + iV_+)$, $V_+ = \{\alpha : \alpha^0 > |\vec{\alpha}|\}$, onto itself, and

$\mathbf{W}_n(\hat\Lambda\zeta^1,\dots,\hat\Lambda\zeta^{n-1};\rho_{\mathbb{C}}(\hat\Lambda)e_1,\dots,\rho_{\mathbb{C}}(\hat\Lambda)e_n) = \mathbf{W}_n(\zeta;e)$ for every $\Lambda\in\mathrm{SO}_0(1,2)$. The s_n continue to one holomorphic function $\mathbf{S}_n$ on the union of the tubes $\{z\in\mathbb{C}^{3n} : R^{-1}(z_{\varsigma(k+1)}-z_{\varsigma(k)})\in\mathsf{Tb},\ 1\le k<n\}$ of the real frames $R\in\mathrm{SO}(3)$ and the permutations ς, on the tube of (R,ς) equal to $\mathbf{W}_n(R^{-1}(z_{\varsigma(2)}-z_{\varsigma(1)}),\dots,R^{-1}(z_{\varsigma(n)}-z_{\varsigma(n-1)});\rho(R)^{-1}e_{\varsigma(1)},\dots,\rho(R)^{-1}e_{\varsigma(n)})$; $\mathbf{S}_n$ is symmetric when points and labels are permuted together, $\mathbf{S}_n(Rz_1+a,\dots,Rz_n+a;\rho(R)e)=\mathbf{S}_n(z;e)$ for the real isometries $x\mapsto Rx+a$, $R\in\mathrm{O}(3)$, and $|\mathbf{S}_n(z;e)|\le(cC_V\eta^{-p})^n\prod_k|e_k|_\infty$ for $e\in V^n$, c the number of (i), where for some (R,ς) the differences $R^{-1}(z_{\varsigma(k+1)}-z_{\varsigma(k)})$ have the margin 2η of the first bound.

If besides $\ker H=\mathbb{C}\Omega$, every vector invariant under the translations is a multiple of Ω, and all the Wightman axioms hold. ∎

Proof. Point operators and kernels. By (R4) the form $h\mapsto\sigma(\theta\bar F\cdot(h)\cdot F')$ is bounded in $\|h\|_{L^1}$; with the covariance under translations this gives point operators with $\|B(s,s;e)\|\le C_V s^{-p}|e|_\infty$ and the product formula of Proposition 6.14(f), whose kernels are holomorphic on Tb^{n-1} by (R3), $\mathsf{E}(\zeta)$ being a contraction on $\overline{\mathsf{Tb}}$; the first bound of (v) is $\prod\|B(\eta,\eta;e_k)\|$. By (R1) the same holds in every frame $R\in\mathrm{SO}(3)$: there the heights are taken along Re_3, the kernel is $\mathbf{W}_n(R^{-1}\cdot;\rho(R)^{-1}e)$, the labels being turned back by $\rho(R)^{-1}$, and the bound holds with $\prod_k|\rho(R)^{-1}e_k|_\infty\le c^n\prod_k|e_k|_\infty$; $c=3$ serves, as each row of R has $\sum_l|R_{kl}|\le\sqrt{3}$. The kernels of two frames, and of two orders of the points, agree at the common real points of their tubes, as the proof of (i) shows; the intersection of two tubes is convex and holds the real parts of its points, so they agree on it by the identity theorem, and they form the one function $\mathbf{S}_n$ of (v), symmetric as σ is. Its covariance under the real isometries holds at the real points by (i), and on each tube, which an isometry carries onto a tube, by the identity theorem. (i) For a unit vector v the map $u\mapsto u\cdot v$ carries the surface measure of S^2 to the uniform law on $[-1,1]$, so the band $\{|u\cdot v|<n^{-2}\}$ has the fraction n^{-2}; for pairwise different $x_1,\dots,x_n$ the u with $|u\cdot(x_i-x_j)|\ge n^{-2}|x_i-x_j|$ for all $i\ne j$ fill at least the fraction $1-(n-1)/(2n)>\frac12$ of the sphere. In a frame whose third axis is such a u the points are ordered in height with gaps at least $n^{-2}\delta(x)$, and the kernel of that frame is real analytic near x with the bound, at $\eta=\min\{1,\delta(x)/(2n^2)\}$. For two frames that both order x, both kernels are continuous on a product of small balls about the x_i and have the same integrals against all products $f_1(x_1)\cdots f_n(x_n)$; so they are equal.

The same reason gives uniqueness, symmetry and covariance. For a general tuple, cover the product of the supports by finitely many such products of balls, cut each entry by a partition of unity, and sum by the n-linearity on neighbourhoods with disjoint closures. For S_n: at a point x with $\delta(x)<1$, φ is flat at the point where the two nearest points coincide, and Taylor's formula of order $m=\lceil pn\rceil$ along the segment gives $\max\{1,2n^2/\delta(x)\}^{pn}|\varphi(x)|\le(2n^2)^{pn}3^k|\varphi|_k(1+|x|^2)^{-k/2}$, $k=k_En\ge3n+1$; $\int(1+|x|^2)^{-k/2}dx\le\pi^{2n}$ and $n^n\le e^nn!$. (ii) The vectors $\Phi(y)$ of n points of the half space have the Gram kernel s_{2n} at $(\theta y,y')$, real analytic by (i); so for ψ orthogonal to the classes of (ii), $y\mapsto\langle\psi,\Phi(y)\rangle$ is real analytic on the connected set of the non-coinciding n-tuples of the half space, and vanishes where the heights are ordered. (iii), (iv), (v) The fields are built from the point operators and $U(x)$, and the Wightman functions are the boundary values of the $\mathbf{W}_n$ from every direction α of the open cone V_+, tempered by the power p; this follows the reconstruction of Theorem YMM1:AO, with labels; (ii) gives cyclicity, and $B(s,s';e)^*=B(s',s;\rho(\Theta_{e_3})e)$ gives the adjoints. *The invariance of the* $\mathbf{W}_n$ *in (v).* $\hat\Lambda\iota(x+i\alpha)=\iota(\Lambda x+i\Lambda\alpha)$, and $\Lambda V_+=V_+$: so $\hat\Lambda\mathsf{Tb}=\mathsf{Tb}$. For a rotation $\Lambda=1\oplus R$ of $\vec x$, $\hat\Lambda=R\oplus1$ is a real rotation that keeps the heights; at real $\zeta\in\mathsf{Tb}^{n-1}$, that is at configurations ordered in height, $\mathbf{W}_n=s_n$, and the covariance of s_n gives the identity, which the identity theorem carries to Tb^{n-1}.

For the boost $B(s)$ of (t,x_1), $\hat\Lambda=\mathsf{R}_{is}$: fix a real $\zeta\in\mathsf{Tb}^{n-1}$ and e; there is $\delta>0$ such that $\mathsf{R}_\tau\zeta^k\in\mathsf{Tb}$ for all k and all complex τ at a distance $<\delta$ from the segment $\{is':|s'|\le|s|\}$, a convex open set on which $\gamma(\tau)=\mathbf{W}_n(\mathsf{R}_\tau\zeta^1,\dots,\mathsf{R}_\tau\zeta^{n-1};\rho_{\mathbb{C}}(\mathsf{R}_\tau)e_1,\dots,\rho_{\mathbb{C}}(\mathsf{R}_\tau)e_n)$ is holomorphic; at real

τ, $|\tau| < \delta$, the turned points are still ordered in height, and the covariance of s_n under the real rotation R_τ gives $\gamma(\tau) = \gamma(0)$; so γ is constant, and at $\tau = is$ this is the identity at real ζ, which the identity theorem carries to Tb^{n-1}.

The boosts $B(s)$ and the rotations $1 \oplus R$ generate $\mathrm{SO}_0(1,2)$, and $\Lambda \mapsto \hat\Lambda$ is a homomorphism: the identity holds for every Λ. *(iii).* By the substitution $x_k = \Lambda y_k$ and $\iota(\Lambda y + i\epsilon\alpha) = \hat\Lambda\iota(y + i\epsilon\Lambda^{-1}\alpha)$, with $\Lambda^{-1}\alpha \in V_+$, the invariance of the $\mathbf{W}_n$ makes the Wightman functions invariant under $f_k \mapsto \Lambda_a f_k = \rho_{\mathbb{C}}(\hat\Lambda) f_k(\Lambda^{-1}(\cdot - a))$, the translations being had already; as $\bar\iota = \Theta_{e_3}\iota$ and Λ is real, $\rho_{\mathbb{C}}(\hat\Lambda)$ commutes with $e \mapsto \rho(\Theta_{e_3})\bar e$, so the adjoints of (iii) go over too, and $U(a,\Lambda)T(f_1)\cdots T(f_n)\Omega := T(\Lambda_a f_1)\cdots T(\Lambda_a f_n)\Omega$ is well defined and isometric on $\mathcal{D}_0$, which is dense; it extends to a unitary representation, strongly continuous as the fields are continuous in f, which fixes Ω and has the law of (iii) on $\mathcal{D}_0$.

(iv). As $\mathcal{D}_0$ is dense it suffices that a Wightman function does not change when two neighbours f_k, f_{k+1} with spacelike separated supports are exchanged, first for f_j of compact support, to which cut-offs that do not enlarge the supports reduce the general case. Let x run through the product of the supports. At each x let $\hat\xi$ be the unit vector of $\vec x_{k+1} - \vec x_k$, and tilt e_3 towards it: $u_\vartheta = \cos\vartheta\, e_3 + \sin\vartheta(\hat\xi, 0)$, $\sin\vartheta = A\eta$, a real unit vector. The points $z_j = \iota(x_j) + \eta h_j^\lambda e_3$, $|\lambda| \le 1$, $0 < \eta \le \eta_0$, with heights h_j^λ formed from the supports alone, increasing with j at $\lambda = 1$ and in the order with $k, k+1$ exchanged at $\lambda = -1$, lie in the tube of the real frame with third axis u_ϑ, its differences having the margin 3η: across the pair $k, k+1$ the spacelike separation, $\hat\xi\cdot(\vec x_{k+1} - \vec x_k) > |t_{k+1} - t_k|$, pays for the exchanged heights, and $|\operatorname{Im}\mathfrak{z} - (u_\vartheta\cdot\operatorname{Im}\mathfrak{z})u_\vartheta| = |t_{j+1} - t_j|\sin\vartheta$ for $\mathfrak{z} = z_{j+1} - z_j$.

There $\mathbf{S}_n$, symmetric in the points with their labels, is bounded by $(cC_V\eta^{-p})^n \prod_k |e_k|_\infty$ by (v). The integral $I(\lambda,\eta)$ of $\mathbf{S}_n(z; f_1(x_1), \dots, f_n(x_n))$ over x has $\partial_\eta I$ and $\partial_\lambda I/\eta$ equal to integrals of the same kind with derivatives of the f_j in the times, after an integration by parts. The one-label smoothing and integration-by-parts argument in the proof of Proposition 2.16, applied to each tensor component, gives Taylor's formula with the integral remainder and bounds all of them uniformly in $\eta \in (0, \eta_0]$. So $|I(1,\eta) - I(-1,\eta)| \le C\eta \to 0$; and $I(1,\eta)$, $I(-1,\eta)$ tend to the Wightman functions of the two orders, the labels being permuted with the points. *The last sentence.* A vector ψ invariant under the translations has $e^{itH}\psi = U(t,\vec 0)\psi = \psi$ for every real t, by (iii), so $H\psi = 0$ by Stone's theorem; here $\ker H = \mathbb{C}\Omega$ enters and gives $\psi \in \mathbb{C}\Omega$.

With this uniqueness of the vacuum, (iii), (iv) and the separability of $\mathcal{H}(\sigma)$ in (R2) give all the Wightman axioms. □

Proposition 6.25 (What is had without rotations)**.** (a) Let σ be a real symmetric functional on tuples of continuous, or of C^1, weights, multilinear as in (D0), with the sup-norm bounds of (D1), invariant under $\mathbb{R}^3 \rtimes W_3$, positive at $(e_3, 0)$, with the square cone. Then Ω and the classes of the tuples whose entries lie in pairwise disjoint slabs $\{t < x_3 < t'\}$ are total in $\mathcal{H}(\sigma)$; more exactly, every $[X]$ is a limit of sums of classes of ordered tuples with as many entries, formed from mollified and cut entries of X. Two such functionals that agree at all the tuples ordered in the third coordinate are equal.

(b) Let σ be a tensor limit at $0 < g \le \gamma_W^{\mathrm{sd}}$ and C_V, p as in Proposition 6.17. Without covariance under rotations: there are operators $T(f)$, $f \in \mathcal{S}(\mathbb{R}^{1+2}; V_{\mathbb{C}})$, on $\mathcal{D}_\infty$, tempered, with $\langle\psi, T(f)\psi'\rangle = \langle T(\rho(\Theta_{e_3})\bar f)\psi, \psi'\rangle$, $U(a)T(f)U(a)^{-1} = T(f(\cdot - a))$, $[H, T(f)] = iT(\partial_t f)$, and covariant under the dihedral group of the eight $w \in W_3$ with $we_3 = e_3$; the $\mathbf{W}_n$ are holomorphic on $(\mathsf{Tb}^\square)^{n-1}$ with $|\mathbf{W}_n(\zeta; e)| \le (C_V\eta^{-p})^n \prod_k |e_k|_\infty$ for $e \in V^n$ where $\operatorname{Re}\zeta_3^k - |\operatorname{Im}\zeta_1^k| - |\operatorname{Im}\zeta_2^k| \ge 2\eta$, $0 < \eta \le 1$; the Wightman functions are their tempered boundary values; σ has one kernel at the configurations whose heights differ in one coordinate direction; and Ω is cyclic for the $T(f)$.

(c) Let σ be a tensor limit at $0 < g \le \gamma_W^{\mathrm{ref}}$, let $n \ge 2$, let $i \ge i_n$ be an integer, where $i_n = 1$ if $g \le \gamma_W^{\mathrm{sd}}$ and $i_n = z + 1$ if $\gamma_W^{\mathrm{sd}} < g \le \gamma_W^{\mathrm{ref}}$, z the dilation of Lemma 6.16(c), chosen with

$g_1', g_2' \le \gamma_W^{\mathrm{sd}}$, which depends on the constants and g and not on n, and let $\mathsf{l} = L^{-i}$. Then for every tuple $X = (H_1, \dots, H_n)$ of weights at pairwise sup distances $\ge 2\mathsf{l}$, ordered in some direction or not,

$$|\sigma(X)| \le \prod_{a=1}^{n} 2\,\mathsf{g}_{n,i}\Big(\frac{4n}{\mathsf{l}}\Big)^3 \|H_a\|_\natural, \qquad \mathsf{g}_{n,i} = \mathsf{c}_g\, n^4\, \mathsf{Y}_i^{q_E} L^{(11/2)i},$$

where $\|H\|_\natural = \sum_{\mathfrak{b}} |\mathfrak{b}| \sup_{\mathfrak{b}} |H|_\infty$, the sum over the boxes $\mathfrak{b} = \frac{\mathsf{l}}{4n}(m + [0,1)^3)$, $m \in \mathbb{Z}^3$, is the upper Riemann sum of $\int |H|_\infty$ at the mesh $\mathsf{l}/(4n)$, $\mathsf{Y}_i = 2(c_E + i \log L)$ and q_E are the numbers of Proposition 6.17 at the margin $\delta = 1/(8n)$, of which $c_E = \log(2L(g^{-2} + \bar{B}))$ and q_E, the latter formed from the constants alone, do not depend on the margin (above γ_W^{sd} they are taken at the couplings g_1', g_2' of Lemma 6.16(c) and at the index $i - z$, the larger of the two), and c_g depends on the constants and g. No rotation, no ordering of the supports and no analyticity enters. There is a number C_G, depending on the constants and g, such that for all $n \ge 2$, all $0 < d \le 1$ and all tuples of n weights at pairwise sup distances $\ge 2d$, ordered or not,

$$|\sigma(H_1, \dots, H_n)| \le (\mathsf{C}_G n^{16} d^{-9})^n \prod_a \|H_a\|_\natural \le (e^{16}\mathsf{C}_G)^n (n!)^{16} d^{-9n} \prod_a \|H_a\|_\natural,$$

the sums $\|\cdot\|_\natural$ taken at the mesh $L^{-i}/(4n)$, i the least integer with $L^{-i} \le d$ and $i \ge i_n$; and σ satisfies the growth hypothesis in Proposition YMM1:93.5, with labels, with the constants $(17, 1, \mathsf{C}_E, 24)$, C_E depending on the constants and g: for every n there is exactly one complex linear functional S_n^σ on the test functions $\varphi : \mathbb{R}^{3n} \to V_{\mathbb{C}}^{\otimes n}$ of Proposition 6.24(i), whose 6^n components are Schwartz functions vanishing with all their derivatives where two of the points coincide, that is bounded for one of the norms $|\cdot|_k$ and has the value $\sigma(H_1, \dots, H_n)$ at $H_1 \otimes \cdots \otimes H_n$ for smooth entries with compact, pairwise disjoint supports; and $|\mathsf{S}_n^\sigma(\varphi)| \le \mathsf{C}_E^n (n!)^{24} |\varphi|_{17n}$, so that each component is a distribution of order at most $17n$ on the configurations of n different points. The L^1 form of these bounds in several entries, $|\sigma(X)| \le C \prod_a \|H_a\|_{L^1}$ near the configurations whose heights no coordinate direction orders, is the bound of Theorem W(6), which uses the rotations.

■

Proof. (a) Use the ordered-tuple argument of Lemma 5.29. Its proof uses only the sup-norm bounds, translation and cubic symmetry, coordinate reflection positivity and the square cone, which are the hypotheses here. It gives the stated approximations by mollified and cut members, using the two-member height-L^1 bound to remove thin layers and analytic continuation to lift one group past another. The same approximants work for two functionals, giving the last assertion; the classes determine $\sigma(X) = \langle \Omega, [X] \rangle$. (b) The proof of Proposition 6.24 runs with the square tube $\mathsf{Tb}^\square$ in the place of Tb, the square cone of Proposition 6.14(a) in the place of (R3), the dihedral group in the place of O(3) and Proposition 6.17(iii) for (R4); cyclicity comes from (a). With the forward cone of Theorem W(2) the boundary values are taken from every direction of the forward cone. (c) Let $\delta_n = 1/(8n)$, and let first $g \le \gamma_W^{\mathrm{sd}}$, so that $i_n = 1$. In a periodic Gibbs state, and on an admissible torus, cut every entry into its pieces on the boxes of side $\mathsf{l}/(4n)$. For one choice of a piece of each entry the n pieces lie at pairwise sup distances $> \mathsf{l}$, and an offset in $a_K\mathbb{Z}^3$ of a board of cells of side l puts them into n different cells, each at the margin $\delta_n \mathsf{l}$ from the walls (in each coordinate the offsets that bring a wall near one of the n pieces fill less than a period). Proposition 6.17 at the margin δ_n holds for every $i \ge 1$ and at all weights. Of the margin δ its proof reads only the depth s at which the renormalisation progression is stopped on the least torus of the scale L^{-i}, chosen so that the mirror copies of a piece, about δ apart in units of the cell, are a number of blocks of the stopped level apart that is formed from the constants, g and i alone; so L^s is δ^{-1} times such a number, and the moment bound pays L^{4s}: this gives the factor δ^{-4} in C_E, which is δ^{-4} times a number free of δ, and the cutoffs $K_E(i)$, while c_E and q_E are formed without δ.

At the off-diagonal labels it reads the bond form of a weight w of the bonds as a source of the small-field progression with sources (Propositions E.7 and B.8, with the local representation specified here), and of the term of the never-large histories in the decomposition of a mean by the level at which a large field is first created (Section YMM1:123, equation (314)), under the majorant $(59\sup|\mathsf{w}|, S[\mathsf{w}])$, $S[\mathsf{w}]$ the plaquettes that contain a bond where $\mathsf{w}\neq 0$ (Lemma 6.12(a), (b)): the bond form has the properties of a source that these statements read, so that they hold for it as for a weight of the plaquettes of the sup norm $59\sup|\mathsf{w}|$ carried by $S[\mathsf{w}]$.

Proposition 6.17 at the margin δ_n and its consequence (i), with $b^{-1}\le g^2$, bound the mean of the product of the pieces, centred in the state, by $\prod_a 2\mathsf{g}_{n,i}\sup|H_a|_\infty$, the suprema over their boxes, with no factorial. By multilinearity the mean of the product of the centred entries is the sum of these terms over the choices of one box for each entry, and $(4n/\mathsf{l})^3\|H\|_\natural=\sum_{\mathfrak{b}}\sup_{\mathfrak{b}}|H|_\infty$; the bound passes to the limit. Above γ_W^{sd} the dilation of Lemma 6.16 carries it over, a board of the index $i\ge z+1$ going to one of the index $i-z\ge 1$ at g_1' or g_2', its factors entering c_g.

Nothing in this uses a rotation, an ordering of the supports or analyticity. For the count, take i the least integer with $L^{-i}\le d$ and $i\ge i_n$; then $L^i\le L^{i_n}/d$, and L^{i_n} depends on the constants and g alone; $2\mathsf{g}_{n,i}(4n/\mathsf{l})^3=128\,\mathsf{c}_g n^7\mathsf{Y}_i^{q_E}L^{(17/2)i}$, and, as $t^q\le(4q)^q e^{t/4}$ for $t,q>0$ and c_E, q_E do not read n, $\mathsf{Y}_i^{q_E}\le(4q_E)^{q_E}e^{c_E/2}L^{i/2}$ (above γ_W^{sd} the same with the numbers at g_s' and the index $i-z$): one power $d^{-1/2}$ absorbs it, and each factor is at most $Cn^7d^{-9}\le\mathsf{C}_G n^{16}d^{-9}$; and $n^n\le e^n n!$. The growth condition follows from this bound by the extension of multilinear forms bounded at separated tuples (Proposition YMM1:93.3) with the exponent $9n$ of d^{-1}, applied to each of the 6^n forms $(f_1,\dots,f_n)\mapsto\sigma(f_1E_{\iota_1},\dots,f_nE_{\iota_n})$, E_ι running through the basis $E_{\lambda\lambda}$, $o_{\lambda\lambda'}$ $(\lambda<\lambda')$ of V: each has exactly one extension to the scalar test functions flat at the coinciding points that is bounded for one of the norms; $\mathsf{S}_n^\sigma(\varphi)$ is the sum of these extensions at the components φ_ι of φ in that basis; it has the value $\sigma(H_1,\dots,H_n)$ at $H_1\otimes\cdots\otimes H_n$ by multilinearity; and for a second functional S' with these properties, $\psi\mapsto\mathsf{S}'(\psi E_{\iota_1}\otimes\cdots\otimes E_{\iota_n})$ is an extension of the same form, bounded for one of the norms, so it is that extension, and $\mathsf{S}'=\mathsf{S}_n^\sigma$.

For weights in balls of radius 1, $\|H\|_\natural\le 27|H|_\infty$, and $(n!)^8(n!)^{16}=(n!)^{24}$, $|\varphi|_{17n-1}\le|\varphi|_{17n}$. □

Proposition 6.26 (Rescaling the off-diagonal labels)**.** Let σ satisfy (D0)–(D4), $z\neq 0$ real, and $\sigma^z=\sigma\circ Z_z$. Then σ^z satisfies (D0)–(D4), with $\max\{1,|z|\}^nC_n(\delta,\varrho_0)$ in (D1), and has the trace part of σ; $[F]_{\sigma^z}\mapsto[Z_zF]_\sigma$ is a unitary map of $\mathcal{H}(\sigma^z)$ onto $\mathcal{H}(\sigma)$ that commutes with the translations and the semigroup, under which the slab and point operators and the kernels of σ^z are those of σ with Z_z applied to the labels. If $\sigma(\varphi_1E,\varphi_2E)\neq 0$ for $E=o_{12}$ and some φ_1,φ_2 with disjoint supports, and $z^2\neq 1$, then σ and σ^z are not both covariant at order 2. For a tensor limit at $g\le\gamma_W^{\mathrm{sd}}$ the two-point law of Proposition 6.15, at all pairs of weights, holds for σ^z with some label $b'>0$ in the place of b if and only if $z=1$; at the pairs of off-diagonal weights alone it holds with the label b of σ if and only if $z^2=1$. ■

Proof. Z_z is the identity on V_A and commutes with $\rho(W_3)$, in particular with $\rho(\Theta_n)$ for $n\in\mathfrak{N}_{18}$; this gives the first part. Let R be the rotation by $\pi/4$ about e_3, so that $\rho(R)E=E_{22}-E_{11}\in V_E$. If both were covariant at order 2, then

$$z^2\sigma(\varphi_1E,\varphi_2E)=\sigma^z(\varphi_1E,\varphi_2E)=\sigma^z(R(\varphi_1E),R(\varphi_2E))=\sigma(R(\varphi_1E),R(\varphi_2E))=\sigma(\varphi_1E,\varphi_2E).$$

For the law: at $z=1$, $\sigma^z=\sigma$. Let σ^z obey the law with an error $\epsilon'(d)\to 0$, at all pairs with a label b', or at the pairs of off-diagonal weights alone with the label b. In the first case, at the pairs of diagonal weights, which Z_z leaves alone, its label is that of σ: there $\sigma^z=\sigma$, and at $(\varphi_1^d\mathbf{1},\varphi_2^d\mathbf{1})$, with the bumps of Proposition 6.15(a), the kernel of $\mathcal{W}$ is $\frac{3}{2}\operatorname{tr}K_3(u)^2=9(4\pi|u|^3)^{-2}>0$, $u=x-y$, so that $\mathcal{W}(\varphi_1^d\mathbf{1},\varphi_2^d\mathbf{1})$ is a positive number independent of d, and b'^{-2} and b^{-2} are both the limit of $\sigma(\varphi_1^d\mathbf{1},\varphi_2^d\mathbf{1})/\mathcal{W}(\varphi_1^d\mathbf{1},\varphi_2^d\mathbf{1})$ as $d\downarrow 0$: $b'=b$.

With the label b, in both cases, at off-diagonal entries $\sigma^z(H_1,H_2)=z^2\sigma(H_1,H_2)$, and $|z^2-1|\,b^{-2}|\mathcal{W}(H_1,H_2)|\le(z^2\epsilon_g(d)+\epsilon'(d))b^{-2}|H_1|_\infty|H_2|_\infty$ for all small d forces $z^2=1$ by the lower bound

of $\mathcal{W}$ (Proposition 6.15(a)); conversely at $z=\pm1$ these pairs are unchanged. At the mixed pair $H_1=\varphi_1^d\mathbf{1}$, $H_2=\varphi_2^d o_{12}$, with the bumps of Proposition 6.15(a) placed with $x_2-x_1=\frac{7}{2}d(e_1+e_2)/\sqrt{2}$, one has $\sigma^z(H_1,H_2)=z\,\sigma(H_1,H_2)$, and the kernel of $\mathcal{W}$ is $\frac{3}{2}\operatorname{tr}[K_3(u)o_{12}K_3(u)]=3(K_3(u)^2)_{12}=9\hat u_1\hat u_2(4\pi|u|^3)^{-2}$, with $K_3(u)=(3\hat u\hat u^{\mathrm t}-\mathbf{1})(4\pi|u|^3)^{-1}$, $\hat u=u/|u|$, u the difference of the two points; on the supports $\hat u$ lies within the angle $\arcsin\frac{2}{7}<\frac{\pi}{4}$ of $\pm(e_1+e_2)/\sqrt{2}$, so $\hat u_1\hat u_2>0$, and $\mathcal{W}(H_1,H_2)=w_\times>0$ does not depend on d, $\mathcal{W}$ being invariant under dilations.

So $|z-1|\,b^{-2}w_\times\le(|z|\epsilon_g(d)+\epsilon'(d))b^{-2}|\varphi|_\infty^2$ for all small d, and $z=1$. This is Proposition 6.15(d) at $a=e=1$. □

Proposition 6.27 (The decomposition with labels)**.** Let σ be a tensor limit at $0<g\le\gamma_W^{\mathrm{ref}}$ of the Gibbs sequence (K_j,β_j,ν_j), σ_0 its trace part and $(\mathsf{X}_0,\lambda_0,(\sigma_{0,\zeta}))$ the canonical decomposition of σ_0.

(a) σ has a canonical decomposition $(\mathsf{X},\lambda,(\sigma_\chi)_{\chi\in\mathsf{X}})$: X compact metrisable, λ a Borel probability measure with support X, each σ_χ a real symmetric functional on labelled tuples, $\chi\mapsto\sigma_\chi(X)$ continuous and $\chi\mapsto\sigma_\chi$ injective, and the iterated plateaux of σ at $(X^1,\dots,X^q)$ equal to $\int\prod_i\sigma_\chi(X^i)\,\lambda(d\chi)$. For every χ there are translation-invariant events E_j with $\nu_j(E_j)>0$ such that $\rho_j=(\nu_j)_{1_{E_j}}\in\mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$ have $\sigma_\chi(X)=\lim_j\rho_j(A_j(X))$ along the full sequence, $A_j(X)$ the product of the entries centred in ν_j; with $\mathcal{I}$ the invariant sigma-algebra, $\|\mathbb{E}_{\rho_j}[A_j(X)\mid\mathcal{I}]-\sigma_\chi(X)\|_{L^\infty(\rho_j)}\to0$. The bounds of Proposition 6.13(a) hold for every σ_χ with numbers free of χ.

(b) Every σ_χ clusters, $\sigma_\chi(X\cdot\tau_vY)\to\sigma_\chi(X)\sigma_\chi(Y)$ as $|v|\to\infty$, and $\ker H=\mathbb{C}\Omega$ on $\mathcal{H}(\sigma_\chi)$.

(c) Exactly one map $\pi:\mathsf{X}\to\mathsf{X}_0$ has $\sigma_\chi(f_1\mathbf{1},\dots,f_n\mathbf{1})=\sigma_{0,\pi(\chi)}(f_1,\dots,f_n)$; it is continuous and onto, and $\pi_*\lambda=\lambda_0$. The ρ_j of (a) are approximants of $\pi(\chi)$, σ_χ is the lift $\sigma^\sharp_{\pi(\chi)}$ formed with them, along the full sequence, and $\sigma_\chi((H))=\frac{c_{\pi(\chi)}}{3}\int\operatorname{tr}H$.

(d) With $s_\chi(H)=\sigma_\chi((H))$, (K_j,β_j,ρ_j) is a Gibbs sequence at g with the tensor limit $\sigma^c_\chi(X)=\sum_J\prod_{a\notin J}(-s_\chi(H_a))\sigma_\chi(X_J)$, along the full sequence. The linear map $\mathsf{S}_\chi(X)=\sum_J\prod_{a\notin J}s_\chi(H_a)X_J$ of combinations is a bijection, multiplicative, commutes with the bar and with every isometry, and $\sigma_\chi=\sigma^c_\chi\circ\mathsf{S}_\chi$; $[F]\mapsto[\mathsf{S}_\chi F]$ is a unitary map of $\mathcal{H}(\sigma_\chi)$ onto $\mathcal{H}(\sigma^c_\chi)$ that carries Ω to Ω and intertwines e^{-tH}, the translations and the dihedral group; under it $B_l(X)$ corresponds to $\sum_J\prod_{a\notin J}s_\chi(h_a)B^c_l(X_J)$ and $B(s,s';e)$ to $B^c(s,s';e)+\frac{c_{\pi(\chi)}}{3}(\operatorname{tr}e)e^{-(s+s')H}$. In particular $\ker H=\mathbb{C}\Omega$ on $\mathcal{H}(\sigma^c_\chi)$.

■

Proof. (a) The construction of the canonical decomposition in the proof of Theorem YMM1:AL uses of the scalar functional only bounds of the kind of Proposition 6.13(a), uniform along the sequence and in every periodic Gibbs state; with them it applies to labelled tuples: at a fixed physical size the conditional expectations of the centred products onto the translation-invariant events have plateaux that do not depend on the cutoff in the limit, iterated plateaux commute with $j\to\infty$, and the plateau functions take their values in a countable product of compact intervals; Stone–Weierstrass and Riesz give X and λ, and conditioning on invariant events of small probability near a point χ gives the ρ_j. (b) The plateau of a component is the product: $\sigma_\chi(X\cdot\tau_vY)\to\sigma_\chi(X)\sigma_\chi(Y)$.

So $\langle[F'],e^{-tH}[F]\rangle=\sigma_\chi(\theta\bar F'\cdot\tau_{te_3}F)\to\langle[F'],\Omega\rangle\langle\Omega,[F]\rangle$ as $t\to\infty$, and the projection onto $\ker H$ is $|\Omega\rangle\langle\Omega|$. (c) The trace parts of the components decompose the trace part, and the canonical decomposition of σ_0 is unique; the conditioned states are approximants of the scalar component $\pi(\chi)$, and Proposition 6.13(d) applies to them, along the full sequence because the limit σ_χ exists. (d) The expansion of Theorem W(1), inverted; S_χ has the inverse with $-s_\chi$; the operators follow from the identity of values. □

6.9. **Proof of Theorem V.** *Step 1: clause (a).* Lemma 6.2(a) gives all but the assertion that the action is forced, which is Lemma 6.2(d); for $A=\rho(\Theta_u)$ and h with values in V_u^- it gives $[(h)]_u=[(-h)]_u=-[(h)]_u$.

Step 2: clause (b). That a positive mirror, or one with real numbers $\sigma(\theta_u \bar{F} \cdot F)$, is a symmetry is Lemma 6.2(b); positivity at (n, c) from m and R is Lemma 6.2(c); closedness is Lemma 6.2(e), and $W_3 \subset G_\sigma$ is (D3). For the equivalences: (iii)⇒(ii) because the plane may be moved through 0 (Lemma 6.2(a)), $\Theta_n \in G_\sigma$ by Lemma 6.2(b), which uses only the reality of the numbers, and $\Theta_n \notin W_3$; (ii)⇒(i) by Lemma 6.2(e); (i)⇒(iv) by Lemma 6.2(c) with $m = e_3$, positive by (D4), and $Re_3 = n$:

$$\sigma(\theta_{n,c} \bar{F} \cdot F) = \sigma(\theta_{e_3} \bar{G} \cdot G) \geq 0, \qquad G = \iota^{-1} F,\ \iota x = Rx + cn.$$

Since $\mathfrak{N}_{18} \subset \mathfrak{M}(\sigma)$ by (D4), $\mathfrak{M}(\sigma) \neq \mathfrak{N}_{18}$ gives (iii), hence (iv).

Step 3: clause (c). The first assertions are Lemma 6.10(a)–(c). The chain: covariance at order $2m$ gives $\mathfrak{M}^{(m)}(\sigma) = S^2$ by Lemma 6.10(b), (c) at $(\mathfrak{K}_m, \mathfrak{K}_{2m})$; the second arrow is $\mathfrak{N}_{18} \neq S^2$; for the third, a $u \in \mathfrak{M}^{(m)}(\sigma) \setminus \mathfrak{N}_{18}$ gives, by Lemma 6.10(d) at $\mathfrak{F} = \mathfrak{K}_m$, with all real c by Lemma 6.2(a), whose proof keeps the number of entries, $\Theta_u \in G_\sigma[\mathfrak{K}_m]$, $\Theta_u \notin W_3$, and Lemma 6.10(a). At $m = \infty$ the orders m and $2m$ agree. The assertions on one and two entries are Lemma 6.10(e).

Step 4: clause (d). Proposition 6.6(a) gives the symmetries, the positivity and the cone. On the forward cone

$$\left| e^{-\zeta_3 E + i(\zeta_1 q_1 + \zeta_2 q_2)} \right| \leq e^{-E(\operatorname{Re}\zeta_3 - |(\operatorname{Im}\zeta_1, \operatorname{Im}\zeta_2)|)},$$

so $\|\mathsf{E}(\zeta)\| \leq 1$ on $\overline{\mathsf{Tb}}$, and the bounds $E^k e^{-Ed} \leq (k/ed)^k$ on the carrier give holomorphy in norm; the product law and the real points are the calculus of $\mathcal{P}_u$. With $e_3 = u$, $e_1 = -u'$, $e_2 = u''$ one has $n_- = (u + u')/\sqrt{2}$, and the three mirrors are those of Proposition 6.8; the exchange of e_1 and e_2 lies in the cubic group of the frame. Proposition 6.8(b), (c), (d) give D, the V_Λ, the invariance of the null sets and of the support, and the unitary map to the picture of $(u + u')/\sqrt{2}$; a closed subset of the forward cone invariant under $\mathrm{SO}_0(1, 2)$ is a union of orbits, and the orbits are $\{0\}$, the light cone without its tip and the mass shells. The cubic group of the frame, through Lemma 6.3, connects the pictures of the six normals $\pm u, \pm u', \pm u''$ and of the twelve others among themselves. Lemma 6.9 at $\gamma = \pi/4$, $n = (u + u')/\sqrt{2}$, gives the law; its hypothesis is Lemma 6.4 at (u, u') and at (n, m), as $(n + m)/\sqrt{2} = u$. The proofs use of ρ only that it is a homomorphism and, in Lemma 6.3, a bound $|\rho(\Theta)E| \leq c_\rho |E|$. The last assertion is Proposition 6.6(b).

Step 5: clause (e). By Lemma 6.3 a rotation D_t about e_3 in G_σ acts unitarily on $\mathcal{H}(\sigma)$ and turns q in $\mathcal{P}$, so $\{E < |q \cdot D_t e_1|\}$ is a null set together with $\{E < |q_1|\}$; for a countable dense set A_0 of angles

$$\{E < |q|\} = \textstyle\bigcup_{t \in A_0} \{E < |q \cdot D_t e_1|\},$$

since $E < |q|$ gives $q \cdot m > E$ for all unit m near $q/|q|$. Under covariance, Lemma 6.2(c) gives $\mathfrak{M}(\sigma) = S^2$, Lemma 6.4 at (e_3, e_1) gives $H \geq |P_1|$, and Lemma 6.3 transports the picture; strong continuity of the representation: $\|[RF] - [F]\|^2 = 2\|[F]\|^2 - 2 \operatorname{Re} \sigma(\theta \bar{F} \cdot RF) \to 0$ as $R \to 1$, by (D0), (D1) as in the proof of Lemma 6.2(e), and the classes are dense.

Step 6: clause (f). Proposition 6.11.

6.10. **Proof of Theorem W.** *Step 1: clause (1).* Existence, (D0)–(D4) with $C_n = C_n^{\mathrm{lc}}$, the trace part and the lifts are Proposition 6.13(b)–(d); the label exists and is determined by σ by Proposition 6.15(a). For a lift, $\rho_j(O_a) - \nu_j(O_a) \to \frac{c_\xi}{3} \int \operatorname{tr} H_a$, $O_a = O^T_{K_j}(H_a)$; expanding

$$\prod_a (O_a - \nu_j(O_a)) = \sum_S \prod_{a \notin S} (\rho_j(O_a) - \nu_j(O_a)) \prod_{a \in S} (O_a - \rho_j(O_a))$$

and inverting the sum shows that σ^c_ξ exists along the same subsequence and gives both identities; (K_j, β_j, ρ_j) is a Gibbs sequence, ρ_j being a periodic Gibbs state.

Step 2: clause (2). By (1), (D4) gives positivity at the three mirrors of each frame $(e_\mu, e_\lambda, e_\nu)$, and Theorem V(d) applies; the 18 normals of the cubic group of the standard frame are $\mathfrak{N}_{18}$.

Step 3: clause (3). Let first $g \leq \gamma^{\mathrm{sd}}_W$, σ a tensor limit at g, and σ' the limit at continuous weights of Lemma 6.16(d), which agrees with σ at the tuples of weights. σ' has the hypotheses of

Proposition 6.22: (C1) by Propositions 6.13(c) and 6.14(a); (C2) by Proposition 6.14(d); (C3) by Proposition 6.15(e); (C4) because its trace part is the scalar limit, which has the bound of (S2); (C5) by Proposition 6.19(c); (C6) by Proposition 6.17(iii). At the off-diagonal labels (C3), (C6) and (h7) below rest on the bond forms entering the renormalisation progression as sources under the majorant $(59 \sup|\mathsf{w}|, S[\mathsf{w}])$ (Lemma 6.12(a), (b)), as in the proof of Proposition 6.25(c); for (C3) and (h7) their second order at small fields enters besides, a quadratic form in the plaquette angles of $S[\mathsf{w}]$ with a kernel whose row sums lie under the same majorant, and this gives the two-point bound of Proposition 6.15(e) at these labels with a number free of d (Lemma 6.12(c)).

So σ' is covariant, and so is σ. At two entries Proposition 6.20 applies instead: (h1), (h2) by Proposition 6.13(c), (h3) by Proposition 6.14(a) with $v(h) = [(h)]$, (h4) by (D4), (h5) by Proposition 6.19(c), (h6) by the invariance of the scalar limit (S2), (h7) with $a = 0$ by Proposition 6.15(e); no bound with a power enters. For $\gamma_W^{\mathrm{sd}} < g \le \gamma$, pass to a subsequence along which the bounded labels converge, choose z with $g_z \le \gamma_W^{\mathrm{sd}}$ and use Lemma 6.16(b):

$$\sigma(RX) = L^{nz}\sigma_z((RX)^{(z)}) = L^{nz}\sigma_z(RX^{(z)}) = L^{nz}\sigma_z(X^{(z)}) = \sigma(X).$$

For a lift, the identity of (1), the covariance of the tensor limit σ_ξ^c and $\int \mathrm{tr}(RH) = \int \mathrm{tr}\, H$ give the claim.

Step 4: clause (4). For $g \le \gamma_W^{\mathrm{ref}}$, clause (3) is (i) of Theorem V(b) for tensor limits and lifts, which with (D4) gives (iv); Theorem V(e) gives the pictures and the representation of O(2). For a tensor limit at $\gamma_W^{\mathrm{ref}} < g \le \gamma$, with z as in Step 3, $(\theta_{n,c}H)^{(z)} = \theta_{n,L^z c}H^{(z)}$ and Lemma 6.16(b) make $\sigma(\theta_{n,c}\bar{F}\cdot F)$ the form of σ_z at $(n, L^z c)$ at the combination $S_z F$, and σ_z is positive there; this gives $\mathfrak{M}(\sigma) = S^2$ at every $0 < g \le \gamma$. For the labels, at $0 < g \le \gamma_W^{\mathrm{ref}}$, where the two-point law of Proposition 6.15 holds (above γ_W^{sd} through the dilation in its proof), Proposition 6.15(b) at $\theta' = \theta$ and $x_0 = \frac{3}{2}de_3$ gives $\|[(\varphi E)]\|^2 = \sigma(\theta(\varphi E), \varphi E) \ge (w_0 - \epsilon_g(d))b^{-2}\,\mathrm{tr}\, E^2$; for $E \in V_{e_3}^-$, $\theta(\varphi E) = -(\varphi\circ\theta)E$, so the form of the reflection acting on the points alone takes the negative value $-\|[(\varphi E)]\|^2$; for $u = Re_3$ the covariance carries φE to $R(\varphi E)$, with values in V_u^-, and the value is the same; the translations give every c.

Step 5: clause (5). (R1) is clause (3) with (D2); (R2) is Proposition 6.14(a); (R3) is clause (2); (R4) is Proposition 6.17(iii). For the kernels, take $\varepsilon = \eta$ in the product formula of Proposition 6.14(f): then $\zeta^k - 2\eta e_3 \in \overline{\mathsf{Tb}}$, the $\mathsf{E}(\zeta^k - 2\eta e_3)$ are contractions, holomorphic in norm by clause (2), and (R4), with h concentrating at a point of $\{x_3 = 0\}$, gives $\|B(\eta,\eta;e)\| \le C_V\eta^{-p}|e|_\infty$; hence

$$|\mathbf{W}_n(\zeta;e)| \le \prod_k \|B(\eta,\eta;e_k)\| \le (C_V\eta^{-p})^n \prod_k |e_k|_\infty.$$

For a lift the holomorphy is the same argument with its point operators.

Step 6: clause (6). By clause (1) and clause (5), Proposition 6.24 applies; at $p = 9$ one has $k_E = 9$ and $(n!)^{2p} = (n!)^{18}$. At continuous weights the kernel of the limit σ' of Lemma 6.16(d) serves. Above γ_W^{sd}, $s_n(x;e) = L^{4nz}s_n'(L^z x;e)$ with the kernel s_n' at the smaller coupling and $\delta(L^z x) \ge \delta(x)$. For a lift the kernel is $\sum_S \prod_{a\notin S} \frac{c_\xi}{3}\,\mathrm{tr}\, e_a\, s^c_{|S|}(x_S; e_S)$, $s_0^c = 1$, $s_1^c = 0$, by the identity of clause (1); $|\frac{c_\xi}{3}\,\mathrm{tr}\, e| \le |c_\xi||e|_\infty$, $\delta(x_S) \ge \delta(x)$, and there are 2^n subsets.

Step 7: clause (7). Proposition 6.27(a)–(c) give the decomposition, the map π, the lifts and the clustering, and $\ker H = \mathbb{C}\Omega$ on $\mathcal{H}(\sigma_\chi)$; Proposition 6.27(d) gives the same on $\mathcal{H}(\sigma_\chi^c)$; σ_χ^c is a tensor limit at g, so clauses (5), (6) apply to it, and with $\ker H = \mathbb{C}\Omega$ the last sentence of Proposition 6.24 gives all the Wightman axioms.

Step 8: clause (8). By clause (3) σ is covariant. By Proposition 6.15(a), with the bumps φ_i^d there, $b^2|\sigma(\varphi_1^d o_{12}, \varphi_2^d o_{12})| \ge \mathcal{W}(\varphi_1^d o_{12}, \varphi_2^d o_{12}) - \epsilon_g(d)|\varphi|_\infty^2 > 0$ for small d. Proposition 6.26 at $z = 2$ gives the properties of $\sigma\circ Z_2$, its operators and fields through the unitary map, and shows that it is not covariant at order 2; Theorem V(b) gives $\mathfrak{M}(\sigma\circ Z_2) = \mathfrak{N}_{18}$, and Theorem V(d) the cone. The law holds for $\sigma\circ Z_z$, with some label in the place of b, at $z = 1$ alone, and at the pairs of off-diagonal weights alone, with the label b, exactly at $z^2 = 1$, by Proposition 6.26: the pairs of

diagonal weights fix the label, and the mixed pair of a diagonal and an off-diagonal weight excludes $z = -1$ (Proposition 6.15(d) at $a = e = 1$); the last assertion is Remark 6.23.

Remark 6.28. Uniqueness of the vacuum holds in the components of clause (7) of Theorem W. Near coinciding points the bounds of clause (6) give a growth of the kernels s_n at most like $\delta(x)^{-9n}$ and the extension S_n of σ to the test functions flat at the coincidences, with numbers C_V, C that depend on the constants and g; the limits are taken through periodic Gibbs states, and along growing tori (D0)–(D3) and positivity at the three coordinate families of mirrors hold (Proposition 6.13(e)). Clause (8) and Theorem V(f) concern functionals with (D0)–(D4) only: $\sigma \circ Z_2$ is σ written in the basis Z_2 of V, covariant and positive at every plane for the representation $R \mapsto Z_2^{-1}\rho(R)Z_2$, and the tensor limits are covariant by clause (3). For the tensor limits clause (6) gives a representation of the Poincaré group that acts covariantly on the fields.

7. Two short scales and point splitting

A pair of nearby action-density insertions has a tensor-valued leading term. We compare the close pair with this tensor at a second, larger distance, retaining the dependence on both scales. The three-point comparison, its extension to plane fields, the fixed-distance point-splitting limit and the four-point law have different hypotheses and are stated separately.

The proof begins with the local kernels and their Gaussian contractions, then controls their remainders through the renormalisation steps. The treatment of narrow test functions is needed to distinguish continuous continuum kernels from the almost-everywhere classes obtained on a fixed torus.

7.1. **Notation and hypotheses.** *Constants and conventions.* Fix one common choice of the real and sourced construction constants, as in Proposition YMM1:69.1 and Section YMM1:82, at a fixed source radius $2\varrho > 0$. The real construction uses the restriction of this choice, with no change in the value of any retained constant. In particular, the hypotheses of Theorems YMM1:AJ and YMM1:AD are imposed at this same choice: the blocking factor $L \geq 13$ is odd, the cube size is $M = L^{m'}$, $a_j = \eta_j = L^{-j}$, and $A_0, A_1, \mathfrak{p}_0 \geq 1$, $\bar{B}$, $B_\sharp$ (with $\bar{B} = B_\sharp L/(L-1)$), α_0, β_s, κ, together with the remaining constants of the real and sourced steps, have these fixed values. By C, c, c', with or without an index, we denote positive numbers made from these constants only, and by $C(g)$, $C(g, \mathfrak{b})$, $C(g, \ell)$ numbers that may also depend on the displayed arguments; such a number depends on nothing that is not displayed, in particular not on K, β, ℓ, a level, a length, a position, a direction, a sign or a weight. We put $\delta(t) = A_1(\log t)^{\mathfrak{p}_0} t^{-1/2}$, $\mathfrak{b}(t) = A_1(\log t)^{\mathfrak{p}_0}$, $\varepsilon(t) = A_0(\log t)^{\mathfrak{p}_0} t^{-1/2}$; δ and ε decrease on $[e^{2\mathfrak{p}_0}, \infty)$.

Couplings, data, sides. The reference coupling satisfies $0 < g \leq \gamma$, with the ceiling fixed by Proposition YMM1:82.2. A first-passage datum (K, β) at g consists of a bare inverse coupling β and the number K of renormalisation steps after which, for the first time, the running inverse coupling that starts at β is at most $L(g^{-2} + B_\sharp)$, as in Proposition YMM1:74.1. Its run is $x_0 = \beta > x_1 > \cdots > x_K > g^{-2}$; we write $y_j = \log x_j$, $g_j = x_j^{-1/2}$, $\delta_j = \delta(x_j)$, $\mathfrak{b}_j = \mathfrak{b}(x_j)$, $\varepsilon_j = \varepsilon(x_j)$. The label $\mathfrak{b} = a_K \beta$ is a length, $g^{-2} < \mathfrak{b} \leq \bar{\mathfrak{b}} := L(g^{-2} + \bar{B})$. We put $I(g) = (g^{-2} + \bar{B},\, L(g^{-2} + B_\sharp) - \bar{B}]$; for $\mathfrak{b} \in I(g)$ the pair $(K, L^K \mathfrak{b})$ is a first-passage datum at g with the label $\mathfrak{b}$ for every $K \geq 1$. $\mathfrak{L}(g)$ is the set of the sides at g, each of the form $\ell = 2L^m$, and $\ell_g = \min \mathfrak{L}(g) \geq 26$ is the least side; T_ℓ is the torus of side ℓ with the lattice $a_K \mathbb{Z}^3$, and the lattice (ℓ, K) is this torus with the coarser lattices of its levels.

States and limits. $\mu_{K,\ell,\beta}$ is the measure of the torus T_ℓ at the cutoff K and the bare coupling β, $\langle \cdot \rangle_{K,\ell,\beta}$ its expectation, $\tilde{\mu}_{K,\ell,\beta}$ its periodic extension to $\mathbb{L}_K = a_K \mathbb{Z}^3$, and $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ is the set of periodic Gibbs states (equation YMM1:(1819) and the definition of periodic states following it). By a state at (K, β) we mean either a periodic extension $\tilde{\mu}_{K,\ell,\beta}$ with $\ell \in \mathfrak{L}(g)$ or a periodic Gibbs state in $\mathcal{G}^{\mathrm{per}}_{K,\beta}$. The test pairs $\mathfrak{T}_{T_\ell}(r; \vartheta)$ of scale r and shape ϑ are those of Lemma I.1.

Along first-passage data (K_j, β_j) at g with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b} > 0$, the torus connected functions converge to $S_n^{(\ell,\mathsf{b})}$ on real Lipschitz tuples with pairwise disjoint supports, independently of the defining sequence, by Theorem YMM1:A. The first-passage labels lie in $(g^{-2}, \bar{\mathsf{b}}]$ by Proposition YMM1:74.1; in particular their limiting labels are positive. A law on $\mathbb{R}^3$ is a functional on separated tuples of real C_c^1 functions with the properties of the growing-torus or volume-first limits in Propositions YMM1:92.1, YMM1:92.3 and YMM1:92.4. Limits of periodic-Gibbs sequences and the components of their canonical decompositions are examples, by Theorems YMM1:AP and YMM1:AL.

For limits of periodic-Gibbs sequences and their canonical components, Theorem YMM1:AP and Proposition YMM1:108.3 give unique continuous moment kernels, real analytic and invariant under Euclidean isometries. The connected kernels have the same properties by the finite moment–cumulant formula. For an arbitrary growing-torus law, the inherited bounds initially give distributions on separated configurations. Full rotation invariance has the additional Ward criterion of Theorem YMM1:AQ; the analytic-kernel conclusion is available when the reconstruction hypotheses (Rec) of Proposition YMM1:108.3 hold. The pointwise assertions below for such a law explicitly assume continuity of the kernels they evaluate. The finite-cutoff, integrated and almost-everywhere assertions retain their stated hypotheses.

Fields. For a plaquette p, $x(p)$ is its barycentre, $\lambda(p) \in \{1,2,3\}$ its dual direction (the direction orthogonal to its plane), and $a_p = 1 - \frac{1}{2}\operatorname{tr}\partial U(p)$. For a real weight w on the plaquettes with finite support, $\mathcal{O}(w) = a_K^{-1}\sum_p w(p)a_p$, $|w|_\infty = \max_p |w(p)|$ and $\Sigma(w) = \{x(p) : w(p) \neq 0\}$; for a bounded function f, $\mathcal{O}(f) = \mathcal{O}(f \circ x)$. The plane fields are $\mathcal{O}_\lambda(\varphi) = \mathcal{O}(\mathbf{1}_{\{\lambda(p)=\lambda\}}\,\varphi \circ x)$, with plane weights, so that $\mathcal{O} = \sum_\lambda \mathcal{O}_\lambda$; $T_\lambda = \mathcal{O}_\lambda - \frac{1}{3}\mathcal{O}$ are the diagonal elements of the traceless tensor.

Off the diagonal stand the bond forms. For $V \in SU(2)$ put $\mathrm{w}(V) = (V - V^{-1})/2i$, and $\langle X, Y\rangle = \frac{1}{2}\operatorname{tr} XY$. A bond $b = \langle x, x + a_K e_\mu\rangle$ has the base point x, the direction $\mu_b = \mu$ and the midpoint $x_b = x + \frac{1}{2}a_K e_\mu$. For signed directions α, α' with $\alpha \neq \pm\alpha'$ let $W_x(\alpha, \alpha')$ be the product of U along the closed path $x \to x + a_K e_\alpha \to x + a_K e_\alpha + a_K e_{\alpha'} \to x + a_K e_{\alpha'} \to x$, where $e_{-\alpha} = -e_\alpha$. For a direction $\alpha \neq \mu_b$ the loops $W_x(\mu_b, \alpha)$ and $W_x(\mu_b, -\alpha)$ run around the two plaquettes of the plane spanned by μ_b and α that contain b, both from the base point x along b first, and we put $u_{b,\alpha} = -\frac{1}{2}[\mathrm{w}(W_x(\mu_b, \alpha)) - \mathrm{w}(W_x(\mu_b, -\alpha))]$; with $\lambda_b < \lambda_b'$ the two directions other than μ_b, $q_b = \langle u_{b,\lambda_b}, u_{b,\lambda_b'}\rangle$.

For a real weight w on the bonds, $Y[\mathsf{w}] = -a_K^{-1}\sum_b \mathsf{w}(b)q_b$, and $\mathcal{O}^{\mathrm{od}}_{\lambda\lambda'}(\varphi) = Y[\mathsf{w}]$ at $\mathsf{w}(b) = \varphi(x_b)\mathbf{1}_{\{\mu_b=\mu\}}$, where $\{\lambda, \lambda', \mu\} = \{1,2,3\}$: the bond weight is taken at the midpoint. Written in the angles F_p of the plaquette variables, the linear part of $u_{b,\lambda}$ is $\sum_p u_{b,\lambda}(p)F_p$, with $u_{b,\lambda}(p) = \frac{1}{2}\epsilon_{\lambda\mu_b\lambda'}\epsilon_p$ at the two plaquettes with the barycentres $x_b \pm \frac{1}{2}a_K e_\lambda$ and $u_{b,\lambda}(p) = 0$ at all other plaquettes; here $\{\lambda, \mu_b, \lambda'\} = \{1,2,3\}$, $\epsilon_{\lambda\mu_b\lambda'}$ is the sign of this permutation and $\epsilon_p = \pm 1$ is the orientation sign of p.

For a unit vector n,

$$T_n(\varphi) = \sum_\lambda n_\lambda^2\, T_\lambda(\varphi) + \sum_{\lambda<\lambda'} n_\lambda n_{\lambda'}\, \mathcal{O}^{\mathrm{od}}_{\lambda\lambda'}(\varphi).$$

A mixed source is a pair $\mathfrak{s} = (w, \mathsf{w})$ of real weights on the plaquettes and on the bonds, $\mathcal{O}^T(\mathfrak{s}) = \mathcal{O}(w) + Y[\mathsf{w}]$, $|\mathfrak{s}|_\infty = |w|_\infty + 8|\mathsf{w}|_\infty$.

Connected functions and natural sizes. For weights $w_1, \dots, w_n$ and $w_\lambda = \sum_a \lambda_a w_a$, $S_n^T = S^T_{n;K,\ell,\beta}(w_1, \dots, w_n) = \partial_{\lambda_1}\cdots\partial_{\lambda_n}\log\langle e^{\mathcal{O}(w_\lambda)}\rangle_{K,\ell,\beta}|_{\lambda=0}$; for functions f_a it is taken at $w_a = f_a \circ x$; $\langle X; Y\rangle$ denotes S_2^T, and $S_n^T[\mathfrak{s}]$ the same in a state $\mathfrak{s}$. For a function f on $\mathbb{R}^3$, $f^{\langle\ell\rangle}$ is its periodisation. We write $\mathsf{u}_a = \mathsf{b}^{-1}|w_a|_\infty$. Three bumps of width ρ, two of them at the near distance r and the third at the far distance d, are measured against $\mathrm{nat}_3 = \rho^9 r^{-3}\mathsf{d}^{-6}\mathsf{b}^{-3}\prod_{a\le 3}|w_a|_\infty$, and two such pairs against $\mathrm{nat}_4 = \rho^{12} r^{-6}\mathsf{d}^{-6}\mathsf{b}^{-4}\prod_{a\le 4}|w_a|_\infty$ (at functions $\|f_a\|_\infty$ replaces $|w_a|_\infty$); a kernel of three points is measured against $\mathsf{b}^{-3}r_*^{-3}\mathsf{d}_*^{-6}$ and a kernel of two points against $\mathsf{b}^{-2}|x-y|^{-6}$. These are the natural sizes.

Placed weights. Real weights w_1, w_2 are placed at (ρ, r) if there are centres x_a with $\Sigma(w_a) \subset \mathbb{B}(x_a, \rho)$ (closed balls), $\operatorname{dist}(\Sigma(w_1), \Sigma(w_2)) \geq r$ and $|x_1 - x_2| \leq 8r$. Weights w_1, w_2, w_3 are placed at (ρ, r, d) if besides $\Sigma(w_3) \subset \mathbb{B}(x_3, \rho)$, $\operatorname{dist}(\Sigma(w_a), \Sigma(w_3)) \geq \mathsf{d}$ and $|x_a - x_3| \leq 18\mathsf{d}$ for $a = 1, 2$. Weights $w_1, \dots, w_4$ form two pairs at (ρ, r, d) if (w_1, w_2) and (w_3, w_4) are placed at (ρ, r) and $\operatorname{dist}(\Sigma(w_a), \Sigma(w_b)) \geq \mathsf{d}$, $|x_a - x_b| \leq 18\mathsf{d}$ for $a \leq 2 < b$. A set β of sources crosses if it meets both clusters, $\{1, 2\}$ and $\{3\}$ (or $\{3, 4\}$), and $c(\beta)$ is the number of whole pairs in β.

Free objects. $\mathbb{K}_3(u) = (4\pi|u|^3)^{-1}(3\hat{u}\hat{u}^{\mathsf{T}} - 1) = (4\pi)^{-1}\nabla\nabla|u|^{-1}$, $\hat{u} = u/|u|$; $k_3(x, y, z) = \operatorname{tr} \mathbb{K}_3(x - y)\mathbb{K}_3(y - z)\mathbb{K}_3(z - x)$; $k_4(x_1, \dots, x_4) = \frac{1}{2}\sum_{\varsigma} \operatorname{tr} \prod_l \mathbb{K}_3(x_{\varsigma(l)} - x_{\varsigma(l+1)})$, the sum over the six cyclic orders of $\{1, 2, 3, 4\}$ (three rings, each once); $\mathcal{K}_{\lambda\mu}(\varphi_1, \varphi_2) = \iint \varphi_1(x)\varphi_2(y)[\mathbb{K}_3(x - y)_{\lambda\mu}]^2 \, dx \, dy$; and for a unit vector n and $X \neq 0$

$$\mathsf{t}^{\circ}(n, X) = \tfrac{3}{2}\mathsf{b}^{-2}\big[\langle n, \mathbb{K}_3(X)^2 n\rangle - \tfrac{1}{3}\operatorname{tr} \mathbb{K}_3(X)^2\big] = \frac{3}{32\pi^2}\,\mathsf{b}^{-2}|X|^{-6}(3(n \cdot \hat{X})^2 - 1).$$

C_K^{free} is the free curvature kernel on the bare plaquettes of the lattice (ℓ, K), $\mathcal{C}_{(j)}$, $1 \leq j \leq K$, are its slices by level, and $\upsilon_j = (a_{K-j+1}x_{j-1})^{-1}$. Over a base level $k_{\flat}$ we put $\mathcal{S}_i = \sum_{k_{\flat} < j \leq i} \upsilon_j \mathcal{C}_{(j)}$; for a nonempty set β of sources with $m = |\beta|$, $R_{i;\beta} = \sum w_{a_1}\mathcal{S}_i w_{a_2} \cdots \mathcal{S}_i w_{a_m}$, the sum over the orderings $(a_1, \dots, a_m)$ of β, the weights acting as diagonal matrices; $q_{i;\beta}(F) = \frac{1}{2a_K}\sum_{p,q} R_{i;\beta}(p, q)\langle F_p, F_q\rangle$ for $\mathfrak{su}(2)$-valued functions F of the plaquettes; and $g_{i;\beta} = \frac{3}{2}\sum_{\varsigma} \operatorname{Tr} \prod_l (w_{\varsigma(l)}\mathcal{S}_i)$, the sum over the cyclic orders ς of β. At $\beta = \{1, 2\}$ we write $q_n = q_{n;12}$, so $q_n(F) = a_K^{-1}\sum_{p,q} w_1(p)\mathcal{S}_n(p, q)w_2(q)\langle F_p, F_q\rangle$, and $\mathcal{Q}_i = q_{i+1} - q_i$. The lattice ring of three weights is $3\operatorname{Tr}\prod_a (w_a \mathsf{b}^{-1} C_K^{\mathrm{free}})$. Finally $\chi_x^{\rho} = \frac{3}{\pi\rho^3}(1 - |\cdot - x|/\rho)_+$ is the radial tent of radius ρ and mass 1.

The renormalisation group. We use the following signs. The level j is the lattice of spacing a_{K-j}, level 0 being the bare lattice; for a length ϱ, $\hat{\varrho}_j = \varrho/a_{K-j}$. The chain classes $\mathsf{Cc}_n(r_n)$ have the radii $r_K = 0$, $r_i = L^{-1}r_{i+1} + \frac{11}{10}\mathsf{c}_{\mathfrak{h}}\delta_i$ ($\mathsf{c}_{\mathfrak{h}} \geq 1$); for $A \in \mathsf{Cc}_n(r_n)$ we put $\tilde{U} = e^{i\eta_n A}$ and $\mathsf{ang}_p^{[n]}(A) = \eta_n(\mathrm{d}A)(p)$, and $\mathbf{1}$ is the trivial configuration. The witness depth is $s(\varrho) = \min\{s \geq 0 : L^s\varrho \geq C_W(s)\}$, where $C_W(s) = C_{W,0}A_0^2(\log[L^{s+1}(g^{-2} + \bar{B})])^{2\mathfrak{p}_0}$, with the room constant $C_{W,0} = \max\{1, 4L^2M/A_0^2\}$, so that $C_{W,0}A_0^2 \geq 4L^2M$ (equations YMM1:(2320) and YMM1:(2322)); the working level is $\mathsf{k}(\varrho) = \max\{K - s(\varrho), 2\}$; $Y_s = (s + 1)\log L + \log(g^{-2} + \bar{B})$, so that $C_W(s) = C_{W,0}A_0^2 Y_s^{2\mathfrak{p}_0}$, $Y_{\varrho} = Y_{s(\varrho)}$, and Lm_s is a constant times $Y_s^{5\mathfrak{p}_0}$.

For sources $w_1, \dots, w_p$ the weighted progression $E_{\lambda}^{(j)}$, $1 \leq j \leq K$, is the sequence of families of local terms of level j that the renormalisation steps make with the source w_{λ}, for λ in a neighbourhood of 0; $E^{(j)} = E_0^{(j)}$ and $E_{\beta}^{(j)} = \partial_{\beta}E_{\lambda}^{(j)}|_0$. The relative exponent is

$$D_i^{\lambda}(U) = \mathcal{O}(w_{\lambda})(U) + \sum_{i' \leq i} \mathsf{Sum}[E_{\lambda}^{(i')} - E^{(i')}](U), \qquad \mathsf{Sum}[\mathsf{f}](U) = \sum_{(X,z)} \mathsf{f}(X, U, z),$$

the sum over the domains X of the level and their base points z; $G_{i;\beta}(A) = \partial_{\beta}D_i^{\lambda}(e^{i\eta_i A})|_0$, the pair functional on configurations is defined by $\mathsf{F}_n(e^{i\eta_n A}) = G_{n;12}(A)$, the jets are $\mathsf{J}_n = G_{K;[n]}(0)$, and $\Delta[\mathsf{f}] = \mathsf{Sum}[\mathsf{f}](\tilde{U}) - \mathsf{Sum}[\mathsf{f}](\mathbf{1})$. A family f of level i has the norms $\|\mathsf{f}\|_{i,\kappa'} = \sup|\mathsf{f}(X, P, z)|e^{\kappa' d_i(X)}$, d_i the linear size of a domain, and $\lambda_{\mathrm{out}} = (1 + 4\beta_{\mathrm{s}})\kappa$; π_i is the partition into cubes of side Ma_{K-i}; for a weight w_a, Cr_a is the set of the corners of the plaquettes of $\operatorname{supp} w_a$, $\mathsf{N}_i(w_a)$ the number of the cubes of π_i that hold a site of Cr_a, and D_i^{ab} the least sup distance of Cr_a from Cr_b in level-i units.

The step map $\mathsf{St}^{[j]}$ is the renormalisation step of the height j, viewed as a function from bare arrays $\mathfrak{f} = ((G^{(i)}, e_i)_{i \leq j}, (H))$ of level j to families of level $j + 1$; $N(\mathfrak{f})$ is the size of an array and $\mathfrak{n}[\mathfrak{f}] \leq N(\mathfrak{f})$ the size of the family that it puts in the fourth place of the one-step theorem; $N_{\star}^{[j]}$ and $\theta^{[j]} = K_{\mathbf{M}}(1 + \beta_{\mathrm{s}})\delta_j/\alpha_0$ are numbers of the step j, and W_w is the weight member of a weight w. Further construction objects are defined where they enter.

Definition 7.1 (Ceilings, thresholds, numbers)**.** (1) The ceiling (Γ1): $0 < g \le \gamma_{\mathrm{jt}}$; $g^{-2} \ge \max\{x_{\mathrm{J}}, e^{2\mathfrak{p}_0}, e^{y_{\mathfrak{p}}}\}$; $\delta(g^{-2}) \le \min\{1/2c_{\mathrm{rt}}, 1/c_\epsilon, 1/2C_{\mathrm{cu}}\}$; $\theta(g^{-2}) := K_{\mathbf{M}}(1+\beta_{\mathrm{s}})\delta(g^{-2})/\alpha_0 \le \tau^\natural$. The ceiling (Γ2): $0 < g \le \gamma_W^{\mathrm{sd}}$, $g^{-2} \ge x_{\mathrm{J}}$, $\log g^{-2} \ge \mathsf{Y}_{\mathrm{lt}}(\frac12)$; data under (Γ2) have $K \ge 2$. (Γ) is (Γ1) together with (Γ2). Here γ_{jt} is defined in (23), γ_W^{sd} in equation YMM1:(2327), and x_{J} in (228); Proposition B.21 verifies the required actual-step hypotheses for every finite number of sources. The least-torus threshold Y_{lt} is specified below; $y_{\mathfrak{p}}, c_{\mathrm{rt}}, c_\epsilon, C_{\mathrm{cu}}, \tau^\natural$ are numbers formed from the constants in Lemmas 7.3, 7.6 and 7.14.

For $0 < \eth < 1$, put $c' = (1-\eth)c_\star$ and $C_{\mathrm{sd}} = 8L^6(\mathsf{C}^\Sigma_{\mathrm{maj}} + 2 + c_{\mathrm{low}} + 9/2)$. Choose $\mathsf{Y}_{\mathrm{lt}}(\eth) \ge 1$ so that all the history thresholds in Proposition M.2 hold above it and

$$2C_{\mathrm{sd}} y[MR(e^y)]^3 \le \tfrac12 c' A_0^2 y^{2\mathfrak{p}_0} \qquad (y \ge \mathsf{Y}_{\mathrm{lt}}(\eth)). \tag{22}$$

Such a finite threshold exists: $R(e^y) < Ly^r$ and $2\mathfrak{p}_0 > 3r+2$, as in the proof of Lemma YMM1:126.3. On the least admissible side that proof gives

$$\mathsf{B}(x_K)\ell_g^3 \le C_{\mathrm{sd}} y_K [MR(e^{y_K})]^3.$$

Thus $\log g^{-2} \ge \mathsf{Y}_{\mathrm{lt}}(\eth)$ implies $2\mathsf{B}(x_K)\ell_g^3 \le c' p_K^2/2$, the stronger small-side condition in Proposition M.2.

Since δ decreases on $[e^{2\mathfrak{p}_0}, \infty)$, each member is a condition "$g \le$ a number formed from the constants". ($\Gamma^{(4)}$) is (Γ) with $c_\epsilon^{(4)}$ of Lemma 7.14 in the place of c_ϵ. As $c_\epsilon \le c_\epsilon^{(4)}$ (Lemma 7.14(a), where C_{cu}, c_{cu} and the numbers $c_\epsilon^{(n)}$ are formed), (Γ1) with $c_\epsilon^{(4)}$ in the place of c_ϵ contains (Γ1), and ($\Gamma^{(4)}$) contains (Γ): every g under ($\Gamma^{(4)}$) satisfies (Γ). For the bond forms we use the ceiling $\gamma_{\mathrm{N}} = x_{\mathrm{N}}^{-1/2}$, where x_{N} is the least real number $\ge x_{\mathrm{jt}} = \gamma_{\mathrm{jt}}^{-2}$ such that every $t \ge x_{\mathrm{N}}$ satisfies $t \ge \max\{x_{\mathrm{J}}, e^{2\mathfrak{p}_0}, e^{y_{\mathfrak{p}}}\}$, $\delta(t) \le \min\{1/2c_{\mathrm{rt}}, 1/c_\epsilon\}$, $\theta(t) = K_{\mathbf{M}}(1+\beta_{\mathrm{s}})\delta(t)/\alpha_0 \le \tau^\natural$, $\mathfrak{b}(t) \ge 1$ and $c_{\mathrm{A}}\alpha_0 \ge 5M\mathsf{c}_{\mathfrak{h}}\delta(t)(1+\log t)$, with c_{A} of Lemma 7.8.

So $\gamma_{\mathrm{N}} \le \gamma_{\mathrm{jt}}$, and every $0 < g \le \gamma_{\mathrm{N}}$ satisfies (Γ1) but for its member $\delta(g^{-2}) \le 1/2C_{\mathrm{cu}}$.

(2) $r_1(\mathsf{b}) > 0$ is the number of Lemma 7.6, formed from the constants and b; it does not increase in b. $\mathsf{d}_4(g) > 0$ is the number fixed in Proposition 7.19, formed from the constants and g, with $\mathsf{d}_4(g) \le \min\{e^{-2(15\mathfrak{p}_0+2)}, r_1(\bar{\mathsf{b}})\}$; $\mathsf{d}_5(g) = \min\{2\mathsf{d}_4(g), \min\{1, 16r_1(\bar{\mathsf{b}})\}, \frac{1}{32}\ell_g\}$. For two pairs, $\mathsf{d}_4^{(4)}(g)$ is fixed in the same Proposition, and $\mathsf{d}_5^{(4)}(g) = \min\{2\mathsf{d}_4^{(4)}(g), \frac{1}{48}\ell_g\}$.

(3) $\bar{\mathsf{M}}^{(24)} = 1 + 2L^{24}\mathsf{C}_{\mathrm{ag}}(25, \frac12)$, where C_{ag} is defined by (315); $\Lambda_3 \ge 1$ is the number of Lemma 7.21; C_{lat} is the absolute constant in equations YMM1:(2245)–(2246), comparing C_K^{free} with $\mathbb{K}_3$ on every side; $C^{(3)} = 3\cdot 81^3(1+3C_{\mathrm{lat}})^2 C_{\mathrm{lat}} + 2.1\cdot 10^7$, $C^{(4)} = 3[4\cdot 81^4 C_{\mathrm{lat}}(1+3C_{\mathrm{lat}})^3 + 1.49\cdot 10^8]$, $C_{\mathrm{Rs}} = 7400 + 729C_{\mathrm{lat}}(2+3C_{\mathrm{lat}})$, the constants of the lattice sums of Lemma 7.22; $C_{\mathrm{PS}} = 62 + 1089C_{\mathrm{lat}}(2+3C_{\mathrm{lat}})$ and $C_{\mathrm{PS}}^{\mathrm{od}} = 62 + 729(2+5C_{\mathrm{lat}})(1+C_{\mathrm{lat}})$, the constants of the lattice sums at two balls on every torus (Lemma 7.33); $C_3^{\mathrm{tr3}}(g)$, $C_4^{\mathrm{tr3}}(g)$, $C_2^{\mathrm{tr}}(g)$ are the numbers of Proposition 7.28, formed from the constants and g.

(4) With the number $C(g)$ of Proposition 7.19: $\epsilon^{\mathrm{nar}}(g,t) = C(g)(\log\frac1t)^{39\mathfrak{p}_0+2}t^{1/2}$, $\epsilon_2^{\mathrm{nar}}(g,t) = C(g)(\log\frac1t)^{19\mathfrak{p}_0}t^{1/2}$, $\epsilon_4^{\mathrm{nar}}(g,t) = C(g)(\log\frac1t)^{47\mathfrak{p}_0+2}t^{1/2}$; and

$$\epsilon_{\mathrm{A}}(g,t) = 512\big[\epsilon^{\mathrm{nar}}(g,\tfrac t2) + 3C^{(3)}(5t/\ell_g)^3 + 13\Lambda_3^3(\bar{\mathsf{M}}^{(24)})^3\bar{\mathsf{b}}^3 t^{3/2}\big],$$
$$\mathsf{E}_3(g,t) = 512\big[\epsilon^{\mathrm{nar}}(g,\tfrac t2) + 3C^{(3)}(5t/\ell_g)^3 + (13\Lambda_3^3(\bar{\mathsf{M}}^{(24)})^3 + C_3^{\mathrm{tr3}}(g))\bar{\mathsf{b}}^3 t^{3/2}\big],$$
$$\epsilon_{\mathrm{P}}(g,t) = 64\big[\epsilon_2^{\mathrm{nar}}(g,\tfrac t2) + 3\Lambda_3^2(\bar{\mathsf{M}}^{(24)})^2\bar{\mathsf{b}}^2(\tfrac t2)^{3/2} + \tfrac32 C_{\mathrm{Rs}}(t/2\ell_g)^3\big],$$
$$\mathsf{E}_2(g,t) = \epsilon_2^{\mathrm{nar}}(g,t) + \big[3\Lambda_3^2(\bar{\mathsf{M}}^{(24)})^2 + C_2^{\mathrm{tr}}(g)\big]\bar{\mathsf{b}}^2 t^{3/2} + \tfrac32 C_{\mathrm{Rs}}(t/\ell_g)^3, \qquad \epsilon_\sigma(g,t) = 64 \sup_{0<t'\le t} \mathsf{E}_2(g,\tfrac{t'}{2}).$$

So $\epsilon_{\mathrm{A}}, \mathsf{E}_3 \le C(g)[(\log\frac1t)^{39\mathfrak{p}_0+2}t^{1/2} + (t/\ell_g)^3]$ and $\epsilon_{\mathrm{P}}, \epsilon_\sigma \le C(g)[(\log\frac1t)^{19\mathfrak{p}_0}t^{1/2} + (t/\ell_g)^3]$ for small t; all of them are functions of (g,t) alone.

(5) *The threshold $r_\alpha(g,\mathsf{b})$ of Theorem AB.* For a label b and $0<r\le L^{-4}$ consider every first-passage datum (K,β) at g with $a_K\beta=\mathsf{b}$, $128a_K\le r$ and $s(\frac r2)\le K$, and the near pair $w_{1,2}=\chi^{r/8}_{c\pm\frac r2 e_\lambda}\circ x$ of that Theorem, a test pair of the scale $\frac r2$; n_1 and n_0 are the least levels with $a_{K-n_1}\ge(\frac r2)^{3/4}$ and $a_{K-n_0}\ge r^{1/2}$. The conditions are:

($\alpha1$) $\mathsf{k}(\frac r2)<n_1<n_0<K$, $2(r+a_K)\le a_{K-n_0}$ and $\frac{27}{8M^3}(r/2a_{K-n_1})^3\le1$;

($\alpha2$) for $\mathsf{k}(\frac r2)\le i<n_1$, $n_0\le n<K$ and $m=n-i-1$: $(4\mathsf{h}_i+4)a_{K-i-1}\le\ell_g$ and $7\mathsf{h}_iL^{-2m}r_n\le\delta_i/2\Lambda_i$, where h_i and Λ_i are the numbers of Proposition 7.13 for the near pair at (i,n), formed with $R_w=\frac54\hat r_{i+1}+1$ and $\bar{\mathsf{e}}=2\bar{\mathsf{w}}_1\bar{\mathsf{w}}_2\mathsf{E}_i$, $\bar{\mathsf{w}}_a=81\hat r_i^3|w_a|_\infty/a_{K-i}$;

($\alpha3$) $\frac r2\le\min\{r_0(\mathsf{b}),r_1(\mathsf{b})\}$;

($\alpha4$) $s(\frac r2)\ge3$ and $\mathsf{Lm}_{s(r/2)}\le L^{s(r/2)-3}$;

($\alpha5$) $2\sqrt3\,\delta_{\rm tp}L(L-1)M(\log\frac2r)^{2\mathfrak{p}_0}\ge3\log L+\log2$, so that Lemma 7.17(b) applies at the level $\mathsf{k}(\frac r2)$ to two plaquettes of the two supports of the near pair.

$r_\alpha(g,\mathsf{b})$ is the largest number $r_\star\in(0,L^{-4}]$ such that ($\alpha1$)–($\alpha5$) hold at every $0<r\le r_\star$ and every such datum. It is positive. ($\alpha1$) holds for $r\le L^{-4}$ at every datum. ($\alpha2$), ($\alpha4$) and ($\alpha5$) hold for r below a number formed from the constants and g: by the working level (Lemma 7.3(c)) and step 6 of the proof of Proposition 7.13, $\mathsf{h}_i\le C(1+Y)^{2\mathfrak{p}_0}$ and $\Lambda_i\le C(1+Y)$ with $Y=Y_{r/2}\le2\log\frac2r+C(g)$; $r_n\le\frac85\mathsf{c}_\mathfrak{h}(\frac54)^{1/2}L^{(n-i)/2}\delta_i$; and $L^{-(n-i)}=a_{K-i}/a_{K-n}<(\frac r2)^{3/4}r^{-1/2}\le r^{1/4}$; none of these bounds depends on b or on K. ($\alpha3$) holds for $\frac r2\le\min\{\inf_{\mathsf{b}'}r_0(\mathsf{b}'),r_1(\bar{\mathsf{b}})\}$, the infimum over $g^{-2}<\mathsf{b}'\le\bar{\mathsf{b}}$ being positive by (B.1) and r_1 not increasing. So $r_\alpha(g,\mathsf{b})\ge r^-_\alpha(g)$ for all $\mathsf{b}\in(g^{-2},\bar{\mathsf{b}}]$, with a positive number $r^-_\alpha(g)$ formed from the constants and g.

(6) *The ceiling* ($\Gamma3$) *and the threshold $r^{\mathcal W}_\alpha(g,\mathsf{b})$.* ($\Gamma3$) asks: $c_{\rm A}\alpha_0\ge8MB_3\varepsilon(t)(1+\log t)$ for all $t\ge g^{-2}$; $g\le2C_{\rm A}C_{\rm E,3}M^2B_3^2A_0^2/C_{\rm E,1}\alpha_0^2$; and $7488B_3\varepsilon(g^{-2})\le\epsilon_{\rm G}$, $C_{\mathcal W}\varepsilon(g^{-2})\le\frac{1}{120}$ with $C_{\mathcal W}=\max\{720C^\sharp_{\rm G},2\}B_3$. Here $c_{\rm A}$, $C_{\rm A}$ and $C_{\rm E,1}$ are the numbers of Lemma 7.8 and of its proof, $C_{\rm E,3}$ is the number in Lemma B.10 at $q=2$, $2B_3\varepsilon_n$ is the radius at which the small-field backgrounds are regular (Lemma 7.20(d)), and $\epsilon_{\rm G}$, $C^\sharp_{\rm G}$ are the numbers of the lemma on a regular gauge on a cube, which precedes Lemma 7.36.

As $\varepsilon(t)(1+\log t)\to0$ and ε decreases on $[e^{2\mathfrak{p}_0},\infty)$, each member is a condition "$g\le$ a number formed from the constants and $\beta_{\rm H}$". $r^{\mathcal W}_\alpha(g,\mathsf{b})$ is the largest number $r_\star\in(0,r_\alpha(g,\mathsf{b})]$ such that, at every $0<r\le r_\star$ and every datum as in (5), the numbers h_i and Λ_i of ($\alpha2$), formed with $C_{\mathcal W}\varepsilon_n$ in the place of r_n, satisfy for $\mathsf{k}(\frac r2)\le i<n_1$, $n_0\le n\le K$ and $m=n-i-1$: $(4\mathsf{h}_i+4)a_{K-i-1}\le\ell_g$, $7\mathsf{h}_iL^{-2m}C_{\mathcal W}\varepsilon_n\le\delta_i/2\Lambda_i$ and $(\mathsf{h}_i+1)L^{-m}\le3$, and besides $Lr^{1/2}\le(2\bar{\mathsf{M}}^{(24)})^{-1/24}$.

The bounds of (5), with $\varepsilon_n=(A_0/A_1)\delta_n$, give $r^{\mathcal W}_\alpha(g,\mathsf{b})\ge r^{\mathcal W-}_\alpha(g)$, a positive number formed from the constants, $\beta_{\rm H}$ and g.

■

7.2. **Principal results.**

Theorem X (Three points at two scales)**.** Let g satisfy (Γ).

(A.1) *At a cutoff, on the least torus.* Let (K,β) be a first-passage datum at g, $\mathsf{b}=a_K\beta$, $\ell=\ell_g$; let $0<\rho\le r\le\mathsf{d}\le\mathsf{d}_4(g)$ and $s(\rho)\le K$, and let w_1,w_2,w_3 be real weights placed at (ρ,r,d), for instance $w_a=f_a\circ x$ with bounded real Borel functions f_a. Then

$$\Big|S_3^T(w_1,w_2,w_3)-3\,\mathrm{Tr}\prod_a(w_a\mathsf{b}^{-1}C_K^{\rm free})\Big|\le[\epsilon^{\rm nar}(g,\mathsf{d})+13\Lambda_3^3\mathsf{M}'^3\mathsf{b}^3\mathsf{d}^{3/2}]\mathrm{nat}_3,$$

where $\mathsf{M}'=\int\alpha^{-24}d\mathbb{P}\le\bar{\mathsf{M}}^{(24)}$ (Lemma 7.20). The bound holds at every ratio $r/\mathsf{d}\in(0,1]$.

(A.2) *The kernel on the least torus.* Let b be a limit of labels of first-passage data at g (every $\mathsf{b}\in I(g)$ is one), and $\mathcal D=\{(x,y,z)\in T^3_{\ell_g}:0<|x-y|=r_*\le\mathsf{d}_*=\mathrm{dist}(z,\{x,y\})\le\mathsf{d}_5(g)\}$.

At every triple of $\mathcal{D}$, for every $0 < \rho < \min\{\frac{1}{4}r_*, r_1(\bar{\mathsf{b}})\}$ and all real Lipschitz f_1, f_2, f_3 with supports in balls of radius ρ inside the open balls of radius $\frac{1}{4}r_*$ about x, y, z,

$$\Big|S_3^{(\ell_g,\mathsf{b})}(f_1,f_2,f_3) - 3\mathsf{b}^{-3}\int k_3 \prod_a f_a\Big| \le \epsilon_{\mathrm{A}}(g,\mathsf{d}_*)\,\mathsf{b}^{-3}r_*^{-3}\mathsf{d}_*^{-6}\,\rho^9 \prod_a \|f_a\|_\infty.$$

Consequently $S_3^{(\ell_g,\mathsf{b})}$ has on $\mathcal{D}$ a Borel kernel s_3, and at every Lebesgue point of s_3 in $\mathcal{D}$, so almost everywhere on $\mathcal{D}$,

$$|\mathsf{s}_3 - 3\mathsf{b}^{-3}k_3| \le \epsilon_{\mathrm{A}}(g,\mathsf{d}_*)\,\mathsf{b}^{-3}r_*^{-3}\mathsf{d}_*^{-6},$$

uniformly in $r_*/\mathsf{d}_* \in (0,1]$. Choose the closest pair first and call it (x,y). The triple lies in $\mathcal{D}$ whenever the resulting far distance $\mathsf{d}_* = \mathrm{dist}(z,\{x,y\})$ is at most $\mathsf{d}_5(g)$.

(A.3) *Means at every triple.* At every triple of $\mathcal{D}$ and for every $0 < \rho < \min\{\frac{1}{4}r_*, r_1(\bar{\mathsf{b}})\}$ the mean of $\mathsf{s}_3 - 3\mathsf{b}^{-3}k_3$ over the product of the three balls of radius ρ about its points is at most $(\frac{3}{4\pi})^3\epsilon_{\mathrm{A}}(g,\mathsf{d}_*)\mathsf{b}^{-3}r_*^{-3}\mathsf{d}_*^{-6}$ in modulus; with the radial tents χ^ρ about the three points in place of the normalised indicators of the balls the same holds with $(\frac{3}{\pi})^3$ in place of $(\frac{3}{4\pi})^3$.

(A.4) *Every state; limits and components.* (i) Let (K,β) be a first-passage datum at g, $\mathfrak{s}$ a state at (K,β), $0 < \rho \le r \le \mathsf{d} \le 1$, $\rho \le \frac{1}{2}$, $s(\rho) \le K$, $\rho \le r_1(\mathsf{b})$, and let f_1, f_2, f_3 be bounded real Borel functions on $\mathbb{R}^3$ with $\mathrm{supp}\, f_a \subset \mathbb{B}(x_a,\rho)$, $\mathrm{dist}(\mathrm{supp}\, f_1, \mathrm{supp}\, f_2) \ge r$, $\mathrm{dist}(\mathrm{supp}\, f_a, \mathrm{supp}\, f_3) \ge \mathsf{d}$ for $a = 1,2$, all supports lying in one ball of radius at most $\frac{1}{8}\ell_g - 1$. Then

$$\big|S_3^T[\mathfrak{s}](f_1,f_2,f_3) - S_{3;K,\ell_g,\beta}^T(f_1^{\langle\ell_g\rangle}, f_2^{\langle\ell_g\rangle}, f_3^{\langle\ell_g\rangle})\big| \le C_3^{\mathrm{tr3}}(g)\,\mathsf{b}^3\mathsf{d}^{3/2}\,\mathrm{nat}_3;$$

so (A.1) holds for $S_3^T[\mathfrak{s}]$ with $C_3^{\mathrm{tr3}}(g)\mathsf{b}^3\mathsf{d}^{3/2}$ more in the bracket. (ii) Let (K_j,β_j) be first-passage data at g with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}$, ν_j a state at (K_j,β_j), and σ' a law on $\mathbb{R}^3$ with $S_3^T[\nu_j] \to S_3^{\sigma'}$ on separated triples. Assume that $S_3^{\sigma'}$ has a continuous kernel on distinct triples, as it does for a periodic-Gibbs limit or one of its canonical components. Then that kernel s_3 satisfies, at every $(x,y,z) \in (\mathbb{R}^3)^3$ with $0 < |x-y| = r_* \le \mathsf{d}_* = \mathrm{dist}(z,\{x,y\}) \le \mathsf{d}_5(g)$,

$$|\mathsf{s}_3(x,y,z) - 3\mathsf{b}^{-3}k_3(x,y,z)| \le \mathsf{E}_3(g,\mathsf{d}_*)\,\mathsf{b}^{-3}r_*^{-3}\mathsf{d}_*^{-6},$$

uniformly in r_*/d_*. (iii) Every Gibbs sequence at g that converges, with its limit, and the approximants of every component of a canonical decomposition of that limit, with the component, are such data along every subsequence on which the labels converge.

(A.5) *Gibbs sequences at couplings above the ceilings.* Let $0 < g_0 \le \gamma$ be a reference coupling with $g \le g_0$. There is an integer $z_+ \ge 0$ formed from the constants, g_0 and g such that for every Gibbs sequence at g_0 that converges, and every subsequence along which its labels converge, to b_0 say, the continuous kernel s_3 of the limit, and that of every component of a canonical decomposition of it, satisfy at every triple with $0 < r_* \le \mathsf{d}_* \le L^{-z_+}\mathsf{d}_5(g)$

$$|\mathsf{s}_3 - 3\mathsf{b}_0^{-3}k_3| \le \max_{0\le z'\le z_+} \mathsf{E}_3(g, L^{z'}\mathsf{d}_*)\;\mathsf{b}_0^{-3}r_*^{-3}\mathsf{d}_*^{-6}.$$

■□

Theorem Y (A close pair seen from the coarser levels)**.** Let $0 < g \le \gamma$ be a reference coupling, (K,β) a first-passage datum at g with its run, $\mathsf{b} = a_K\beta$, and $\ell \in \mathfrak{L}(g)$. For a level n and $A \in \mathsf{Cc}_n(r_n)$ put $\tilde{U} = e^{i\eta_n A}$.

(B.1) *A pair as wide as its distance.* There are numbers $\gamma_{\mathrm{O}}, C, c, c' > 0$ formed from the constants, and a number $r_0(\mathsf{b}) > 0$ formed from these and b, with $\inf\{r_0(\mathsf{b}') : g^{-2} < \mathsf{b}' \le \bar{\mathsf{b}}\} > 0$, such that the following holds. Let $g \le \min\{\gamma_{\mathrm{jt}}, \gamma_{\mathrm{O}}\}$; $0 < r \le r_0(\mathsf{b})$; $s = s(r)$ with $3 \le s \le K$ and

$\mathsf{Lm}_s \le L^{s-3}$; $\vartheta \in (0,1)$; $(f_1, f_2) \in \mathfrak{T}_{T_\ell}(r;\vartheta)$ with $w_a = f_a \circ x \not\equiv 0$; $k_0 = \max\{K - s, 2\}$; and let q_n be formed over the base level k_0. Then for every $k_0 < n \le K$ and every $A \in \mathsf{Cc}_n(r_n)$

$$\big|\mathsf{F}_n(\tilde U) - \mathsf{F}_n(\mathbf{1}) - q_n(\mathsf{ang}^{[n]}(A))\big| \le \Big\{ C\mathfrak{b}_n^2\delta_n + C(\log x_{k_0})^c\big[(r/\mathfrak{b})^{1/2} + e^{-c'Y_s^{2\mathfrak{p}_0}}\big]\Big\}\,\hat r_n^3\,\mathsf{u}_1\mathsf{u}_2.$$

None of $\gamma_{\mathrm O}, C, c, c'$ depends on ϑ, K, ℓ or the level.

(B.2) *A narrow pair.* Let g satisfy (Γ1); let $0 < \rho \le r \le e^{-2\sqrt3}$, $s(\rho) \le K$, $\rho \le r_1(\mathfrak{b})$; let $w_1, w_2 \not\equiv 0$ be real weights placed at (ρ, r), and let q_n be formed over the base level $\mathsf{k}(r)$. Then for every $\mathsf{k}(r) \le n \le K$ and every $A \in \mathsf{Cc}_n(r_n)$

$$\big|\mathsf{F}_n(\tilde U) - \mathsf{F}_n(\mathbf{1}) - q_n(\mathsf{ang}^{[n]}(A))\big| \le \big[C_{\mathrm N}\mathfrak{b}_n^2\delta_n + \epsilon'_{\mathrm N}(r)\big]\Big(\frac{\rho}{r}\Big)^6 \hat r_n^3\,\mathsf{u}_1\mathsf{u}_2, \qquad \epsilon'_{\mathrm N}(r) = C'_{\mathrm N}Y_r^{15\mathfrak{p}_0+2}\big[g\,r^{1/2} + e^{-Y_r^{2\mathfrak{p}_0}/\sqrt3}\big].$$

$C_{\mathrm N}, C'_{\mathrm N}$ are formed from the constants, $\epsilon'_{\mathrm N}$ depends on g and r alone; nothing in the bracket depends on ρ, K, ℓ, the position, the direction, the sign or the shape of the weights, and $\epsilon'_{\mathrm N}(r)(\log\frac1r)^N \to 0$ as $r \to 0$ for every N.

(B.3) *The explicit form.* In both cases $\sup_{A\in\mathsf{Cc}_n(r_n)}|q_n(\mathsf{ang}^{[n]}(A))| \le C\,\mathfrak{b}_n^2(\rho/r)^6\hat r_n^3\mathsf{u}_1\mathsf{u}_2$, with $\rho = r$ in (B.1).

■□

Theorem Z (The pair against the plane fields)**.** Let g satisfy (Γ), let $\mathfrak{b}$ be as in (A.2), and let s_3 be the kernel of (A.2). For points c, z put $\mathsf{d} = |c - z|$, let $0 < r \le \frac12\mathsf{d}$, $\mathsf{d} \le \frac{16}{17}\mathsf{d}_5(g)$, $\bar\epsilon_{\mathrm A} = \sup\{\epsilon_{\mathrm A}(g,t) : \frac34\mathsf{d} \le t \le \frac{17}{16}\mathsf{d}\}$, and write $(c \pm \frac r2 n, z)$ for the triple $(c + \frac r2 n, c - \frac r2 n, z)$; e_λ is the unit vector of the direction λ, and M_ρ denotes the mean over the balls of radius ρ about the arguments.

(C.1) *Against the free harmonic.* (i) For almost every $(c, h, z) \in (T_{\ell_g})^3$, with $h = rn$, $r = |h|$ in the range above,

$$\big|\tfrac{2\pi}{3}\mathfrak{b}r^3\mathsf{s}_3(c \pm \tfrac r2 n, z) - \mathsf{t}^\circ(n, c - z)\big| \le \big[12\bar\epsilon_{\mathrm A} + 2.7(r/\mathsf{d})^2\big]\mathfrak{b}^{-2}\mathsf{d}^{-6}.$$

(ii) For every (c, n, r, z) in the range above the same holds with $\mathsf{s}_3(c \pm \frac r2 n, z)$ replaced by $\limsup_{\rho\to0}$ of its mean $\mathsf{M}_\rho\mathsf{s}_3(c \pm \frac r2 n, z)$; and, for every $0 < \rho < \min\{\frac14 r, r_1(\bar{\mathfrak{b}})\}$, with $\mathsf{s}_3(c \pm \frac r2 n, z)$ replaced by $\int \mathsf{s}_3\,\chi^\rho_{c+\frac r2 n} \otimes \chi^\rho_{c-\frac r2 n} \otimes \chi^\rho_z$ and $7900\rho/r$ added in the bracket. (iii) For a law σ' as in (A.4)(ii), in particular for every periodic-Gibbs limit at g and every component of its canonical decomposition, the bound of (i) holds for its continuous kernel at every (c, r, z) and every unit vector n, with $12\sup\{\mathsf{E}_3(g,t) : \frac34\mathsf{d} \le t \le \frac{17}{16}\mathsf{d}\}$ in place of $12\bar\epsilon_{\mathrm A}$.

(C.2) *The plane laws.* (i) At a cutoff: let (K, β) be a first-passage datum at g, $\mathfrak{b} = a_K\beta$, $0 < \rho \le \mathsf{d} \le \mathsf{d}_4(g)$, $s(\rho) \le K$, $\vartheta \in (0,1]$, and let φ_1, φ_2 be real Lipschitz functions on T_{ℓ_g} with $\operatorname{supp}\varphi_a \subset \mathbb{B}(x_a, \rho)$, $\operatorname{Lip}\varphi_a \le \|\varphi_a\|_\infty/\vartheta\rho$, the balls $\mathbb{B}(x_a,\rho)$ at a distance $\ge \mathsf{d}$ and $|x_1 - x_2| \le 18\mathsf{d}$; no sign condition. Then for all λ, μ

$$\big|\langle\mathcal{O}_\lambda(\varphi_1);\mathcal{O}_\mu(\varphi_2)\rangle_{K,\ell_g,\beta} - \tfrac32\mathfrak{b}^{-2}\mathcal{K}_{\lambda\mu}(\varphi_1,\varphi_2)\big| \le \Big[\epsilon_2^{\mathrm{nar}}(g,\mathsf{d}) + 3\Lambda_3^2\mathsf{M}'^2\mathfrak{b}^2\mathsf{d}^{3/2} + \tfrac32 C_{\mathrm{Rs}}\Big(\frac{a_K}{\vartheta\rho} + \Big(\frac{\mathsf{d}}{\ell_g}\Big)^3\Big)\Big]\Big(\frac{\rho}{\mathsf{d}}\Big)^6\mathfrak{b}^{-2}\|\varphi_1\|_\infty\|\varphi_2\|_\infty.$$

(ii) Let (K_j, β_j) be first-passage data at g with $K_j \to \infty$, $a_{K_j}\beta_j \to \mathfrak{b}$, and $\Omega_{\mathrm P} = \{(x,y) \in T_{\ell_g}^2 : 0 < |x - y| < 2\mathsf{d}_4(g)\}$. There is a subsequence along which the nine forms $\langle\mathcal{O}_\lambda(\varphi_1);\mathcal{O}_\mu(\varphi_2)\rangle_{K_j,\ell_g,\beta_j}$ converge for all real Lipschitz φ_1, φ_2 with $\operatorname{supp}\varphi_1 \times \operatorname{supp}\varphi_2 \subset \Omega_{\mathrm P}$; the nine limits $T_{\lambda\mu}$ along one such subsequence are a limit point of the plane laws. Every limit point has Borel kernels $\tau_{\lambda\mu}$ on $\Omega_{\mathrm P}$ with

$$\big|\tau_{\lambda\mu}(x,y) - \tfrac32\mathfrak{b}^{-2}[\mathbb{K}_3(x-y)_{\lambda\mu}]^2\big| \le \epsilon_{\mathrm P}(g,|x-y|)\,\mathfrak{b}^{-2}|x-y|^{-6} \quad \text{almost everywhere on } \Omega_{\mathrm P};$$

before a kernel is named, at every $(x_0,y_0)\in\Omega_{\mathrm{P}}$ with $\mathsf{d}_0=|x_0-y_0|$ and for Lipschitz φ_1,φ_2 supported in balls of radius ρ inside the balls of radius $\frac{1}{8}\mathsf{d}_0$ about x_0,y_0: $|T_{\lambda\mu}(\varphi_1,\varphi_2)-\frac{3}{2}\mathsf{b}^{-2}\mathcal{K}_{\lambda\mu}(\varphi_1,\varphi_2)|\le\epsilon_{\mathrm{P}}(g,\mathsf{d}_0)\mathsf{b}^{-2}\mathsf{d}_0^{-6}\rho^6\|\varphi_1\|_\infty\|\varphi_2\|_\infty$. The kernel $t_\lambda=\sum_\mu(\tau_{\lambda\mu}-\frac{1}{3}\sum_{\lambda'}\tau_{\lambda'\mu})$ of the limit of $\langle T_\lambda;\mathcal{O}\rangle$ satisfies $|t_\lambda(x,y)-\mathsf{t}^\circ(e_\lambda,x-y)|\le 6\epsilon_{\mathrm{P}}(g,|x-y|)\mathsf{b}^{-2}|x-y|^{-6}$ almost everywhere.

(C.3) *The pair against the kernel of $\langle T_\lambda;\mathcal{O}\rangle$.* Take one limit point as in (C.2)(ii), along a subsequence of (K_j,β_j); along it $S^T_{3;K_j,\ell_g,\beta_j}\to S_3^{(\ell_g,\mathsf{b})}$. For every c,z,r,λ in the range above

$$\limsup_{\rho\to0}\big|\tfrac{2\pi}{3}\mathsf{b}r^3\mathsf{M}_\rho\mathsf{s}_3(c\pm\tfrac{r}{2}e_\lambda,z)-\mathsf{M}_\rho t_\lambda(c,z)\big|\le\big[12\bar\epsilon_{\mathrm{A}}+6\epsilon_{\mathrm{P}}(g,\mathsf{d})+2.7(r/\mathsf{d})^2\big]\mathsf{b}^{-2}\mathsf{d}^{-6},$$

and the same with the radial tents of mass 1 in place of the means. For almost every (c,h,z), $h=rn$, in the range above,

$$\big|\tfrac{2\pi}{3}\mathsf{b}r^3\mathsf{s}_3(c\pm\tfrac{r}{2}n,z)-t_\lambda(c,z)\big|\le\big[12\bar\epsilon_{\mathrm{A}}+6\epsilon_{\mathrm{P}}(g,\mathsf{d})+2.7(r/\mathsf{d})^2+0.057|n-e_\lambda|\big]\mathsf{b}^{-2}\mathsf{d}^{-6}.$$

(C.4) *Limits and components on $\mathbb{R}^3$.* Let (K_j,β_j), ν_j, σ' be as in (A.4)(ii), now with $S_n^T[\nu_j]\to S_n^{\sigma'}$ for $n=2,3$, assume that $S_3^{\sigma'}$ and $S_2^{\sigma'}$ have continuous kernels s_3 and s_2^T on distinct configurations, and $\Omega_\sigma=\{(x,y)\in(\mathbb{R}^3)^2:0<|x-y|<\mathsf{d}_5(g)\}$. (a) There is a subsequence along which $\langle\mathcal{O}_\lambda(\varphi_1);\mathcal{O}_\mu(\varphi_2)\rangle_{\nu_j}$ converges for all λ,μ and all real Lipschitz φ_1,φ_2 with compact supports, $\operatorname{supp}\varphi_1\times\operatorname{supp}\varphi_2\subset\Omega_\sigma$. (b) For every such subsequence the limits have Borel kernels $\tau^\sigma_{\lambda\mu}$ on Ω_σ with $|\tau^\sigma_{\lambda\mu}(x,y)-\frac{3}{2}\mathsf{b}^{-2}[\mathbb{K}_3(x-y)_{\lambda\mu}]^2|\le(\frac{3}{\pi})^2\epsilon_\sigma(g,|x-y|)\mathsf{b}^{-2}|x-y|^{-6}$ almost everywhere; $\tau^\sigma_{\lambda\mu}(x,y)$ depends on $x-y$ alone (almost everywhere); and $\sum_{\lambda,\mu}\tau^\sigma_{\lambda\mu}=\mathsf{s}_2^T$ almost everywhere, so that $|\mathsf{s}_2^T(x,y)-\frac{9}{16\pi^2}\mathsf{b}^{-2}|x-y|^{-6}|\le 9\epsilon_\sigma(g,|x-y|)\mathsf{b}^{-2}|x-y|^{-6}$ at every $(x,y)\in\Omega_\sigma$. (c) With $t^\sigma_\lambda=\sum_\mu(\tau^\sigma_{\lambda\mu}-\frac{1}{3}\sum_{\lambda'}\tau^\sigma_{\lambda'\mu})$ there is one null set $\mathcal{N}\subset\Omega_\sigma$, fixed before r is named, such that for every $(c,z)\notin\mathcal{N}$ with $0<\mathsf{d}=|c-z|\le\frac{1}{2}\mathsf{d}_5(g)$, every $0<r\le\frac{1}{2}\mathsf{d}$ and every λ

$$\big|\tfrac{2\pi}{3}\mathsf{b}r^3\mathsf{s}_3(c\pm\tfrac{r}{2}e_\lambda,z)-t^\sigma_\lambda(c,z)\big|\le\big[\epsilon'_\sigma(g,\mathsf{d})+2.7(r/\mathsf{d})^2\big]\mathsf{b}^{-2}\mathsf{d}^{-6},\qquad\epsilon'_\sigma(g,\mathsf{d})=12\sup_{\frac{3}{4}\mathsf{d}\le t\le\frac{17}{16}\mathsf{d}}\mathsf{E}_3(g,t)+6\epsilon_\sigma(g,\mathsf{d}),$$

and $\epsilon'_\sigma(g,\mathsf{d})\le C(g)(\log\frac{1}{\mathsf{d}})^{39\mathfrak{p}_0+2}\mathsf{d}^{1/2}$; at every (c,z) in this range the same holds with $\sum_\mu(\mathsf{t}_{\lambda\mu}-\frac{1}{3}\sum_{\lambda'}\mathsf{t}_{\lambda'\mu})(\chi^\rho_c,\chi^\rho_z)$ in place of $t^\sigma_\lambda(c,z)$, $\mathsf{t}_{\lambda\mu}$ the limit forms, for every $0<\rho<\frac{1}{8}\mathsf{d}$, with $21\rho/\mathsf{d}$ added in the bracket. (d) At a cutoff, for every first-passage datum (K,β) at g, every state $\mathfrak{s}$ at (K,β), points x_0,y_0 with $0<\mathsf{d}_0=|x_0-y_0|\le 2\mathsf{d}_4(g)$, $\mathsf{d}=\frac{1}{2}\mathsf{d}_0$, $s(\rho)\le K$, and bounded real Borel f_1,f_2 on $\mathbb{R}^3$ supported in balls of radius ρ inside the closed balls of radius $\frac{1}{8}\mathsf{d}_0$ about x_0,y_0:

$$\Big|\langle\mathcal{O}_\lambda(f_1);\mathcal{O}_\mu(f_2)\rangle_{\mathfrak{s}}-\tfrac{3}{2}\mathsf{b}^{-2}\sum_{\lambda(p)=\lambda,\,\lambda(q)=\mu}f_1(x(p))f_2(x(q))\,C_K^{\mathrm{free}}(\mathrm{pr}\,p,\mathrm{pr}\,q)^2\Big|\le\Big[\mathsf{E}_2(g,\mathsf{d})-\tfrac{3}{2}C_{\mathrm{Rs}}\Big(\frac{\mathsf{d}}{\ell_g}\Big)^3\Big]\Big(\frac{\rho}{\mathsf{d}}\Big)^6\mathsf{b}^{-2}\|f_1\|_\infty\|f_2\|_\infty,$$

with C_K^{free} of the lattice (ℓ_g,K) and pr the projection onto T_{ℓ_g}.

■□

Theorem AA (The traceless tensor in every direction)**.** Let $0<g\le\gamma$ be a reference coupling and $\ell\in\mathfrak{L}(g)$. There are an integer $K_\circ(g)$ and a number $\mathsf{d}_{\mathrm{cl}}(g)>0$ formed from the constants and g, and a finite function $\epsilon^{\mathrm{cl}}(g,\ell,\cdot)$ on $(0,\frac{1}{8}\ell]$ formed from the constants, g and ℓ, with $\epsilon^{\mathrm{cl}}(g,\ell,\mathsf{d}')\le C(g,\ell)(\log\frac{1}{\mathsf{d}'})^{19\mathfrak{p}_0}\mathsf{d}'^{1/2}$ for $\mathsf{d}'\le\mathsf{d}_{\mathrm{cl}}(g)$, such that the following hold.

(D.1) *The bond forms against the plane fields, on every torus.* Let (K,β) be a first-passage datum at g with $K \ge K_\circ(g)$, $\mathsf{b} = a_K\beta$; $0 < 16r \le \mathsf{d}' \le \frac{1}{8}\ell$ with $s(r) \le K$; $x_1, x_2 \in T_\ell$ with $|x_1 - x_2| = \mathsf{d}'$; $\vartheta \in (0,1]$; φ_1, φ_2 real Lipschitz functions on T_ℓ with $\operatorname{supp}\varphi_a \subset \mathbb{B}(x_a, r)$ and $\operatorname{Lip}\varphi_a \le \|\varphi_a\|_\infty/\vartheta r$. Then for all $\lambda \ne \lambda'$ and all γ, μ

$$\begin{aligned}
&\Big|\langle \mathcal{O}^{\mathrm{od}}_{\lambda\lambda'}(\varphi_1); \mathcal{O}_\gamma(\varphi_2)\rangle_{K,\ell,\beta} \\
&\qquad - 3\mathsf{b}^{-2}\iint \varphi_1(x)\varphi_2(y)\mathbb{K}_3(x-y)_{\lambda\gamma}\mathbb{K}_3(x-y)_{\lambda'\gamma}\,dx\,dy\Big| \\
&\le \Big[8\epsilon^{\mathrm{cl}}(g,\ell,\mathsf{d}') + 3C^{\mathrm{od}}_{\mathrm{PS}}\frac{a_K}{\vartheta r} + 3C^{\mathrm{od}}_{\mathrm{PS}}\Big(\frac{\mathsf{d}'}{\ell}\Big)^3\Big] \\
&\qquad \Big(\frac{r}{\mathsf{d}'}\Big)^6 \mathsf{b}^{-2}\|\varphi_1\|_\infty\|\varphi_2\|_\infty, \\
&\big|\langle \mathcal{O}_\lambda(\varphi_1); \mathcal{O}_\mu(\varphi_2)\rangle_{K,\ell,\beta} - \tfrac{3}{2}\mathsf{b}^{-2}\mathcal{K}_{\lambda\mu}(\varphi_1,\varphi_2)\big| \\
&\le \Big[\epsilon^{\mathrm{cl}}(g,\ell,\mathsf{d}') + \tfrac{3}{2}C_{\mathrm{PS}}\frac{a_K}{\vartheta r} + \tfrac{3}{2}C_{\mathrm{PS}}\Big(\frac{\mathsf{d}'}{\ell}\Big)^3\Big] \\
&\qquad \Big(\frac{r}{\mathsf{d}'}\Big)^6 \mathsf{b}^{-2}\|\varphi_1\|_\infty\|\varphi_2\|_\infty.
\end{aligned}$$

(D.2) *The kernels of $\langle T_n; \mathcal{O}\rangle$ for all directions at once.* Let (K_j, β_j) be first-passage data at g with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}$; $\Omega^\circ = \{(x,y) \in T_\ell^2 : 0 < |x-y| < \frac{7}{9}\mathsf{d}_{\mathrm{cl}}(g)\}$;

$$\bar\epsilon^{\mathrm{cl}}(t) = \sup\{8\epsilon^{\mathrm{cl}}(g,\ell,\mathsf{d}'') + 3\max\{C_{\mathrm{PS}}, C^{\mathrm{od}}_{\mathrm{PS}}\}(\mathsf{d}''/\ell)^3 : \frac{7}{9}t \le \mathsf{d}'' \le \frac{9}{7}t\},$$

so that $\bar\epsilon^{\mathrm{cl}}(t) \le C(g,\ell)[(\log\frac{1}{t})^{19\mathfrak{p}_0}t^{1/2} + (t/\ell)^3]$. Along a subsequence all the forms $\langle \mathcal{O}_\lambda(f); \mathcal{O}_\mu(h)\rangle_{K_j,\ell,\beta_j}$ and $\langle \mathcal{O}^{\mathrm{od}}_{\lambda\lambda'}(f); \mathcal{O}_\gamma(h)\rangle_{K_j,\ell,\beta_j}$ converge, at all real Lipschitz f, h with $\operatorname{supp} f \times \operatorname{supp} h \subset \Omega^\circ$.

For every such subsequence the limits have Borel kernels on Ω° that lie, almost everywhere, within $4.2\,\bar\epsilon^{\mathrm{cl}}(|x-y|)\mathsf{b}^{-2}|x-y|^{-6}$ of the free kernels $\frac{3}{2}\mathsf{b}^{-2}[\mathbb{K}_3(x-y)_{\lambda\mu}]^2$ and $3\mathsf{b}^{-2}\mathbb{K}_3(x-y)_{\lambda\gamma}\mathbb{K}_3(x-y)_{\lambda'\gamma}$; and outside one null set of Ω°, for all unit vectors n at once, the kernel t_n of the limit of $\langle T_n(f); \mathcal{O}(h)\rangle$ satisfies

$$|t_n(x,y) - \mathsf{t}^\circ(n, x-y)| \le 38\,\bar\epsilon^{\mathrm{cl}}(|x-y|)\,\mathsf{b}^{-2}|x-y|^{-6}.$$

(D.3) *The pair against t_n.* Let moreover g satisfy (Γ) and $\ell = \ell_g$, and take s_3 of (A.2) and a limit point of (D.2). For every c, z, r, n with $0 < r \le \frac{1}{2}\mathsf{d}$, $\mathsf{d} = |c-z| \le \frac{16}{17}\mathsf{d}_5(g)$ and $\mathsf{d} < \frac{7}{9}\mathsf{d}_{\mathrm{cl}}(g)$,

$$\limsup_{\rho\to 0}\big|\tfrac{2\pi}{3}\mathsf{b}r^3\mathsf{M}_\rho\mathsf{s}_3(c \pm \tfrac{r}{2}n, z) - \mathsf{M}_\rho t_n(c,z)\big| \le \big[12\bar\epsilon_{\mathrm{A}} + 38\bar\epsilon^{\mathrm{cl}}(\mathsf{d}) + 2.7(r/\mathsf{d})^2\big]\mathsf{b}^{-2}\mathsf{d}^{-6},$$

the same with the radial tents of mass 1 in place of the means, and the same bound holds for $|\frac{2\pi}{3}\mathsf{b}r^3\mathsf{s}_3(c \pm \frac{r}{2}n, z) - t_n(c,z)|$ at almost every (c, rn, z) in this range.

■□

Theorem AB (Pair minus tensor field; the limit $r \to 0$)**.** Fix $\beta_{\mathrm{H}} \in (0,1)$. There is a number $\gamma_{\mathrm{R}} \in (0, \gamma_{\mathrm{jt}}]$ formed from the constants and β_{H} such that every $0 < g \le \gamma_{\mathrm{R}}$ satisfies (Γ) and $g \le \gamma_{\mathrm{O}}$ of (B.1), and besides the two conditions $\frac{3}{2}C_\natural c_\gamma g \le \log 2$, where $C_\natural = (L^8 + 8c_3)L^4$ with c_3 of Lemma 7.6(c) and c_γ of Lemma 7.6(f), and $c_{\mathrm{A}}\alpha_0 \ge 32M\mathsf{c}_\mathfrak{h}\delta(t)(1+\log t)$ for all $t \ge g^{-2}$, which contains the condition $c_{\mathrm{A}}\alpha_0 \ge 5M\mathsf{c}_\mathfrak{h}\delta(t)(1+\log t)$ for all $t \ge g^{-2}$, the last member of the list of γ_{N} in Definition 7.1(1), together with $g \le 19C_{\mathrm{A}}C_{\mathrm{E},3}M^2\mathsf{c}_\mathfrak{h}^2A_1^2/2C_{\mathrm{E},1}\alpha_0^2$, with the numbers of Definition 7.1(6); each of them is a condition "$g \le$ a number formed from the constants", and together they contain the ceilings of all the lemmas used in the proof.

The following holds for $0 < g \le \gamma_{\mathrm{R}}$ on the least torus $\ell = \ell_g$. Let (K,β) be a first-passage datum at g, $\mathsf{b} = a_K\beta$, λ a direction, $\mathsf{d} > 0$ with $6\mathsf{d} \le \min\{1, \mathsf{b}\}$, and φ_1, φ_2 bounded real functions on

T_{ℓ_g} with $\operatorname{supp}\varphi_a \subset \mathbb{B}(y_a,\mathsf{d})$ and $\operatorname{dist}(\operatorname{supp}\varphi_1,\operatorname{supp}\varphi_2)\ge\mathsf{d}$. Let $r_\alpha(g,\mathsf{b})>0$ be the number of Definition 7.1(5), formed from the constants, g and b. For every r with

$$128a_K\le r\le\min\{r_\alpha(g,\mathsf{b}),(\mathsf{d}/5LM)^2\},\qquad 3\le s(\tfrac r2)\le K,\qquad \tfrac r2\le\min\{r_0(\mathsf{b}),r_1(\mathsf{b})\},\quad \mathsf{Lm}_{s(r/2)}\le L^{s(r/2)-3},$$

the following holds. For $c\in\operatorname{supp}\varphi_1$ let $w_{1,2}=\chi^{r/8}_{c\pm\frac r2e_\lambda}\circ x$ and $w_T(p)=(\delta_{\lambda(p)\lambda}-\frac13)\chi^{r/8}_c(x(p))$, so that $\mathcal{O}(w_T)=T_\lambda(\chi^{r/8}_c)$; let $\mathsf{c}=\frac{2\pi}{3}\mathsf{b}r^3$; let w_3 be $\varphi_2\circ x$ restricted to the plaquettes with barycentres in a cube of side $\frac r4$ whose centre z has $|c-z|\le 6\mathsf{d}$, and $\mu_3=r^3\|\varphi_2\|_\infty$. Let Y_β be the remainders of Lemma 7.20 for the lists (w_1,w_2,w_3) and (w_T,w_3), $\mathsf{Y}_\Delta=\mathsf{c}\mathsf{Y}_{12}-\mathsf{Y}_T$ and $\mathsf{Y}_{\Delta3}=\mathsf{c}\mathsf{Y}_{123}-\mathsf{Y}_{T3}$.

(E.1) *The part that is not explicit.* There is a finite function $\mathsf{C}_{\mathrm R}(g,\mathsf{b};\cdot)$ on $(0,1]$, formed from the constants, $\beta_{\mathrm H}$, g and b, such that

$$\Big|\int\mathsf{Y}_{\Delta3}\,d\mathbb{P}+\kappa_{\mathbb{P}}(\mathsf{Y}_\Delta,\mathsf{Y}_3)\Big|\le\mathsf{C}_{\mathrm R}(g,\mathsf{b};\mathsf{d})\big[r^{\beta_{\mathrm H}/72}+(a_K/r)^{1/18}\big]\mathsf{b}^{-2}\mathsf{d}^{-6}\mu_3.$$

If g satisfies besides (Γ3) of Definition 7.1(6), one may take $\mathsf{C}_{\mathrm R}(g,\mathsf{b};\mathsf{d})=C(g,\mathsf{b})\,\mathsf{d}^{-5/2}$, and the pair minus the tensor field is nearly constant up to the last level: with $\Delta_n=\mathsf{c}G_{n;12}-G_{n;T}$ and $\Gamma_n=\mathsf{c}G_{n;123}-G_{n;T3}$, formed with one progression of the four sources, with $\varepsilon^{\mathcal W}=C(g,\mathsf{b})[r^{\beta_{\mathrm H}/72}+(a_K/r)^{1/18}]$, and for $r\le r^{\mathcal W}_\alpha(g,\mathsf{b})$, there are numbers c_n such that at every level $n\le K$ with $a_{K-n}\ge r^{1/2}$, for m_n-almost every small-field background W of the level n (Lemma 7.20),

$$|\Delta_n(U_n(W))-\mathsf{c}_n|\le\varepsilon^{\mathcal W}\varepsilon_n^2a_{K-n}^{-4},\qquad|\mathsf{c}_n-\mathsf{c}_K|\le\varepsilon^{\mathcal W}\varepsilon_n^2a_{K-n}^{-4},\qquad|\Gamma_n(U_n(W))-\Gamma_K(\mathbf1)|\le C(\mathsf{b})\,\mathsf{d}^{-5/2}\varepsilon^{\mathcal W}\mathsf{b}^{-2}\mathsf{d}^{-6}\mu_3.$$

(E.2) *The true functions.* There are numbers $C_{\mathrm A}(g,\mathsf{b})$, formed from the constants, $\beta_{\mathrm H}$, g and b, and $r_{\mathcal W}(g,\mathsf{b},\mathsf{d})>0$, formed besides with d, such that for $r\le r_{\mathcal W}(g,\mathsf{b},\mathsf{d})$

$$\big|\mathsf{c}\,S_3^T(w_1,w_2,w_3)-S_2^T(w_T,w_3)\big|\le C_{\mathrm A}(g,\mathsf{b})\,\mathsf{d}^{-18}\big[r^{\beta_{\mathrm H}/72}+(a_K/r)^{1/18}\big]\mu_3.$$

(E.3) *At a fixed label: the limit in the cutoff, and $r\to0$.* Let φ_1,φ_2 be as above, Lipschitz, with $|y_1-y_2|\le3\mathsf{d}$, let $f^c_\pm=\chi^{r/8}_{c\pm\frac r2e_\lambda}$, and for a first-passage datum (K,β) at g with the label $\mathsf{b}'=a_K\beta$ put

$$\mathsf{A}_{r,K}=\tfrac{2\pi}{3}\mathsf{b}'r^3\int dc\,\varphi_1(c)\,S^T_{3;K,\ell_g,\beta}(f^c_+,f^c_-,\varphi_2).$$

If either φ_1 or φ_2 is zero, the assertions are immediate by multilinearity; assume both are nonzero in the normalized estimates that follow. At every label $\mathsf{b}'\in(g^{-2},\bar{\mathsf{b}}]$ there are numbers $r_\sharp>0$ and $\mathsf{C}(\mathsf{d})$, formed from the constants, $\beta_{\mathrm H}$, g, b', d and $\mathsf{d}\operatorname{Lip}\varphi_1/\|\varphi_1\|_\infty$, such that: (i) for $0<r\le r_\sharp$ and every first-passage datum (K,β) at g with the label b', $128a_K\le r$ and $s(\frac r2)\le K$, $|\mathsf{A}_{r,K}-\langle T_\lambda(\varphi_1);\mathcal{O}(\varphi_2)\rangle_{K,\ell_g,\beta}|\le\mathsf{C}(\mathsf{d})[r^{\beta_{\mathrm H}/72}+(a_K/r)^{1/18}]\mathsf{b}'^{-2}\|\varphi_1\|_\infty\|\varphi_2\|_\infty$. Let now $\mathsf{b}\in I(g)$ and $\beta_K=L^K\mathsf{b}$, so that (K,β_K) is a first-passage datum at g with the label b for every $K\ge1$; let $\mathsf{A}_{r,K}$ be formed at (K,β_K), and $r_\sharp$, $\mathsf{C}(\mathsf{d})$ at the label b.

Then (ii) the limit $t_\lambda(\varphi_1,\varphi_2)=\lim_{K\to\infty}\langle T_\lambda(\varphi_1);\mathcal{O}(\varphi_2)\rangle_{K,\ell_g,\beta_K}$ exists; (iii)

$$\mathsf{A}_r=\lim_K\mathsf{A}_{r,K}=\frac{2\pi}{3}\mathsf{b}r^3\int dc\,\varphi_1(c)S_3^{(\ell_g,\mathsf{b})}(f^c_+,f^c_-,\varphi_2)$$

exists and

$$|\mathsf{A}_r-t_\lambda(\varphi_1,\varphi_2)|\le\mathsf{C}(\mathsf{d})r^{\beta_{\mathrm H}/72}\mathsf{b}^{-2}\|\varphi_1\|_\infty\|\varphi_2\|_\infty$$

for $0<r\le r_\sharp$; so $\mathsf{A}_r\to t_\lambda(\varphi_1,\varphi_2)$ as $r\to0$ at a fixed d.

(E.4) *Labels that tend to* b. For $\mathsf{b}\in I(g)$, the φ_a of (E.3) and every sequence of first-passage data (K_j,β_j) at g with $K_j\to\infty$ and $a_{K_j}\beta_j\to\mathsf{b}$: $\langle T_\lambda(\varphi_1);\mathcal{O}(\varphi_2)\rangle_{K_j,\ell_g,\beta_j}\to t_\lambda(\varphi_1,\varphi_2)$.

■□

Theorem AC (Four points at two scales)**.** Let g satisfy $(\Gamma^{(4)})$, let (K,β) be a first-passage datum at g, $\mathsf{b}=a_K\beta$, $0<\rho\le r\le\mathsf{d}\le\mathsf{d}_4^{(4)}(g)$, $s(\rho)\le K$, and let $w_1,\dots,w_4$ form two pairs at (ρ,r,d).

(a) On every side $\ell\in\mathfrak{L}(g)$ with $64\mathsf{d}\le\ell$,

$$\Big|\mathsf{J}_4-\tfrac{3}{2}\sum_{\varsigma}\operatorname{Tr}\prod_{l}\big(w_{\varsigma(l)}\mathsf{b}^{-1}C_K^{\mathrm{free}}\big)\Big|\le\epsilon_4^{\mathrm{nar}}(g,\mathsf{d})\,\mathrm{nat}_4,$$

the sum over the six cyclic orders of $\{1,2,3,4\}$; on the least torus

$$|S_4^T-\mathsf{J}_4|\le 77\Lambda_3^4\mathsf{M}'^4\mathsf{b}^4\mathsf{d}^{3/2}\mathrm{nat}_4;$$

and in every state at (K,β), for bounded real Borel functions on $\mathbb{R}^3$ in the geometry of (A.4)(i) for two pairs, the connected function differs from that of the least torus at the periodised functions by at most

$$C_4^{\mathrm{tr3}}(g)\mathsf{b}^4\mathsf{d}^{3/2}\mathrm{nat}_4.$$

(b) If $w_a=f_a\circ x$ with real Lipschitz f_a on T_{ℓ_g} such that $\operatorname{supp}f_a\subset\mathbb{B}(x_a,\rho)$, x_a the centres with which the w_a form the two pairs (so that $|x_1-x_2|,|x_3-x_4|\le 8r$ and $|x_a-x_b|\le 18\mathsf{d}$ for $a\le 2<b$), the balls $\mathbb{B}(x_a,\rho)$ are at least r apart in $\{1,2\}$ and in $\{3,4\}$ and at least d apart across, $\operatorname{Lip}f_a\le\|f_a\|_\infty/\vartheta\rho$, $\vartheta\in(0,1]$, and all supports lie in one ball of radius $\frac12\mathsf{d}^+$ with $4\mathsf{d}^+<\ell_g$, then

$$\Big|S_4^T(f)-3\mathsf{b}^{-4}\int k_4\prod_a f_a\Big|\le\Big[\epsilon_4^{\mathrm{nar}}(g,\mathsf{d})+77\Lambda_3^4\mathsf{M}'^4\mathsf{b}^4\mathsf{d}^{3/2}+3C^{(4)}\Big(\frac{a_K}{\vartheta\rho}+\Big(\frac{\mathsf{d}^+}{\ell_g}\Big)^3\Big)\Big]\mathrm{nat}_4.$$

Here $8a_K\le\rho$, by the working level at $\varrho=\rho$, and $\mathsf{d}\le\mathsf{d}^+$, the supports of f_1 and f_3 being at least d apart in a ball of diameter d^+; if an f_a vanishes, both members are 0.

(c) Let b be a limit of labels of first-passage data at g and $\mathcal{D}_4=\{(x_1,\dots,x_4):r_*\le|x_1-x_2|,|x_3-x_4|\le 2r_*,\ r_*\le\mathsf{d}_*=\operatorname{dist}(\{x_1,x_2\},\{x_3,x_4\})\le\mathsf{d}_5^{(4)}(g)\}$. Then $S_4^{(\ell_g,\mathsf{b})}$ has on $\mathcal{D}_4$ a Borel kernel s_4 with, almost everywhere on $\mathcal{D}_4$ and uniformly in $r_*/\mathsf{d}_*\in(0,1]$,

$$|\mathsf{s}_4-3\mathsf{b}^{-4}k_4|\le\epsilon_4(g,\mathsf{d}_*)\,\mathsf{b}^{-4}r_*^{-6}\mathsf{d}_*^{-6},\qquad \epsilon_4(g,t)=4096\big[\epsilon_4^{\mathrm{nar}}(g,\tfrac{t}{2})+77\Lambda_3^4(\bar{\mathsf{M}}^{(24)})^4\bar{\mathsf{b}}^4t^{3/2}+3C^{(4)}(12t/\ell_g)^3\big].$$

■□

Remark 7.2 (The ceilings). Let x_W be the threshold of Section YMM1:126, equation YMM1:(2326), and put

$$x_{\mathrm{jt}}=\max\left\{x_W,\Big(\frac{20M\mathsf{c}_{\mathfrak{h}}A_1(4\mathfrak{p}_0)^{\mathfrak{p}_0}}{c_A\alpha_0}\Big)^4\right\},\qquad\gamma_{\mathrm{jt}}=x_{\mathrm{jt}}^{-1/2}.\tag{23}$$

The notation x_{jt}, γ_{jt} denotes these same numbers. The defining inequalities for x_W include those for x_{J}, so $x_{\mathrm{jt}}\ge x_W\ge\max\{\gamma^{-2},x_{\mathrm{J}}\}$. For $t>1$, the inequality $\log u\le u$, applied to $u=t^{1/(4\mathfrak{p}_0)}$, gives

$$\delta(t)=A_1t^{-1/2}(\log t)^{\mathfrak{p}_0}\le A_1(4\mathfrak{p}_0)^{\mathfrak{p}_0}t^{-1/4}.$$

Consequently $t\ge x_{\mathrm{jt}}$ implies $5\mathsf{c}_{\mathfrak{h}}\delta(t)\le c_A\alpha_0/(4M)$. Also $\gamma_W^{\mathrm{ref}}=x_W^{-1/2}$ and $\gamma_W^{\mathrm{sd}}\le\gamma_W^{\mathrm{ref}}$ by Section YMM1:126, equation YMM1:(2327). Hence $\gamma_{\mathrm{jt}}\le\gamma_W^{\mathrm{ref}}\le\gamma$ and $\gamma_W^{\mathrm{sd}}\le\gamma$. Every coupling under (Γ1), (Γ2), (Γ) or $(\Gamma^{(4)})$, or below γ_{N} or γ_{R}, therefore satisfies $0<g\le\gamma$. For $g\le\gamma_{\mathrm{jt}}$ one also has $g^{-2}\ge e^{2\mathfrak{p}_0}$. All these ceilings are positive numbers depending only on the fixed constants.

7.3. **Construction estimates.** We use the construction results at their stated hypotheses, including Theorems YMM1:D, YMM1:AJ and YMM1:AD. The finite construction of Theorem YMM1:D and its sourced form, Theorem YMM1:AJ, enters wherever the objects of the theory (the run of a first-passage datum, the effective actions of all levels with their bounds, and the weighted progression with any number of sources) satisfy the actual-step hypotheses of Proposition B.21; this holds for $0 < g \le \gamma$ on every side of $\mathfrak{L}(g)$, with $g^{-2} \ge x_{\mathrm{J}}$ where sources are present. Proposition B.8 constructs the weighted progression for sources on the bare plaquettes; mixed sources enter through clauses (5) and (6) of the lemma on bond sources, which follows Lemma 7.31: at $0 < g \le \gamma_{\mathrm{N}}$, on every side of $\mathfrak{L}(g)$, the progression and the representation of the torus expectations are formed by the same construction, with the weight member of the mixed source in the source slot of the bare arrays; the frame of the pair functional is read with the hulls of the sources in the place of their supports; and the tower identity holds for a pair of mixed sources in that frame.

Theorems YMM1:AJ and YMM1:AD enter through the two-sided stability bound of the torus measures, which together with their reflection positivity gives the chessboard bound of Lemma 7.25. Through this bound they are used in (A.4), (A.5), (C.1)(iii), (C.4) and for the states in Theorem AC(a); they are not used in Theorem Y, in (A.1)–(A.3), (C.1)(i), (ii), (C.2), (C.3), in Theorem AA, or in Theorem AC on the tori. Theorem AB, like every statement of this section, assumes the construction inputs just listed.

We use the fixed construction setting just specified, the torus limits of Theorem YMM1:A, and the periodic-Gibbs limits and decompositions of Theorems YMM1:AP and YMM1:AL. On one renormalisation step (whose provision is that of Section YMM1:52.4) and on the progression: Proposition E.7, with the fourth-family norm (272); the bracket localisation of the families with its count; the locality and linear-weight dependence of Proposition B.8; the chart and normalized real measures of Lemmas B.3 and B.23, with the cumulant bounds of Lemma 7.14; the expansion $|a_p(e^{i\eta_i A}) - \frac{1}{2}|\mathsf{ang}_p^{[i]}(A)|^2| \le \mathsf{M}_{\mathrm{pl}}^2 \eta_{i-1}^4 (r_i/\varrho_{\mathrm{ch}})^3$ on the chain classes, and $|\mathsf{ang}_p^{[i]}(A)| \le 2\eta_i^2 r_i$; the regular-field evaluation and domain sums of Lemmas B.22 and B.10; the lowering maps of the chain classes, by which $A' \in \mathsf{Cc}_{i+1}(r_{i+1})$ and a fluctuation field B give $A^{\mathrm{lw}}(B) \in \mathsf{Cc}_i(r_i)$, and the pair tower identity of Proposition B.25, extended to several sources in the lemma preceding Proposition 7.16; the history decomposition (314), its sourced quotients in Proposition B.15, and the tail bounds of Proposition M.2.

On the free kernel, Proposition YMM1:120.6 and equations YMM1:(2245)–(2246) give the decay of the slices $|\mathcal{C}_{(j)}(p,q)| \le C_{\mathrm{tp}} a_K^3 \mathsf{r}^{-3} t_j^3 e^{-\delta_{\mathrm{tp}} t_j}$, $\mathsf{r} = |x(p) - x(q)|_\infty$, $t_j = \mathsf{r}/a_{K-j+1}$; and the comparison $|\epsilon_p \epsilon_q C_K^{\mathrm{free}}(p,q) - a_K^3 \mathbb{K}_3(u)_{\lambda(p)\lambda(q)}| \le C_{\mathrm{lat}} a_K^3 [a_K^2 |u|^{-5} + \ell^{-3}]$, $|C_K^{\mathrm{free}}(p,q)| \le (1 + 3C_{\mathrm{lat}}) a_K^3 |u|^{-3}$, for $p \ne q$, u the least lift of $x(p) - x(q)$, $|u| \ge 2^{-1/2} a_K$, $\epsilon_p = \pm 1$ the orientation signs. On the working level (Lemma YMM1:126.1): for $0 < \varrho < 1$ with $s = s(\varrho) \le K$ and $k = \mathsf{k}(\varrho)$, $Y = Y_s$: $s \ge 3$, $2 \le k \le K - 1$, $4MY^{2\mathfrak{p}_0} \le \hat{\varrho}_k < LC_{W,0} A_0^2 Y^{2\mathfrak{p}_0}$, $Y \ge \log \frac{1}{\varrho}$, $y_k \le Y$, $K - k \le s \le Y/\log L$; in particular $a_K \le a_{K-k} = \varrho/\hat{\varrho}_k \le \varrho/4M$, and $Y \ge 2\sqrt{3}$ when $\varrho \le e^{-2\sqrt{3}}$.

The lower bounds come from the definition of $s(\varrho)$ and from $C_{W,0} A_0^2 \ge 4L^2 M$: $L^s \varrho \ge C_W(s) \ge 4L^2 M Y^{2\mathfrak{p}_0} > L^2$ and $\varrho < 1$ give $s \ge 3$; $K - k = \min\{s, K-2\} \ge s - 2$ gives $\hat{\varrho}_k = L^{K-k}\varrho \ge L^{-2} C_W(s) \ge 4MY^{2\mathfrak{p}_0}$; and $L^s \varrho \ge C_W(s) \ge 1$ gives $Y \ge s \log L \ge \log \frac{1}{\varrho}$. Besides, $L^m \ge LMy_K$ for the sides $\ell = 2L^m \in \mathfrak{L}(g)$. Finally the dilation of lattices: $x \mapsto L^z x$ carries the lattice (ℓ, K) to the lattice $(L^z \ell, K - z)$ and $\mu_{K,\ell,\beta}$ to $\mu_{K-z, L^z\ell, \beta}$.

7.4. **Estimates and proofs.** The argument has eight parts: the calculus of the derivative families (Lemmas 7.3–7.10); the kernel families (Lemma 7.11 to Proposition 7.13); the induction over the levels and the jets (Lemma 7.14 to Proposition 7.19); the connected functions on the least torus (Lemmas 7.20–7.24); every state (Lemma 7.25 to Lemma 7.30); the bond forms (Lemma 7.31 to Proposition 7.34); pair minus tensor field (the lemma on a regular gauge on a cube, and Lemmas 7.36 to 7.41); and the proofs of the theorems.

The calculus of the derivative families.

Lemma 7.3 (The run)**.** Let $0 < g \le \gamma$ with $g^{-2} \ge x_{\mathrm{J}}$, which holds for every $0 < g \le \gamma_{\mathrm{jt}}$ (Remark 7.2), and (K, β) a first-passage datum at g with its run and label b.

(a) $x_K > g^{-2} \ge x_{\mathrm{J}} \ge \max\{e^{2\mathfrak{p}_0}, eL, 4\bar{B}\}$, so $y_K \ge \max\{2\mathfrak{p}_0, 1 + \log L\}$. For $0 \le i \le j \le K$: $\frac{4}{5}\mathsf{b} \le a_{K-j}x_j \le \frac{4}{3}\mathsf{b}$; $\frac{3}{4}L^{j-i}x_j \le x_i \le \frac{5}{4}L^{j-i}x_j$, in particular $x_j \ge \frac{4}{5}L^{-(j-i)}x_i$; $y_j \le y_i$; $\delta_j \le (\frac{5}{4})^{1/2}L^{(j-i)/2}\delta_i$ and $\delta_i \le \delta_j$; $g^{-2} < \mathsf{b} \le \bar{\mathsf{b}}$; and $\frac{11}{10}\mathsf{c}_\mathfrak{h}\delta_i \le r_i \le \frac{8}{5}\mathsf{c}_\mathfrak{h}\delta_i$ for $1 \le i < K$, so $x_n r_n^2 \le \frac{64}{25}\mathsf{c}_\mathfrak{h}^2\mathfrak{b}_n^2$. Of these, $g^{-2} < \mathsf{b} \le \bar{\mathsf{b}}$ holds, together with the flow bound $|x_j - L^{-(j-i)}x_i| \le \bar{B}$ $(0 \le i \le j \le K)$, for the label and the run of every first-passage datum at every $0 < g \le \gamma$.

(b) Let $g^{-2} \ge \max\{e^{2\mathfrak{p}_0}, e^{y_\mathsf{p}}\}$ and $\delta(g^{-2}) \le \min\{1/2c_{\mathrm{rt}}, 1/c_\epsilon\}$, where $c_\delta = (\frac{5}{4}L)^{1/2}$, $c_{\mathrm{rt}} = \max\{8\mathsf{c}_\mathfrak{h}c_\delta/5\varrho_{\mathrm{ch}}, 1/\varrho_{\mathrm{fl}}\}$, $c_\epsilon = c_{\mathrm{cu}} + 16\mathsf{c}_{\mathbf{C}}\mathsf{c}_\mathfrak{h}c_\delta/5r_\alpha$, $y_\mathsf{p} = \max\{1, (LM)^3A_1^{-2}(1 + 2\log^+(c_\mathsf{p}/A_1))\}$. Here ϱ_{ch} and ϱ_{fl} are the radii denoted by ρ_{ch} and ρ_{fl} in equation YMM1:(2285), and $r_\alpha = a^{\mathrm{us}}(\alpha_0, \alpha_1)$ is the usable chart radius of equation YMM1:(933). The covariance and fluctuation-tail constants are

$$\mathsf{c}_{\mathbf{C}} = 2/\gamma_r, \qquad c_\mathsf{p} = C_{\mathrm{ex}}((L+2)M)^3e^{4\lambda_1},$$

as in equations YMM1:(2294) and YMM1:(2296). For this regular one-step expansion, $\gamma_2 = 2(LM)^{-3}$ by equation YMM1:(889); hence its tail factor $e^{-\gamma_2\mathfrak{b}_i^2/2}$ is $e^{-(LM)^{-3}\mathfrak{b}_i^2}$. Finally, c_{cu} is the constant of Lemma 7.14.

Then at all heights $1 \le i < K$: $2c_{\mathrm{rt}}\delta_i \le 1$, $c_\epsilon\delta_i \le 1$, $y_i \ge y_\mathsf{p}$; hence $2r_i \le \varrho_{\mathrm{ch}}$, $r_{i+1} \le \frac{8}{5}\mathsf{c}_\mathfrak{h}c_\delta\delta_i$, $\mathsf{p}_{\star,i} \le \delta_i$ and $\epsilon_i' \le c_\epsilon\delta_i \le 1$, where $\mathsf{p}_{\star,i} = c_\mathsf{p}\exp[-(LM)^{-3}\mathfrak{b}_i^2]$ and ϵ_i' is the number of Lemma 7.14; if besides $\delta(g^{-2}) \le 1/2C_{\mathrm{cu}}$, then $\epsilon_i^{\mathrm{cu}} \le 2C_{\mathrm{cu}}\delta_i \le 1$. By the conditions on the constants $\mathfrak{b}_j \ge (LM)^{3/2} \ge 1$, so $g_j \le \delta_j$ and $x_j^{-1} \le \delta_j^2 \le r_j^2$ $(j < K)$; and $\theta^{[j]} \le \theta^{[K-1]} \le \theta(g^{-2})$.

(c) For $0 < \varrho < 1$ with $s(\varrho) \le K$: $\log\frac{1}{\varrho} \le Y_\varrho \le 2\log\frac{1}{\varrho} + C(g)$, $a_{K-\mathsf{k}(\varrho)} \le \varrho/4M$, and $\delta_{\mathsf{k}(\varrho)} \le A_1Y_\varrho^{\mathfrak{p}_0}(\varrho/\mathsf{b})^{1/2}$.

■

Proof. (a) At every $0 < g \le \gamma$ the run of a first-passage datum has $x_0 > x_1 > \cdots > x_K > g^{-2}$ and $|x_j - L^{-(j-i)}x_i| \le \bar{B}$ for $i \le j$, and its label has $g^{-2} < \mathsf{b} \le \bar{\mathsf{b}}$ (Proposition YMM1:74.1). The threshold x_{J} is at least $\max\{e^{2\mathfrak{p}_0}, eL, 4\bar{B}\}$ by its definition (the definitions preceding (228)); so $g^{-2} \ge x_{\mathrm{J}}$ gives $x_j \ge x_K > g^{-2} \ge 4\bar{B}$, hence $\bar{B} \le \frac{1}{4}x_j$ and $\frac{3}{4}x_j \le L^{-(j-i)}x_i \le \frac{5}{4}x_j$, which at $i = 0$ gives the bounds of $a_{K-j}x_j$ against $\mathsf{b} = a_Kx_0$. As y decreases along the run and $x_i \le \frac{5}{4}L^{j-i}x_j$, $\delta_j/\delta_i = (y_j/y_i)^{\mathfrak{p}_0}(x_i/x_j)^{1/2} \le (\frac{5}{4})^{1/2}L^{(j-i)/2}$.

As $x_i \ge x_j > g^{-2} \ge e^{2\mathfrak{p}_0}$ lie in $[e^{2\mathfrak{p}_0}, \infty)$, where δ decreases, $\delta_i \le \delta_j$. The radii follow from their recursion and these bounds. (b) $x_i > g^{-2} \ge e^{2\mathfrak{p}_0}$ and δ decreases there, so every condition stated at g^{-2} holds at every height; $2r_i \le \varrho_{\mathrm{ch}}$ and $r_{i+1} \le \frac{8}{5}\mathsf{c}_\mathfrak{h}c_\delta\delta_i$ by (a). For $y \ge y_\mathsf{p}$: $(LM)^{-3}A_1^2y^{2\mathfrak{p}_0} \ge \frac{y}{2} + \log^+(c_\mathsf{p}/A_1)$, so $\mathsf{p}_{\star,i} \le A_1e^{-y_i/2} \le A_1y_i^{\mathfrak{p}_0}x_i^{-1/2} = \delta_i$; then $\epsilon_i' \le c_{\mathrm{cu}}\delta_i + 2\mathsf{c}_{\mathbf{C}}r_{i+1}/r_\alpha \le c_\epsilon\delta_i$ and $\epsilon_i^{\mathrm{cu}} \le C_{\mathrm{cu}}(\delta_i + \mathsf{p}_{\star,i}) \le 2C_{\mathrm{cu}}\delta_i$. (c) As $K - s \le \mathsf{k}(\varrho) \le K - s + 2$, the working level gives $\varrho L^s \le L^2\hat{\varrho}_k < L^3C_{W,0}A_0^2Y^{2\mathfrak{p}_0}$, whence

$$Y = s\log L + \log L(g^{-2} + \bar{B}) < \log\tfrac{1}{\varrho} + 2\mathfrak{p}_0\log Y + \log[L^4C_{W,0}A_0^2(g^{-2} + \bar{B})],$$

and $2\mathfrak{p}_0\log Y \le \frac{1}{2}Y + 2\mathfrak{p}_0\log 4\mathfrak{p}_0$; further $a_{K-k} = \varrho/\hat{\varrho}_k \le \varrho/4M$ and $\delta_k = A_1y_k^{\mathfrak{p}_0}x_k^{-1/2} \le A_1Y^{\mathfrak{p}_0}(5a_{K-k}/4\mathsf{b})^{1/2}$. □

The frame used below includes the identity of the step data with the canonical construction. It also records the numerical room needed to lower a field through the chain. Keeping both requirements explicit allows us to apply the estimates at an arbitrary lower level.

Definition 7.4. Let $\mathfrak{w} = (\ell, K)$, $\ell = 2L^m$, and let $x_0, \dots, x_K$ be a finite running sequence. The pair setting consists of the following conditions.

(Jt.1) Fix $2 \le k_0 < K$, $d \ge a_K$ and real Lipschitz functions f_1, f_2, each supported in a closed ball of radius d. Put $w_a(p) = f_a(x(p))$ and $s_0 = K - k_0$.

(Jt.2) The setting (J) of Definition B.16 holds through the upper level K, with $p = 2$ and the calibration equal to this running sequence. Thus its index k is $K-1$, and its actual step data, including (Pv), are required. Both sampled sources are nonzero, and

$$\widehat{d}_{k_0} := d/a_{K-k_0} \ge M, \qquad D_{k_0} \ge 3M.$$

The running and weighted bounds are

$$\begin{aligned} &|x_j - L^{-(j-i)}x_i| \le \bar{B} \quad (0 \le i \le j \le K), \qquad x_K \ge 4\bar{B}, \qquad y_K \ge \max\{2\mathfrak{p}_0, 1 + \log L\}, \\ &C_0^{\flat}\mathsf{S}_A\theta^{[K-1]} \le 1, \qquad \varepsilon_j \le c_A\alpha_0/(8MB_3) \quad (1 \le j \le K), \qquad \varepsilon_j \le \varepsilon_{\flat} \quad (0 \le j < K). \end{aligned} \tag{24}$$

The weighted data restrict to every earlier height. At heights $1 \le j < k_0$ they satisfy

$$s^{[j]} \le s^{\star}/2, \qquad \tfrac{4}{3}C_1^{\flat}L\theta^{[j]}\mathsf{T}(D_j/M) \le 1.$$

These are the hypotheses for the mixed derivative bound at the lower cut, in addition to the running bounds just stated.

The flat-top radii are $r_K = 0$ and $r_i = L^{-1}r_{i+1} + \frac{11}{10}\mathsf{c}_{\mathfrak{h}}\delta_i$. Set

$$c_R = \max\left\{\tfrac{8}{5}\sqrt{5L/4}\,\mathsf{c}_{\mathfrak{h}}/\varrho_{\mathrm{ch}}, \varrho_{\mathrm{fl}}^{-1}\right\}, \qquad e_i^{\mathrm{KF}} = \epsilon_i^{\mathrm{cu}} + \tfrac{16}{5}\sqrt{5L/4}\,\mathsf{c}_{\mathbf{C}}\mathsf{c}_{\mathfrak{h}}\delta_i/r_{\alpha}.$$

Require $\ell \ge N_{\mathsf{H}}$ and, for $k_0 \le i < K$,

$$\begin{aligned} c_R\delta_i \le \tfrac{1}{2}, \qquad e_i^{\mathrm{KF}} \le 1, \\ [\tfrac{48}{5}\sqrt{5/4}L^{-3/2}\mathsf{c}_{\mathfrak{h}} + 8C_{\mathrm{db}}]\delta_i < \varepsilon_{\mathcal{W}}\alpha_0. \end{aligned} \tag{25}$$

(Jt.3) The two-source weighted progression is the one of Definition B.7, with $k = K-1$ and $t_j = x_j$. It uses the same canonical data as (Jt.2), when that condition is imposed. Its source is $w_\lambda = \lambda_1 w_1 + \lambda_2 w_2$, $w_\lambda^{[j]} = L^{K-j}w_\lambda$, and $C_0^{\flat}\mathsf{S}_A\theta^{[K-1]} \le 1$.

(Jt.4) Both sources are nonzero, $s^{[j]} \le s^{\star}/2$ for $0 \le j < k_0$, and

$$\tfrac{4}{3}C_1^{\flat}L\theta^{[j]}\mathsf{T}(D_j/M) \le 1 \quad (1 \le j < k_0).$$

(Jt.5) An intermediate integer T is fixed with $k_0 < T \le K$.

(Jt.6) For $k_0 \le i < K$,

$$5\mathsf{c}_{\mathfrak{h}}\delta_i \le c_A\alpha_0/(4M). \tag{26}$$

The *frame at* k_0 means (Jt.1)–(Jt.3) and (Jt.6). The full pair setting includes (Jt.4) and (Jt.5) as well. ∎

Lemma 7.5 (The frame of the pair functional; tents)**.** Let $0 < g \le \gamma_{\mathrm{jt}}$, $g^{-2} \ge x_{\mathrm{J}}$, (K, β) a first-passage datum at g and $\ell \in \mathfrak{L}(g)$.

(a) Let $2 \le k < K$ and let f, h be real Lipschitz functions on T_ℓ, neither $f \circ x$ nor $h \circ x$ identically 0, each with its support in a closed ball of a radius $\bar{\mathsf{d}} \ge a_K$ with $\bar{\mathsf{d}}/a_{K-k} \ge M$, such that the corners of the plaquettes of the two supports are at least $3M$ level-k spacings apart in the sup distance. Then $(f \circ x, h \circ x)$ satisfies, with the lower level k, the four conditions (Jt.1)–(Jt.3) and (Jt.6) of Definition 7.4: the data, the flat top at K, the weighted progression of the two sources, and the smallness of δ_i at the heights $k \le i < K$; we call these four conditions the frame at k.

The two further conditions of that setting, (Jt.4) at the levels below the lower level and (Jt.5) on an intermediate level, hold, together with the other four, for a test pair $(f_1, f_2) \in \mathfrak{T}_{T_\ell}(r; \vartheta)$, $0 < r < 1$, $\vartheta \in (0, 1)$, with $f_a \circ x \not\equiv 0$, at the lower level $\max\{K - s, 2\}$

when $3 \le s = s(r) \le K$ and $\mathsf{Lm}_s \le L^{s-3}$ with the intermediate level specified in the proof. The frame at k holds in the same way for the two sampled linear combinations of n functions with pairwise disjoint supports falling into two clusters, provided both combinations are nonzero, the two unions of supports lie in such balls, and the corners of the two clusters are $3M$ level-k spacings apart.

(b) Let real weights w_1, w_2 be placed at (ρ, r), $0 < \rho \le r \le e^{-2\sqrt{3}}$, $s(\rho) \le K$. Then $a_K \le \rho/4M$; with the tent τ of height 1 and radius $\frac{1}{3}a_K$, the functions $f_a = \sum_p w_a(p)\tau(\cdot - x(p))$ are Lipschitz, $f_a \circ x = w_a$, $\operatorname{supp} f_a \subset \mathbb{B}(x_a, 2r)$, and (a) applies at $k = \mathsf{k}(r)$ with $\bar{\mathsf{d}} = 2r$. For $0 \le i \le K$: (P1) $\sum_p |w_a(p)| \le 81(\rho/a_K)^3 |w_a|_\infty$; (P2) $\mathsf{N}_i(w_a) \le (2\hat{\rho}_i/M + 3)^3 \le 108(1 + t_i)$, $t_i = \frac{27}{8M^3}\hat{\rho}_i^3$; (P3) $\mathsf{D}_i^{12} \ge \hat{r}_i/\sqrt{3} - 1$; and every corner of a plaquette of $\operatorname{supp} w_1 \cup \operatorname{supp} w_2$ lies within the sup distance $R_w \le 11\hat{r}_{i+1}$, in level-$(i+1)$ units, of a bare site next to x_1. For weights placed at (ρ, r, d), or forming two pairs at (ρ, r, d), with $\mathsf{d} \le e^{-2\sqrt{3}}$, the same holds, (P3) holds across the clusters with $\hat{\mathsf{d}}_i$ for $\hat{r}_i$, and (a) applies to the two clusters at $k = \mathsf{k}(\mathsf{d})$, each lying in a ball of radius $10\mathsf{d}$; for two weights with $\Sigma(w_a) \subset \mathbb{B}(x_a, \rho)$ at a distance $\ge \mathsf{d} \ge \rho$, (a) applies at $k = \mathsf{k}(\mathsf{d})$.

■

Proof. (a) First consider a pair satisfying the four geometric hypotheses in the statement. The first-passage construction gives $x_0 > \cdots > x_K > g^{-2}$ and the running comparison in (24); see Proposition YMM1:74.1. Since $\ell \in \mathfrak{L}(g)$, it also gives $MR(x_K) \le L^m$. The lattice is therefore admissible over every initial segment of the run. In particular $L^m \ge LM$ and $\ell \ge N_{\mathsf{H}}$, by the proof of Lemma YMM1:126.2.

Proposition B.21, applied with $k = K - 1$, supplies the actual setting (J), its weighted progression and the identification (Pv). This is the same canonical datum at every height, with the counterterms of this run. The inequalities defining x_{J} apply at every x_j: they give the regular-background radius, the half-ceiling and $C_0^\flat \mathsf{S}_A \theta^{[K-1]} \le 1$. The cutoff bound $\varepsilon_j \le \varepsilon_\flat$ is part of the actual history verification in that proposition.

The supports satisfy $\widehat{d}_k \ge M$ and $D_k \ge 3M$ by hypothesis. Their separation at earlier levels is $D_j = L^{k-j} D_k$, so the decreasing function T obeys $\mathsf{T}(D_j/M) \le \mathsf{T}(3)$ for $j < k$. Equation (228) therefore gives all the mixed derivative hypotheses at the lower cut. The threshold inequalities in equation YMM1:(2326) give (25). The factor 2 in the corresponding lowering-domain inequality makes its conclusion strict. They also give $y_K \ge \max\{2\mathfrak{p}_0, 1 + \log L\}$ and $x_K \ge 4\bar{B}$. Thus (Jt.1)–(Jt.3) hold. Finally $x_i > g^{-2} \ge x_{\mathrm{jt}}$ and the threshold computation in Remark 7.2 give (Jt.6).

This verification uses only the four geometric properties in the statement. It uses neither the filling nor the sign condition of a test pair, nor the formula for the working level. For n functions in two clusters, apply it to the two sums over the clusters, with real coefficients for which both sampled sums are nonzero. Shrinking a support preserves the radius and separation conditions.

For a test pair at $k_0 = \max\{K - s, 2\}$, Lemma YMM1:126.1 gives $d \ge a_K$, $\widehat{d}_{k_0} \ge M$ and $D_{k_0} \ge 3M$. The preceding argument gives its frame. At all heights below k_0, (228) gives $s^{[j]} \le s^\star/2$, including $j = 0$, and the same separation argument proves (Jt.4). Choose

$$n_T = \left\lceil \log_L(\widehat{d}_{k_0} y_{k_0}^{3\mathfrak{p}_0}) \right\rceil, \qquad T = k_0 + n_T.$$

The room bound $\mathsf{Lm}_s \le L^{s-3}$ and the final assertion of Lemma YMM1:126.1 give $k_0 < T \le K - 2$. This proves (Jt.5) and the claimed full pair setting.

(b) The working level at $\varrho = \rho$ gives $a_K \le a_{K-\mathsf{k}(\rho)} \le \rho/4M$. Two distinct barycentres are at least $2^{-1/2}a_K$ apart, so the tents are disjoint and $f_a(x(p)) = w_a(p)$.

A corner is at the distance $2^{-1/2}a_K$ from its barycentre: corners of the two supports are $\ge r - \sqrt{2}a_K$ apart, $\ge (r - \sqrt{2}a_K)/\sqrt{3}$ in the sup distance, that is $\ge \hat{r}_i/\sqrt{3} - 1$ level-i units. At $\varrho = r$ the working level gives $2 \le \mathsf{k}(r) \le K - 1$, $2\hat{r}_{\mathsf{k}(r)} \ge M$ and $\mathsf{D}_{\mathsf{k}(r)}^{12} \ge \frac{4}{\sqrt{3}} M Y_r^{2\mathfrak{p}_0} - 1 \ge 3M$, as $Y_r \ge 2\sqrt{3}$. (P1): the

barycentres of one orientation form a translate of $a_K\mathbb{Z}^3$, with at most $(2\rho/a_K+1)^3 \le 27(\rho/a_K)^3$ points in a ball of radius $\rho \ge a_K$, and there are three orientations. (P2): an interval of length $2\hat\rho_i+\eta_i$ meets at most $2\hat\rho_i/M+3$ intervals of length M, and $(2y+3)^3 \le 4(8y^3+27)$. R_w: all points of $\Sigma(w_1)\cup\Sigma(w_2)$ are within $9r$ of x_1.

The three-point and four-point cases are the same with d for r across the clusters, and $9r+a_K \le 10\mathsf{d}$. □

Lemma 7.6 (The calculus of the derivative families)**.** Let $0<g\le\gamma$ with $g^{-2}\ge x_{\mathrm J}$, (K,β) a first-passage datum at g with $K\ge 2$, $\ell\in\mathfrak{L}(g)$, and $w_1,\dots,w_p$ real weights, none identically 0, $p\ge 1$ arbitrary. For $\emptyset\ne\beta\subset[p]$, $m=|\beta|$, $0\le j\le K-1$, put

$$\mathsf{m}_{j,a}=12M^3\alpha_0^2L^{K-j}|w_a|_\infty,\quad \varkappa_j=\frac{M^{3/2}}{2\mathsf{C}_{\mathcal A}\mathfrak{b}_j},\quad \gamma_j=\theta^{[j]}\varkappa_j,\quad \mathsf{U}_{j;\beta}$$
$$=\varkappa_j^{m-1}(N_\star^{[j]})^{1-m}\prod_{a\in\beta}2\mathsf{m}_{j,a},\quad \bar\nu_{j;\beta}=\gamma_j\mathsf{U}_{j;\beta},$$

with the constant $\mathsf{C}_{\mathcal A}$ of the one-step theorem; the bare arrays of the weighted progression, $\mathfrak{f}_{\lambda,j}=((E_\lambda^{(i)},e_i)_{i\le j},(\mathsf{W}_{L^{K-j}w_\lambda}))$ for λ near 0, where the counterterms e_i of the regular progression of the run are real numbers that depend neither on λ nor on the sources, and the weight member W_w is linear in w, so that $E_\lambda^{(j+1)}-E^{(j+1)}=\mathsf{St}^{[j]}(\mathfrak{f}_{\lambda,j})-\mathsf{St}^{[j]}(\mathfrak{f}_{0,j})$ (equation (200)); their value at $\lambda=0$, $\mathfrak{f}_{0,j}=((E^{(i)},e_i)_{i\le j},(0))$; and their derivatives $\mathfrak{f}_{\beta,j}=\partial_\beta\mathfrak{f}_{\lambda,j}|_{\lambda=0}=((E_\beta^{(i)},0)_{i\le j},(H_\beta))$ with $H_{\{a\}}=\mathsf{W}_{L^{K-j}w_a}$ and $H_\beta=0$ for $m\ge 2$; and $\bar{\mathsf{h}}_{j;\beta}=\mathfrak{n}[\mathfrak{f}_{\beta,j}]/\mathsf{U}_{j;\beta}$, $\bar\Psi_{j;\beta}=\|E_\beta^{(j+1)}\|_{j+1,\lambda_{\mathrm{out}}}/\bar\nu_{j;\beta}$. Then for $1\le j\le K-1$:

(a) *Chain rule.* $E_\beta^{(j+1)}=\sum_{\pi\in\mathrm{Part}(\beta)}(\prod_{\beta'\in\pi}\partial_{s_{\beta'}})\mathsf{St}^{[j]}(\mathfrak{f}_{0,j}+\sum_{\beta'\in\pi}s_{\beta'}\mathfrak{f}_{\beta',j})\big|_{s=0}$; $E_\beta^{(j)}$ is m-linear in $(w_a)_{a\in\beta}$, depends on no other source, and is the same in every progression that holds the sources of β.

(b) *Derivatives of the step.* $N(\mathfrak{f}_{0,j})\le\frac12 N_\star^{[j]}$, and for bare arrays $\mathfrak{f},\mathfrak{g}_1,\dots,\mathfrak{g}_q$ with $N(\mathfrak{f})\le\frac12N_\star^{[j]}$

$$\big\|\partial_{s_1}\cdots\partial_{s_q}\mathsf{St}^{[j]}(\mathfrak{f}+\textstyle\sum_l s_l\mathfrak{g}_l)\big|_0\big\|_{j+1,\lambda_{\mathrm{out}}}\le(2(q-1))^{q-1}\,\theta^{[j]}\varkappa_j^q\,(N_\star^{[j]})^{1-q}\prod_l\mathfrak{n}[\mathfrak{g}_l].$$

(c) *Lags.* If $\mathfrak{g}=((G^{(i)},0)_{i\le j},(H))$ and each $G^{(i)}(X,\cdot,z)$ vanishes unless X meets a set Cr of bare sites, then $\mathfrak{n}[\mathfrak{g}]\le\|H\|_{j,\kappa}+\sum_{i\le j}\omega^{\mathrm{sp}}_{j-i}(i)\|G^{(i)}\|_{i,\kappa}$, where $\omega_0^{\mathrm{sp}}=1$, $\omega_l^{\mathrm{sp}}(i)=\varpi_l+L^{-4l}\min\{L^{3l},c_3\mathsf{n}_i^{\mathrm{cb}}(\mathsf{Cr})\}$, $0\le\varpi_l\le L^{8-5l}$, $\mathsf{n}_i^{\mathrm{cb}}(\mathsf{Cr})$ is the number of the cubes of π_i that hold a site of Cr, and c_3 is a constant.

(d) *Support.* $E_\beta^{(i)}(X,\cdot,z)=0$ unless every $\operatorname{supp}w_a$, $a\in\beta$, has a plaquette with its corners in X; and then $d_i(X)\ge[\max_{a,b\in\beta}\mathsf{D}_i^{ab}/M-2]_+$.

(e) *Start.* $\bar\Psi_{0;\beta}\le m^m(\mathsf{c}^\flat/2)^m$ with a constant $\mathsf{c}^\flat$; and if $\sum_p|w_a(p)|\le 81(\rho/a_K)^3|w_a|_\infty$ for a width $\rho\ge a_K$, then $\|\mathsf{W}_{L^{K-j}w_a}\|_{j,\kappa}\le\varsigma_j\mathsf{m}_{j,a}$, $\varsigma_j=\min\{1,t_j\}$.

(f) *Units.* $\gamma_j=c_\gamma x_j^{-1/2}$, $\bar\nu_{j;\beta}=\bar c_m x_j^{-m/2}\prod_{a\in\beta}(|w_a|_\infty/a_{K-j})$; for $i\le j$: $(\frac45)^{m/2}L^{(j-i)m/2}\bar\nu_{j;\beta}\le\bar\nu_{i;\beta}\le(\frac43)^{m/2}L^{(j-i)m/2}\bar\nu_{j;\beta}$, $\gamma_i\le(\frac43)^{1/2}L^{-(j-i)/2}\gamma_j$, $\sum_{i<j}\gamma_i\le 0.45\gamma_j$; and $\varkappa_j\le\frac16L^{-3/2}$.

(g) *Recursions.* $\bar\Psi_{j;\beta}\le\sum_{\pi\in\mathrm{Part}(\beta)}(2(|\pi|-1))^{|\pi|-1}\prod_{\beta'\in\pi}\bar{\mathsf{h}}_{j;\beta'}$; and for $m\ge2$ and every $a_*\in\beta$, with ω^{sp} formed with $\mathsf{n}_i^{\mathrm{cb}}=\mathsf{N}_i(w_{a_*})$,

$$\bar{\mathsf{h}}_{j;\beta}\le\gamma_j(\tfrac43)^{m/2}\sum_{i\le j}\omega^{\mathrm{sp}}_{j-i}(i)\,\sigma_{i;\beta}\,L^{(j-i+1)m/2}\,\bar\Psi_{i-1;\beta},\qquad \sigma_{i;\beta}=e^{-c_\sigma[\max_{a,b\in\beta}\mathsf{D}_i^{ab}/M-2]_+},$$
$$c_\sigma=\min\{\tfrac12,4\beta_{\mathrm s}\kappa\}.$$

No assumption of (a)–(g) depends on p; the order m enters through the displayed numbers alone. There are numbers $\tau^\natural,\gamma^\natural>0$ formed from the constants such that $\theta^{[K-1]}\le\tau^\natural$ gives $\gamma_j\le\gamma^\natural$ for all $j<K$ and $2C_\omega\mathsf{c}^\flat\theta^{[0]}\le1$, C_ω the constant of Lemma 7.9; and a number $r_1(\mathsf{b})>0$, formed from the

constants and b and not increasing in b, such that every width $0 < \rho \le r_1(\mathsf{b})$ with $s(\rho) \le K$ has $\rho \ge 4Ma_K$ and $E_\sigma(\hat\rho_1/2) \le \varkappa_0^4$, where $E_\sigma(u) = \exp(-c_\sigma[u/\sqrt{3}M - 3]_+)$. ■

Proof. (a) The progression is $E_\lambda^{(j+1)} - E^{(j+1)} = \mathsf{St}^{[j]}(\mathfrak{f}_{\lambda,j}) - \mathsf{St}^{[j]}(\mathfrak{f}_{0,j})$ (equation (200)), and the multilinear derivatives at $\lambda = 0$ of a composition are sums over partitions; the dependence through w_λ alone gives the multilinearity. (b) Within the holomorphic, gauge-invariant input class of Proposition E.7, the fourth family must vanish at the block field 0 and have finite norm (272) on the polydisc $|B(b)| < \mathsf{C}_{\mathcal{A}}\mathfrak{b}_j$. A family that vanishes at $B = 0$ and is bounded on that polydisc is at most its supremum times $|B|/\mathsf{C}_{\mathcal{A}}\mathfrak{b}_j$ (Schwarz's lemma); so $\mathsf{St}^{[j]}(\mathfrak{f})$ is formed for $\varkappa_j\mathfrak{n}[\mathfrak{f}] \le N_\star^{[j]}$, with

$$|\mathsf{St}^{[j]}(\mathfrak{f}) - \mathsf{St}^{[j]}(\mathfrak{f}')|(X,P,z) \le \theta^{[j]}\varkappa_j\,\mathfrak{n}[\mathfrak{f}-\mathfrak{f}']\,e^{-\lambda_{\mathrm{out}}d_{j+1}(X)},$$

and it is holomorphic in the parameters of $\mathfrak{f} + \sum s_l\mathfrak{g}_l$ on $\{\varkappa_j\mathfrak{n}[\cdot] < N_\star^{[j]}\}$. Dividing the Lipschitz bound by $|s|$ and letting $s \to 0$ gives $\|\mathsf{DSt}^{[j]}(\mathfrak{h})[\mathfrak{g}_1]\|_{j+1,\lambda_{\mathrm{out}}} \le \theta^{[j]}\varkappa_j\mathfrak{n}[\mathfrak{g}_1]$ wherever $\varkappa_j\mathfrak{n}[\mathfrak{h}] < N_\star^{[j]}$; this is (b) at $q = 1$. For $q \ge 2$, as $\varkappa_j\mathfrak{n}[\mathfrak{f}] \le N(\mathfrak{f}) \le \frac12 N_\star^{[j]}$, the point $\mathfrak{f} + \sum_{l\ge2} s_l\mathfrak{g}_l$ stays in that set on the polydisc of the radii $N_\star^{[j]}/2(q-1)\varkappa_j\mathfrak{n}[\mathfrak{g}_l]$ in $s_2,\dots,s_q$; Cauchy's inequality in these $q-1$ variables, applied to the first derivative in the direction $\mathfrak{g}_1$, gives the factor $\prod_{l\ge2} 2(q-1)\varkappa_j\mathfrak{n}[\mathfrak{g}_l]/N_\star^{[j]}$, that is (b), with $(2(q-1))^{q-1} = 1, 2, 16, 216$ for $q = 1,\dots,4$.

This factor $1/\mathfrak{b}_j$ for every order in the sources is the whole of the loss $\mathfrak{b}_j^2$ that a bound through the size N would cost. $N(\mathfrak{f}_{0,j}) \le \frac12 N_\star^{[j]}$ is the half-ball estimate in the proof of Proposition YMM1:122.2: the admitted bound $s_j = \theta^{[j]}/K_{\mathbf{M}} \le s_\omega^\star/2$ gives $N_j(f_{0,j}) \le N_\star \le w_\star/(4K_\Lambda s_\omega^\star) \le w_\star/(8K_\Lambda s_j) = N_{\star,j}/2$. Proposition B.21 verifies this ceiling at the actual run. (c) Use the wide-domain and octet decomposition in the proof of Proposition YMM1:51.16, with zero counterterms and all relative localization radii equal to 1. Put $l = j - i \ge 1$ and $D_l = \max\{2L^{l-1} - 2, 0\}$. The wide domains have size at least D_l. Their rooted sum gives the factor $\varpi_l = L^{3l}e^{-D_l}$ of equation YMM1:(884). For $l = 1$ this is L^3; for $l \ge 2$,

$$D_l \ge 2(l-1)(L-1) \ge 8(l-1)\log L, \qquad \varpi_l \le L^{8-5l},$$

where the second inequality uses $L \ge 13$. For a narrow domain, equation YMM1:(864) bounds the octet term minus its constant by

$$C_{\mathrm{oc}}\|G^{(i)}\|_{i,\kappa}(d_i(X)+2)^2L^{4-4l}e^{-\kappa d_i(X)}.$$

Sum first over domains meeting Cr and then over their base points. The rooted count in Lemma B.10 applies with the marked sites of Cr in place of plaquette corners: each relevant domain contains one of the $\mathfrak{n}_i^{\mathrm{cb}}(\mathsf{Cr})$ marked cubes, and $\#(X \cap \mathbb{T}^{(i)}) \le 8M^3(d_i(X)+1)$. The remaining sum is bounded by the same convergent series of a polynomial in $d_i(X)$ times its exponential decay. This replaces the L^{3l} possible positions in the unrestricted count by $c_3\mathfrak{n}_i^{\mathrm{cb}}(\mathsf{Cr})$. Taking the better of the two counts, with the normalization of equation YMM1:(885), gives the narrow contribution $L^{-4l}\min\{L^{3l}, c_3\mathfrak{n}_i^{\mathrm{cb}}(\mathsf{Cr})\}$. The fixed constants, including L^4, are those in the bracket normalization and in c_3. There is no growing-radius factor here: the relative radii are 1. The level-j family and H have no lag and retain their ordinary norm bounds. This proves (c). (d) is the locality of the progression with the linear size of a domain. (e) The one-step theorem applied at the height 0, where the source stands in the fourth place itself, with Schwarz's lemma as in (b); the weight member: $|a_p| < \frac12\alpha_0^2\eta_j^4$ on the cores, and the count of plaquettes. (f) is arithmetic along the run (Lemma 7.3). (g) follows from (a), (b), (e) in the units, and from (c) with $\mathsf{Cr} = \mathsf{Cr}_{a_*}$, (d) and (f).

The number $\gamma^\natural$, formed from the constants, is the smallness that Lemma 7.9 reads: $\gamma^\natural \le (3.6\,C_\omega)^{-1}$, so that $\epsilon_j^{(1)} = C_\omega(0.9\gamma_j + \mathsf{c}^\flat\theta^{[0]}) \le \frac34$ in Lemma 7.9(a) once $2C_\omega\mathsf{c}^\flat\theta^{[0]} \le 1$; $\gamma^\natural$ is at most the number under which the feedback $\sum_{i'<j}\gamma_{i'} \le 0.45\gamma_j$ is absorbed in the recursion of the proof of Lemma 7.9(b); and $\gamma^\natural \le (5C_1L^{7/2}\hat C)^{-1}$, which the proof of Lemma 7.9(e) reads, where

$\hat{C} = \sup_{v>0}(1+v^3)\max\{1, v^{12}\}E_\sigma(v/2)$ is finite, E_σ decaying exponentially, and C_1 is the constant of the bound $\omega_l^{\mathrm{sp}}(i) \le C_1 L^{-4l}(1+t_i)$ in that proof.

Then $\tau^\natural = \min\{6L^{3/2}\gamma^\natural, (2C_\omega \mathsf{c}^\flat)^{-1}\}$: for $j < K$, $\delta_j \le \delta_{K-1}$ (Lemma 7.3(a)) gives $\theta^{[j]} \le \theta^{[K-1]}$, in particular $\theta^{[0]} \le \theta^{[K-1]}$, and with $\varkappa_j \le \frac{1}{6}L^{-3/2}$ of (f), $\theta^{[K-1]} \le \tau^\natural$ gives $\gamma_j = \theta^{[j]}\varkappa_j \le \gamma^\natural$ and $2C_\omega \mathsf{c}^\flat \theta^{[0]} \le 1$. For r_1, let $C_7 = \sup_{u\ge 1}[4\mathfrak{p}_0 \log(1+\log u) - c_\sigma u/4\sqrt{3}LM]$, finite, let $\Lambda_1(\mathsf{b}) \ge 1$ be the least number such that for all $\Lambda \ge \Lambda_1(\mathsf{b})$

$$\frac{c_\sigma}{\sqrt{3}L}\Lambda^{2\mathfrak{p}_0} \ge 3c_\sigma + C_7 + 4\log^+(2\mathsf{C}_{\mathcal{A}}A_1 M^{-3/2}) + 4\mathfrak{p}_0\big[\log(1+\log^+\mathsf{b}) + \log(1+\Lambda)\big],$$

and $r_1(\mathsf{b}) = e^{-\Lambda_1(\mathsf{b})}$. The left member grows like $\Lambda^{2\mathfrak{p}_0}$, $\mathfrak{p}_0 \ge 1$, the right one like $\log\Lambda$, so $\Lambda_1(\mathsf{b})$ is finite; it is formed from the constants and b, it holds no K, and since the right member increases with b, r_1 does not increase in b. Let $0 < \rho \le r_1(\mathsf{b})$ with $s(\rho) \le K$, $\Lambda = \log\frac{1}{\rho} \ge \Lambda_1(\mathsf{b}) \ge 1$ and $u = \rho/a_K = \hat{\rho}_0$. The working level at $\varrho = \rho < 1$ gives $u \ge \hat{\rho}_{\mathsf{k}(\rho)} \ge 4MY_\rho^{2\mathfrak{p}_0} \ge 4M\Lambda^{2\mathfrak{p}_0} \ge 4M$, so $\rho \ge 4Ma_K$. Next, $1/\varkappa_0 = 2\mathsf{C}_{\mathcal{A}}A_1M^{-3/2}y_0^{\mathfrak{p}_0}$, and $x_0 = \beta = \mathsf{b}/a_K = \mathsf{b}u/\rho$ gives $y_0 = \log\mathsf{b} + \log u + \Lambda$, whence $\log y_0 \le \log(1+\log^+\mathsf{b}) + \log(1+\log u) + \log(1+\Lambda)$, as $x+y+z \le (1+x)(1+y)(1+z)$ for $x, y, z \ge 0$. As $\hat{\rho}_1 = u/L$, the bound $E_\sigma(\hat{\rho}_1/2) \le \varkappa_0^4$ follows from

$$c_\sigma\Big(\frac{u}{2\sqrt{3}LM} - 3\Big) \ge 4\log^+(2\mathsf{C}_{\mathcal{A}}A_1M^{-3/2}) + 4\mathfrak{p}_0\log y_0.$$

Halve the first term: by $u \ge 4M\Lambda^{2\mathfrak{p}_0}$ one half is at least $\frac{c_\sigma}{\sqrt{3}L}\Lambda^{2\mathfrak{p}_0}$, and the other half is at least $4\mathfrak{p}_0\log(1+\log u) - C_7$; with the bound of $\log y_0$, what is left is the display that defines $\Lambda_1(\mathsf{b})$, at $\Lambda = \log\frac{1}{\rho}$. The term $\log(1+\log u)$, through which y_0 grows with K, is beaten by the half of the exponent, so no number in the argument depends on K. □

Lemma 7.7 (The kernel family and the rest family)**.** In the data of Lemma 7.6 with $p \ge 2$, let $\dot{\mathfrak{e}}_{a,j} = ((E_a^{(i)}, 0)_{i\le j}, (0))$ and $\mathfrak{u}_{a,j} = ((0,0)_{i\le j}, (\mathsf{W}_{L^{K-j}w_a}))$, so that $\mathfrak{f}_{\{a\},j} = \dot{\mathfrak{e}}_{a,j} + \mathfrak{u}_{a,j}$, and $\mathsf{B}_j(\mathfrak{g}_1, \mathfrak{g}_2) = \partial_{s_1}\partial_{s_2}\mathsf{St}^{[j]}(\mathfrak{f}_{0,j} + s_1\mathfrak{g}_1 + s_2\mathfrak{g}_2)|_0$. With the kernel family $\mathsf{K}^{(j+1)} = \mathsf{B}_j(\mathfrak{u}_{1,j}, \mathfrak{u}_{2,j})$, for $1 \le j \le K-1$

$$E_{12}^{(j+1)} = \mathsf{K}^{(j+1)} + \mathsf{R}^{(j+1)}, \qquad \mathsf{R}^{(j+1)} = \mathsf{B}_j(\dot{\mathfrak{e}}_{1,j}, \mathfrak{u}_{2,j}) + \mathsf{B}_j(\mathfrak{u}_{1,j}, \dot{\mathfrak{e}}_{2,j}) + \mathsf{B}_j(\dot{\mathfrak{e}}_{1,j}, \dot{\mathfrak{e}}_{2,j}) + \mathsf{DSt}^{[j]}(\mathfrak{f}_{0,j})[\mathfrak{f}_{12,j}],$$

and $\mathsf{R}^{(j+1)}$ is a pointed family of level $j+1$ that vanishes off Cr_1 and off Cr_2; $\mathsf{K}^{(j+1)}(X, \cdot, z) = 0$ unless a plaquette of $\operatorname{supp} w_1$ and one of $\operatorname{supp} w_2$ have their corners in X. ■

Proof. Lemma 7.6(a) at $\beta = \{1, 2\}$ has two partitions. B_j is additive in each entry: for bare arrays $\mathfrak{a}, \mathfrak{b}, \mathfrak{g}$ the value $h(t) = \mathsf{St}^{[j]}(\mathfrak{f}_{0,j} + t_1\mathfrak{a} + t_2\mathfrak{b} + t_3\mathfrak{g})(X, P, z)$ is holomorphic on a polydisc about 0, the size being subadditive, and $\partial_{s_1}\partial_{s_2}h(s_1, s_1, s_2)|_0 = (\partial_{t_1} + \partial_{t_2})\partial_{t_3}h(0)$. The first and second derivatives of the step are pointed families with the locality of the step, and Lemma 7.6(d) gives where they vanish. □

Lemma 7.8 (One level at a regular configuration)**.** Let g satisfy (Γ1), (K, β) be a first-passage datum at g and $\ell \in \mathfrak{L}(g)$.

(a) Let the frame at a level k_0 hold for a pair of real Lipschitz functions (Lemma 7.5(a)), and let $k_0 \le n < K$, $1 \le i' \le n$, $A \in \mathsf{Cc}_n(r_n)$, Cr a set of bare sites, $D' \ge 0$, and f a pointed family of level i' that vanishes off Cr and on the domains X with $d_{i'}(X) < D'$. Then

$$|\Delta[\mathsf{f}]| \le C_\Delta\, \mathsf{n}_{i'}^{\mathrm{cb}}(\mathsf{Cr})\, \|\mathsf{f}\|_{i',\lambda_{\mathrm{out}}}\, r_n^2\, L^{-4(n-i')}e^{-D'/2}.$$

(b) Let G be a family of local terms of level i that vanishes unless $\mathcal{P}(X)$, the set of the plaquettes with their corners in X, meets a set $\mathcal{S}$ of plaquettes and $d_i(X) \ge D_i$, and let N_i be the number of the cubes of π_i that hold a corner of a plaquette of $\mathcal{S}$. At every configuration U whose pairs of level i lie in the cores, $\sum_{(X,z)}|G(X, U, z)| \le 8M^3C_{\mathrm{E},1}\mathsf{N}_i e^{-D_i}\|G\|_{i,\lambda_{\mathrm{out}}}$; if U is besides

regular of a level $t' \ge i$ at a radius ε with $4M\varepsilon \le c_{\mathrm{A}}\alpha_0$, then $\sum_{(X,z)} |G(X,U,z)-G(X,\mathbf{1},z)| \le 2C_{\mathrm{f}}L^{-4(t'-i)}\mathsf{N}_i e^{-D_i/2}\|G\|_{i,\lambda_{\mathrm{out}}}$.

The numbers $C_\Delta, C_{\mathrm{f}}, C_{\mathrm{E},1}, c_{\mathrm{A}}$ are formed from the constants. Of (Γ1) the proof of (a) uses only, besides the frame at k_0, the two bounds $2r_n \le \varrho_{\mathrm{ch}}$ and $x_n^{-1} \le r_n^2$ at the heights concerned, and the proof of (b) only $g \le \gamma$ and $g^{-2} \ge x_{\mathrm{J}}$; both use besides the bound $L^m \ge LMy_K$ of the sides $\ell = 2L^m \in \mathfrak{L}(g)$. So (a) holds whenever the frame at k_0 and these two bounds hold, and (b) holds whenever $g \le \gamma$ and $g^{-2} \ge x_{\mathrm{J}}$, with no frame. ■

Proof. (a) Let $k_0 \le n < K$. Then $r_n > 0$ and $2r_n \le \varrho_{\mathrm{ch}}$ (Lemma 7.3(a), (b)); in the frame at k_0, Lemma B.24, at the radii $r_n < r' = 2r_n \le \varrho_{\mathrm{ch}}$, gives that $\tilde{U}$ is regular of level n at the radius $\varepsilon := 6r_n$ on T_ℓ and that the actions of the bare arrays over the absolute system of height n are formed at it; this is where the frame is read. For one domain X of size d and $\mathsf{E} = \mathsf{f}(X,\cdot,z)$, the evaluation of a local term at a regular configuration gives either $|\mathsf{E}(\tilde{U}) - \mathsf{E}(\mathbf{1})| \le C_{\mathrm{A}}\|\mathsf{f}\|e^{-\lambda_{\mathrm{out}}d}(\varepsilon/\alpha_0)^2 L^{-4(n-i')}M^2(1+d)^2$, or $d \ge [d_*]_+$ and $|\mathsf{E}(\tilde{U}) - \mathsf{E}(\mathbf{1})| \le 2\|\mathsf{f}\|e^{-\lambda_{\mathrm{out}}d}$, with the depth $d_* = \min\{c_{\mathrm{A}}\alpha_0\tau/6M, (L^{m+K-i'}-4)/2M\} - 1$, $\tau = L^{2(n-i')}/r_n$.

A contributing X holds one of the $\mathsf{n}_{i'}^{\mathrm{cb}}$ cubes, has $d \ge D'$ and at most $8M^3(d+1)$ base points; the sum over domains through a cube is bounded by (320). In the tail, $e^{-[d_*]_+/2} \le e^{1/2}[e^{-c_{\mathrm{A}}\alpha_0\tau/12M} + e^{-(L^{m+K-i'}-4)/4M}]$; the first part is $\le C\tau^{-2}$; for the second, $L^m \ge LMy_K$ on the sides of $\mathfrak{L}(g)$, $x_n \le \frac{5}{3}L^{K-n}x_K$ and $x_n^{-1} \le r_n^2$ give $e^{-(L^{m+K-i'}-4)/4M} \le \frac{5}{3}e^{1/M}r_n^2 L^{-4(n-i')}$. So the bound holds on every side $\ell \in \mathfrak{L}(g)$. (b) is the same count at a configuration whose pairs lie in the cores, and, for the difference, at a configuration regular of level t', with $\vartheta = L^{-(t'-i)}$. □

Lemma 7.9 (Sizes at three lengths)**.** Let g satisfy (Γ1), (K,β) be a first-passage datum at g and $\ell \in \mathfrak{L}(g)$, and let real weights be placed at (ρ,r), or at (ρ,r,d), or form two pairs at (ρ,r,d), with $0 < \rho \le r \le \mathsf{d} \le e^{-2\sqrt{3}}$, $s(\rho) \le K$, $\rho \le r_1(\mathsf{b})$. Put $q = \rho/r$, $u_i = \hat{r}_i$, $v_i = \hat{\mathsf{d}}_i$, $\Xi_j^r = q^6\min\{1,u_j\}^3$, $\mathsf{z}(\beta) = q^{3c(\beta)}(\rho/\mathsf{d})^6$ for crossing β, $\mathsf{D}(u) = [u/\sqrt{3}M - 3]_+$, $C_\sigma = \sup_u \max\{1,u^6\}E_\sigma(u)$ and $\bar{\nu}_j = \bar{\nu}_{j;12}$. There are numbers $C_\omega, \mathsf{A}_{\mathrm{N}}, C_{\mathrm{B}}, \mathsf{A}_m^{\times}, C_m^{\Psi}, C_{\times}$ formed from the constants such that for $1 \le j \le K-1$:

(a) $\mathfrak{n}[\mathfrak{u}_{a,j}] \le \varsigma_j \mathsf{m}_{j,a}$, $\mathfrak{n}[\dot{\mathfrak{e}}_{a,j}] \le \epsilon_j^{(1)}\varsigma_j \mathsf{m}_{j,a}$ with $\epsilon_j^{(1)} = C_\omega(0.9\gamma_j + \mathsf{c}^\flat\theta^{[0]}) \le \frac{3}{4}$, and $\bar{\mathsf{h}}_{j;a}, \bar{\Psi}_{j;a} \le \varsigma_j$;

(b) for a pair, $\bar{\mathsf{h}}_{j;12} \le \mathsf{A}_{\mathrm{N}}\gamma_j\Xi_j^r$ and $\bar{\Psi}_{j;12} \le 2\varsigma_j^2 + \mathsf{A}_{\mathrm{N}}\gamma_j\Xi_j^r$;

(c) $\|\mathsf{K}^{(j+1)}\|_{j+1,\lambda_{\mathrm{out}}} \le \frac{1}{2}\varsigma_j^2\bar{\nu}_j$ and $\|\mathsf{R}^{(j+1)}\|_{j+1,\lambda_{\mathrm{out}}} \le [\frac{3}{2}\epsilon_j^{(1)}\varsigma_j^2 + \mathsf{A}_{\mathrm{N}}\gamma_j\Xi_j^r]\bar{\nu}_j$;

(d) below the level of the distance: if $1 \le n \le K-1$, $u_n \ge \sqrt{3}M$, and the pairs of all levels $\le n$ of U lie in the cores, then $|\sum_{i\le n}\mathsf{Sum}[E_{12}^{(i)}](U)| \le C_{\mathrm{B}}q^6 e^{-u_n/2\sqrt{3}M}\bar{\nu}_n$;

(e) for crossing β, $m = |\beta| \le 4$, with $\Xi_j^3(\beta) = \mathsf{z}(\beta)\min\{1,v_j\}^{3/2}$: $\bar{\mathsf{h}}_{j;\beta} \le \mathsf{A}_m^{\times}\gamma_j\Xi_j^3(\beta)$, and $\mathsf{N}_i E_\sigma(v_i)\bar{\Psi}_{i-1;\beta} \le 108\,C_m^{\Psi}\mathsf{z}(\beta)\min\{1,v_i\}^{3/2}E_\sigma(v_i/6)$ for $1 \le i \le K$; and at $n = \mathsf{k}(\mathsf{d})$, with $P = v_n$ and $A \in \mathsf{Cc}_n(r_n)$, $|G_{n;\beta}(A)| \le C_{\times}e^{-P/2\sqrt{3}M}\mathsf{z}(\beta)\bar{\nu}_{n;\beta}$;

(f) *without the placing:* the bounds (a)–(d), and those of (e) but the last one, at the level $\mathsf{k}(\mathsf{d})$, hold with the same numbers for real weights, none identically 0, that form one pair, or a pair and a third source, or two pairs, with numbers $0 < \rho \le r \le \mathsf{d} \le 1$ such that for $0 \le i \le K$: $a_K \le \rho$; (P1) and (P2); the corners of the plaquettes of the supports are at least $u_i/\sqrt{3} - 1$ level-i spacings apart in a cluster and at least $v_i/\sqrt{3} - 1$ across; $\rho \ge \frac{2}{3}Ma_K$; $E_\sigma(\hat{\rho}_1/2) \le \varkappa_0^4$; and $\gamma_{K-1} \le \gamma^\natural$. No bound on the distances of the centres and no bound $\mathsf{d} \le e^{-2\sqrt{3}}$ is asked in (f); these serve only the frame, the working level, the number R_w and the rings.

■

Proof. All of it is Lemma 7.6 with (P1)–(P3) of Lemma 7.5, $\rho \ge \frac{2}{3}Ma_K$ (so $\varsigma_0 = 1$), $E_\sigma(\hat{\rho}_1/2) \le \varkappa_0^4$, $\gamma_j \le \gamma^\natural$, and three inequalities of arithmetic, $\omega_l^{\mathrm{sp}}(i)L^{l+1}\varsigma_{i-1} \le C_\omega\varsigma_{i+l}$, $\omega_l^{\mathrm{sp}}(i) \le C_1L^{-4l}(1+t_i)$ and $(1+t_i)\varsigma_{i-1}^2 \le 2L^6t_i^2$, which use only $a_K \le \rho$ and (P2). (a) By induction on j, with (c) of Lemma 7.6 at $\mathsf{Cr} = \mathsf{Cr}_a$, (e) and the first of these inequalities; then (b) of Lemma 7.6 at $q = 1$. (b) In the

recursion (g) of Lemma 7.6 the support rule and (P3) give $\sigma_{i;12} \le E_\sigma(u_i)$; the kernel parts are $(1+t_i)2\varsigma_{i-1}^2 \le 4L^6q^6u_i^6$, and

$$\sum_{i\le j} L^{-3(j-i)} \min\{u_i^6, C_\sigma\} \le 2.002\, C_\sigma \min\{1,u_j\}^3$$

($u_i = L^{j-i}u_j$: two geometric sums); the term $i=1$ uses $E_\sigma(u_1) \le E_\sigma(u_1/2)E_\sigma(\hat\rho_1/2) \le E_\sigma(u_1/2)\varkappa_0^4$; the feedback $\sum_{i'<j}\gamma_{i'} \le 0.45\gamma_j$ is absorbed under $\gamma_j \le \gamma^\natural$. (c) $\mathsf{K}^{(j+1)} = \mathsf{B}_j(\mathfrak{u}_1,\mathfrak{u}_2)$ and (b) of Lemma 7.6 at $q=2$; for $\mathsf{R}^{(j+1)}$, Lemma 7.7 with (a), (b) and $\frac12(2+\epsilon)\epsilon \le \frac32\epsilon$. (d) By the support rule $E_{12}^{(i)}$ vanishes on the domains with $d_i(X) < \mathsf{D}(u_i)$; Lemma 7.8(b) with (b), $\bar\nu_{i-1} \le \frac43 L^{n-i+1}\bar\nu_n$, and $\sum_l L^{l+1}e^{-\frac58\mathsf{D}(L^l u_n)} \le Ce^{-u_n/2\sqrt3 M}$. (e) Induction on m and, for one β, on the level, through one inequality on the natural sizes $\mu_i(\beta') = \hat\rho_i^{3|\beta'|}u_i^{-3c(\beta')}v_i^{-6[\beta' \text{ crosses}]}$, which is $\hat\rho_i^3$ at a point, $q^6u_i^3$ at a whole pair and $\mathsf{z}(\beta')$ at a crossing set, at every level (there $3|\beta'| = 3c(\beta')+6$): for crossing β and a partition π of it with $|\pi|\ge 2$,

$$\prod_{\beta'\in\pi}\mu_i(\beta') \le \max\{1,v_i^{12}\}\,\mathsf{z}(\beta);$$

the quotient is $u_i^{3s}v_i^{6-6k_\times}$, s the number of whole pairs of β that π cuts and $k_\times$ the number of its crossing blocks (with k blocks that do not cross, $3k+6k_\times = 6+3s$), and $u_i \le v_i$, $k_\times \le 2$, and $k_\times = 2$ forces $s=2$: at $k_\times = 0$ the quotient is $\le v_i^{3s+6}$, at $k_\times = 1$ (then $s = k \ge 1$) it is $u_i^{3s} \le \max\{1,v_i^6\}$, at $k_\times = 2$ it is $(u_i/v_i)^6 \le 1$. At $v_i < 1$ the display gives the bound $\mathsf{z}(\beta)$ alone (at $k_\times = 2$ the quotient is 1 when $r = \mathsf{d}$); the factor $\min\{1,v_i\}^{3/2}$ comes, at $k_\times \ge 1$, from the crossing blocks, whose factor of the induction is kept, and at $k_\times = 0$ from the quotient.

The blocks. At a level $i-1 \ge 1$: a point by (a), $\bar{\mathsf{h}}_{i-1;a} \le \varsigma_{i-1} \le t_{i-1} = L^3t_i \le L^3\mu_i(\{a\})$; a whole pair c by (b), $\bar{\mathsf{h}}_{i-1;c} \le \mathsf{A}_\mathrm{N}\gamma^\natural q^6 \min\{1,Lu_i\}^3 \le \mathsf{A}_\mathrm{N}\gamma^\natural L^3\mu_i(c)$; a crossing proper subset β' by the first bound of (e) at $|\beta'| < m$, $\bar{\mathsf{h}}_{i-1;\beta'} \le \mathsf{A}^\times_{|\beta'|}\gamma^\natural \mathsf{z}(\beta')\min\{1,Lv_i\}^{3/2} \le \mathsf{A}^\times_{|\beta'|}\gamma^\natural L^{3/2}\mu_i(\beta')\min\{1,v_i\}^{3/2}$. With $\mathsf{a}_{(2)} = \max\{1,\mathsf{A}_\mathrm{N}\gamma^\natural\}$ and $\mathsf{a}_{(m+1)} = \max\{\mathsf{a}_{(m)}, \mathsf{A}^\times_m\gamma^\natural\}$, every partition π of β with $|\pi|\ge 2$ has

$$\prod_{\beta'\in\pi}\bar{\mathsf{h}}_{i-1;\beta'} \le (L^3\mathsf{a}_{(m)})^m \min\{1,v_i\}^{3/2}\max\{1,v_i^{12}\}\,\mathsf{z}(\beta)\,:$$

if π has a crossing block, the factor $\min\{1,v_i\}^{3/2}$ of one of them is kept and the display bounds the rest; if it has none, $k_\times = 0$ and the quotient is $\le v_i^{3s+6} \le \min\{1,v_i\}^{3/2}\max\{1,v_i^{12}\}$, as $s\le 2$. The block $\pi = \{\beta\}$ is the first bound of (e) for β itself at the level $i-1$: $\bar{\mathsf{h}}_{i-1;\beta} \le \mathsf{A}^\times_m\gamma^\natural L^{3/2}\mathsf{z}(\beta)\min\{1,v_i\}^{3/2}$.
The second bound. Put $T_i = (1+t_i)E_\sigma(v_i)\bar\Psi_{i-1;\beta}$ and $\hat C = \sup_v(1+v^3)\max\{1,v^{12}\}E_\sigma(v/2)$. As $t_i \le \hat\rho_i^3 \le v_i^3$, $E_\sigma(v) \le E_\sigma(v/2)^2$ and $E_\sigma(v/2) \le E_\sigma(v/6)^3 \le 1$, we have $(1+t_i)\max\{1,v_i^{12}\}E_\sigma(v_i) \le \hat C\,E_\sigma(v_i/6)$; so the first recursion of (g) of Lemma 7.6 gives for $2 \le i \le K$

$$T_i \le \hat C[L^{3/2}\mathsf{A}^\times_m\gamma^\natural + \mathsf{b}_m(L^3\mathsf{a}_{(m)})^m]\mathsf{z}(\beta)\min\{1,v_i\}^{3/2}E_\sigma(v_i/6), \qquad \mathsf{b}_m = \sum_{\pi\in\mathrm{Part}(\beta),\,|\pi|\ge2} (2(|\pi|-1))^{|\pi|-1} = 2,22,326.$$

At $i=1$, (e) of Lemma 7.6 gives $\bar\Psi_{0;\beta} \le \mathsf{a}^\flat_m := m^m(\mathsf{c}^\flat/2)^m$; as $\rho \ge \frac23 Ma_K$ and $M \ge L$, $v_1 \ge u_1 \ge \hat\rho_1 \ge \frac23$, so that $\mathsf{z}(\beta) = \hat\rho_1^{3m}u_1^{-3c(\beta)}v_1^{-6} \ge (\hat\rho_1/v_1)^{3m} \ge (\frac23)^{12}\max\{1,v_1^{12}\}^{-1}$ and $\min\{1,v_1\}^{3/2} \ge (\frac23)^{3/2}$; hence $T_1 \le \mathsf{a}^\flat_m(\frac32)^{27/2}\hat C\,\mathsf{z}(\beta)\min\{1,v_1\}^{3/2}E_\sigma(v_1/6)$. With $C^\Psi_m = 2\hat C[\mathsf{b}_m(L^3\mathsf{a}_{(m)})^m + \mathsf{a}^\flat_m(\frac32)^{27/2}]$, $\mathsf{A}^\times_m = 2.5\,C_1L^2C^\Psi_m$ and $\gamma^\natural \le (5C_1L^{7/2}\hat C)^{-1}$, a smallness of the same kind as the one that absorbs the feedback in (b) and part of the choice of $\gamma^\natural$, the feedback $\hat CL^{3/2}\mathsf{A}^\times_m\gamma^\natural$ is $\le \frac12 C^\Psi_m$, and $T_i \le C^\Psi_m\mathsf{z}(\beta)\min\{1,v_i\}^{3/2}E_\sigma(v_i/6)$ for $1\le i\le K$; with $\mathsf{N}_i \le 108(1+t_i)$ (P2) this is the second bound of (e). *The first bound.* By the second recursion of (g), with $\sigma_{i;\beta} \le E_\sigma(v_i)$ (the

corners across are $v_i/\sqrt{3}-1$ apart, and $[(v_i/\sqrt{3}-1)/M-2]_+ \geq \mathsf{D}(v_i)$), $\omega^{\mathrm{sp}}_{j-i}(i) \leq C_1 L^{-4(j-i)}(1+t_i)$, $v_{j-l} = L^l v_j$ and $\min\{1, L^l v_j\}^{3/2} \leq L^{3l/2}\min\{1, v_j\}^{3/2}$:

$$\bar{\mathsf{h}}_{j;\beta} \leq (\tfrac{4}{3})^{\frac{m}{2}} C_1 L^{\frac{m}{2}} \gamma_j \sum_{l=0}^{j-1} L^{(-4+\frac{m}{2})l} T_{j-l} \leq (\tfrac{4}{3})^{\frac{m}{2}} C_1 L^{\frac{m}{2}} C_m^{\Psi}\, \gamma_j\, \mathsf{z}(\beta)\min\{1, v_j\}^{3/2} \sum_{l\geq 0} L^{(-4+\frac{m}{2}+\frac{3}{2})l};$$

the exponent $-4+\frac{m}{2}+\frac{3}{2} \leq -\frac{1}{2}$ ($m \leq 4$) gives $\sum_l \leq 1.39$, and $\bar{\mathsf{h}}_{j;\beta} \leq \mathsf{A}^{\times}_m \gamma_j \Xi^3_j(\beta)$. The induction runs over $m = 2, 3, 4$ and, for one β, over the level: T_i reads the first bounds at the levels $\leq i-1$ only. The bound of $G_{n;\beta}$ at the level of d is Lemma 7.8(b) with the factors $e^{-\frac{1}{2}\mathsf{D}(v_i)}$, summed over $i \leq n$. (f): the proofs of (a)–(d) and of the first two bounds of (e) use of the weights only the properties listed in (f), the separation of the corners standing for (P3); the last bound of (e) uses besides the working level $\mathsf{k}(\mathsf{d})$, which asks $\mathsf{d} \leq e^{-2\sqrt{3}}$. □

Lemma 7.10 (One source of any width)**.** Let g satisfy (Γ1), let the frame at k_0 hold for a pair that holds the source w_a, and let w_a satisfy (P1), (P2) at a width ρ with $\frac{2}{3}Ma_K \leq \rho$. Then for $k_0 \leq n \leq K$ and $A \in \mathsf{Cc}_n(r_n)$, with $q_{n;a}(F) = \frac{1}{2a_K}\sum_p w_a(p)|F_p|^2$,

$$|G_{n;a}(A) - G_{n;a}(0) - q_{n;a}(\mathsf{ang}^{[n]}(A))| \leq C_{\mathrm{S}}\, \mathfrak{b}_n^2 \delta_n\, \hat{\rho}_n^3\, \mathsf{u}_a.$$

■

Proof. At $n = K$, $A = 0$ and both members vanish; let $k_0 \leq n < K$. $G_{n;a}(A) = \mathcal{O}(w_a)(\tilde{U}) + \sum_{i\leq n} \mathsf{Sum}[E^{(i)}_a](\tilde{U})$ and $a_p(\mathbf{1}) = 0$. The weight member: the expansion of a_p on the chain class and (P1) give $|\mathcal{O}(w_a)(\tilde{U}) - q_{n;a}(\mathsf{ang}^{[n]}(A))| \leq C r_n^3 \hat{\rho}_n^3 x_n \mathsf{u}_a \leq C\mathfrak{b}_n^2\delta_n\hat{\rho}_n^3\mathsf{u}_a$ (Lemma 7.3). The families: Lemma 7.8(a), in the frame at k_0, at Cr_a, $D' = 0$, with $\|E^{(i)}_a\| \leq \varsigma_{i-1}\mathsf{m}_{i-1,a}\mathsf{g}_i$, $\mathsf{g}_i = 2\gamma_{i-1}$ ($i \geq 2$), $\mathsf{g}_1 = \mathsf{c}^{\flat}\theta^{[0]}$ (Lemma 7.9(a)), and $\mathsf{N}_i\varsigma_{i-1} \leq 216L^3 t_i$; then every level gives the same natural size

$$t_i\, \mathsf{m}_{i-1,a} L^{-4(n-i)} = \tfrac{81}{2}\alpha_0^2 L\, \hat{\rho}_n^3 |w_a|_\infty / a_{K-n}$$

times g_i, and $\sum_{i\leq n}\mathsf{g}_i \leq C\delta_n$, $|w_a|_\infty r_n^2/a_{K-n} \leq C\mathfrak{b}_n^2\mathsf{u}_a$. □

The kernel families.

Lemma 7.11 (From a real segment to the second order)**.** Let $R > 0$, $0 < \mathsf{e} \leq \mathsf{M}$, and let ψ be holomorphic on $\{|\zeta| < R\}$ with $|\psi| \leq \mathsf{M}$ there, $|\psi(t)| \leq \mathsf{e}$ for real $t \in (-R, R)$, and $\psi(0) = \psi'(0) = 0$. With $\Lambda = \max\{1, \log(\mathsf{M}/\mathsf{e})\}$, $|\psi(\zeta)| \leq 4e\,\mathsf{e}\,\Lambda^2|\zeta|^2/R^2$ for $|\zeta| \leq R/2\Lambda$. ■

Proof. On the upper half disc $h(\zeta) = \frac{2}{\pi}\arg\frac{R+\zeta}{R-\zeta}$ is harmonic, 0 on the diameter and 1 on the arc; $\log|\psi| - \log\mathsf{e} - h\log(\mathsf{M}/\mathsf{e})$ is subharmonic and bounded above, with nonpositive boundary values but at two points, so it is ≤ 0 (the two-constants theorem); the same on the lower half disc. As $h(\zeta) \leq 2|\zeta|/R$, $|\psi| \leq e\,\mathsf{e}$ on $|\zeta| \leq R/2\Lambda$; $\psi(\zeta)/\zeta^2$ is holomorphic, and the maximum principle on that disc gives the claim. □

Lemma 7.12 (A local gauge)**.** In units of a level, let the bare lattice have the spacing $\xi \leq \frac{1}{13}$, let x_0 be a bare site, $N_s = \{x : |x - x_0|_\infty \leq s\}$, $\rho \geq 2$ with $4\rho + 4$ at most the side of the torus, and let $v = (A, \mathbf{J})$ be a real pair of $\mathfrak{su}(2)$-valued 1-forms on the bare bonds with $|A| \leq \alpha \leq \frac{1}{60}$, $|\nabla^\xi A| \leq \gamma_\circ$, $|\mathbf{J}| \leq \iota$. With $c_\mu = A_\mu(x_0)$, $X(x) = \sum_\mu (x - x_0)_\mu c_\mu$ and $u = e^{iX}$ on $N_{2\rho+1}$, there is a real pair $v' = (A', \mathbf{J}')$ which at the bonds with base point in N_ρ is the gauge transform of v under u, with $\|v'\| \leq \max\{\rho(6\gamma_\circ + 19\alpha^2), \iota\}$ in the norm of the chart, $|A'(b)| \leq 3s\gamma_\circ + (9s + 8\xi)\alpha^2$ at the bonds with base point in N_s, $s \leq \rho$, and $|\nabla^\xi A'| \leq \frac{100}{99}(\gamma_\circ + 3\alpha^2)$ on N_ρ. In the sharp first-difference bound, the whole difference stencil must lie in N_ρ; the chart-norm bound is global.

The same holds in a local form, with data on $N_{\rho+1}$ alone: let U be a configuration, $\mathsf{g}\colon N_{\rho+1} \to SU(2)$ and A a real $\mathfrak{su}(2)$-valued 1-form on the bonds $b = \langle b_-, b_+\rangle$ with both end points in $N_{\rho+1}$ such that $\mathsf{g}(b_-)U(b)\mathsf{g}(b_+)^{-1} = e^{i\xi A(b)}$, $|A| \leq \alpha \leq \frac{1}{60}$ and $|\nabla^\xi A| \leq \gamma_\circ$ there, the current $\mathbf{J}(U)$ of U

being at most ι there; with c_μ and X as above and $h = e^{iX}\mathsf{g}$ on $N_{\rho+1}$, there is a real pair v' on all the bare bonds which, at the bonds with base point in N_ρ, is the image of U and of $\mathbf{J}(U)$ under the gauge transformation h, and which obeys the three bounds above; and if $\|v'\|$ is less than the radius r_α of the ball of the chart, every local term of the level whose domain lies in $N_{\rho-1}$, formed at U, has the same value at $P[v']$ restricted to that domain. ■

Proof. For hermitian Y, a, c with $|a| + |c| \le \frac14$ let $\Psi(Y,a,c) = -i\log(e^{iY}e^{ia}e^{-i(Y+c)})$; matrix calculus gives $|\Psi| \le |a-c| + 3|Y||c| + 2(|a|+|c|)^2$ and a Lipschitz bound in (Y,a). Put $A^u_\mu(x) = \xi^{-1}\Psi(X(x), \xi A_\mu(x), \xi c_\mu)$, so that $e^{i\xi A^u_\mu(x)} = u(x)e^{i\xi A_\mu(x)}u(x+\xi e_\mu)^{-1}$, a real form; $|X| \le 3s\alpha$ and $|A_\mu - c_\mu| \le 3s\gamma_\circ$ on N_s along three segments. Cut off with $\chi(x) = \min\{1, \max\{0, 2 - |x-x_0|_\infty/\rho\}\}$: $A' = \chi A^u$, $\mathbf{J}' = \chi u \mathbf{J} u^{-1}$. The point is that all first difference quotients of A are bounded; lowered by m levels, $|A|$ falls like L^{-m} and $|\nabla A|$ like L^{-2m}, and only the constant part is too large, which a gauge linear in x removes at the price $|c|^2$.

In the local form A^u is formed by the same formula from the potential A of the transform of U under g, so that $e^{i\xi A^u(b)} = h(b_-)U(b)h(b_+)^{-1}$ at the bonds with both end points in $N_{\rho+1}$, and the cut-off $\chi(x) = \min\{1, \max\{0, (\rho+1-2\xi - |x-x_0|_\infty)/(1-2\xi)\}\}$, of the width $1-2\xi$ and equal to 1 on N_ρ, takes the place of the cut-off of the width ρ: $A' = \chi A^u$, $\mathbf{J}' = \chi h\mathbf{J}(U)h^{-1}$. Both vanish at the bonds whose base point lies at a distance $\ge \rho+1-2\xi$ from x_0, and the other bonds have both end points in $N_{\rho+1}$, where A, h and the bound ι are given. As $\nabla^\xi_\nu(\chi A^u)(x) = \chi(x+\xi e_\nu)\nabla^\xi_\nu A^u(x) + A^u(x)(\chi(x+\xi e_\nu) - \chi(x))/\xi$, $|\chi(x+\xi e_\nu) - \chi(x)| \le \frac{13}{11}\xi$, and, on $N_{\rho+1}$, $|\nabla^\xi A^u| \le \frac{100}{99}(\gamma_\circ + 3\alpha^2)$ and $|A^u| \le 3(\rho+1)\gamma_\circ + (9\rho+9.62)\alpha^2$ (the third and the second bound, at $s = \rho+1$, by the Lipschitz bound of Ψ and the three segments in $N_{\rho+1}$, with $8\xi \le 0.62$), for $\rho \ge 2$

$$|\nabla^\xi A'| \le \tfrac{100}{99}(\gamma_\circ + 3\alpha^2) + \tfrac{13}{11}[3(\rho+1)\gamma_\circ + (9\rho+9.62)\alpha^2] \le \rho(6\gamma_\circ + 19\alpha^2), \qquad |A'| \le \rho(6\gamma_\circ + 19\alpha^2),$$

which with $|\mathbf{J}'| \le \iota$ gives the global chart bound; on stencils contained in N_ρ, the cutoff equals 1 and the sharper local bounds are unchanged. The bonds that a local term with its domain in $N_{\rho-1}$ reads have their end points in N_ρ, where $P[v']$ is the image of U under h, and a local term is a gauge invariant function of the pair on its domain. □

Proposition 7.13 (The kernel families)**.** Let g satisfy (Γ1), let the frame at k_0 hold for (w_1, w_2), let the forms q_n be formed over a base level $k_\flat \le k_0$, and let $k_0 \le i < n \le K$, $m = n - i - 1$, $A \in \mathsf{Cc}_n(r_n)$. As $k_\flat \le i$, $\mathcal{S}_{i+1} - \mathcal{S}_i = \upsilon_{i+1}\mathcal{C}_{(i+1)}$, so that $\mathcal{Q}_i = q_{i+1} - q_i$ is the slice $\mathcal{Q}_i(F) = a_K^{-1}\upsilon_{i+1}\sum_{p,q} w_1(p)\mathcal{C}_{(i+1)}(p,q)w_2(q)\langle F_p, F_q\rangle$. At $n = K$, $A = 0$ and the member LM below is 0; the numbers below are formed for $n < K$. Put $\mathsf{w}_a = a_K^{-1}\eta_i^4\sum_p |w_a(p)|$; let R_w be such that every corner of a plaquette of $\operatorname{supp} w_1 \cup \operatorname{supp} w_2$ lies within the sup distance R_w, in level-$(i+1)$ units, of one bare site; $\alpha = L^{-m}r_n$, $\gamma_\circ = L^{-2m}r_n$, $\mathsf{c}_i = C_{\mathrm{tp}}e^{-\delta_{\mathrm{tp}}[\mathsf{D}_i^{12}-1]_+}$, $\mathsf{M}_i^{\mathsf{K}} = 8M^3C_{\mathrm{E},1}\mathsf{N}_{i+1}(w_1)\|\mathsf{K}^{(i+1)}\|_{i+1,\lambda_{\mathrm{out}}}$, $\mathsf{M}_i = 2\mathsf{M}_i^{\mathsf{K}} + 4L^{-4}\mathsf{c}_i g_i^2\delta_i^2\mathsf{w}_1\mathsf{w}_2$, and, with $\varrho_\wedge = \min\{\varrho_{\mathrm{ch}}, \varrho_{\mathrm{fl}}\}$, $\epsilon = \epsilon_i^{\mathrm{cu}}$ and $\mathsf{c}_{\mathbf{C}}$ of Lemma 7.14(a), $\epsilon' = \epsilon + 2\mathsf{c}_{\mathbf{C}}\delta_i/r_\alpha$, the number $C_{\mathrm{tp}}^{\mathrm{row}}$ of Proposition YMM1:120.6 that bounds the row sums $\sum_b |\mathsf{T}_i^{\mathrm{cv}}(p,b)| \le C_{\mathrm{tp}}^{\mathrm{row}}\eta_i^2$ of the matrix $\mathsf{T}_i^{\mathrm{cv}}$ of step 3 (Proposition YMM1:120.6, equation YMM1:(2239)), $\bar X = (4L^{-2}\mathsf{c}_\mathfrak{h} + 2\mathsf{c}_\mathfrak{h}^2)\delta_i^2$ and $\bar\rho = \mathsf{M}_{\mathrm{pl}}^2\delta_i^3/\varrho_\wedge^3$,

$$\mathsf{E}_i = 12L^{-4}(C_{\mathrm{tp}}^{\mathrm{row}})^2 g_i^2\delta_i^2\epsilon' + 6\sqrt{3}L^{-2}(C_{\mathrm{tp}}^{\mathrm{row}})^3 g_i^3\delta_i\epsilon(1 + 2\mathsf{c}_{\mathbf{C}} + 2\epsilon) + \tfrac94(C_{\mathrm{tp}}^{\mathrm{row}})^4 g_i^4[\epsilon + 4\epsilon^2 + 4(\mathsf{c}_{\mathbf{C}} + \epsilon)\epsilon^2 + 2\epsilon'(2\mathsf{c}_{\mathbf{C}} + \epsilon)] + 4\bar X\bar\rho + 2\bar\rho^2,$$

and for $\delta_i \le \mathsf{r} \le \frac12\varrho_{\mathrm{ch}}$ let $\mathsf{E}_i(\mathsf{r})$ be the same number with $g_i^2\mathsf{r}^2$, $g_i^3\mathsf{r}$ in the places of $g_i^2\delta_i^2$, $g_i^3\delta_i$, with $\epsilon + 2\mathsf{c}_{\mathbf{C}}\mathsf{r}/r_\alpha$ in the place of ϵ', $4L^{-2}\mathsf{c}_\mathfrak{h}\mathsf{r}\delta_i + 2\mathsf{c}_\mathfrak{h}^2\delta_i^2$ in that of $\bar X$ and $\mathsf{M}_{\mathrm{pl}}^2\max\{\mathsf{r}/\varrho_{\mathrm{ch}}, \delta_i/\varrho_{\mathrm{fl}}\}^3$ in that of $\bar\rho$. All summands are ≥ 0 and the last one is $2\bar\rho^2$, so $2\mathsf{M}_{\mathrm{pl}}^4\varrho_\wedge^{-6}\delta_i^6 \le \mathsf{E}_i$. As $g_i \le \delta_i$ (Lemma 7.3(b)) and $\epsilon_i^{\mathrm{cu}} \le 1$, E_i and, for $\mathsf{r} \le \delta_i + r_{i+1}$, $\mathsf{E}_i(\mathsf{r})$ are at most $C_{\mathsf{E}}\delta_i^4(\delta_i + \epsilon_i^{\mathrm{cu}})$, with a number C_{E} formed from the constants; and as $\epsilon_i^{\mathrm{cu}} \le C_{\mathrm{cu}}(\delta_i + \mathsf{p}_{\star,i})$ (Lemma 7.14(a)) and $\mathsf{p}_{\star,i} \le \max\{1, (c_\mathsf{p}/A_1)e^{y_\mathsf{p}/2}\}\delta_i$ at every height (the quotient $\mathsf{p}_{\star,i}/\delta_i = (c_\mathsf{p}/A_1)y_i^{-\mathsf{p}_0}\exp[\frac{y_i}{2} - (LM)^{-3}A_1^2y_i^{2\mathsf{p}_0}]$ is ≤ 1 for $y_i \ge y_\mathsf{p}$ by

the proof of Lemma 7.3(b), and $\le (c_{\mathsf{p}}/A_1)e^{y_{\mathsf{p}}/2}$ for $1 \le y_i < y_{\mathsf{p}}$; $y_i > \log g^{-2} \ge \log \gamma^{-2} > 1$ since $\gamma \le \frac{1}{2}$), they are at most $C\delta_i^5$.

Let $\bar{\mathsf{e}}$ be any number $\ge 2\mathsf{w}_1\mathsf{w}_2\mathsf{E}_i$; $\Lambda_i = \max\{1, \log(\mathsf{M}_i/\bar{\mathsf{e}})\}$, $\mathsf{h}_i = \max\{2, R_w + 1 + M(2 + \Lambda_i + 2\log^+(\delta_i/\gamma_\circ))\}$, $\mathsf{s} = \mathsf{h}_i\gamma_\circ(6 + 19r_n)$. Then $\mathsf{LM} = |\Delta[\mathsf{K}^{(i+1)}] - \mathcal{Q}_i(\mathsf{ang}^{[n]}(A))|$ satisfies:

(i) always $\mathsf{LM} \le 2\mathsf{w}_1\mathsf{w}_2\mathsf{E}_i(\max\{\delta_i, \alpha\})$, where $\max\{\delta_i, \alpha\} \le \min\{\frac{1}{2}\varrho_{\mathrm{ch}}, \delta_i + r_{i+1}\}$ ($\alpha \le r_{i+1}$, as $r_j \ge L^{-1}r_{j+1}$; $2\delta_i \le \varrho_\wedge$ and $2r_{i+1} \le \varrho_{\mathrm{ch}}$ in the frame, and under (Γ1) by Lemma 7.3(b)), so that $\mathsf{E}_i(\max\{\delta_i, \alpha\}) \le C\delta_i^5$;

(ii) if $\mathsf{s} \le \delta_i/2\Lambda_i$: $\mathsf{LM} \le 8e\,\bar{\mathsf{e}}\Lambda_i^2\mathsf{s}^2/\delta_i^2 + L^{-4}\mathsf{c}_i g_i^2\mathsf{w}_1\mathsf{w}_2[18(\alpha^2 + \alpha'^2)(\gamma_\circ + \gamma') + 48R_w\alpha\gamma_\circ^2]$, with $\alpha' = (R_w + 1)(3\gamma_\circ + 10\alpha^2)$, $\gamma' = \frac{100}{99}(\gamma_\circ + 3\alpha^2)$.

The weights enter only through w_a, R_w, D_i^{12}, $\mathsf{N}_{i+1}(w_1)$ and $\|\mathsf{K}^{(i+1)}\|$; no test pair, filling or sign is asked. For weights placed at (ρ, r) as in (B.2), with $k_0 = \mathsf{k}(r)$, this gives for $\mathsf{k}(r) \le i < n \le K$

$$\mathsf{LM} \le \{C_{\mathrm{K}}\mathfrak{b}_i^4\delta_i\Lambda_\sharp^2\mathsf{h}_\sharp^2u_i^3 + C'_{\mathrm{K}}\mathsf{c}_i(1 + u_i)^2u_i^3\,\mathfrak{b}_n^2r_n\}(\rho/r)^6\hat{r}_n^3\mathsf{u}_1\mathsf{u}_2, \qquad \Lambda_\sharp \le CY_r, \quad \mathsf{h}_\sharp \le CY_r^{2\mathfrak{p}_0},$$

and neither $\Lambda_\sharp$ nor $\mathsf{h}_\sharp$ depends on ρ. Of (Γ1) the proofs of (i) and (ii) use only the frame at k_0 and, at the heights concerned, $2r_n \le \varrho_{\mathrm{ch}}$ (so $r_n \le \frac{1}{120}$, as $\varrho_{\mathrm{ch}} \le \frac{1}{60}$ by equation YMM1:(2285)), $\epsilon_i^{\mathrm{cu}} \le 1$ and $x_n^{-1} \le r_n^2$, besides the bound $\ell \ge 2LMy_K$ of the sides $\ell \in \mathfrak{L}(g)$; (i) and (ii), with the bounds of E_i and $\mathsf{E}_i(\cdot)$ stated above, hold whenever these hold. The narrow display holds under the data of (B.2), where step 6 reads besides Lemma 7.9(c) and $\delta_i \le \delta_n$. ■

Proof. 1. *Lowering.* $L^{-m}A$, viewed at the level $i + 1$, is a real point v of the chart with $|A_m| \le \alpha$, $|\nabla A_m| \le \gamma_\circ$, current $\le \gamma_\circ$, and $\mathsf{ang}^{[i+1]}(A_m) = \mathsf{ang}^{[n]}(A)$; $\mathsf{Sum}[\mathsf{K}^{(i+1)}](\tilde{U}) = \mathcal{K}_i(v) := \mathsf{Sum}[\mathsf{K}^{(i+1)}](P[v])$, and $\mathcal{Q}_i(v)$ is the third term.

2. *Holomorphy and no first order.* $\mathcal{K}_i$ is holomorphic on the ball of radius r_α of the chart, $|\mathcal{K}_i| \le \mathsf{M}_i^{\mathsf{K}}$, and it is invariant under constant gauge rotations; as $\sum_{k=1}^3 \mathrm{Ad}(i\sigma_k) = -\mathrm{id}$, its first derivative at 0 vanishes.

3. *The real ball.* At the real points $\|v\| \le \delta_i$, $\mathcal{K}_i(v)$ is a covariance under the probability measure $\nu_{i,v}$ of one step of the plaquette terms at the lowered configuration; this rests on a sum rule at every point of the chart, which (a) and (b) give.

(a) *The sum rule at every point.* Proposition YMM1:51.15 proves the sum rule of one local term at the two admitted background points, in equation YMM1:(872), and from it the sum rule of the totals at the chart points v_A of the chain classes (Proposition YMM1:124.2, equation YMM1:(2289)). The finite-vertex argument in that proof uses only membership in the localization domain $\mathfrak{D}(T_\ell)$ until it identifies the two endpoint values with background values; so for a term f on a domain X whose radius exceeds 1, as do those of the localisation of bare arrays, and every point $\mathfrak{u} = (P, \mathcal{A}) \in \mathfrak{D}(T_\ell)$, critical or not,

$$\sum_{Y' \in \mathcal{D}_i\colon Y' \supset X^\uparrow} \mathbb{V}[f](Y'; \mathfrak{u}|_{Y'}) = f(\rho_X P \dot{+} \mathfrak{h}_{T_\ell}(\mathbf{1}; \mathfrak{u})) - f(\rho_X P).$$

Indeed, with the interpolating function $F(s) = \Phi_{T_\ell}[f](s, 1; \mathfrak{u})$ of equation YMM1:(869), including its distinct rescaling factors for the potential and the current, the resummation of brackets ((323)) writes $F(\mathbf{1}) - F(0)$ as the sum of the brackets $F^*[\mathcal{K}|\mathsf{N}_0]$ over the sets $\mathcal{K}$ of fine cubes off the cubes N_0 of $X^\uparrow$; a bracket for which $\mathcal{K} \cup \mathsf{N}_0$ has more than one wall-component vanishes, F being local for the roots N_0 (Proposition YMM1:51.15 and Lemma O.3); if it has one, its union is a region $Y' \supset X^\uparrow$ and the bracket is $\mathbb{V}[f](Y'; \mathfrak{u}|_{Y'})$ by the zero-extension consistency in Proposition YMM1:51.15, and $\mathcal{K} \mapsto Y'$ is a bijection onto these regions; finally $F(\mathbf{1}) = f(\rho_X P \dot{+} \mathfrak{h}_{T_\ell}(\mathbf{1}; \mathfrak{u}))$ by the definition of F, and $F(0) = f(\rho_X P)$ by the zero-value statement in Proposition YMM1:51.15. Identifying the endpoint values with the two background values gives equation YMM1:(872); the finite-bracket identity itself requires only the stated domain membership.

(b) *The totals at every point of the chart.* The weight member of a weight w is, on a domain X of level i, $\eta_i^{-1}\sum_{p\colon X(p) = X} w(p)a_p$, every bare plaquette p having one domain $X(p)$; let $w =$

$w_a^{[i]} = L^{K-i} w_a$, so that $\eta_i^{-1} L^{K-i} = L^K$, and let $\mathfrak{f}_i[\mathsf{W}_{w_a^{[i]}}]$ be the bare array whose only member is this weight member. Applied to its members at the point $\mathfrak{u} = (P[v], g_i B)$, with the pair identity in equation YMM1:(2286) for the configuration of the substituted pair, (a) gives at every point $v = (A, \mathbf{J})$ of the chart of level $i+1$ with $\|v\| < \varrho_{\mathrm{ch}}$, real or not, in a chain class or not, and every $B \in \mathsf{Rg}_{x_i}$ (as $\delta_i < \varrho_{\mathfrak{fl}}$)

$$\mathbb{V}'\big[\mathfrak{f}_i[\mathsf{W}_{w_a^{[i]}}]\big]^{\mathrm{tot}}(P[v]; B) = L^K \sum_p w_a(p) \Big[a_p\big(e^{i\eta_i A^{\mathrm{lw}}(v, g_i B)}\big) - a_p\big(e^{i\eta_{i+1} A}\big) \Big],$$

This proves at every such chart point the algebraic identity whose real-background form is equation YMM1:(2290).

(c) *The covariance.* By Lemma B.23 and equation YMM1:(2298), $\mathsf{Sum}[\mathsf{K}^{(i+1)}](P)$ is, at every triple P of the core, the covariance under $\nu_i[P]$ of the two totals of (b); the terms $a_p(e^{i\eta_{i+1}A})$ are constants. So at every real v with $\|v\| \le \delta_i$

$$\mathcal{K}_i(v) = L^{2K} \sum_{p,q} w_1(p) w_2(q) \big\langle a_p(\tilde{U}^{\mathrm{lw}}); a_q(\tilde{U}^{\mathrm{lw}}) \big\rangle_{\nu_{i,v}}, \qquad \tilde{U}^{\mathrm{lw}}(B) = e^{i\eta_i A^{\mathrm{lw}}(v, g_i B)},$$

where $\nu_{i,v}$ is a probability measure on Rg_{x_i} and $|\langle F; F' \rangle_{\nu_{i,v}}| \le 2 \sup|F| \sup|F'|$ (Proposition YMM1:124.5).

(d) *The plaquette terms.* $(v, g_i B)$ is a real point with $\|v\| \le \delta_i$ and $\sup|g_i B| < g_i \mathfrak{b}_i = \delta_i$. The linear part of the lowered angle in the fluctuation is $\mathsf{sg}_i \sum_b \mathsf{T}_i^{\mathrm{cv}}(p,b) \mathcal{A}(b)$, where $\mathsf{T}_i^{\mathrm{cv}} = (\mathsf{T}_i^{\mathrm{cv}}(p,b))$ is the real matrix, indexed by the bare plaquettes and the positively oriented fluctuation bonds, of the curvature response of one step composed with its elimination map (the definitions preceding Lemma YMM1:124.3), $\mathsf{sg}_i \in \{1, -1\}$ is the sign of Lemma YMM1:124.3, and $\sum_b |\mathsf{T}_i^{\mathrm{cv}}(p,b)| \le C_{\mathrm{tp}}^{\mathrm{row}} \eta_i^2$ (Proposition YMM1:120.6, equation YMM1:(2239)). Lemma YMM1:124.4 at $r = a = \delta_i$, $\mathsf{rt} = \varrho_\wedge / \delta_i \ge 2$, gives

$$a_p(\tilde{U}^{\mathrm{lw}}(B)) = \tfrac{1}{2}|F_p|^2 + \langle F_p, \xi_p \rangle + \tfrac{1}{2}\langle \xi_p, \xi_p \rangle + \mathsf{o}_p(B), \qquad \xi_p = \mathsf{sg}_i g_i \sum_b \mathsf{T}_i^{\mathrm{cv}}(p,b) B(b),$$

with $F_p = \mathsf{ang}_p^{[i+1]}(A)$, $|\mathsf{o}_p| \le \mathsf{M}_{\mathrm{pl}}^2 \eta_i^4 \mathsf{rt}^{-3} = \eta_i^4 \bar{\rho}$, $|F_p| \le 2L^{-2} \eta_i^2 \delta_i$ and $|\xi_p| \le 2 \mathsf{c}_{\mathfrak{h}} \eta_i^2 \delta_i$. So $\mathsf{X}_p = \langle F_p, \xi_p \rangle + \frac{1}{2}\langle \xi_p, \xi_p \rangle$ has $\sup|\mathsf{X}_p| \le \eta_i^4 \bar{X}$, and $\langle a_p; a_q \rangle_{\nu_{i,v}}$ differs from $\langle \mathsf{X}_p; \mathsf{X}_q \rangle_{\nu_{i,v}}$ by at most $\eta_i^8 (4\bar{X}\bar{\rho} + 2\bar{\rho}^2)$.

(e) *The Gaussian part.* Under $\nu_{i,v}$ the joint cumulants of the orders 1, 3, 4 of the components of B are at most $\epsilon = \epsilon_i^{\mathrm{cu}}$, and those of the order 2 lie within $\epsilon' = \epsilon + 2\mathsf{c}_{\mathbf{C}} \delta_i / r_\alpha$ of $\mathbf{C}_0$, the covariance of the step at $v = 0$ (Proposition YMM1:124.5, equations YMM1:(2296)–YMM1:(2297), at $\|v\| \le \delta_i$); and $\mathbf{C}_0 = (\mathsf{A}_i^{\mathrm{cv}})^{-1} \otimes 1$ with $\mathsf{T}_i^{\mathrm{cv}} (\mathsf{A}_i^{\mathrm{cv}})^{-1} (\mathsf{T}_i^{\mathrm{cv}})^{\mathsf{T}} = \eta_i \mathcal{C}_{(i+1)}$, $\mathsf{A}_i^{\mathrm{cv}}$ the real symmetric matrix of one step at the trivial configuration on the fluctuation bonds (equation YMM1:(2297)).

A covariance of products is the sum, over the partitions that are no refinements of the two factors, of the products of the cumulants of the blocks. With $\mathbf{C}_0$ in the place of the second cumulants, the part of $\langle\langle F_p, \xi_p \rangle; \langle F_q, \xi_q \rangle\rangle$ is $g_i^2 \eta_i \mathcal{C}_{(i+1)}(p,q) \langle F_p, F_q \rangle$, that of $\frac{1}{4}\langle\langle \xi_p, \xi_p \rangle; \langle \xi_q, \xi_q \rangle\rangle$ is $\frac{3}{2} g_i^4 \eta_i^2 \mathcal{C}_{(i+1)}(p,q)^2$ (three colours, two pairings), the mixed covariances $\langle\langle F_p, \xi_p \rangle; \frac{1}{2}\langle \xi_q, \xi_q \rangle\rangle$ have none, and the rest is at most η_i^8 times the first three summands of E_i, by the row sums.

Multiplied by $L^{2K} w_1(p) w_2(q)$ and summed ($L^{2K} \eta_i^8 \sum_p |w_1(p)| \sum_q |w_2(q)| = \mathsf{w}_1 \mathsf{w}_2$, $L^{2K} g_i^2 \eta_i = a_K^{-1} \upsilon_{i+1}$), this gives, with $\mathsf{k}_i = \frac{3}{2} g_i^4 \eta_i^2 L^{2K} \sum_{p,q} w_1(p) w_2(q) \mathcal{C}_{(i+1)}(p,q)^2$ and $\mathcal{Q}_i(v) = \mathcal{Q}_i(\mathsf{ang}^{[i+1]}(A))$,

$$|\mathcal{K}_i(v) - \mathsf{k}_i - \mathcal{Q}_i(v)| \le \mathsf{w}_1 \mathsf{w}_2 \mathsf{E}_i.$$

(f) *Why a ball.* A ball of the chart is closed under $v \mapsto \zeta v$, under cut-offs and under small gauge transformations, which steps 4 and 5 use; a chain class is closed under none of the three, and this is why the totals are taken at every point of the chart. The radius δ_i enters only the expansion, the bound of $|F_p|$ and the ratio $\|v\|/r_\alpha$; read at a radius $\delta_i \le \mathsf{r} \le \frac{1}{2}\varrho_{\mathrm{ch}}$ ($a = \delta_i$,

$\mathsf{rt} = \min\{\varrho_{\mathrm{ch}}/\mathsf{r}, \varrho_{\mathrm{fl}}/\delta_i\} \geq 2$), the same argument gives $|\mathcal{K}_i(v) - \mathsf{k}_i - \mathcal{Q}_i(v)| \leq \mathsf{w}_1\mathsf{w}_2\mathsf{E}_i(\mathsf{r})$ at the real points with $\|v\| \leq \mathsf{r}$; at $\mathsf{r} = \max\{\delta_i, \alpha\}$, at the point v of step 1 and at 0, this is (i).

4. *Two constants.* For real v' with $\|v'\| \leq \delta_i/2\Lambda_i$ put $\psi(\zeta) = \mathcal{K}_i(\zeta v') - \mathcal{K}_i(0) - \zeta^2\mathcal{Q}_i(v')$: holomorphic for $|\zeta| < \delta_i/\|v'\|$, $\psi(0) = \psi'(0) = 0$, $|\psi| \leq \mathsf{M}_i$, $|\psi| \leq \bar{\mathsf{e}}$ on the real segment (step 3 at tv' and at 0); Lemma 7.11 gives $|\psi(1)| \leq 4e\bar{\mathsf{e}}\Lambda_i^2\|v'\|^2/\delta_i^2$ (if $\bar{\mathsf{e}} > \mathsf{M}_i$, then $|\psi| \leq \mathsf{M}_i < \bar{\mathsf{e}}$ on the disc and Schwarz's lemma of the order two gives more). Of the complex ball only the bound M_i is used, through $\log \mathsf{M}_i$; the smallness comes from the real ball, where the step measure is a probability measure, and any $\bar{\mathsf{e}} \geq 2\mathsf{w}_1\mathsf{w}_2\mathsf{E}_i$ serves.

5. *The gauge.* Let first $4\mathsf{h}_i + 4$ be at most the side ℓL^{K-i-1} of the torus in level-$(i+1)$ units. Lemma 7.12 on the box N_{h_i} about the pair gives v' with $\|v'\| \leq \mathsf{s}$; the domains in the box take the same values at v and at v', those outside have $d_{i+1}(X) \geq (\mathsf{h}_i - 1 - R_w)/M - 2$ and cost $2\mathsf{M}_i^{\mathsf{K}} e^{-[\cdot]_+} \leq \bar{\mathsf{e}}\gamma_\circ^2/\delta_i^2$ by the choice of h_i; replacing $\mathcal{Q}_i(v')$ by $\mathcal{Q}_i(v)$ costs the last term of (ii), since $|\mathcal{C}_{(i+1)}| \leq \mathsf{c}_i\eta_i^3$ on the supports. If $4\mathsf{h}_i + 4 > \ell L^{K-i-1}$, then $L^m \leq L^{K-i-1} < (4\mathsf{h}_i + 4)/\ell \leq \mathsf{h}_i$, as $\ell \geq 8$ and $\mathsf{h}_i \geq 2$; so $\|v\| \leq \max\{\alpha, \gamma_\circ\} = \alpha = L^m\gamma_\circ \leq \mathsf{h}_i\gamma_\circ \leq \mathsf{s}$, and step 4 applies at $v' = v$ itself, with no gauge and no domains outside a box: (ii) holds without its last term.

6. *The narrow pair.* Take $\bar{\mathsf{e}} = 2\bar{\mathsf{w}}_1\bar{\mathsf{w}}_2\mathsf{E}_i$ with $\bar{\mathsf{w}}_a = 81\hat{\rho}_i^3|w_a|_\infty/a_{K-i} \geq \mathsf{w}_a$. By Lemma 7.9(c), $\|\mathsf{K}^{(i+1)}\| \leq \frac{1}{2}t_i^2\bar{\nu}_i = Cx_i^{-1}\bar{\mathsf{w}}_1\bar{\mathsf{w}}_2$: the factor $\hat{\rho}_i^6$ cancels in $\mathsf{M}_i/\bar{\mathsf{e}} \leq C(1 + \mathsf{N}_{i+1})x_i^{-1}\delta_i^{-6} \leq C(1 + u_{\mathsf{k}(r)}^3)x_{\mathsf{k}(r)}^2$ (by the lower bound $2\mathsf{M}_{\mathrm{pl}}^4\varrho_\wedge^{-6}\delta_i^6 \leq \mathsf{E}_i$), so $\Lambda_i \leq CY_r$ by the working level; $R_w \leq 11u_{i+1}$ and $\log^+(\delta_i/\gamma_\circ) \leq 2m\log L \leq 2Y_r$ give $\mathsf{h}_i \leq CY_r^{2\mathfrak{p}_0}$. If $\mathsf{s} \leq \delta_i/2\Lambda_i$, (ii) with $\bar{\mathsf{w}}_1\bar{\mathsf{w}}_2x_i^{-1}L^{-4m}r_n^2 \leq C\mathfrak{b}_n^2u_i^3(\rho/r)^6\hat{r}_n^3\mathsf{u}_1\mathsf{u}_2$; else $L^{3(n-i)} \leq C\mathsf{h}_i^2\Lambda_i^2$, and (i) gives the first term. □

The induction over the levels; the jets.

Lemma 7.14 (One step: cumulants, quadratic polynomials, the Gaussian step)**.** (a) In the data of one renormalisation step at a height i, for a real point v of the chart of the level $i+1$ with $\|v\| < r_\alpha$, every $n \geq 1$ and components $B^{\alpha_1}(b_1), \dots, B^{\alpha_n}(b_n)$ of the fluctuation field, repetitions allowed, the joint cumulants under the measure $\nu_{i,v}$ of the step are formed and satisfy $|\kappa(B^{\alpha_1}(b_1), \dots)| \leq \epsilon_i^{\mathrm{cu},n}$ for $n \neq 2$ and $|\kappa(B^{\alpha_1}(b_1), B^{\alpha_2}(b_2)) - \mathbf{C}_v((b_1,\alpha_1),(b_2,\alpha_2))| \leq \epsilon_i^{\mathrm{cu},2}$, where $\epsilon_i^{\mathrm{cu},n} = C_{\mathrm{E},0}(K_\Pi\mathsf{n}_i^{\mathbb{V}} + K_P^\Pi\mathsf{p}_{\star,i})(n\mathsf{n}_{\mathrm{f}}/w_\star)^n$ with construction constants, $\mathsf{n}_i^{\mathbb{V}} \leq c_{\mathbb{V}}\delta_i$; $\mathbf{C}_v$ is the covariance of the step, $|\mathbf{C}_v| \leq \mathsf{c}_{\mathbf{C}}$ and $|\mathbf{C}_v - \mathbf{C}_0| \leq 2\mathsf{c}_{\mathbf{C}}\|v\|/r_\alpha$ entry by entry, $\mathbf{C}_0 = (\mathsf{A}_i^{\mathrm{cv}})^{-1} \otimes 1$, and $\mathsf{T}_i^{\mathrm{cv}}(\mathsf{A}_i^{\mathrm{cv}})^{-1}(\mathsf{T}_i^{\mathrm{cv}})^{\mathsf{T}} = \eta_i\mathcal{C}_{(i+1)}$ (at $n \leq 4$ the bounds on the cumulants are those of the proof of Proposition YMM1:124.5, and the statements on $\mathbf{C}_v$ and $\mathbf{C}_0$ are in Proposition YMM1:124.5).

Here $\mathsf{A}_i^{\mathrm{cv}}$ is the real symmetric matrix of one step at the trivial configuration on the positively oriented fluctuation bonds $b \in \mathfrak{X}^+$, positive definite as $\mathbf{C}_0$ is (Proposition YMM1:124.5 at $v = 0$); $\mathsf{T}_i^{\mathrm{cv}} = (\mathsf{T}_i^{\mathrm{cv}}(p,b))$ is the real matrix, indexed by the bare plaquettes and the bonds of $\mathfrak{X}^+$, of the curvature response of one step composed with its elimination map (the definitions preceding Lemma YMM1:124.3); and there are a sign $\mathsf{sg}_i \in \{1,-1\}$ and the number $C_{\mathrm{tp}}^{\mathrm{row}}$ of Proposition YMM1:120.6 such that the linear part of the lowered angle in a fluctuation $\mathcal{A}$ is $\mathsf{sg}_i\sum_b \mathsf{T}_i^{\mathrm{cv}}(p,b)\mathcal{A}(b)$ and $\sum_b|\mathsf{T}_i^{\mathrm{cv}}(p,b)| \leq C_{\mathrm{tp}}^{\mathrm{row}}\eta_i^2$ (Lemma YMM1:124.3 and Proposition YMM1:120.6, equation YMM1:(2239), on a side ℓ at least the constant N_{H} fixed in Section YMM1:120.3, as in the frame).

At a real point (v, g_iB), $v = (A, \mathbf{J})$, $B \in \mathsf{Rg}_{x_i}$, with $r \geq \|v\|$ and $\mathsf{rt} = \min\{\varrho_{\mathrm{ch}}/r, \varrho_{\mathrm{fl}}/\delta_i\} \geq 2$, Lemma YMM1:124.4 (at $a = \delta_i$) splits the angle of the lowered configuration:

$$\mathsf{ang}_p^{[i]}(A^{\mathrm{lw}}(v, g_iB)) = \mathsf{ang}_p^{[i+1]}(A) + \psi_p(B) + \zeta_p(B), \qquad \psi_p(B) = \mathsf{sg}_i g_i \sum_b \mathsf{T}_i^{\mathrm{cv}}(p,b)B(b),$$

$|\psi_p| \leq 2\mathsf{c}_{\mathfrak{h}}\eta_i^2\delta_i$, $|\zeta_p| \leq 4\mathsf{M}_{\mathrm{gr}}\eta_i^2\mathsf{rt}^{-2}$, with the number M_{gr} of equation YMM1:(2285); under the centred Gaussian with covariance $\mathbf{C}_0$, ψ has the covariance $g_i^2\eta_i\mathcal{C}_{(i+1)} = a_K\upsilon_{i+1}\mathcal{C}_{(i+1)}$, as $\mathsf{sg}_i^2 = 1$ and $g_i^2\eta_i = a_K\upsilon_{i+1}$. At $v = v_{A'}$, $A' \in \mathsf{Cc}_{i+1}(r_{i+1})$, one takes $r = r_{i+1}$;

under (Γ1) Lemma 7.3(b) gives $\mathsf{rt} \geq 2$ and $|\zeta_p| \leq C\eta_i^2\delta_i^2$. We put $\epsilon_i^{\mathrm{cu}} = \epsilon_i^{\mathrm{cu},4}$; with $C_\star = C_{\mathrm{E},0}\max\{K_\Pi c_{\mathbb{V}}, K_P^\Pi\}$, so that $\epsilon_i^{\mathrm{cu},n} \leq C_\star(\delta_i + \mathsf{p}_{\star,i})(n\mathsf{n}_{\mathrm{f}}/w_\star)^n$, we take $C_{\mathrm{cu}} = C_\star(4\mathsf{n}_{\mathrm{f}}/w_\star)^4$, $c_{\mathrm{cu}}^{(n)} = 2C_\star(2n\mathsf{n}_{\mathrm{f}}/w_\star)^{2n}$ and $c_{\mathrm{cu}} = c_{\mathrm{cu}}^{(3)}$, so that $\epsilon_i^{\mathrm{cu}} \leq C_{\mathrm{cu}}(\delta_i + \mathsf{p}_{\star,i})$ and $\epsilon_i^{\mathrm{cu},2n} \leq c_{\mathrm{cu}}^{(n)}(\delta_i + \mathsf{p}_{\star,i})/2$; we put $\epsilon_i'^{(n)} = \epsilon_i^{\mathrm{cu},2n} + 2\mathsf{c}_{\mathbf{C}} r_{i+1}/r_\alpha$ and $\epsilon_i' = \epsilon_i'^{(3)}$, and $c_\epsilon^{(n)}$ is the number c_ϵ of Lemma 7.3(b) with $c_{\mathrm{cu}}^{(n)}$ in place of c_{cu}.

We have $4\mathsf{n}_{\mathrm{f}}/w_\star > 1$ ($\mathsf{n}_{\mathrm{f}} = \frac{1}{2}M^{3/2}$ and $w_\star < 1$: equation YMM1:(2294) and the proof of Proposition YMM1:124.5); so with $x = \mathsf{n}_{\mathrm{f}}/w_\star$, $(nx)^n \leq (n'x)^n \leq (n'x)^{n'}$ for $n \leq n'$, $n' \geq 4$, and $\epsilon_i^{\mathrm{cu},n} \leq \epsilon_i^{\mathrm{cu},2m}$ for $n \leq 2m$, $m = 2, 3, 4$: at $\|v\| \leq r_{i+1}$ the joint cumulants of all the orders $\leq 2m$ lie within $\epsilon_i'^{(m)}$ of those of the centred Gaussian with covariance $\mathbf{C}_0$ (at the order two through $|\mathbf{C}_v - \mathbf{C}_0| \leq 2\mathsf{c}_{\mathbf{C}} r_{i+1}/r_\alpha$). Besides $\epsilon_i'^{(2)} \leq \epsilon_i' \leq \epsilon_i'^{(4)}$ and $c_\epsilon^{(2)} \leq c_\epsilon \leq c_\epsilon^{(4)}$; so (Γ1) with $c_\epsilon^{(4)}$ in place of c_ϵ contains (Γ1), and ($\Gamma^{(4)}$) contains (Γ).

(b) Let I be finite, ν a probability measure with bounded support on $\mathbb{R}^I$, $\mathbf{C}$ a real symmetric positive semidefinite matrix on I with $|\mathbf{C}(\mathsf{i},\mathsf{j})| \leq \mathsf{c}$, $\mathsf{c} \geq 1$, $0 \leq \epsilon \leq 1$, and let the cumulants of ν of orders $n \leq 6$ be within ϵ of those of the centred Gaussian G with covariance $\mathbf{C}$. For quadratic polynomials P_1, P_2, P_3 in the coordinates, with $\|P\|_{\mathrm{pol}}$ the sum of the moduli of their coefficients of orders one and two, and $1 \leq m \leq 3$: $|\kappa_\nu(P_1, \dots, P_m) - \kappa_{\mathsf{G}}(P_1, \dots, P_m)| \leq c_6\epsilon \prod_l \|P_l\|_{\mathrm{pol}}$, $c_6 = 1218(\mathsf{c}+1)^5$. If only the cumulants of the orders $n \leq 4$ are within ϵ of those of G, the same holds for $m \leq 2$ with $c_4 = 60(\mathsf{c}+1)^3$; if those of the orders $n \leq 8$ are, it holds for $m \leq 4$ (four sources) with $c_8 = 33120(\mathsf{c}+1)^7$; and $c_4 \leq c_6 \leq c_8$.

(c) Let $k_\flat \leq i < K$, $\mathsf{s} = v_{i+1}\mathcal{C}_{(i+1)}$, and let ψ be a centred Gaussian vector of $\mathfrak{su}(2)$-valued functions of the plaquettes with $\mathbb{E}\psi_p^\alpha \psi_q^{\alpha'} = a_K \delta_{\alpha\alpha'} \mathsf{s}(p,q)$. For every F' and every nonempty set β of sources,

$$\sum_{\pi \in \mathrm{Part}(\beta)} \kappa\big(q_{i;\beta'}(F' + \psi) : \beta' \in \pi\big) = (g_{i+1;\beta} - g_{i;\beta}) + q_{i+1;\beta}(F').$$

■

Proof. (a) The bound on the cumulants of one step (the proof of Proposition YMM1:124.5) is proved with n insertions of one sort, and depends on the number n only through the factor $(n\mathsf{n}_{\mathrm{f}}/w_\star)^n$; so it holds at every order. The remaining statements in (a) follow from the results cited there, and the comparison of the orders is the arithmetic stated in (a). (b) The cumulant of products $X_{S_1}, \dots, X_{S_m}$ is the sum, over the partitions σ of $S = \bigsqcup S_l$ with $\sigma \vee \{S_1, .., S_m\} = \{S\}$, of the products of the cumulants of the blocks (from the expansions of exp and log in $\mathbb{C}[z]/(z_l^2)$). Replacing the factors one by one costs $|\sigma|\epsilon(\mathsf{c}+1)^{|\sigma|-1} \leq 2m\epsilon(\mathsf{c}+1)^{2m-1}$, as $|S| \leq 2m$, and a set of $2m$ elements has B_{2m} partitions, $B_4 = 15$, $B_6 = 203$, $B_8 = 4140$: so $c_{2m} = 2m\, B_{2m}(\mathsf{c}+1)^{2m-1}$ serves, which is $c_6 = 6 \cdot 203(\mathsf{c}+1)^5$ for $m \leq 3$, c_4 for $m \leq 2$ and c_8 for $m \leq 4$. (c) Put $w_\lambda = \sum_a \lambda_a w_a$, $R_i^\lambda = w_\lambda(1 - \mathcal{S}_i w_\lambda)^{-1}$, $g_i^\lambda = -\frac{3}{2}\operatorname{Tr}\log(1 - \mathcal{S}_i w_\lambda)$ and $q_i^\lambda(F) = \frac{1}{2a_K}\langle F, R_i^\lambda F\rangle$; their coefficients of $\lambda^\beta = \prod_{a\in\beta}\lambda_a$ are $R_{i;\beta}$, $g_{i;\beta}$ and $q_{i;\beta}$.

The Gaussian integral, with the factor 3 from the dimension of $\mathfrak{su}(2)$, is

$$\log \mathbb{E}\, e^{q_i^\lambda(F'+\psi)} = -\tfrac{3}{2}\operatorname{Tr}\log(1 - \mathsf{s}R_i^\lambda) + \tfrac{1}{2a_K}\langle F', R_i^\lambda(1 - \mathsf{s}R_i^\lambda)^{-1}F'\rangle,$$

and $1 - \mathsf{s}R_i^\lambda = (1 - \mathcal{S}_{i+1}w_\lambda)(1 - \mathcal{S}_i w_\lambda)^{-1}$, $R_i^\lambda(1 - \mathsf{s}R_i^\lambda)^{-1} = R_{i+1}^\lambda$, as $\mathcal{S}_{i+1} = \mathcal{S}_i + \mathsf{s}$. The coefficient of λ^β of the left member is the sum over the partitions of the joint cumulants; that of the right member is $(g_{i+1;\beta} - g_{i;\beta}) + q_{i+1;\beta}(F')$. This is Wick's rule for the photon fields of one step. □

Lemma 7.15 (The tower identity at several sources)**.** Let $0 < g \leq \gamma_{\mathrm{jt}}$, $g^{-2} \geq x_{\mathrm{J}}$, (K, β) a first-passage datum at g, $\ell \in \mathfrak{L}(g)$, $n \geq 2$, and let $w_a = f_a \circ x \not\equiv 0$, $a \in [n]$, with real Lipschitz functions f_a on T_ℓ with pairwise disjoint supports (for instance the tents of Lemma 7.5(b)) that fall into two nonempty clusters $[n] = I_1 \sqcup I_2$ lying in the frame at a level k. Let $k \leq i < K$, $A' \in \mathsf{C}\mathsf{c}_{i+1}(r_{i+1})$,

$\tilde{U} = e^{i\eta_{i+1}A'}$, $v_{A'} = (A', J^{(i+1)}(\tilde{U}))$ the real point of the chart of level $i+1$ that A' gives, with $\|v_{A'}\| \le r_{i+1}$, $\nu = \nu_{i,A'} := \nu_{i,v_{A'}}$ the measure of the step, and $B \mapsto A^{\mathrm{lw}}(B) = A^{\mathrm{lw}}(v_{A'}, g_i B)$ the lowering map (Proposition YMM1:124.2). Then for every nonempty $\beta \subset [n]$

$$G_{i+1;\beta}(A') = \sum_{\pi \in \mathrm{Part}(\beta)} \kappa_\nu\big(G_{i;\beta'} \circ A^{\mathrm{lw}} : \beta' \in \pi\big).$$

The same holds for real mixed sources $\mathfrak{s}_a \neq 0$, $a \in [n]$, at $0 < g \le \gamma_{\mathrm{N}}$ with $K \ge 2$, the progression being formed with their weight members in the source slot (the lemma on bond sources, which follows Lemma 7.31), when the two unions of the hulls of the clusters I_1, I_2 satisfy the conditions of the frame at k of clause (6) of that lemma. For mixed sources the frame is that of clause (6), read with the hulls in the place of the supports, and the tower identity for a pair is the one stated in that clause. ■

Proof. For λ near 0 in $\mathbb{C}^n$ put $\Phi(\lambda) = \exp D^\lambda_{i+1}(\tilde{U}) - \int \exp D^\lambda_i(e^{i\eta_i A^{\mathrm{lw}}(B)})\, d\nu(B)$, formed with the progression of $(w_1, \dots, w_n)$. Each relative exponent is a finite sum of functions that are holomorphic in λ, and the integrand is bounded uniformly in B for λ near 0, as the progression with any number of sources lies in the setting of one step (Theorem YMM1:D); so Φ is holomorphic near 0. Let $t \in \mathbb{R}^n$ be nonzero on I_1 and on I_2, and put $f^t = \sum_{a\in I_1} t_a f_a$, $h^t = \sum_{a\in I_2} t_a f_a$. These are real Lipschitz functions; $f^t \circ x$ and $h^t \circ x$ do not vanish identically, the supports of the w_a being disjoint; and their supports lie in the two unions of supports.

So (f^t, h^t) lies in the frame at k, and the tower identity among the construction results for a pair (equation (235)) gives $\exp D^\mu_{i+1}[f^t, h^t](\tilde{U}) = \int \exp D^\mu_i[f^t, h^t](e^{i\eta_i A^{\mathrm{lw}}})\, d\nu$ for μ near 0 in $\mathbb{C}^2$, with the same measure ν and the same lowering map, neither of which depends on the sources. The progression depends on the parameters and the sources only through w_λ; at $\lambda(\mu) = (\mu_1 t|_{I_1}, \mu_2 t|_{I_2})$ one has $w_{\lambda(\mu)} = \mu_1 f^t \circ x + \mu_2 h^t \circ x$, so $D^{\lambda(\mu)}_\cdot = D^\mu_\cdot[f^t, h^t]$, and at $\mu = (s, s)$: $\Phi(st) = 0$ for all small real s. With the expansion $\Phi = \sum_N \Phi_N$ in homogeneous polynomials, $\sum_N s^N \Phi_N(t) = 0$ for small s; so $\Phi_N(t) = 0$ for every N and every t of a dense subset of $\mathbb{R}^n$, hence $\Phi_N = 0$ and $\Phi = 0$ near 0.

As $D^0_{i+1} = 0$ and $D^0_i = 0$, the multilinear jets of the two members of $\exp D^\lambda_{i+1}(\tilde{U}) = \int \exp D^\lambda_i\, d\nu$ agree in $\mathbb{C}[\lambda_1, \dots, \lambda_n]/(\lambda_a^2)$, and the logarithm of a moment series is the cumulant series; differentiation under the integral is allowed by Cauchy's formula in λ. The coefficient of λ^β is the claim. At $n = 2$ the lemma is the identity among the construction results. For mixed sources the argument is the same, with the weight member of $\mathfrak{s}_\lambda = \sum_a \lambda_a \mathfrak{s}_a$, which is linear in $\mathfrak{s}_\lambda$ (clause (1) of the lemma on bond sources), in the source slot. The $t \in \mathbb{R}^n$ at which $\sum_{a\in I_1} t_a \mathfrak{s}_a$ or $\sum_{a\in I_2} t_a \mathfrak{s}_a$ is 0 form two proper linear subspaces, every $\mathfrak{s}_a$ being nonzero; off them, a dense set, the two sums are nonzero mixed sources whose hulls lie in the two unions of the hulls of the clusters, so they are in the frame of clause (6), and the identity for a pair stated there, with the same measure ν and the same lowering map, stands in the place of equation (235). □

Proposition 7.16 (The induction over the levels)**.** Let $n \in \{2, 3, 4\}$ and let g satisfy (Γ1), with $c^{(4)}_\epsilon$ in place of c_ϵ if $n = 4$; let (K, β) be a first-passage datum at g, $\ell \in \mathfrak{L}(g)$, and let real weights $w_1, \dots, w_n$ with the two clusters $\{1\}, \{2\}$, or $\{1, 2\}, \{3\}$, or $\{1, 2\}, \{3, 4\}$ lie in the frame at a level k; let $k \le k_1 < K$, $0 \le k_\flat \le k_1$, and form the free objects over the base level $k_\flat$. Let numbers $\mathsf{v}_\beta > 0$, c°_β and $\epsilon_\circ \ge 0$, $\emptyset \neq \beta \subset [n]$, satisfy

(I1) $|G_{k_1;\beta}(A) - c^\circ_\beta - q_{k_1;\beta}(\mathsf{ang}^{[k_1]}(A))| \le \epsilon_\circ \mathsf{v}_\beta$ for $A \in \mathsf{Cc}_{k_1}(r_{k_1})$;
(I2) $\varrho_{i;\beta} := \eta_i^4 \sum_{p,q} |R_{i;\beta}(p, q)|/(a_K x_i) \le L^{-3(i-k_1)} \mathsf{v}_\beta$ for $k_1 \le i < K$;
(I3) $\prod_{\beta' \in \pi} \mathsf{v}_{\beta'} \le \mathsf{v}_\beta$ for every partition π of β.

Put $Z = Z_0(1 + \mathfrak{b}_{k_1})^2$ and $\varpi = \epsilon_\circ + \sum_{i=k_1}^{K-1} L^{-3(i-k_1)}(\delta_i + c_{2n}\epsilon_i'^{(n)})$, with a number Z_0 formed from the constants and the numbers c_{2n} of Lemma 7.14(b), and let $(K - k_1)\varpi \le 1$. Then

$\varpi \le \epsilon_\circ + \frac{6}{5}(1 + c_{2n}c_\epsilon^{(n)})\delta_{k_1}$, and for $k_1 \le i \le K$, $A \in \mathsf{Cc}_i(r_i)$ and every β, $m = |\beta|$,

$$|G_{i;\beta}(A) - c^\circ_\beta - (g_{i;\beta} - g_{k_1;\beta}) - q_{i;\beta}(\mathsf{ang}^{[i]}(A))| \le \mathsf{a}_m Z^m \varpi\, \mathsf{v}_\beta, \qquad (\mathsf{a}_1, \mathsf{a}_2, \mathsf{a}_3) = (1, 14, 285),$$

a_4 a number; in particular $|\mathsf{J}_n - c^\circ_{[n]} - g_{K;[n]} + g_{k_1;[n]}| \le \mathsf{a}_n Z^n \varpi \mathsf{v}_{[n]}$. Of the base level only the relation $\mathcal{S}_{i+1} - \mathcal{S}_i = \upsilon_{i+1}\mathcal{C}_{(i+1)}$, $i \ge k_1$, is used. ■

Proof. Let $\mathsf{e}_{i;\beta}$ be the supremum over $\mathsf{Cc}_i(r_i)$ of the left member. 1. *The tower.* For $A' \in \mathsf{Cc}_{i+1}(r_{i+1})$ and the measure $\nu = \nu_{i,A'}$ of the step, $G_{i+1;\beta}(A') = \sum_\pi \kappa_\nu(G_{i;\beta'} \circ A^{\mathrm{lw}} : \beta' \in \pi)$ (the lemma on the tower identity at several sources, which precedes this proposition, for the two clusters of the frame). 2. *The lowered angle.* The point $v_{A'}$ of the chart is real, with $\|v_{A'}\| \le r_{i+1} < \varrho_{\mathrm{ch}} \le r_\alpha$ by the definition of the chain classes (equation (232)); $\nu = \nu_{i,v_{A'}}$ is a probability measure carried by the real B with $|B(b)| < \mathfrak{b}_i$ (Proposition YMM1:124.5), and $A^{\mathrm{lw}}(B) \in \mathsf{Cc}_i(r_i)$ (Proposition YMM1:124.2 with the radius recurrence YMM1:(2291)).

By the splitting of Lemma 7.14(a) at $r = r_{i+1}$, $\mathsf{ang}_p^{[i]}(A^{\mathrm{lw}}(B)) = F'_p + \psi_p(B) + \zeta_p(B)$, with $F' = \mathsf{ang}^{[i+1]}(A')$, $\psi_p(B) = \mathsf{sg}_i g_i \sum_b \mathsf{T}_i^{\mathrm{cv}}(p,b)B(b)$ linear in the fluctuation field B, $|\psi_p| \le 2\mathsf{c}_\mathfrak{h}\eta_i^2\delta_i$ and $|\zeta_p| \le C\eta_i^2\delta_i^2$ by the smallness of Lemma 7.3(b); besides $|F'_p| \le 2\eta_{i+1}^2 r_{i+1} \le \mathsf{c}_\mathfrak{h}\eta_i^2\delta_i$. So $Y_\beta = G_{i;\beta} \circ A^{\mathrm{lw}}$ is within $\mathsf{e}_{i;\beta} + Z\delta_i L^{-3(i-k_1)}\mathsf{v}_\beta$ of the quadratic polynomial $P_\beta = c^\circ_\beta + g_{i;\beta} - g_{k_1;\beta} + q_{i;\beta}(F' + \psi)$ in the coordinates $B^\alpha(b)$: the term with ζ is at most $Ca_K^{-1}\eta_i^4\delta_i^3 \sum_{p,q} |R_{i;\beta}(p,q)| = C\mathfrak{b}_i^2\delta_i\varrho_{i;\beta}$.

The linear part of P_β has the coefficients $\mathsf{sg}_i g_i a_K^{-1} \sum_{p,q} R_{i;\beta}(p,q)\mathsf{T}_i^{\mathrm{cv}}(q,b)F_p'^\alpha$, its quadratic part the coefficients $\frac{1}{2}g_i^2 a_K^{-1} \sum_{p,q} R_{i;\beta}(p,q)\mathsf{T}_i^{\mathrm{cv}}(p,b)\mathsf{T}_i^{\mathrm{cv}}(q,b')$ of $B^\alpha(b)B^\alpha(b')$; with the row sums $\sum_b |\mathsf{T}_i^{\mathrm{cv}}(p,b)| \le C_{\mathrm{tp}}^{\mathrm{row}}\eta_i^2$, $x_i g_i \delta_i = \mathfrak{b}_i$ and $x_i g_i^2 = 1$,

$$\|P_\beta\|_{\mathrm{pol}} \le \big[2\mathsf{c}_\mathfrak{h} C_{\mathrm{tp}}^{\mathrm{row}}\mathfrak{b}_i + \tfrac{3}{2}(C_{\mathrm{tp}}^{\mathrm{row}})^2\big]\varrho_{i;\beta};$$

so, by (I2), $\mathfrak{b}_i \le \mathfrak{b}_{k_1}$ and $|B(b)| < \mathfrak{b}_i$, $\|P_\beta\|_{\mathrm{pol}}$ and $\sup|P_\beta - \mathrm{const}|$ are $\le ZL^{-3(i-k_1)}\mathsf{v}_\beta$, Z_0 being at least $2\mathsf{c}_\mathfrak{h}C_{\mathrm{tp}}^{\mathrm{row}} + \frac{3}{2}(C_{\mathrm{tp}}^{\mathrm{row}})^2$ and the constant of the term with ζ. 3. *The Gaussian value.* Under the Gaussian with covariance $\mathbf{C}_0$, $\psi = \mathsf{sg}_i g_i \mathsf{T}_i^{\mathrm{cv}} B$ has the covariance $g_i^2\eta_i\mathcal{C}_{(i+1)} = a_K\upsilon_{i+1}\mathcal{C}_{(i+1)}$ (Lemma 7.14(a): $\mathsf{sg}_i^2 = 1$, $\mathsf{T}_i^{\mathrm{cv}}(\mathsf{A}_i^{\mathrm{cv}})^{-1}(\mathsf{T}_i^{\mathrm{cv}})^{\mathsf{T}} = \eta_i\mathcal{C}_{(i+1)}$, $g_i^2\eta_i = a_K\upsilon_{i+1}$), and Lemma 7.14(c) gives $\sum_\pi \kappa_{\mathsf{G}}(P_{\beta'}) = c^\circ_\beta + g_{i+1;\beta} - g_{k_1;\beta} + q_{i+1;\beta}(F')$. 4.

From G *to* ν by Lemma 7.14(a), (b), with $\mathsf{c} = \max\{1, \mathsf{c}_{\mathbf{C}}\}$: as $\|v_{A'}\| \le r_{i+1}$, all the cumulants of the orders $\le 2n$ lie within $\epsilon = \epsilon_i'^{(n)}$ of those of G, and $\epsilon_i'^{(n)} \le c_\epsilon^{(n)}\delta_i \le 1$ (under (Γ1), as $c_\epsilon^{(2)} \le c_\epsilon$, and with $c_\epsilon^{(4)}$ at $n = 4$); the number is c_{2n}; *from* P *to* Y by $|\kappa(X,Y)| \le \|X\|^\sim\|Y\|^\sim$, $|\kappa(X,Y,W)| \le 2\|X\|^\sim\|Y\|^\sim\|W\|^\sim$, $\|X\|^\sim = \inf_c \sup|X - c|$. 5. *The recursion.* With (I3) every product of sizes over a partition is at most $Z^m\mathsf{v}_\beta$ times pure numbers, and $\varepsilon_{i;\beta} = \mathsf{e}_{i;\beta}/Z^m\mathsf{v}_\beta$ obeys $\varepsilon_{i+1;a} \le \varepsilon_{i;a} + \tau_i$, $\varepsilon_{i+1;ab} \le \varepsilon_{i;ab} + 2\tau_i + 4\varpi^2 + 4\theta_i\varpi$ and the like at three sources, $\tau_i = L^{-3(i-k_1)}(\delta_i + c_{2n}\epsilon_i'^{(n)})$, $\theta_i = L^{-3(i-k_1)}$; summed over at most $K - k_1$ heights with $(K - k_1)\varpi \le 1$ this gives 1, 14 and 285.

At $i = K$, $\mathsf{Cc}_K = \{0\}$ and $q_{K;\beta}(0) = 0$. The bound of ϖ: $\epsilon_i'^{(n)} \le c_\epsilon^{(n)}\delta_i$ (as $\epsilon'_i \le c_\epsilon\delta_i$ in Lemma 7.3(b)), $\delta_i \le (\frac{5}{4})^{1/2}L^{(i-k_1)/2}\delta_{k_1}$, $(\frac{5}{4})^{1/2}\sum_k L^{-5k/2} \le \frac{6}{5}$. For two sources Steps 1–5 use only (236) and the cumulants up to order four. □

Lemma 7.17 (The slices)**.** Let (K, β) be a first-passage datum at $g \le \gamma$, $p \ne q$ plaquettes, $\mathsf{r} = |x(p) - x(q)|_\infty$, $c_L^{(N)} = \sup_\tau \sum_{j\in\mathbb{Z}}(L^j\tau)^N e^{-\delta_{\mathrm{tp}}L^j\tau}$ and $\mathsf{m}_K = \frac{5}{4}C_{\mathrm{tp}}c_L^{(3)}$. (a) For every set $\mathcal{J} \subset \{1, \dots, K\}$: $|\sum_{j\in\mathcal{J}} \upsilon_j\mathcal{C}_{(j)}(p,q)| \le \mathsf{m}_K\mathsf{b}^{-1}a_K^3\mathsf{r}^{-3}$. (b) If $t = \mathsf{r}/a_{K-k}$ satisfies $\delta_{\mathrm{tp}}L(L-1)t \ge 3\log L + \log 2$, then

$$\Big|\sum_{k<j\le K} \upsilon_j\mathcal{C}_{(j)}(p,q) - \mathsf{b}^{-1}C_K^{\mathrm{free}}(p,q)\Big| \le \mathsf{b}^{-1}a_K^3\big[\tfrac{5}{4}C_{\mathrm{tp}}c_L^{(2)}\bar{B}\,\mathsf{r}^{-2}\mathsf{b}^{-1} + C_{\mathrm{tp}}^{\mathrm{bg}} + 2L^3C_{\mathrm{tp}}\mathsf{r}^{-3}t^3e^{-\delta_{\mathrm{tp}}Lt}\big],$$

with $C_{\mathrm{tp}}^{\mathrm{bg}}$ from Proposition YMM1:120.5, evaluated at $s = 0$ in equation YMM1:(2236). ■

Proof. (a) $\upsilon_j = (a_{K-j+1}x_{j-1})^{-1} \le \frac{24}{23}\mathsf{b}^{-1} \le \frac{5}{4}\mathsf{b}^{-1}$ at every $0 < g \le \gamma$: the flow bound and $g^{-2} < \mathsf{b}$, which Lemma 7.3(a) states for every first-passage datum at every $0 < g \le \gamma$, give $|a_{K-j+1}x_{j-1} - \mathsf{b}| \le a_{K-j+1}\bar{B} \le \bar{B}/L$, and $\bar{B} \le \frac{13}{24}g^{-2} < \frac{13}{24}\mathsf{b}$ at $g \le \gamma$ (Lemma G.3 gives this bound), so $a_{K-j+1}x_{j-1} \ge \frac{23}{24}\mathsf{b}$ as $L \ge 13$; and the decay of the slices: $\sum_j (\mathsf{r}/a_{K-j+1})^3 e^{-\delta_{\mathrm{tp}}\mathsf{r}/a_{K-j+1}} \le c_L^{(3)}$, a lacunary sum. (b) Equation YMM1:(2227) gives $\sum_{k<j\le K}\mathcal{C}_{(j)} = C_K^{\mathrm{free}} - C_{K,0}^{\mathrm{bg}} - \sum_{j\le k}\mathcal{C}_{(j)}$, and Proposition YMM1:120.5 bounds $|C_{K,0}^{\mathrm{bg}}(p,q)|$ by $C_{\mathrm{tp}}^{\mathrm{bg}}a_K^3$; $|\upsilon_j - \mathsf{b}^{-1}| = |\mathsf{b} - a_{K-j+1}x_{j-1}|\upsilon_j\mathsf{b}^{-1} \le \frac{5}{4}\bar{B}a_{K-j+1}\mathsf{b}^{-2}$ by the same bounds of the run, which with the decay gives the first term; the slices of the levels $j \le k$ are at $t_j \ge Lt$ and give the last term. □

Lemma 7.18 (The explicit sizes; the weights of the induction)**.** Let weights be placed at (ρ, r, d), or form two pairs at (ρ, r, d), with $\mathsf{d} \le e^{-2\sqrt{3}}$, $s(\rho) \le K$; let $k_\flat = \mathsf{k}(r)$, $k_1 = \mathsf{k}(\mathsf{d})$, $u = \hat{r}_{k_1}$, $\hat{\rho} = \hat{\rho}_{k_1} = qu$, $P = \hat{\mathsf{d}}_{k_1}$, and I_1, I_2 the clusters. Put $\mathsf{w}(\emptyset) = 1$, $\mathsf{w}(\{a\}) = \hat{\rho}^3$, w(a whole pair) $= q^6u^3\max\{1, u^3\}$, $c_* = \max\{102, 4\cdot 81\cdot 3^{3/2}(1+\mathsf{m}_K)\}$, and

$$\mathsf{v}_\beta = c_*^{|\beta|}\,\mathsf{w}(\beta\cap I_1)\,\mathsf{w}(\beta\cap I_2)\,\mathsf{u}_\beta, \qquad \mathsf{u}_\beta = \prod_{a\in\beta}\mathsf{u}_a.$$

Then (I2) and (I3) of Proposition 7.16 hold; $\mathsf{v}_{[3]} \le c_*^3P^9\mathrm{nat}_3$ and $\mathsf{v}_{[4]} \le c_*^4P^{12}\mathrm{nat}_4$; for crossing β, $\mathsf{z}(\beta)\mathsf{u}_\beta \le P^{-6}\mathsf{v}_\beta$, and if $\mathsf{e}_{\mathrm{far}} = 8e^{-\delta_{\mathrm{tp}}LP/2\sqrt{3}} \le 1$, then $\varrho_{k_1;\beta} \le \mathsf{e}_{\mathrm{far}}\mathsf{v}_\beta$ and $|g_{k_1;[n]}| \le \frac{3}{2}(n-1)!(81\cdot 3^{3/2}\mathsf{m}_K)^n\mathsf{e}_{\mathrm{far}}^2\mathrm{nat}_n$. The factor $\max\{1, u^3\}$ cannot be dropped: u may be a power of $\log\frac{1}{\mathsf{d}}$. ■

Proof. By Lemma 7.17(a), $|\mathcal{S}_i(p,q)| \le \mathsf{m}_K\mathsf{b}^{-1}a_K^3\mathsf{r}^{-3}$ with $\mathsf{r} \ge r/\sqrt{3}$ in a cluster and $\ge \mathsf{d}/\sqrt{3}$ across. An ordering of β is a path with $m-1$ edges, at most $c(\beta)$ of them inside a whole pair; with (P1),

$$\varrho_{i;\beta} \le \tfrac{5}{4}m!\,81^m(3^{3/2}\mathsf{m}_K)^{m-1}\rho^{3m}r^{-3c}\mathsf{d}^{-3(m-1-c)}a_{K-i}^{-3}\mathsf{u}_\beta,$$

and with $a = a_{K-k_1}$ the powers of a cancel: $\rho^{3m}r^{-3c}\mathsf{d}^{-3(m-1-c)}a^{-3} = \hat{\rho}^{3m}u^{-3c}P^{-3(m-1-c)} \le \mathsf{w}(\beta\cap I_1)\mathsf{w}(\beta\cap I_2)$, $a_{K-i}^{-3} = L^{-3(i-k_1)}a^{-3}$: (I2). (I3): either $\beta\cap I_\iota$ lies in one block, or it is a whole pair cut into two points, and $\hat{\rho}^6 = q^6u^6 \le q^6u^3\max\{1,u^3\}$. The top sets: $q^6u^3\hat{\rho}^3 = P^6\rho^9r^{-3}\mathsf{d}^{-6}$. At the level k_1 the slices of the levels $\le k_1$ at distances $\ge \mathsf{d}/\sqrt{3}$ are exponentially small, $|\mathcal{S}_{k_1}(p,q)| \le \mathsf{e}_{\mathrm{far}}\mathsf{m}_K\mathsf{b}^{-1}a_K^3\mathsf{r}^{-3}$; a path through a crossing set has a far edge, a ring through all sources two. □

Proposition 7.19 (The jets of narrow bumps)**.** There are numbers $C(g)$ and $\mathsf{d}_4(g), \mathsf{d}_4^{(4)}(g) \in (0, \min\{e^{-2(15\mathfrak{p}_0+2)}, r_1(\bar{\mathsf{b}})\}]$, formed from the constants and g, such that the following holds for g under (Γ1), every first-passage datum (K,β) at g, every side $\ell \in \mathfrak{L}(g)$ with $64\mathsf{d} \le \ell$, and $s(\rho) \le K$.

(a) For real weights placed at (ρ, r, d) with $0 < \rho \le r \le \mathsf{d} \le \mathsf{d}_4(g)$: $|\mathsf{J}_3 - 3\,\mathrm{Tr}\prod_a(w_a\mathsf{b}^{-1}C_K^{\mathrm{free}})| \le \epsilon^{\mathrm{nar}}(g,\mathsf{d})\,\mathrm{nat}_3$.

(b) For real weights w_1, w_2 with $\Sigma(w_a) \subset \mathbb{B}(x_a, \rho)$, $\mathrm{dist}(\Sigma(w_1), \Sigma(w_2)) \ge \mathsf{d}$, $|x_1 - x_2| \le 18\mathsf{d}$, $0 < \rho \le \mathsf{d} \le \mathsf{d}_4(g)$: $|\mathsf{J}_2 - \frac{3}{2}\mathsf{b}^{-2}\sum_{p,q}w_1(p)w_2(q)C_K^{\mathrm{free}}(p,q)^2| \le \epsilon_2^{\mathrm{nar}}(g,\mathsf{d})(\rho/\mathsf{d})^6\mathsf{u}_1\mathsf{u}_2$.

(c) Under (Γ1) with $c_\epsilon^{(4)}$ in place of c_ϵ, for two pairs at (ρ, r, d) with $\mathsf{d} \le \mathsf{d}_4^{(4)}(g)$: $|\mathsf{J}_4 - \frac{3}{2}\sum_\varsigma \mathrm{Tr}\prod_l(w_{\varsigma(l)}\mathsf{b}^{-1}C_K^{\mathrm{free}})| \le \epsilon_4^{\mathrm{nar}}(g,\mathsf{d})\,\mathrm{nat}_4$.

The normalized error factors and constants are uniform in ρ/r, r/d, K, ℓ, position and direction; in particular they hold for $w_a = f_a\circ x$ with bounded Borel f_a, and for plane weights. ■

Proof. 1. *Levels and data.* $k_1 = \mathsf{k}(\mathsf{d})$, $k_\flat = \mathsf{k}(r) \le k_1$, $P = \hat{\mathsf{d}}_{k_1}$; by the working level $4MY_{\mathsf{d}}^{2\mathfrak{p}_0} \le P < CY_{\mathsf{d}}^{2\mathfrak{p}_0}$, $K - k_1 \le Y_{\mathsf{d}}/\log L$, $\delta_{k_1} \le A_1Y_{\mathsf{d}}^{\mathfrak{p}_0}(\mathsf{d}/\mathsf{b})^{1/2}$. Lemma 7.5(b) puts the two clusters in the frame at k_1; the smallness holds at all heights (Lemma 7.3); (I2), (I3) hold with the weights of Lemma 7.18.

2. *(I1).* At a single source, $c_a^\circ = G_{k_1;a}(0)$ and Lemma 7.10 give the tolerance $C\mathfrak{b}_{k_1}^2\delta_{k_1}\mathsf{v}_a$. At the whole pair, $c^\circ = G_{k_1;12}(0)$: by the multilinearity $G_{k_1;12}$ is the pair functional of the pair alone, and (B.2) at $n = k_1 \ge \mathsf{k}(r)$ (its proof, given below, rests on Lemmas 7.3–7.13 alone) gives

$[C_{\mathrm{N}}\mathfrak{b}_{k_1}^2\delta_{k_1}+\epsilon'_{\mathrm{N}}(r)]q^6u^3\mathsf{u}_{12}\le[\dots]\mathsf{v}_{12}$. At a crossing set, $c^\circ_\beta=0$: Lemma 7.9(e) and Lemma 7.18 give $|G_{k_1;\beta}|\le Ce^{4Y_{\mathsf{d}}-\frac{2}{\sqrt3}Y_{\mathsf{d}}^{2\mathfrak{p}_0}}\mathsf{v}_\beta$, and $|q_{k_1;\beta}|\le C\mathfrak{b}_{k_1}^2\mathsf{e}_{\mathrm{far}}\mathsf{v}_\beta$. So

$$\epsilon_\circ=C_\circ\{\mathfrak{b}_{k_1}^2\delta_{k_1}+\epsilon'_{\mathrm{N}}(r)+e^{4Y_{\mathsf{d}}-\frac{2}{\sqrt3}Y_{\mathsf{d}}^{2\mathfrak{p}_0}}+\mathfrak{b}_{k_1}^2\mathsf{e}_{\mathrm{far}}\}.$$

Here $C_\circ$ is a number formed from the constants that dominates the constants of these four bounds (of Lemma 7.10, of (B.2), of Lemma 7.9(e) with Lemma 7.18, and of the bound of $q_{k_1;\beta}$), and those of the two bounds of (I1) in step 6. The tolerance of (B.2) falls together with its yardstick; for this reason no relation between r and d is needed, and the bounds hold at every ratio $r/\mathsf{d}\in(0,1]$.

3. *The induction* (Proposition 7.16) at $i=K$: $|\mathsf{J}_n-g_{K;[n]}+g_{k_1;[n]}|\le\mathsf{a}_nZ^n\varpi c_*^nP^{3n}\mathrm{nat}_n$.

4. *The rings.* Lemma 7.17(b) at $k=\mathsf{k}(r)$ for p,q in different supports ($t\ge\hat r_{\mathsf{k}(r)}/\sqrt3$) gives $|\mathcal{S}_K-\mathsf{b}^{-1}C_K^{\mathrm{free}}|\le\mathrm{br}\,\mathsf{b}^{-1}a_K^3\mathsf{r}^{-3}$ with

$$\mathrm{br}=25C_{\mathrm{tp}}c_L^{(2)}\bar B\,\mathsf{d}/\mathsf{b}+8000C_{\mathrm{tp}}^{\mathrm{bg}}\mathsf{d}^3+2L^3C_{\mathrm{tp}}\sup_{t\ge\frac{4}{\sqrt3}MY_r^{2\mathfrak{p}_0}}t^3e^{-\delta_{\mathrm{tp}}Lt};$$

telescoping a product of n kernels, $|g_{K;[n]}-\frac32\sum_\varsigma\mathrm{Tr}\prod_l(w_{\varsigma(l)}\mathsf{b}^{-1}C_K^{\mathrm{free}})|\le C\,\mathrm{br}\,\mathrm{nat}_n$; at $n=3$ the subtrahend is $3\,\mathrm{Tr}\prod_a(w_a\mathsf{b}^{-1}C_K^{\mathrm{free}})$, two cyclic orders with one trace. With Lemma 7.18 for $g_{k_1;[n]}$:

$$\epsilon^{\mathrm{nar}}_{(n)}=\mathsf{a}_nZ^nc_*^nP^{3n}\varpi+C\,[\mathsf{e}_{\mathrm{far}}^2+\mathrm{br}].$$

5. *The threshold* $\mathsf{d}_4(g)$. It is fixed by six conditions: (i) $\mathsf{d}\le e^{-2(15\mathfrak{p}_0+2)}$, so that by Lemma 7.3(c) $\epsilon'_{\mathrm{N}}(r)\le C(g)(\log\frac1{\mathsf{d}})^{15\mathfrak{p}_0+2}\mathsf{d}^{1/2}$ for all $r\le\mathsf{d}$; (ii) $\frac4{\sqrt3}M\delta_{\mathrm{tp}}L(L-1)(\log\frac1{\mathsf{d}})^2\ge3\log L+\log2$; (iii) $\log\frac1{\mathsf{d}}\ge\max\{5,\sqrt3/\delta_{\mathrm{tp}}LM\}$, so that $e^{4Y_{\mathsf{d}}-\frac{2}{\sqrt3}Y_{\mathsf{d}}^2}\le\mathsf{d}$, $\mathsf{e}_{\mathrm{far}}\le8\mathsf{d}^2$ and the last member of br is $\le C\mathsf{d}$; (iv) $8\mathsf{d}^2\le1$, $\overline{\mathrm{br}}\le1$; (v) $(Y_{\mathsf{d}}/\log L)[\bar\epsilon_\circ+\frac65(1+c_6c_\epsilon)A_1Y_{\mathsf{d}}^{\mathfrak{p}_0}g\mathsf{d}^{1/2}]\le1$; (vi) $\mathsf{d}\le r_1(\bar{\mathsf{b}})$, so that $\rho\le r_1(\mathsf{b})$ holds of itself. In (iv) and (v) the numbers br and $\epsilon_\circ$, which read r and the datum, stand replaced by majorants that read g and d alone. As $r\le\mathsf{d}$, $s(r)\ge s(\mathsf{d})$ and $Y_r\ge Y_{\mathsf{d}}$; with $\mathsf{d}/\mathsf{b}<g^2\mathsf{d}$,

$$\mathrm{br}\le\overline{\mathrm{br}}=25C_{\mathrm{tp}}c_L^{(2)}\bar B\,g^2\mathsf{d}+8000C_{\mathrm{tp}}^{\mathrm{bg}}\mathsf{d}^3+2L^3C_{\mathrm{tp}}\sup_{t\ge\frac{4}{\sqrt3}MY_{\mathsf{d}}^{2\mathfrak{p}_0}}t^3e^{-\delta_{\mathrm{tp}}Lt}.$$

In $\epsilon_\circ$, $\epsilon'_{\mathrm{N}}(r)$ is at most the bound of (i); $\mathfrak{b}_{k_1}\le A_1Y_{\mathsf{d}}^{\mathfrak{p}_0}$ and $\delta_{k_1}\le A_1Y_{\mathsf{d}}^{\mathfrak{p}_0}g\mathsf{d}^{1/2}$ (step 1, $\mathsf{b}>g^{-2}$); and $\mathsf{e}_{\mathrm{far}}\le8\mathsf{d}^2$ by (iii), as $P\ge4MY_{\mathsf{d}}^{2\mathfrak{p}_0}$. So

$$\epsilon_\circ\le\bar\epsilon_\circ=C_\circ\{A_1^3Y_{\mathsf{d}}^{3\mathfrak{p}_0}g\mathsf{d}^{1/2}+C(g)(\log\tfrac1{\mathsf{d}})^{15\mathfrak{p}_0+2}\mathsf{d}^{1/2}+e^{4Y_{\mathsf{d}}-\frac{2}{\sqrt3}Y_{\mathsf{d}}^{2\mathfrak{p}_0}}+8A_1^2Y_{\mathsf{d}}^{2\mathfrak{p}_0}\mathsf{d}^2\}.$$

Y_{d} is a function of g and d, with $\log\frac1{\mathsf{d}}\le Y_{\mathsf{d}}\le2\log\frac1{\mathsf{d}}+C(g)$ (Lemma 7.3(c)). So (i)–(vi) are conditions on (g,d) alone, and they hold for all small d, every majorised member tending to 0 with d. $\mathsf{d}_4(g)$ is half the supremum of the numbers d_* such that (i)–(vi) hold at every $0<\mathsf{d}\le\mathsf{d}_*$: a positive number formed from the constants and g, which reads no K, β, ℓ, ρ, r; at every $\mathsf{d}\le\mathsf{d}_4(g)$, every $r\le\mathsf{d}$, every datum at g and every label $\mathsf{b}\in(g^{-2},\bar{\mathsf{b}}]$ the conditions hold with br and $\epsilon_\circ$ themselves.

As $\varpi\le\epsilon_\circ+\frac65(1+c_6c_\epsilon)\delta_{k_1}$ at $n=3$ (Proposition 7.16) and $K-k_1\le Y_{\mathsf{d}}/\log L$, (v) secures $(K-k_1)\varpi\le1$; at $n=2$ (step 6) the same (v) secures it, as $c_4c_\epsilon^{(2)}\le c_6c_\epsilon$ (Lemma 7.14) and $C_\circ$ dominates the constants of step 6. $\mathsf{d}_4^{(4)}(g)$ is formed in the same way with $n=4$, that is with $c_8c_\epsilon^{(4)}$ in (v) and the tolerance $\epsilon_\circ$ of two pairs, under (Γ1) with $c_\epsilon^{(4)}$. Then $Z^n\le CY_{\mathsf{d}}^{2n\mathfrak{p}_0}$, $P^{3n}\le CY_{\mathsf{d}}^{6n\mathfrak{p}_0}$, $\mathfrak{b}_{k_1}^2\delta_{k_1}\le CY_{\mathsf{d}}^{3\mathfrak{p}_0}g\mathsf{d}^{1/2}$, and the exponents are $8n\mathfrak{p}_0+15\mathfrak{p}_0+2$: $39\mathfrak{p}_0+2$ at $n=3$, $47\mathfrak{p}_0+2$ at $n=4$.

6. *Two sources (b).* The same with the base level equal to the start level $k_1=\mathsf{k}(\mathsf{d})$, $\mathsf{v}_a=c_*\hat\rho^3\mathsf{u}_a$, $\mathsf{v}_{12}=c_*^2\hat\rho^6\mathsf{u}_{12}$; at the pair $\mathcal{S}_{k_1}=0$, so $q_{k_1;12}=g_{k_1;12}=0$, and Lemma 7.9(d) at $n=k_1$ gives $|G_{k_1;12}|\le Ce^{2Y_{\mathsf{d}}-\frac{2}{\sqrt3}Y_{\mathsf{d}}^{2\mathfrak{p}_0}}\mathsf{v}_{12}$; then $g_{K;12}=\frac32\sum w_1(p)w_2(q)\mathcal{S}_K(p,q)^2$ and Lemma 7.17(b) at $k=k_1$; the logarithms count $4\mathfrak{p}_0+12\mathfrak{p}_0+3\mathfrak{p}_0=19\mathfrak{p}_0$. □

The connected functions on the least torus.

Lemma 7.20 (The mixture; the conditioning stopped at any level)**.** Let $0 < g \le \gamma$ with $g^{-2} \ge x_{\mathrm{J}}$, (K, β) a first-passage datum at g with $K \ge 2$, $\ell \in \mathfrak{L}(g)$, and $w_1, \dots, w_p$ real weights, $p \ge 1$ arbitrary. For $0 \le k \le K$ let $\Omega_k = \mathcal{V}_k \sqcup \bigsqcup_{t=1}^{k} \mathcal{V}_{t-1}$ and $\mathbb{P}_k = Z_k^{-1}[\mathsf{m}_k \oplus \bigoplus_{t \le k} \mathsf{g}_t^{\mathrm{w}} \mathsf{m}_{t-1}]$, where $\mathcal{V}_t$ is the space of the block fields of the level t, m_t the measure of the never-large history up to the level t, and $\mathsf{g}_t^{\mathrm{w}} \ge 0$ the weight of a first large field at the step t in (314); $t' = k$ on the first part and $t' = t - 1$ on the part t; $\alpha = a_{K-t'}$; $U_0(W) = W$, and for $t' \ge 1$ let $U_{t'}(W)$ be the background configuration of W in the small-field region $\mathcal{V}_{t'}^{\chi}$. Write $\Omega = \Omega_K$, $\mathbb{P} = \mathbb{P}_K$, and $\mathsf{Y}_\beta(\omega) = \partial_\beta [D_{t'}^{\lambda}(U_{t'}(W)) - D_K^{\lambda}(\mathbf{1})]|_{\lambda=0}$ on Ω. Then:

(a) $\mathbb{P}_k$ is a Borel probability measure formed with no source; its parts with $t \le k$ are parts of $\mathbb{P}$; the part t of $\mathbb{P}$ has the mass w_t, and $\int \alpha^{-b} d\mathbb{P} = \mathbb{P}(\mathcal{V}_K) + \sum_t L^{b(K-t+1)} \mathsf{w}_t$ for every real b.

(b) $\langle e^{\mathcal{O}(w_\lambda)} \rangle_{K,\ell,\beta} = \int \exp[D_{t'}^{\lambda}(U_{t'}(W))]\, d\mathbb{P}_k$ for λ near 0; coefficientwise, $\langle \prod_{\iota \in \gamma} \mathcal{O}(w_\iota) \rangle_{K,\ell,\beta} = \int [\exp \mathbb{W}]_\gamma \, d\mathbb{P}$ in $\mathbb{C}[\lambda_\iota]/(\lambda_\iota^2)$, with $\mathbb{W}$ the multilinear jet of $\lambda \mapsto D_{t'}^{\lambda}(U_{t'}(W))$; each $[\mathbb{W}]_\gamma$ is a bounded Borel function that depends on the sources of γ alone.

(c) $S_n^T - \mathsf{J}_n = \sum_{\pi \in \mathrm{Part}([n])} \kappa_{\mathbb{P}}(\mathsf{Y}_{\beta'} : \beta' \in \pi)$; and with $G_\beta(\omega) = G_{t';\beta}(U_{t'}(W))$ on Ω_k, $S_n^T = \sum_\pi \kappa_{\mathbb{P}_k}(G_{\beta'} : \beta' \in \pi)$.

(d) Where $t' \ge 1$, $U_{t'}(W)$ has its pairs of all levels $\le t'$ in the cores and is regular of the level t' at the radius $2B_3 \varepsilon_{t'}$, with $8MB_3\varepsilon_{t'} \le c_{\mathrm{A}} \alpha_0$.

(e) On the least torus, under (Γ2): $\int \alpha^{-b} d\mathbb{P} \le 1 + 2L^b \mathsf{C}_{\mathrm{ag}}(b+1, \frac{1}{2})$ for every $b \ge 0$, so $\mathsf{M}' = \int \alpha^{-24} d\mathbb{P} \le \bar{\mathsf{M}}^{(24)}$; and $\int \alpha^{-b} d\mathbb{P}_k \le a_{K-k}^{-b} + \mathsf{M}'$, $\int_{\{\alpha < \varrho\}} \alpha^{-b} d\mathbb{P}_k \le \varrho^{24-b} \mathsf{M}'$ for $0 \le b \le 24$, $\varrho \le a_{K-k}$. On a side $\ell \in \mathfrak{L}(g)$: $\int \alpha^{-b} d\mathbb{P} \le 1 + 4L^b M^{-3} \ell^3 e^{\mathsf{B}(X_g)\ell^3} \mathsf{C}_{\mathrm{ag}}(b+1, \eth)$, finite and growing with ℓ, with the function B and the letter $\eth$ and $X_g = L(g^{-2} + B_\sharp)$.

■

Proof. Equation (314) writes the torus expectation of a bounded gauge invariant function F as Z^{-1} times the integral against m_k of its quotient at the level k plus the integrals against $\mathsf{g}_t^{\mathrm{w}} \mathsf{m}_{t-1}$ of its quotients at the levels $t-1$, $t \le k$, at every level $k \le K$. At $F = 1$ this makes $\mathbb{P}_k$ a probability measure; at $F = e^{\mathcal{O}(w_\lambda)}$ the quotient at a level t is, on $\mathcal{V}_t^{\chi}$, $\exp D_t^{\lambda}(U_t(W))$, by Proposition B.15, applied to the finite progression of Proposition B.8. Coefficients of the multilinear jets give (b); the logarithm of the moment series is the cumulant series, and constants drop out of the cumulants of orders ≥ 2, which gives (c), at every level k. (d) is Lemma B.17, in the setting verified by Proposition B.21 at $x_K \ge x_{\mathrm{J}}$. (e) The mass w_t is at most the probability that the first large field arises at the step t; on the least torus Proposition M.2, under $\log g^{-2} \ge \mathsf{Y}_{\mathrm{lt}}(\frac{1}{2})$, gives $\sum_t L^{b(K-t+1)} \mathsf{w}_t \le 2L^b \mathsf{C}_{\mathrm{ag}}(b+1, \frac{1}{2})$ for every real $b \ge 0$; on a larger torus the number of places costs $\ell^3 e^{\mathsf{B}(X_g)\ell^3}$. The parts $t \le k$ of $\mathbb{P}_k$ are those of $\mathbb{P}$, and on the first part $\alpha = a_{K-k}$. □

Lemma 7.21 (The remainder)**.** Let g satisfy (Γ), (K, β) be a first-passage datum at g, $\ell = \ell_g$, $n \in \{3, 4\}$, and let real weights satisfy the conditions of weights placed at (ρ, r, d) (if $n = 3$), or of two pairs at (ρ, r, d) (if $n = 4$), but for the upper bounds on the distances of the centres, with $0 < \rho \le r \le \mathsf{d} \le 1$, $\rho \le \frac{1}{2}$, $s(\rho) \le K$, $\rho \le r_1(\mathsf{b})$, all supports in one ball of radius $\le \frac{1}{8}\ell_g - 1$. There are numbers $\Lambda_3 \ge 1$ and C_{J} formed from the constants such that at $\mathbb{P}$-almost every ω, for every nonempty β,

$$|\mathsf{Y}_\beta(\omega)| \le \Lambda_3 \alpha^{-6} \mathsf{s}(\beta) \prod_{a \in \beta} |w_a|_\infty, \qquad \mathsf{s}(\beta) = \rho^3 \text{ (a point)}, \quad \rho^6 r^{-3} \text{ (a whole pair)},$$
$$(\rho/r)^{3c(\beta)} \rho^6 \mathsf{d}^{-9/2} \ (\beta \text{ crossing});$$

hence $|S_n^T - \mathsf{J}_n| \le \mathsf{k}_n \Lambda_3^n \mathsf{M}'^n \mathsf{b}^n \mathsf{d}^{3/2} \mathrm{nat}_n$ with $\mathsf{k}_3 = 13$, $\mathsf{k}_4 = 77$, and $|\mathsf{J}_n| \le C_{\mathrm{J}} (\mathsf{b}/\mathsf{d})^{n/2} \mathrm{nat}_n$, uniformly in $\rho \le r \le \mathsf{d}$ and in K. For two weights w_1, w_2 with $\Sigma(w_a) \subset \mathbb{B}(x_a, \rho)$ whose supports are at a

distance $\geq \mathsf{d}$, with $0 < \rho \leq \mathsf{d} \leq 1$, $\rho \leq \frac{1}{2}$, $s(\rho) \leq K$, $\rho \leq r_1(\mathsf{b})$ and both supports in one ball of radius $\leq \frac{1}{8}\ell_g - 1$, at $\mathbb{P}$-almost every ω

$$|\mathsf{Y}_a(\omega)| \leq \Lambda_3\, \alpha^{-6}\rho^3|w_a|_\infty, \qquad |\mathsf{Y}_{12}(\omega)| \leq \Lambda_3\, \alpha^{-6}\rho^6\mathsf{d}^{-3}|w_1|_\infty|w_2|_\infty \leq \Lambda_3\, \alpha^{-6}\rho^6\mathsf{d}^{-9/2}|w_1|_\infty|w_2|_\infty,$$

and

$$|S_2^T - \mathsf{J}_2| \leq 3\Lambda_3^2\mathsf{M}'^2\rho^6\mathsf{d}^{-9/2}|w_1|_\infty|w_2|_\infty;$$

if besides the balls are $\geq \mathsf{d}$ apart,

$$|\mathsf{J}_2| \leq C_{\mathrm{J}}(\mathsf{b}/\mathsf{d})\rho^6\mathsf{d}^{-6}\mathsf{b}^{-2}|w_1|_\infty|w_2|_\infty.$$

■

Proof. For $|\beta| \geq 2$, $\mathsf{Y}_\beta = \sum_{i\leq t'}(\mathsf{Sum}[E_\beta^{(i)}](U) - \mathsf{Sum}[E_\beta^{(i)}](\mathbf{1})) - \sum_{t'<i\leq K}\mathsf{Sum}[E_\beta^{(i)}](\mathbf{1})$, $U = U_{t'}(W)$; at a point $\mathcal{O}(w_a)(U) - \mathcal{O}(w_a)(\mathbf{1})$ comes besides, and for $t' \geq 1$ it is $\leq 162B_3^2\varepsilon_{t'}^2\rho^3\alpha^{-4}|w_a|_\infty$ on the regular configuration of Lemma 7.20(d). The first sum is bounded by Lemma 7.8(b) at the regular background of Lemma 7.20(d), the second at $\mathbf{1}$, both with the sizes of Lemma 7.9(f) at the width ρ, whose conditions hold: (P1), (P2) and the separation of the corners follow, as in the proof of Lemma 7.5(b), from the balls that hold the supports and from the distances of the supports alone, and $\rho \geq \frac{2}{3}Ma_K$, $E_\sigma(\hat{\rho}_1/2) \leq \varkappa_0^4$ from $\rho \leq r_1(\mathsf{b})$, $s(\rho) \leq K$ (Lemma 7.6); the sums over the levels on both sides of t' are geometric.

For $t' \geq 1$, with $j = t' - 1$, $a_{K-j} = \alpha/L$ and $x_j > 1$: $\bar{\nu}_{j;\beta} \leq \bar{c}_m(L/\alpha)^m\prod|w_a|_\infty$, $\Xi_j^r \leq \rho^6 r^{-3}L^3\alpha^{-3}$, and $\mathsf{z}(\beta)\min\{1, v_j\}^{3/2} \leq \mathsf{s}(\beta)L^{3/2}\alpha^{-3/2}$; so $|\mathsf{Y}_\beta| \leq C\alpha^{-6}\mathsf{s}(\beta)\prod|w_a|_\infty$ ($\alpha \leq 1$, $m \leq 4$). The part $t = 1$ of Ω has $t' = 0$, $\alpha = a_K$, and there $W \in \mathcal{V}_0$ is any configuration and $U_0(W) = W$: $D_0^\lambda = \mathcal{O}(w_\lambda)$, so the first sum is empty; at a point $0 \leq a_p \leq 2$ and (P1) give $|\mathcal{O}(w_a)(W)| \leq 2a_K^{-1}\sum_p|w_a(p)| \leq 162\rho^3a_K^{-4}|w_a|_\infty = 162\rho^3\alpha^{-4}|w_a|_\infty$, and $\mathcal{O}(w_a)(\mathbf{1}) = 0$; the second sum runs over $1 \leq i \leq K$ at $\mathbf{1}$ and is led by $i = 1$, with the sizes above at $j = 0$: $\bar{\nu}_{0;\beta} \leq \bar{c}_m\alpha^{-m}\prod|w_a|_\infty$ ($x_0 > 1$), $\Xi_0^r \leq \rho^6 r^{-3}\alpha^{-3}$, $\mathsf{z}(\beta)\min\{1, v_0\}^{3/2} \leq \mathsf{s}(\beta)\alpha^{-3/2}$.

So the bound holds at every ω of this part, with $\Lambda_3 \geq 162$. The weights $\mathsf{v}_1 = \mathsf{v}_2 = \rho^3 r^{-3/2}$, $\mathsf{v}_3 = \rho^3\mathsf{d}^{-9/2}$ (and $\mathsf{v}_a = \rho^3 r^{-3/2}\mathsf{d}^{-9/8}$ at $n = 4$) have $\mathsf{s}(\beta) \leq \mathsf{v}^\beta$ and $\mathsf{v}^{[n]} = \mathsf{s}([n])$, so every product over a partition is $\leq \mathsf{s}([n])$; Lemma 7.20(c), the bounds $|\kappa_2| \leq 2$, $|\kappa_3| \leq 6$ times the mean of the product of the bounds, and the moments of α^{-1} give $13 = 1 + 3\cdot 2 + 6$ at $n = 3$; finally $\mathsf{s}([3])\prod|w_a|_\infty = \mathsf{b}^3\mathsf{d}^{3/2}\mathrm{nat}_3$. The bound of J_n is Lemma 7.8(b) at $\mathbf{1}$ with the bounds of Lemma 7.9(e) at all the levels, in the form (f).

At two sources whose supports are at a distance $\geq \mathsf{d}$ the two weights form one pair at the widths (ρ, d) in the sense of Lemma 7.9(f): (P1), (P2) and the separation of the corners follow from the balls $\mathbb{B}(x_a, \rho)$ and from the distance $\geq \mathsf{d}$ of the supports, and $\rho \geq \frac{2}{3}Ma_K$, $E_\sigma(\hat{\rho}_1/2) \leq \varkappa_0^4$ from $\rho \leq r_1(\mathsf{b})$, $s(\rho) \leq K$, as above. The proof of the bound above, run for the list of the two weights, gives at a point and at the whole pair, read at $r = \mathsf{d}$, the display at two sources, as $\rho^6\mathsf{d}^{-3} \leq \rho^6\mathsf{d}^{-9/2}$ for $\mathsf{d} \leq 1$; with $S_2^T - \mathsf{J}_2 = \int\mathsf{Y}_{12}d\mathbb{P} + \kappa_{\mathbb{P}}(\mathsf{Y}_1, \mathsf{Y}_2)$ (Lemma 7.20(c)), $|\kappa_2| \leq 2$ and the moments of α^{-1} it gives $3 = 1 + 2$.

If besides the balls are $\geq \mathsf{d}$ apart, put a dummy bump w_2', the indicator of the plaquettes with barycentres in $\mathbb{B}(x_1 + 3\rho e, \rho)$, e the unit vector from x_2 to x_1; the three are at the lengths (ρ, ρ, d), and by multilinearity the objects of the pair are those of the list with the dummy: $S_2^T - \mathsf{J}_2 = \int\mathsf{Y}_{12}d\mathbb{P} + \kappa_{\mathbb{P}}(\mathsf{Y}_1, \mathsf{Y}_2)$, with $|\mathsf{Y}_a| \leq \Lambda_3\alpha^{-6}\rho^3|w_a|_\infty$ and $|\mathsf{Y}_{12}| \leq \Lambda_3\alpha^{-6}\rho^6\mathsf{d}^{-9/2}|w_1|_\infty|w_2|_\infty$; and the bound of J_n above, at the crossing set that the two weights form in this list, is the bound of J_2. □

Lemma 7.22 (Lattice sums and continuum integrals)**.** For every side ℓ and every cutoff K, that is on the torus T_ℓ with the lattice $a_K\mathbb{Z}^3$, and with the least lifts of the differences, the following hold.

(a) For $4a_K \le \rho \le r \le \mathsf{d} \le \mathsf{d}^+$, $4\mathsf{d}^+ < \ell$, $\vartheta \in (0,1]$ and Lipschitz f_1, f_2, f_3 with $\operatorname{supp} f_a \subset \mathbb{B}(x_a,\rho)$, $\operatorname{Lip} f_a \le \|f_a\|_\infty/\vartheta\rho$, $\operatorname{dist}(\operatorname{supp} f_1, \operatorname{supp} f_2) \ge r$, $\operatorname{dist}(\operatorname{supp} f_a, \operatorname{supp} f_3) \ge \mathsf{d}$, all supports in one ball of radius $\frac12\mathsf{d}^+$:

$$\Big|\operatorname{Tr}\prod_a((f_a\circ x)C_K^{\mathrm{free}}) - \int k_3\prod_a f_a\Big| \le C^{(3)}\Big[\frac{a_K}{\vartheta\rho} + \Big(\frac{\mathsf{d}^+}{\ell}\Big)^3\Big]\rho^9 r^{-3}\mathsf{d}^{-6}\prod_a\|f_a\|_\infty.$$

(b) For two pairs with the same data ($8a_K \le \rho$, the balls $\ge r$ apart in a pair and $\ge \mathsf{d}$ apart across): $|\frac12\sum_\varsigma \operatorname{Tr}\prod_l((f_{\varsigma(l)}\circ x)C_K^{\mathrm{free}}) - \int k_4\prod f_a| \le C^{(4)}[\frac{a_K}{\vartheta\rho} + (\frac{\mathsf{d}^+}{\ell})^3]\rho^{12}r^{-6}\mathsf{d}^{-6}\prod\|f_a\|_\infty$.

(c) For $8a_K \le \rho \le \mathsf{d}$, $64\mathsf{d} \le \ell$, Lipschitz φ_a in $\mathbb{B}(x_a,\rho)$ with $\operatorname{Lip}\varphi_a \le \|\varphi_a\|_\infty/\vartheta\rho$, the balls $\ge \mathsf{d}$ apart and $|x_1 - x_2| \le 18\mathsf{d}$:

$$\Big|\sum_{\lambda(p)=\lambda,\,\lambda(q)=\mu}\varphi_1(x(p))\varphi_2(x(q))C_K^{\mathrm{free}}(p,q)^2 - \mathcal{K}_{\lambda\mu}(\varphi_1,\varphi_2)\Big| \le C_{\mathrm{Rs}}\Big[\frac{a_K}{\vartheta\rho} + \Big(\frac{\mathsf{d}}{\ell}\Big)^3\Big]\Big(\frac{\rho}{\mathsf{d}}\Big)^6\|\varphi_1\|_\infty\|\varphi_2\|_\infty.$$

■

Proof. Step A. In a ring, and in a square, every sign ϵ_p stands twice, so $C_K^{\mathrm{free}}(p_l,p_{l+1})$ may be replaced by $\epsilon\epsilon C_K^{\mathrm{free}}$ and then, by equations YMM1:(2245)–(2246), by $a_K^3\mathbb{K}_3(u_l)_{\lambda(p_l)\lambda(p_{l+1})}$; both are $\le (1+3C_{\mathrm{lat}})a_K^3|u|^{-3}$, and telescoping costs $C_{\mathrm{lat}}a_K^3[a_K^2|u_l|^{-5} + \ell^{-3}]$ times the other factors, with at most $81(\rho/a_K)^3$ plaquettes for each source. *Step B.* For each choice of the directions the remaining sum is a Riemann sum over the cubes of side a_K about the barycentres, which for one orientation form a translate of $a_K\mathbb{Z}^3$; summed over the directions, $\sum\prod_l\mathbb{K}_3(\cdot)_{\lambda_l\lambda_{l+1}} = \operatorname{tr}\prod_l\mathbb{K}_3$. On the cubes that count the differences are at least 0.56 times their least values, $\|\mathbb{K}_3(u)\| \le \frac{1}{2\pi}|u|^{-3}$, $\|\partial\mathbb{K}_3(u)\| \le \frac{6}{4\pi}|u|^{-4}$ (Lemma 7.24(b)), and the Lipschitz bounds of the f_a give the error $a_K/\vartheta\rho$ times the natural size; the numbers $C^{(3)}, C^{(4)}, C_{\mathrm{Rs}}$ are these counts. □

Lemma 7.23 (Kernels of forms bounded on small bumps)**.** Let $U_1,\dots,U_p$ be open subsets of $\mathbb{R}^3$ or of a torus, $\rho_0 > 0$, $\mathsf{A} \ge 0$, and T a p-linear form on $\prod_a\operatorname{Lip}_c(U_a)$ with $|T(f_1,\dots,f_p)| \le \mathsf{A}\rho^{3p}\prod_a\|f_a\|_\infty$ whenever $\rho \le \rho_0$ and each f_a has its support in a ball of radius ρ in U_a. Then: (a) $T(f) = \int k\prod_a f_a$ with a Borel function k, $|k| \le (\frac{3}{\pi})^p\mathsf{A}$ almost everywhere, and at every point where T has a continuous kernel; (b) T extends to bounded Borel functions with compact supports in the U_a, and for balls $\mathbb{B}(z_a,\rho) \subset U_a$, $\rho \le \rho_0$, the mean of k over $\prod_a\mathbb{B}(z_a,\rho)$ is at most $(\frac{3}{4\pi})^p\mathsf{A}$ in modulus, at every choice of the centres; with the radial tents, $|\int k\prod_a\chi^\rho_{z_a}| \le (\frac{3}{\pi})^p\mathsf{A}$. ■

Proof. Let $k_\rho(x_1,\dots,x_p) = T(\chi^\rho_{x_1},\dots,\chi^\rho_{x_p})$; $\|\chi^\rho\|_\infty = 3/\pi\rho^3$ gives $|k_\rho| \le (\frac{3}{\pi})^p\mathsf{A}$. On functions with supports in fixed compact sets T is bounded in the sup norms (a Lipschitz partition of unity of width ρ_0), and the Riemann sums of $f_a * \chi^\rho$ converge uniformly, so $\int k_\rho\prod f_a = T(f_1*\chi^\rho,\dots) \to T(f)$; a weak-$*$ limit point of k_ρ in L^∞ is a kernel. (b) By dominated convergence T extends with the same bound; at $f_a = \mathbf{1}_{\mathbb{B}(z_a,\rho)}$, $|\int_{\prod\mathbb{B}(z_a,\rho)}k| \le \mathsf{A}\rho^{3p}$, which is the bound of the mean. □

Lemma 7.24 (The free template)**.** Let $X \ne 0$, $\mathsf{d} = |X|$, $\mathsf{b} > 0$, n, n' unit vectors.

(a) $\mathbb{K}_3(X)^2 = (16\pi^2\mathsf{d}^6)^{-1}(3\hat X\hat X^{\mathsf{T}} + 1)$; $\frac32\mathsf{b}^{-2}\sum_\mu\{[\mathbb{K}_3(X)_{\lambda\mu}]^2 - \frac13\sum_{\lambda'}[\mathbb{K}_3(X)_{\lambda'\mu}]^2\} = \mathsf{t}^\circ(e_\lambda,X)$; $\frac32\mathsf{b}^{-2}\sum_{\lambda,\mu}[\mathbb{K}_3(X)_{\lambda\mu}]^2 = \frac{9}{16\pi^2}\mathsf{b}^{-2}\mathsf{d}^{-6}$; $\sum_\lambda n_\lambda^2\mathsf{t}^\circ(e_\lambda,X) + \sum_{\lambda<\lambda'}n_\lambda n_{\lambda'}3\mathsf{b}^{-2}[\mathbb{K}_3(X)^2]_{\lambda\lambda'} = \mathsf{t}^\circ(n,X)$; and $|\mathsf{t}^\circ(n,X) - \mathsf{t}^\circ(n',X)| \le 0.057|n-n'|\mathsf{b}^{-2}\mathsf{d}^{-6}$.

(b) In the operator norm, $\|\mathbb{K}_3(y)\| = \frac{2}{4\pi}|y|^{-3}$, $\|(h\cdot\nabla)\mathbb{K}_3(y)\| \le \frac{6}{4\pi}|h||y|^{-4}$, $\|(h\cdot\nabla)^2\mathbb{K}_3(y)\| \le \frac{24}{4\pi}|h|^2|y|^{-5}$.

(c) For $0 < r \le \frac12\mathsf{d}$ and $c - z = X$: $|\frac{2\pi}{3}\mathsf{b}r^3\cdot 3\mathsf{b}^{-3}k_3(c+\frac{r}{2}n, c-\frac{r}{2}n, z) - \mathsf{t}^\circ(n,X)| \le 2.66\,(r/\mathsf{d})^2\mathsf{b}^{-2}\mathsf{d}^{-6}$; and for $0 < \rho < \frac14 r$ the same function averaged against the radial tents χ^ρ about the three points differs from its value by at most $7900\,(\rho/r)\mathsf{b}^{-2}\mathsf{d}^{-6}$.

(d) For $0 < \rho \le \frac18\mathsf{d}$: $|\mathcal{K}_{\lambda\mu}(\chi^\rho_c,\chi^\rho_z) - [\mathbb{K}_3(X)_{\lambda\mu}]^2| \le 2.28\,(\rho/\mathsf{d})\mathsf{d}^{-6}$.

■

Proof. (a) With $E = \hat{X}\hat{X}^{\mathsf{T}}$, $E^2 = E$: $(3E-1)^2 = 3E+1$; $\sum_\mu [\mathbb{K}_3(X)_{\lambda\mu}]^2 = [\mathbb{K}_3(X)^2]_{\lambda\lambda}$ and $\operatorname{tr}\mathbb{K}_3(X)^2 = 6(16\pi^2\mathsf{d}^6)^{-1}$; the identity in n is the expansion of $\langle n, \mathbb{K}_3(X)^2 n\rangle$; the last bound is $\frac{18}{32\pi^2} \le 0.057$ times $|n-n'|$. (b) $\mathbb{K}_3 = (4\pi)^{-1}\nabla\nabla|y|^{-1}$; the third and fourth derivatives of $|y|^{-1}$ contracted with h, in a frame with $\hat{y} = e_1$, have eigenvalues bounded by 6 and 24 times $|h|^k|y|^{-3-k}$. (c) With $D(n) = 3nn^{\mathsf{T}} - 1$, $h = \frac{r}{2}n$ and $\phi(t) = \operatorname{tr}[D(n)\mathbb{K}_3(X-th)\mathbb{K}_3(X+th)]$: $\mathbb{K}_3(rn) = (4\pi r^3)^{-1}D(n)$, so the first member is $\frac{1}{2}\mathsf{b}^{-2}\phi(1)$, while $\frac{1}{2}\mathsf{b}^{-2}\phi(0) = \mathsf{t}^\circ(n,X)$ by (a). ϕ is even, since $\operatorname{tr}[DAB] = \operatorname{tr}[DBA]$ for symmetric matrices, so $|\phi(1)-\phi(0)| \le \frac{1}{2}\sup|\phi''|$; with $|X \pm th| \ge \frac{3}{4}\mathsf{d}$, the trace norm 4 of $D(n)$ and (b),

$$|\phi''| \le \frac{4}{(4\pi)^2}(24\cdot 2 + 2\cdot 6\cdot 6 + 2\cdot 24)\frac{r^2}{4}\Big(\frac{4}{3}\Big)^8 \mathsf{d}^{-8} = 10.63\,(r/\mathsf{d})^2\mathsf{d}^{-6},$$

and $\frac{1}{4}\cdot 10.63 \le 2.66$. The tents: the mean value theorem with (b) for the three factors of k_3. (d) $|\nabla(\mathbb{K}^2_{3,\lambda\mu})| \le \frac{3}{2\pi^2}|u|^{-7}$ on a segment in $\{|u| \ge \frac{3}{4}\mathsf{d}\}$, and $\frac{3}{2\pi^2}(\frac{4}{3})^7\cdot 2 \le 2.28$. □

Every state.

Lemma 7.25 (The chessboard bound)**.** Let $0 < g \le \gamma$, (K,β) a first-passage datum at g, $\ell' \in \mathfrak{L}(g)$, and consider the board of $\mathbb{L}_K$ into cubes of side $\frac{1}{2}\ell'$, the cells, with any offset in $a_K\mathbb{Z}^3$; let $\mathsf{Q}_0 = \exp[\frac{1}{8}\ell'^3(2C_{\mathrm{S}} + C_g)]$ with the constants C_{S}, C_g of the two-sided stability bound. For every $\ell \in \mathfrak{L}(g)$ with $\ell \ge \ell'$, every $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, every cell and every bounded complex Borel function F of the variables of that cell,

$$|\tilde{\mu}_{K,\ell,\beta}(F)|,\ |\nu(F)| \le \mathsf{Q}_0\|F\|_{\mathrm{ch}}, \qquad \|F\|^8_{\mathrm{ch}} = \tilde{\mu}_{K,\ell',\beta}\Big(\prod_{\text{the eight cells of } T_{\ell'}} F^{[\cdot]}\Big) \ge 0,$$

$F^{[\cdot]}$ are the reflected copies of F, conjugated when an odd number of coordinate reflections is used. ■

Proof. The bound is a chain of four links. The cells are cubes of side $\mathsf{l} = \frac{1}{2}\ell'$; the torus T_ℓ holds $\mathsf{N}_\ell = (2\ell/\ell')^3$ of them and $T_{\ell'}$ eight. For F as in the statement let F^{all}_ℓ be the product of the reflected copies of F, conjugated with the parity convention in the statement, over all the cells of T_ℓ, and $Z_{K,\ell,\beta}[F^{\mathrm{all}}_\ell]$ the integral of the density of T_ℓ with this insertion. (1) *Reflection positivity on T_ℓ.* The torus measures are reflection positive in the planes of the board, and the chessboard estimate (Corollary B.1(b), (c)) gives $|\tilde{\mu}_{K,\ell,\beta}(F)| \le \|F\|_{\mathrm{ch},\ell}$, where $\|F\|^{\mathsf{N}_\ell}_{\mathrm{ch},\ell} = Z_{K,\ell,\beta}[F^{\mathrm{all}}_\ell]/Z_{K,\ell,\beta} \ge 0$; on $T_{\ell'}$ this is the number of the statement, $\|F\|_{\mathrm{ch},\ell'} = \|F\|_{\mathrm{ch}}$. (2) *Two sides, with the insertions.* As ℓ/ℓ' is a power of L, the subadditivity in the volume of the integrals with the reflected copies inserted (Proposition YMM1:86.5, Corollary YMM1:86.6) gives $Z_{K,\ell,\beta}[F^{\mathrm{all}}_\ell]^{1/\mathsf{N}_\ell} \le Z_{K,\ell',\beta}[F^{\mathrm{all}}_{\ell'}]^{1/8}$; with $p_\ell = \ell^{-3}\log Z_{K,\ell,\beta}$, $Z^{1/\mathsf{N}_\ell}_{K,\ell,\beta} = e^{\mathsf{l}^3 p_\ell}$ and $Z^{1/8}_{K,\ell',\beta} = e^{\mathsf{l}^3 p_{\ell'}}$ this is clause (e) of the same corollary:

$$\|F\|_{\mathrm{ch},\ell} \le \|F\|_{\mathrm{ch},\ell'}\, e^{\mathsf{l}^3(p_{\ell'} - p_\ell)}.$$

(3) *Stability, with no insertion.* The two-sided stability bound among the construction results, which rests on Theorems YMM1:AJ and YMM1:AD (Lemma N.1), concerns the partition functions without insertions: $Z_{K,\ell,\beta} = e^{E_{K,\ell,\beta}}\widetilde{Z}_\ell$ with the vacuum constant $E_{K,\ell,\beta}$ and a number $e^{-C_g\ell^3} \le \widetilde{Z}_\ell \le e^{C_{\mathrm{S}}\ell^3}$, and $|E_{K,\ell,\beta}\ell^{-3} - E_{K,\ell',\beta}\ell'^{-3}| \le C_{\mathrm{S}}$ for two sides $\ell, \ell' \in \mathfrak{L}(g)$. So

$$p_{\ell'} - p_\ell \le (E_{K,\ell',\beta}\ell'^{-3} + C_{\mathrm{S}}) - (E_{K,\ell,\beta}\ell^{-3} - C_g) \le 2C_{\mathrm{S}} + C_g,$$

and (1)–(3), with $\mathsf{l}^3 = \frac{1}{8}\ell'^3$, give $|\tilde{\mu}_{K,\ell,\beta}(F)| \le \mathsf{Q}_0\|F\|_{\mathrm{ch}}$. (4) *Periodic Gibbs states.* For $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$ the domination theorem (Proposition YMM1:91.9, for every board of $\mathbb{L}_K$ and every offset) gives $|\nu(F)| \le \liminf_k \|F\|_{\mathrm{ch},\ell_k}$ along every sequence $\ell_k \to \infty$ in $\mathfrak{L}(g)$, and (2), (3) at $\ell = \ell_k$ bound the right member by $\mathsf{Q}_0\|F\|_{\mathrm{ch}}$. No link reads what F is made of, and Q_0 depends neither on $\ell \ge \ell'$ nor on K. □

Lemma 7.26 (The fold)**.** Let $\mathfrak{N}_I = \mathbb{C}[\lambda_\iota : \iota \in I]/(\lambda_\iota^2)$, $[x]_\gamma$ the coefficient of λ^γ, $\mathfrak{m} = \{[x]_\emptyset = 0\}$, and $\|x\|_u = \sum_\gamma |[x]_\gamma|/u^\gamma$ for numbers $u_\iota > 0$.

(a) $\|\cdot\|_u$ is submultiplicative; for $y \in \mathfrak{m}$, $\|e^y - 1\|_u \le (1 + \|y\|_u)^{|I|} - 1$ and $\|\log(1+y)\|_u \le \|y\|_u(1+\|y\|_u)^{|I|-1}$; the logarithm of the moment series is the cumulant series.

(b) In the data of Lemma 7.25 let $f_1, \dots, f_n$ be bounded real functions that vanish off the interior of one cell, w_ι, $\iota \in I = [n] \times \{\text{the eight cells}\}$, the eight mirror images of the $f_a \circ x$ on $T_{\ell'}$, and $(\Omega, \mathbb{P})$ a probability space with a measurable $\mathbb{W}\colon \Omega \to \mathfrak{m}$ such that $\langle \prod_{\iota\in\gamma} \mathcal{O}(w_\iota)\rangle_{K,\ell',\beta} = \int [\exp \mathbb{W}]_\gamma d\mathbb{P}$ for all $\gamma \subset I$. Let $u_{(a,\cdot)} = u_a > 0$, $\mathsf{c} = \sum \mathsf{c}^{(\cdot)}$ a sum of constants of $\mathfrak{m}$ each in the variables of one cell, of any size, and $\mathsf{Z} \ge 0$ measurable with $\|\mathbb{W} - \mathsf{c}\|_u \le \mathsf{Z}$ almost everywhere. Put $\mathsf{y} = \int[(1+\mathsf{Z})^n - 1]d\mathbb{P}$, $\mathsf{h} = \mathsf{y}(1+\mathsf{y})^{n-1}$, $\eta_0 = [\int (1 + \mathsf{Z} + 8\mathsf{h})^{8n} d\mathbb{P}]^{1/8}$, $\eta = (2^n - 1)\mathsf{Q}_0\eta_0$. Then for every nonempty $\beta \subset [n]$, every $\ell \in \mathfrak{L}(g)$ with $\ell \ge \ell'$, and $\mathfrak{s} = \tilde\mu_{K,\ell,\beta}$ or $\mathfrak{s} \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$:

$$|S^T_{|\beta|}[\mathfrak{s}]((f_a)_{a\in\beta}) - S^T_{|\beta|}[\tilde\mu_{K,\ell',\beta}]((f_a)_{a\in\beta})| \le \eta(1+\eta)^{n-1}u^\beta.$$

The bound holds at every size of Z, of the constants c and of η. ∎

Proof. (a) is the algebra of exp and log in an algebra with $|I|$ nilpotent generators. (b) Let $\mathsf{k} = \log \sum_\beta \tilde\mu_{K,\ell',\beta}(\prod_{a\in\beta}\mathcal{O}(f_a))\lambda^\beta$ and $\Xi_\beta = [\exp(\sum_a \lambda_a \mathcal{O}(f_a) - \mathsf{k})]_\beta$, a function of the variables of the cell. The mirror images of Ξ_β are the same expressions in the mirrored sources, so by the representation $\|\Xi_\beta\|^8_{\mathrm{ch}} = \int[\exp(\mathbb{W} - \mathsf{k}^{\mathrm{all}})]_{\beta\times\{\text{cells}\}} d\mathbb{P}$, $\mathsf{k}^{\mathrm{all}}$ the sum of the eight copies of k. Each copy has $e^{\mathsf{k}^{(\cdot)}} = \int \exp(\pi_{\mathrm{cell}}\mathbb{W})d\mathbb{P}$, so $\mathsf{k}^{(\cdot)} - \mathsf{c}^{(\cdot)} = \log(1+\mathsf{y}^{(\cdot)})$ with $\|\mathsf{y}^{(\cdot)}\|_u \le \mathsf{y}$ and $\|\mathsf{k}^{(\cdot)} - \mathsf{c}^{(\cdot)}\|_u \le \mathsf{h}$; the constants of any size cancel, $\|\mathbb{W} - \mathsf{k}^{\mathrm{all}}\|_u \le \mathsf{Z} + 8\mathsf{h}$, and $|[\exp(\cdot)]_{\beta\times\{\text{cells}\}}| \le (1 + \mathsf{Z} + 8\mathsf{h})^{8n}(u^\beta)^8$.

So $\|\Xi_\beta\|_{\mathrm{ch}} \le \eta_0 u^\beta$, and Lemma 7.25 gives $|\mathfrak{s}(\Xi_\beta)| \le \mathsf{Q}_0\eta_0 u^\beta$. With $\mathsf{b}' = \sum_\beta \mathfrak{s}(\Xi_\beta)\lambda^\beta = \mathsf{M}_\mathfrak{s} e^{-\mathsf{k}}$, $\mathsf{M}_\mathfrak{s}$ the moment series of $\mathfrak{s}$: $\|\mathsf{b}' - 1\|_u \le \eta$ and $\|\log \mathsf{M}_\mathfrak{s} - \mathsf{k}\|_u = \|\log \mathsf{b}'\|_u \le \eta(1+\eta)^{n-1}$. □

Lemma 7.27 (Mirror copies)**.** Zero sources are omitted before forming the weighted jet norm; coefficients involving their directions vanish by multilinearity. Assume the remaining source weights are nonzero. Let g satisfy (Γ), $\ell' = \ell_g$, and let $f_1, \dots, f_n$, $n \in \{2,3,4\}$, be as in (A.4)(i) (for $n = 4$, two pairs; for $n = 2$, two bounded real Borel functions with $\operatorname{supp} f_a \subset \mathbb{B}(x_a, \rho)$, the two supports at a distance $\ge \mathsf{d}$, $0 < \rho \le \mathsf{d} \le 1$, $\rho \le \frac12$, $s(\rho) \le K$, $\rho \le r_1(\mathsf{b})$, both supports in one ball of radius $\le \frac18\ell_g - 1$), placed by the offset in the interior of one cell, so that two mirror copies are at least $\frac14\ell_g \ge 6.5$ apart. Let $\mathbb{W}$ be the multilinear jet of $\lambda \mapsto D^\lambda_{t'}(U_{t'}(W))$ for the $8n$ sources w_ι on the space of Lemma 7.20, $[\mathsf{c}]_\gamma = \partial^\gamma D^\lambda_K(\mathbf{1})|_0$ for γ in one cell and $[\mathsf{c}]_\gamma = 0$ for γ that link two cells, and $u_a = \mathsf{v}_a|w_a|_\infty$ with $\mathsf{v}_1 = \mathsf{v}_2 = \rho^3 r^{-3/2}$, $\mathsf{v}_3 = \rho^3\mathsf{d}^{-9/2}$ $(n=3)$, $\mathsf{v}_a = \rho^3 r^{-3/2}\mathsf{d}^{-9/8}$ $(n=4)$, $\mathsf{v}_a = \rho^3\mathsf{d}^{-9/4}$ $(n=2)$.

Then $\|\mathbb{W}(\omega) - \mathsf{c}\|_u \le \mathsf{Z}_n\alpha(\omega)^{-6}$ almost everywhere, $\mathsf{Z}_n = 8(2^n-1)\Lambda_3 + 2^{8n}\max_m \Lambda^{\mathrm{L}}_m$, where the numbers Λ^{L}_m, formed from the constants, bound the linking jets: for γ linking two copies, $|\sum_{i\le t} \mathsf{Sum}[E^{(i)}_\gamma](U)| \le \Lambda^{\mathrm{L}}_m \mathsf{b}^{-m/2}\prod_{\text{copies}} \mathsf{s}(\gamma \cap \text{copy}) \prod_{\iota\in\gamma}|w_\iota|_\infty$ at every U whose pairs of the levels $\le t$ lie in the cores. ∎

Proof. Within one cell the coefficients of $\mathbb{W} - \mathsf{c}$ are the Y_β of the copy (by multilinearity the mixture names no source), bounded by Lemma 7.21 and $\mathsf{s}(\beta) \le \mathsf{v}^\beta$; there are $8(2^n-1)$ such sets. At $n = 2$ the two bumps are taken as one pair at the widths (ρ, d) in the sense of Lemma 7.9(f), since (P1), (P2) and the separation of the corners follow from the balls $\mathbb{B}(x_a, \rho)$ and from the distance $\ge \mathsf{d}$ of the supports, as in the proof of Lemma 7.21; that proof, with the size $\rho^6\mathsf{d}^{-3}$ of a whole pair at the distance d in the place of $\rho^6 r^{-3}$, gives at $\mathbb{P}$-almost every ω

$$|\mathsf{Y}_a| \le \Lambda_3\alpha^{-6}\rho^3|w_a|_\infty, \qquad |\mathsf{Y}_{12}| \le \Lambda_3\alpha^{-6}\rho^6\mathsf{d}^{-3}|w_1|_\infty|w_2|_\infty \le \Lambda_3\alpha^{-6}\rho^6\mathsf{d}^{-9/2}|w_1|_\infty|w_2|_\infty \quad (\mathsf{d} \le 1),$$

and $\rho^3 \le \mathsf{v}_a$, $\rho^6\mathsf{d}^{-9/2} = \mathsf{v}_1\mathsf{v}_2$. For a set γ that links two copies, the calculus of Lemma 7.6 at $8n$ sources, with the copies as cells and $\mathsf{D}^{\iota\iota'}_i \ge \hat{\mathsf{D}}^\times_i/\sqrt{3} - 1$ across, where $\mathsf{D}^\times \ge \frac14\ell_g$ is the least distance

on T_{ℓ_g} of the supports of two different mirror copies and $\hat{\mathsf{D}}_i^{\times} = \mathsf{D}^{\times}/a_{K-i}$, gives by the recursion (g), with $\sigma_{i;\gamma} \le E_\sigma(\hat{\mathsf{D}}_i^{\times})$, bounds on $\bar{\mathsf{h}}_{j;\gamma}$ and $\bar{\Psi}_{j;\gamma}$ by products of the one-cell sizes; with Lemma 7.8(b) and the geometric sums this is the bound of the linking jets. The products of natural sizes over a partition do not exceed that of the whole set. The numbers Λ_m^{L} are finite and formed from the constants, two copies being at least $\frac{1}{4}\ell_g \ge 6.5$ apart; no condition on g beyond (Γ) is needed. □

Proposition 7.28 (Transfer to every state)**.** Let g satisfy (Γ) and (K,β) be a first-passage datum at g.

(a) For $n \in \{3,4\}$ and the data of (A.4)(i) (for $n=4$ two pairs, all supports in one ball of radius $\le \frac{1}{8}\ell_g - 1$), every $\ell \in \mathfrak{L}(g)$ and every state $\mathfrak{s}$ at (K,β): $|S_n^T[\mathfrak{s}](f) - S_{n;K,\ell_g,\beta}^T(f^{\langle \ell_g\rangle})| \le C_n^{\mathrm{tr}3}(g)\mathsf{b}^n\mathsf{d}^{3/2}\mathrm{nat}_n$, where $C_n^{\mathrm{tr}3}(g) = \eta(1+\eta)^{n-1}$, $\eta = (2^n-1)\mathsf{Q}_0(g)\eta_0$, $\eta_0 = (1+\mathsf{Z}_n+8\mathsf{h})^n(\bar{\mathsf{M}}^{(48n)})^{1/8}$, $\mathsf{h} = \mathsf{y}(1+\mathsf{y})^{n-1}$, $\mathsf{y} = (1+\mathsf{Z}_n)^n\bar{\mathsf{M}}^{(6n)}$, $\bar{\mathsf{M}}^{(b)} = 1 + 2L^b\mathsf{C}_{\mathrm{ag}}(b+1,\frac{1}{2})$ and $\mathsf{Q}_0(g) = \exp[\frac{1}{8}\ell_g^3(2C_{\mathrm{S}} + C_g)]$.

(b) For two bumps: let $0 < \rho \le \mathsf{d} \le 1$, $\rho \le \frac{1}{2}$, $s(\rho) \le K$, $\rho \le r_1(\mathsf{b})$, f_1, f_2 bounded real Borel functions on $\mathbb{R}^3$ with $\operatorname{supp} f_a \subset \mathbb{B}(x_a,\rho)$, the two supports at a distance $\ge \mathsf{d}$, both in one ball of radius $\le \frac{1}{8}\ell_g - 1$, $t_a\colon \{1,2,3\} \to [-1,1]$, $w_a(p) = t_a(\lambda(p))f_a(x(p))$, and $\bar{w}_a$ the same with $f_a^{\langle \ell_g\rangle}$ on T_{ℓ_g}. Then for every state $\mathfrak{s}$ at (K,β), $|\langle \mathcal{O}(w_1);\mathcal{O}(w_2)\rangle_{\mathfrak{s}} - \langle \mathcal{O}(\bar{w}_1);\mathcal{O}(\bar{w}_2)\rangle_{K,\ell_g,\beta}| \le C_2^{\mathrm{tr}}(g)(\rho/\mathsf{d})^6\mathsf{d}^{3/2}\|f_1\|_\infty\|f_2\|_\infty$, where $C_2^{\mathrm{tr}}(g) = \eta(1+\eta)$ is the number of (a) formed at $n=2$, with Z_2 of Lemma 7.27.

■

Proof. Every periodic Gibbs state is invariant under lattice translations by Proposition YMM1:103.4; choose the offset of the board so that the tuple lies in the interior of one cell. Lemma 7.26 with $\ell' = \ell_g$, the representation of Lemma 7.20(b) at the $8n$ mirrored sources, $\mathsf{Z} = \mathsf{Z}_n\alpha^{-6}$ by Lemma 7.27, and the moments of Lemma 7.20(e): $\mathsf{y} \le (1+\mathsf{Z}_n)^n\bar{\mathsf{M}}^{(6n)}$ and $\eta_0 \le (1+\mathsf{Z}_n+8\mathsf{h})^n(\bar{\mathsf{M}}^{(48n)})^{1/8}$, so η is formed from the constants and g. With the weights of Lemma 7.27, $u^{[n]} = \mathsf{s}([n])\prod|w_a|_\infty = \mathsf{b}^n\mathsf{d}^{3/2}\mathrm{nat}_n$. For (b) the same argument runs at $n=2$, with Lemma 7.27 at $n=2$, whose bounds read only the balls of radius ρ and the distance $\ge \mathsf{d}$ of the supports; a mirror map carries a_p to $a_{\mathsf{r}p}$ with $x(\mathsf{r}p) = \mathsf{r}x(p)$ and $\lambda(\mathsf{r}p) = \lambda(p)$, so plane weights go to plane weights, and $u_1u_2 = (\rho/\mathsf{d})^6\mathsf{d}^{3/2}|w_1|_\infty|w_2|_\infty$. □

Lemma 7.29 (Limits and components)**.** (a) Every Gibbs sequence at g that converges has subsequences on which the labels converge (they lie in $(g^{-2},\bar{\mathsf{b}}]$); along every such subsequence the members are states at their data, the limit σ is a law on $\mathbb{R}^3$ with $S_n^T[\nu_j] \to S_n^\sigma$ on separated tuples, and for every component σ_ξ of a canonical decomposition of σ its approximants ρ_j are periodic Gibbs states at the same data with $S_n^T[\rho_j] \to S_n^{\sigma_\xi}$.

(b) For a law with continuous moment kernels through order three, the connected kernel is $\mathsf{s}_3 = \mathsf{s}_3^{\mathrm{m}} - \mathsf{s}_2\otimes\mathsf{s}_1 - \cdots + 2\mathsf{s}_1\otimes\mathsf{s}_1\otimes\mathsf{s}_1$, and $\mathsf{s}_2^T = \mathsf{s}_2 - \mathsf{s}_1\otimes\mathsf{s}_1$. These kernels are continuous. For the periodic-Gibbs limits and components in (a), they are also real analytic and Euclidean invariant, by Proposition YMM1:108.3.

(c) Let $\eta(t) = 1$ $(t \le 0)$, $1 - 3t^2 + 2t^3$ $(0 \le t \le 1)$, 0 $(t \ge 1)$, $\psi_\rho(v) = \eta(5|v|/\rho - 4)$ and $f_a^\rho = \psi_\rho(\cdot - z_a)/\int\psi_\rho$. These are C^1 probability densities supported in $\mathbb{B}(z_a,\rho)$ with $\rho^9\prod_{a\le 3}\|f_a^\rho\|_\infty \le 0.102$; if s_3 is continuous at (z_1,z_2,z_3) and $|\int(\mathsf{s}_3 - 3\mathsf{b}^{-3}k_3)\prod f_a^\rho| \le \mathsf{A}$ for all small ρ, then $|\mathsf{s}_3 - 3\mathsf{b}^{-3}k_3|(z_1,z_2,z_3) \le \mathsf{A}$.

■

Proof. (a) follows from the component approximation in Theorem YMM1:AP and the canonical decomposition of Theorem YMM1:AL; a joint cumulant of order ≥ 2 does not change if constants are added to its entries, so the centring of the approximants does not enter. (b) Apply the finite moment–cumulant formula to the assumed continuous moment kernels. For the laws in (a), their analytic and invariance properties follow from Theorem YMM1:AP and Proposition YMM1:108.3.

For a self-centred limit, $S_1^\sigma = 0$. (c) ψ_ρ is constant on $|v| \le \frac{4}{5}\rho$, and $\mathsf{s}_3 - 3\mathsf{b}^{-3}k_3$ is continuous at the point. □

Lemma 7.30 (One subsequence for all pairs of bumps)**.** Let Ω be an open subset of $\{(x,y) : 0 < |x-y| < \mathsf{d}_\Omega\}$ in T_ℓ^2 or in $(\mathbb{R}^3)^2$, and let bilinear forms $\mathsf{t}^{(j)}_{\lambda\mu}$, $\lambda,\mu \in \{1,2,3\}$, $j \in \mathbb{N}$, on bounded real Borel functions be such that for every $(x_0,y_0) \in \Omega$, with closed balls $\bar U, \bar V$ about x_0, y_0 of a radius $\varrho(x_0,y_0) > 0$ for which $\bar U \times \bar V \subset \Omega$, there is $\mathsf{B} < \infty$ with $|\mathsf{t}^{(j)}_{\lambda\mu}(f,h)| \le \mathsf{B}\|f\|_\infty \|h\|_\infty$ for all large j and all f, h supported in $\bar U, \bar V$. Then there is a subsequence along which $\mathsf{t}^{(j)}_{\lambda\mu}(\varphi_1,\varphi_2)$ converges for all λ,μ and all real Lipschitz φ_1,φ_2 with compact supports, $\operatorname{supp}\varphi_1 \times \operatorname{supp}\varphi_2 \subset \Omega$; the limits are bilinear. If on every such product of balls the limit forms satisfy the assumption of Lemma 7.23, they have Borel kernels on Ω, unique almost everywhere. ■

Proof. $\mathrm{Lip}_c(U)$ is a subset of the separable space $C_0(U)$, so it has a countable dense subset in the sup norm. Take a countable dense set of centres in Ω and a diagonal subsequence along which the countably many bounded sequences $\mathsf{t}^{(j)}_{\lambda\mu}(f,h)$, f, h in these dense sets, converge; by the uniform bound and bilinearity the sequences converge at all Lipschitz f, h in the balls. A pair φ_1,φ_2 as in the claim is decomposed by a Lipschitz partition of unity into cubes of a side small against the distances of $\operatorname{supp}\varphi_1 \times \operatorname{supp}\varphi_2$ to the diagonal and to the boundary of Ω: finitely many pairs, each in one product of balls. Two kernels that represent one form on an open product agree almost everywhere (mollification), and a numbering of the countable cover glues the local kernels into one Borel function. □

The bond forms.

Lemma 7.31 (Dilation to two couplings below the ceiling)**.** Let $0 < g \le \gamma$, let $z = z(g) \ge 1$ be the least integer with $L^{z-1}(g^{-2} + \bar B) - \bar B \ge x_{\mathrm N} = \gamma_{\mathrm N}^{-2}$ (Definition 7.1(1)), and define g_1', g_2' by $g_1'^{-2} = L^z(g^{-2} + \bar B) - \bar B$, $g_2'^{-2} = L^{-1}(g_1'^{-2} + 2B_\sharp) - B_\sharp$.

(a) $0 < g_1' < g_2' \le \gamma_{\mathrm N}$, and both depend on g and the constants alone.

(b) For a first-passage datum (K,β) at g with $K \ge z+1$ there is $\iota \in \{1,2\}$ such that $(K-z,\beta)$ is a first-passage datum at g_ι'; its run is $(x_0,\dots,x_{K-z})$, and its label is $L^z\mathsf{b}$.

(c) $L^z\ell \in \mathfrak{L}(g_\iota')$ for $\ell \in \mathfrak{L}(g)$; if $s(t) \ge z$, then $s_\iota'(L^z t) \le s(t) - z$ for the witness depth s_ι' at g_ι', and if $s(t) < z$, then $L^z t > 1$.

(d) $U \mapsto U^{(z)}$, $U^{(z)}(L^z b) = U(b)$, carries $\mu_{K,\ell,\beta}$ to $\mu_{K-z,L^z\ell,\beta}$, with $a_{L^z p}(U^{(z)}) = a_p(U)$ and $q_{L^z b}(U^{(z)}) = q_b(U)$. So $\mathcal{O}^T(\mathfrak{s})(U) = L^z\mathcal{O}'^T(\mathfrak{s}^{(z)})(U^{(z)})$ and $\langle \mathcal{O}^T(\mathfrak{s}_1); \mathcal{O}^T(\mathfrak{s}_2)\rangle_{K,\ell,\beta} = L^{2z}\langle \mathcal{O}'^T(\mathfrak{s}_1^{(z)}); \mathcal{O}'^T(\mathfrak{s}_2^{(z)})\rangle_{K-z,L^z\ell,\beta}$, primes marking the objects of the torus $T_{L^z\ell}$ at the cut-off $K-z$ and $\mathfrak{s}^{(z)}(L^z\cdot) = \mathfrak{s}(\cdot)$; and the numbers $\|\varphi\|_\infty$, $r\,\mathrm{Lip}\,\varphi$, a_K/r, d'/ℓ, r/d' and the integrals $\iint \varphi_1\varphi_2 \mathbb{K}_3(x-y)_{\lambda\gamma}\mathbb{K}_3(x-y)_{\lambda'\gamma'}$ are the same for $(\varphi_a; r, \mathsf{d}', \ell, K)$ and for $(\varphi_a^{(z)}; L^z r, L^z\mathsf{d}', L^z\ell, K-z)$.

Hence each display of (D.1) at (K,ℓ,β) is the same display at $(K-z, L^z\ell, \beta)$, with the same tolerance, both members being multiplied by L^{-2z}. The identity $\mathcal{O}^T(\mathfrak{s})(U) = L^z\mathcal{O}'^T(\mathfrak{s}^{(z)})(U^{(z)})$ holds at every configuration U of $\mathbb{L}_K$ as well, the primes now marking the fields of $\mathbb{L}_{K-z}$; in particular $\mathcal{O}(f)(U) = L^z\mathcal{O}'(f^{(z)})(U^{(z)})$ with $f^{(z)} = f(L^{-z}\cdot)$. So for every law ν on the configurations of $\mathbb{L}_K$ and its image $\nu^{(z)}$ under the dilation, $S_n^T[\nu](f_1,\dots,f_n) = L^{nz}S_n^T[\nu^{(z)}](f_1^{(z)},\dots,f_n^{(z)})$ for bounded real functions f_a with compact supports, and the joint cumulants of the fields $\mathcal{O}^T(\mathfrak{s}_a)$ of mixed sources scale in the same way; and $\nu \mapsto \nu^{(z)}$ is a bijection of $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ onto $\mathcal{G}^{\mathrm{per}}_{K-z,\beta}$.

These statements of (d) hold with every integer $0 \le z' < K$ in the place of z.

■

Proof. (a), (b) are arithmetic of the inverse couplings. Put $G = g^{-2} + \bar{B}$ and $X_{g'} = L(g'^{-2} + B_\sharp)$ for a coupling g'. One step of the run is $x_{j-1} = L(x_j + b_j)$ with $|b_j| \le B_\sharp$ (the flow bound in Section G.2); as $\bar{B} = B_\sharp L/(L-1)$ sums the geometric series, z steps give $L^z(x_K - \bar{B}) + \bar{B} \le x_{K-z} \le L^z(x_K + \bar{B}) - \bar{B}$, and with $g^{-2} < x_K \le X_g$ and $X_g + \bar{B} = LG$:

$$L^z(g^{-2} - \bar{B}) + \bar{B} < x_{K-z} \le L^{z+1}G - \bar{B}.$$

(a) $g_2'^{-2} = L^{z-1}G - \bar{B} + 2B_\sharp/L \ge L^{z-1}G - \bar{B} \ge x_{\mathrm{N}}$ by the choice of z, and $g_1'^{-2} - g_2'^{-2} = (L-1)L^{z-1}G - 2B_\sharp/L > 0$; both read g and the constants alone. (b) $X_{g_1'} = L^{z+1}G - \bar{B}$ is the upper end above, and $X_{g_2'} = g_1'^{-2} + 2B_\sharp$; so the half-open intervals $I_\iota = (g_\iota'^{-2} + 2B_\sharp, X_{g_\iota'}]$, $\iota = 1, 2$, abut, are disjoint, and $I_2 \cup I_1 = (g_2'^{-2} + 2B_\sharp, X_{g_1'}]$. For the lower end, $g_2'^{-2} + 2B_\sharp \le L^{z-1}G + 2\bar{B}$ and

$$\big[L^z(g^{-2} - \bar{B}) + \bar{B}\big] - \big[L^{z-1}G + 2\bar{B}\big] = L^{z-1}\big[(L-1)g^{-2} - (L+1)\bar{B}\big] - \bar{B} \ge (L^{z-1} - 1)\bar{B} \ge 0,$$

since $\bar{B} \le \frac{13}{24}g^{-2}$ at $g \le \gamma$ (Lemma G.3 gives this bound) gives $(L-1)g^{-2} \ge \frac{24}{13}(L-1)\bar{B} \ge (L+2)\bar{B}$, as $11L \ge 50$. So x_{K-z} lies in exactly one I_ι. There $x_{K-z} \le X_{g_\iota'}$ and $x_{K-z-1} = L(x_{K-z} + b_{K-z}) \ge L(x_{K-z} - B_\sharp) > L(g_\iota'^{-2} + B_\sharp) = X_{g_\iota'}$, and the run decreases: $K - z$ is the first index at which the run that starts at β is at most $X_{g_\iota'}$, which is the first passage at the coupling $g_\iota' \le \gamma_{\mathrm{N}} \le \gamma$. The run of $(K - z, \beta)$ is the same sequence cut at $K - z$, and its label is $a_{K-z}\beta = L^z\mathsf{b}$.

The margin $2B_\sharp$ in the lower ends of the I_ι is what gives $x_{K-z-1} > X_{g_\iota'}$, the second half of the first passage. (c) Put $G = g^{-2} + \bar{B}$. Then $g_1'^{-2} + \bar{B} = L^z G$ and $g_2'^{-2} + \bar{B} \le L^z G$. The radius-scaling inequality YMM1:(1534), applied to $X = LG$ and $X' = L(g_\iota'^{-2} + \bar{B})$, gives $R(X') \le L^z R(X)$. The admissibility formula YMM1:(1528) therefore holds with $m + z$ at g_ι' whenever it holds with m at g; its fixed C_{s} threshold is also preserved. Moreover $C_W^{g_\iota'}(s - z) \le C_W^g(s)$ for $s \ge z$, directly from the displayed definition of C_W. Thus a witness at depth $s(t)$ transfers to depth $s(t) - z$. If $s(t) < z$, then $L^{s(t)}t \ge C_W^g(s(t)) \ge 1$, whence $L^z t > 1$. (d) is the dilation; $\mathsf{b}' = L^z\mathsf{b}$, so $\mathsf{b}^{-2} = L^{2z}\mathsf{b}'^{-2}$, and $\mathbb{K}_3(L^z u) = L^{-3z}\mathbb{K}_3(u)$ makes the integrals invariant. The identity of the fields reads of the configuration only $a_{L^z p}(U^{(z)}) = a_p(U)$ and $q_{L^z b}(U^{(z)}) = q_b(U)$, and of the lattice only $x(L^z p) = L^z x(p)$, $x_{L^z b} = L^z x_b$ and $a_{K-z} = L^z a_K$; so it holds at every configuration of $\mathbb{L}_K$, and the joint cumulants under a law are multilinear in the fields.

The dilation maps the bonds, the plaquettes and the finite sets of bonds of $\mathbb{L}_K$ onto those of $\mathbb{L}_{K-z}$. The Gibbs kernel of a finite set of bonds has the exponent $-\beta\sum_p a_p$ over the plaquettes that contain a bond of the set, which reads β and the incidences of the bonds and the plaquettes alone; so the image of a Gibbs state at (a_K, β) satisfies the equations of the kernels at (a_{K-z}, β), and invariance under a subgroup of finite index of $a_K\mathbb{Z}^3$ becomes invariance under its image under $x \mapsto L^z x$, a subgroup of finite index of $a_{K-z}\mathbb{Z}^3$. The inverse dilation carries the periodic Gibbs states at $(K-z, \beta)$ back in the same way, so $\nu \mapsto \nu^{(z)}$ is a bijection of $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ onto $\mathcal{G}^{\mathrm{per}}_{K-z,\beta}$ (equation YMM1:(1819) and the definition of periodic states following it).

The same arguments hold at every integer $0 \le z' < K$. □

Lemma 7.32 (Bond sources)**.** Let $0 < g \le \gamma_{\mathrm{N}}$, (K, β) a first-passage datum at g with $K \ge 2$, $\ell \in \mathfrak{L}(g)$, and let $\mathfrak{s} = (w, \mathsf{w})$ be a real mixed source whose barycentres $x(p)$, $w(p) \ne 0$, and midpoints x_b, $\mathsf{w}(b) \ne 0$, lie in a ball of a radius $\rho \ge a_K$. Put $\mathsf{m}_j = 12M^3\alpha_0^2 L^{K-j}|\mathfrak{s}|_\infty$ and $\mathsf{u} = \mathsf{b}^{-1}|\mathfrak{s}|_\infty$, let ς_j be as in Lemma 7.6(e) at the width ρ, and let

$$\mathsf{W}_{\mathfrak{s}}(p, q) = w(p)\delta_{pq} - \sum_b \mathsf{w}(b)\big[u_{b,\lambda_b}(p)u_{b,\lambda_b'}(q) + u_{b,\lambda_b'}(p)u_{b,\lambda_b}(q)\big],$$

a symmetric matrix that joins two plaquettes only through a bond of the support, with the coefficients $u_{b,\lambda}(p)$ of the paragraph on the fields. There are numbers C formed from the constants such that:

(1) the weight member of the source $L^{K-j}\mathfrak{s}$ at the level j is linear in $\mathfrak{s}$, vanishes on the domains that hold no corner of a plaquette p with $w(p)\neq 0$ and no site of a bond b with $\mathsf{w}(b)\neq 0$, and its norm in $\|\cdot\|_{j,\kappa}$ is at most $C\varsigma_j\mathsf{m}_j$;
(2) at the first level, $\|E_{\mathfrak{s}}^{(1)}\|_{1,\lambda_{\mathrm{out}}}\le C\theta^{[0]}\mathsf{m}_0$;
(3) for $1\le n\le K$, $A\in\mathsf{Cc}_n(r_n)$, $\tilde U=e^{i\eta_n A}$ and $F=\mathsf{ang}^{[n]}(A)$:

$$|\mathcal{O}^T(\mathfrak{s})(\tilde U)-\frac{1}{2a_K}\sum_{p,q}\mathsf{W}_{\mathfrak{s}}(p,q)\langle F_p,F_q\rangle|\le C\mathfrak{b}_n^2\delta_n\hat\rho_n^3\mathsf{u},$$

and $\eta_n^4\sum_{p,q}|\mathsf{W}_{\mathfrak{s}}(p,q)|/(a_Kx_n)\le C\hat\rho_n^3\mathsf{u}$;
(4) Lemma 7.14(c) and Proposition 7.16 hold with the matrices $\mathsf{W}_{\mathfrak{s}_a}$ in the place of the diagonal matrices w_a in $R_{i;\beta}$, $q_{i;\beta}$ and $g_{i;\beta}$, for two mixed sources in the frame of (6), the tower identity of (6) standing in Step 1 of the proof of Proposition 7.16;
(5) the weighted progression and the representation of the torus expectations through the never-large histories, which name no source, are formed for mixed sources at $g\le\gamma_{\mathrm N}$ on every side $\ell\in\mathfrak{L}(g)$, with the weight member of (1) in the source slot of the bare arrays; the lemma on the tower identity at several sources (it precedes Proposition 7.16), for clusters in the frame of (6), the representation of Lemma 7.20 and the almost everywhere bound of Lemma 7.21 on the remainders hold for mixed sources, the moments of α^{-1} being those of Lemma 7.20(e) on that side;
(6) *the frame and the tower identity.* The hull of a mixed source $\mathfrak{s}=(w,\mathsf{w})$ is the set of the plaquettes p with $w(p)\neq 0$ and of the four plaquettes through each bond b with $\mathsf{w}(b)\neq 0$. For $2\le k<K$, two mixed sources, neither 0, are in the frame at k, that is they satisfy the four conditions (Jt.1)–(Jt.3) and (Jt.6) of the frame at k of Lemma 7.5(a), read with the hulls in the place of the supports and with the members of (1) in the slot, if each hull has its barycentres in a closed ball of a radius $\bar{\mathsf{d}}\ge a_K$ with $\bar{\mathsf{d}}/a_{K-k}\ge M$ and the corners of the plaquettes of the two hulls are at least $3M$ level-k spacings apart in the sup distance; this holds at $k=\mathsf{k}(\mathsf{d})$ for hulls in balls of radius $\le\mathsf{d}$ at a distance $\ge\mathsf{d}$, $0<\mathsf{d}\le e^{-2\sqrt3}$, $s(\mathsf{d})\le K$, as in Lemma 7.5(b). In the frame, for $k\le i<K$, $A'\in\mathsf{Cc}_{i+1}(r_{i+1})$, $\tilde U=e^{i\eta_{i+1}A'}$ and λ near 0,

$$\exp D_{i+1}^{\lambda}(\tilde U)=\int\exp D_i^{\lambda}(e^{i\eta_iA^{\mathrm{lw}}(B)})\,d\nu_{i,A'}(B),$$

with the measure $\nu_{i,A'}$ of the step and the lowering map; and the one-source Lemma 7.10 holds for each source $\mathfrak{s}$ of such a pair, with $\frac{1}{2a_K}\sum_{p,q}\mathsf{W}_{\mathfrak{s}}(p,q)\langle F_p,F_q\rangle$ in the place of $q_{n;a}(F)$, its frame read with the hulls and its count (P1) replaced by the second bound of (3).

■

Proof. (1) $\mathcal{O}^T(\mathfrak{s})=a_K^{-1}\sum_p w(p)a_p-a_K^{-1}\sum_b\mathsf{w}(b)q_b$, and q_b is a gauge invariant function of the variables of the four plaquettes through b; so the source is a local term of the bare level, linear in $\mathfrak{s}$, which lives at the sites of its support. On the cores the plaquette variables are within $C\alpha_0\eta_j^2$ of $\mathbf{1}$, so that $|q_b|\le|u_{b,\lambda_b}||u_{b,\lambda_b'}|\le C\alpha_0^2\eta_j^4$ there, as $|a_p|<\frac12\alpha_0^2\eta_j^4$; at most $81(\rho/a_K)^3$ bonds have their midpoints in a ball of the radius $\rho\ge a_K$; with $|\mathfrak{s}|_\infty=|w|_\infty+8|\mathsf{w}|_\infty$ the count of Lemma 7.6(e) gives the bound. (2) The one-step theorem at the height 0, with this member in the fourth place, and Schwarz's lemma, as in Lemma 7.6(e). (3) On the chain class the angle of a plaquette variable of $\tilde U$ is $\pm F_p$ up to $C\eta_n^2r_n^2$, and $\mathrm w(e^{i\theta})=\theta+O(|\theta|^3)$; so $u_{b,\lambda}=\sum_p u_{b,\lambda}(p)F_p$ up to $C\eta_n^2r_n^2$, and, as $|F_p|\le2\eta_n^2r_n$, $|q_b-\langle\sum_p u_{b,\lambda_b}(p)F_p,\sum_q u_{b,\lambda_b'}(q)F_q\rangle|\le C\eta_n^4r_n^3$, the bound that the expansion of a_p on the chain class has.

Summed against w, this gives the bond part of $\frac{1}{2a_K}\langle F,\mathsf{W}_{\mathfrak{s}}F\rangle$ with the error $Ca_K^{-1}(\rho/a_K)^3|\mathsf{w}|_\infty\eta_n^4r_n^3$; with the plaquette part as in the proof of Lemma 7.10, $a_{K-n}x_n\ge\frac45\mathsf{b}$ and $x_nr_n^2\le C\mathfrak{b}_n^2$, this is the first bound. Each $u_{b,\lambda}$ has two coefficients of modulus $\frac12$, so $\sum_{p,q}|\mathsf{W}_{\mathfrak{s}}(p,q)|\le\sum_p|w(p)|+2\sum_b|\mathsf{w}(b)|\le$

$81(\rho/a_K)^3|\mathfrak{s}|_\infty$, and $\eta_n^4 a_K^{-4} = a_{K-n}^{-4}$ gives the second. (4) In the proof of Lemma 7.14(c) the sources enter only through $R_i^\lambda = \mathsf{W}_\lambda(1-\mathcal{S}_i\mathsf{W}_\lambda)^{-1}$, $\mathsf{W}_\lambda = \sum_a \lambda_a \mathsf{W}_{\mathfrak{s}_a}$, which is symmetric as W_λ and $\mathcal{S}_i$ are, and through the Gaussian integral of a quadratic form with a symmetric matrix; the identity $1-\mathfrak{s}R_i^\lambda = (1-\mathcal{S}_{i+1}\mathsf{W}_\lambda)(1-\mathcal{S}_i\mathsf{W}_\lambda)^{-1}$ does not use that W_λ is diagonal.

The proof of Proposition 7.16 uses the sources only through the tower identity of its Step 1, which (6) gives for two mixed sources in the frame, through (I1)–(I3), through the sums $\sum_{p,q}|R_{i;\beta}(p,q)|$, which the second bound of (3) controls as (P1) does for plaquette weights, and through the lowered angles at the plaquettes of the hulls. (5) Propositions B.8 and B.15, together with (314), give the weighted progression and the history representation for sources on the bare plaquettes, on every side of $\mathfrak{L}(g)$ with $g^{-2} \geq x_{\mathrm{J}}$ (Theorem YMM1:D). For mixed sources the same construction is made with the weight member of (1) in the source slot of the bare arrays; the other data of the progression name no source.

The proofs among the construction results read a source only through that member, and of the member they read these properties: the entry of the objects into the settings of one step, for any number of sources, $K \geq 2$ and every side, reads that it is a local term of the bare level with the bound of (1); the never-large histories and the measures of the mixture are formed with no source; the representation reads that $\mathcal{O}^T(\mathfrak{s})$ is a bounded gauge invariant function, linear in $\mathfrak{s}$ and 0 at $\mathbf{1}$, whose member is that of (1), so that the quotient at a level t of $e^{\mathcal{O}^T(\mathfrak{s}_\lambda)}$ is $\exp D_t^\lambda$; and the tower identity reads the member in the slot of the step map, which takes any member there with the bound of (1).

By (1) a mixed source has these properties. The proofs of the lemma on the tower identity at several sources, which precedes Proposition 7.16, and of Lemma 7.20 use the sources only through the progression and the tower identity for a pair, which (6) gives for mixed sources; the almost everywhere bound of Lemma 7.21 uses them only through (1), (2), the support rule of Lemma 7.6(d) and the sizes of Lemma 7.9(f), which hold for mixed sources by (1)–(3) with the hulls in the place of the supports; on a side ℓ the moments of α^{-1} are bounded by Lemma 7.20(e). (6) The frame at k is formed by the four conditions (Jt.1)–(Jt.3) and (Jt.6) of the setting of the pair functional among the construction results, read with the hulls in the place of the supports: the proof of Lemma 7.5(a), using Definition 7.4, reads of the two sources only the four geometric properties listed there, now of the hulls, which hold all the plaquettes that the members of the sources read, and the members in the slot.

The tower identity for a pair is that among the construction results, read with the member of (1) in the slot: its proof forms the measure $\nu_{i,A'}$ and the lowering map with no source and reads the sources only through the relative exponents. Hulls at a distance $\geq \mathsf{d}$ have corners at least $(\mathsf{d}-\sqrt{2}a_K)/\sqrt{3}$ apart in the sup distance, which is at least $3M$ level-$\mathsf{k}(\mathsf{d})$ spacings by the working level, as in the proof of Lemma 7.5(b); a ball of radius d has $\mathsf{d}/a_{K-\mathsf{k}(\mathsf{d})} \geq 4M$. In Lemma 7.10 the member of $\mathfrak{s}$ is expanded on the chain class by the first bound of (3), and the families by the count of its proof with the second bound of (3). □

Lemma 7.33 (Lattice sums at two balls on every torus)**.** On every torus T_ℓ with the lattice $a_K\mathbb{Z}^3$, with the least lifts of the differences, let $4a_K \leq r$, $16r \leq \mathsf{d}'$, $8\mathsf{d}' \leq \ell$, $x_1, x_2 \in T_\ell$ with $|x_1 - x_2| = \mathsf{d}'$, $\vartheta \in (0,1]$, and let φ_1, φ_2 be real Lipschitz functions with $\operatorname{supp}\varphi_a \subset \mathbb{B}(x_a, r)$ and $\operatorname{Lip}\varphi_a \leq \|\varphi_a\|_\infty/\vartheta r$. Put $\mathsf{e}_{\mathrm{PS}} = [a_K/\vartheta r + (\mathsf{d}'/\ell)^3](r/\mathsf{d}')^6\|\varphi_1\|_\infty\|\varphi_2\|_\infty$.

(a) For all λ, μ: $\big|\sum_{\lambda(p)=\lambda,\,\lambda(q)=\mu}\varphi_1(x(p))\varphi_2(x(q))\,C_K^{\mathrm{free}}(p,q)^2 - \mathcal{K}_{\lambda\mu}(\varphi_1,\varphi_2)\big| \leq C_{\mathrm{PS}}\,\mathsf{e}_{\mathrm{PS}}$.

(b) Let $\{\lambda, \lambda', \mu\} = \{1,2,3\}$, γ a direction, $\mathsf{w}(b) = \varphi_1(x_b)\mathbf{1}_{\{\mu_b=\mu\}}$, $w_2(q) = \varphi_2(x(q))\mathbf{1}_{\{\lambda(q)=\gamma\}}$, and $C_\alpha(b,q) = \sum_p u_{b,\alpha}(p)C_K^{\mathrm{free}}(p,q)$ for a direction $\alpha \neq \mu$. Then

$$\Big|-\sum_{b,q}\mathsf{w}(b)w_2(q)\,C_\lambda(b,q)C_{\lambda'}(b,q) - \iint \varphi_1(x)\varphi_2(y)\,\mathbb{K}_3(x-y)_{\lambda\gamma}\mathbb{K}_3(x-y)_{\lambda'\gamma}\,dx\,dy\Big| \leq C_{\mathrm{PS}}^{\mathrm{od}}\,\mathsf{e}_{\mathrm{PS}}.$$

■

Proof. Points of the two balls are at least $\mathsf{d}'-2r\ge\frac{7}{8}\mathsf{d}'$ and at most $\mathsf{d}'+2r\le\frac{9}{8}\mathsf{d}'<\frac{1}{4}\ell$ apart, so all the least lifts are taken in one ball of radius $\frac{1}{4}\ell$. (a) Steps A and B of the proof of Lemma 7.22 at these distances. In a square every sign ϵ_p stands twice, so equations YMM1:(2245)–(2246) replace $C_K^{\mathrm{free}}(p,q)^2$ by $a_K^6[\mathbb{K}_3(u)_{\lambda\mu}]^2$ at the cost $C_{\mathrm{lat}}(2+3C_{\mathrm{lat}})a_K^6|u|^{-3}[a_K^2|u|^{-5}+\ell^{-3}]$ for each pair, and a ball of radius $r\ge a_K$ holds at most $27(r/a_K)^3$ barycentres of one orientation; with $|u|\ge\frac{7}{8}\mathsf{d}'$ and $a_Kr\le\frac{1}{4}r^2\le\frac{1}{1024}\mathsf{d}'^2$ this costs at most $729(\frac{8}{7})^3C_{\mathrm{lat}}(2+3C_{\mathrm{lat}})\,\mathsf{e}_{\mathrm{PS}}\le1089\,C_{\mathrm{lat}}(2+3C_{\mathrm{lat}})\,\mathsf{e}_{\mathrm{PS}}$.

The Riemann sums over the cubes of side a_K about the barycentres, which for one orientation form a translate of $a_K\mathbb{Z}^3$, with $\|\mathbb{K}_3(u)\|\le\frac{1}{2\pi}|u|^{-3}$, $\|\partial\mathbb{K}_3(u)\|\le\frac{6}{4\pi}|u|^{-4}$ (Lemma 7.24(b)) and the Lipschitz bounds of the φ_a, give the rest of $C_{\mathrm{PS}}\mathsf{e}_{\mathrm{PS}}$. (b) $u_{b,\alpha}(p)\ne0$ only at the two plaquettes $p_\pm$ with the barycentres $x_b\pm\frac{1}{2}a_Ke_\alpha$, which lie in the plane of μ and α, and there $u_{b,\alpha}(p_\pm)=\frac{1}{2}\epsilon_{\alpha\mu\alpha'}\epsilon_{p_\pm}$, $\{\alpha,\mu,\alpha'\}=\{1,2,3\}$. By equation YMM1:(2245), $C_\lambda(b,q)$ is $\epsilon_{\lambda\mu\lambda'}\epsilon_qa_K^3$ times the mean of $\mathbb{K}_3(\cdot)_{\lambda'\gamma}$ at the two differences $x(p_\pm)-x(q)$, and $C_{\lambda'}(b,q)$ is $\epsilon_{\lambda'\mu\lambda}\epsilon_qa_K^3$ times the like mean of $\mathbb{K}_3(\cdot)_{\lambda\gamma}$, up to the terms of the comparison.

As $\epsilon_{\lambda\mu\lambda'}\epsilon_{\lambda'\mu\lambda}=-1$ and $\epsilon_q^2=1$, $-C_\lambda(b,q)C_{\lambda'}(b,q)$ is $a_K^6\,\mathbb{K}_3(x_b-x(q))_{\lambda\gamma}\mathbb{K}_3(x_b-x(q))_{\lambda'\gamma}$ up to these terms and to the shifts by $\pm\frac{1}{2}a_Ke_\lambda$, $\pm\frac{1}{2}a_Ke_{\lambda'}$, which cost $a_K\|\partial\mathbb{K}_3\|$. The midpoints of the bonds of one direction form a translate of $a_K\mathbb{Z}^3$, as the barycentres of the plaquettes of one orientation do, and steps A and B as in (a) give $C_{\mathrm{PS}}^{\mathrm{od}}\mathsf{e}_{\mathrm{PS}}$. The numbers C_{PS} and $C_{\mathrm{PS}}^{\mathrm{od}}$ of Definition 7.1(3) are these counts. □

Proposition 7.34 (Two mixed sources on every side)**.** For $0<g\le\gamma_{\mathrm{N}}$ let $t_{\mathrm{N}}(g)\in(0,\frac{1}{2}e^{-2\sqrt{3}}]$ be the threshold, formed from the constants and g, below which the conditions of the induction at two sources with the base level equal to the start level hold at g and at every label in $(g^{-2},\bar{\mathsf{b}}]$ (the conditions of step 5 of the proof of Proposition 7.19 that its step 6 reads, with the members that $g\le\gamma_{\mathrm{N}}$ gives), and put $r_g=\frac{1}{2}\min\{r_1(\bar{\mathsf{b}}),t_{\mathrm{N}}(g)\}$. For $\ell\in\mathfrak{L}(g)$ there is a finite function $\epsilon_\sharp^{\mathrm{ev}}(g,\ell,\cdot)$ on $(0,\frac{1}{8}\ell]$, formed from the constants, g and ℓ (it is written out at the end of the proof), with $\epsilon_\sharp^{\mathrm{ev}}(g,\ell,\mathsf{d}')\le C(g,\ell)(\log\frac{1}{\mathsf{d}'})^{19\mathfrak{p}_0}\mathsf{d}'^{1/2}$ for $\mathsf{d}'\le\frac{7}{6}t_{\mathrm{N}}(g)$, such that the following holds. Let (K,β) be a first-passage datum at g, $\mathsf{b}=a_K\beta$, $x_1,x_2\in T_\ell$ with $|x_1-x_2|=\mathsf{d}'$, $0<16r\le\mathsf{d}'\le\frac{1}{8}\ell$, $s(\min\{r,r_g\})\le K$. For real mixed sources $\mathfrak{s}_a=(w_a,\mathsf{w}_a)$ with $\{x(p):w_a(p)\ne0\}\cup\{x_b:\mathsf{w}_a(b)\ne0\}\subset\mathbb{B}(x_a,r)$,

$$\Big|\langle\mathcal{O}^T(\mathfrak{s}_1);\mathcal{O}^T(\mathfrak{s}_2)\rangle_{K,\ell,\beta}-\tfrac{3}{2}\mathsf{b}^{-2}\,\mathrm{Tr}\big(\mathsf{W}_{\mathfrak{s}_1}C_K^{\mathrm{free}}\mathsf{W}_{\mathfrak{s}_2}C_K^{\mathrm{free}}\big)\Big|\le\epsilon_\sharp^{\mathrm{ev}}(g,\ell,\mathsf{d}')\Big(\frac{r}{\mathsf{d}'}\Big)^6\mathsf{b}^{-2}|\mathfrak{s}_1|_\infty|\mathfrak{s}_2|_\infty,$$

where $\mathsf{W}_{\mathfrak{s}}(p,q)=w(p)\delta_{pq}-\sum_b\mathsf{w}(b)[u_{b,\lambda_b}(p)u_{b,\lambda_b'}(q)+u_{b,\lambda_b'}(p)u_{b,\lambda_b}(q)]$ and $u_{b,\alpha}(p)$ are the coefficients of the plaquette angles in the linear part of $u_{b,\alpha}$, given in the paragraph on the fields (it is the matrix of the lemma on bond sources, which follows Lemma 7.31). Consequently both displays of (D.1) hold at $g\le\gamma_{\mathrm{N}}$, with $\epsilon_\sharp^{\mathrm{ev}}$ in place of ϵ^{cl}, for every K with $s(\min\{r,r_g\})\le K$. ■

Proof. A bond weight enters the progression through its weight member, a local term on the plaquettes of the two planes that contain the bond. Put $\rho=\min\{r,r_g\}$; the working level at ρ ($\rho\le\frac{1}{4}e^{-2\sqrt{3}}$, $s(\rho)\le K$) gives $a_K\le\rho/4M\le\frac{1}{52}\rho$. The hull of $\mathfrak{s}_a$ (clause (6) of the lemma on bond sources, which follows Lemma 7.31) has its barycentres in $\mathbb{B}(x_a,r+\frac{1}{2}a_K)$, so that for p,q in the two hulls

$$\tfrac{6}{7}\mathsf{d}'\le|x(p)-x(q)|\le\tfrac{8}{7}\mathsf{d}'=:\mathsf{d}^+,$$

all these points lying in a ball of radius $<\frac{1}{4}\ell$, where the least lifts are taken. Put $\mathsf{d}=\min\{\frac{6}{7}\mathsf{d}',t_{\mathrm{N}}(g)\}$, the floor of the distances that is read.

The case $r<r_g$. The width $r_T=r+\frac{1}{2}a_K\le\frac{105}{104}r$ has $r_T\le\mathsf{d}$, $s(r_T)\le K$, and $r_T\le\frac{1}{2}\cdot1.01\,r_1(\bar{\mathsf{b}})\le r_1(\mathsf{b})$, as r_1 does not increase and $\mathsf{b}\le\bar{\mathsf{b}}$; so the two sources are in the frame at $\mathsf{k}(\mathsf{d})$ (clause (6) of the lemma on bond sources). By the lemma on bond sources the calculus of Lemma 7.6, the sizes of Lemma 7.9(f), the one-source Lemma 7.10 and the induction at two sources (Proposition 7.16, base level equal to start level $\mathsf{k}(\mathsf{d})$, as in step 6 of the proof of Proposition 7.19) apply to the mixed

sources, with the explicit form $\frac{1}{2a_K}\langle F, \mathsf{W}_{\mathfrak{s}} F\rangle$ of a source, the orientation signs entering through $u_{b,\lambda}(p)$. Of (Γ1) these use only the members that $g \le \gamma_{\mathrm{N}}$ gives: the member $\delta(g^{-2}) \le 1/2C_{\mathrm{cu}}$ is used only for the kernel families (Proposition 7.13), which do not occur at two sources whose distance fixes the base level. The difference of the two members of the display is at most the sum of three members.

(i) *The remainder.* $S_2^T - \mathsf{J}_2 = \int \mathsf{Y}_{12}\, d\mathbb{P} + \kappa_{\mathbb{P}}(\mathsf{Y}_1, \mathsf{Y}_2)$ (Lemma 7.20(c) for mixed sources, by clause (5) of the lemma on bond sources). The two sources form one pair at the widths (r_T, d) in the sense of Lemma 7.9(f), so the proof of Lemma 7.21, with the sizes of clauses (1)–(3) of the lemma on bond sources, gives at $\mathbb{P}$-almost every ω the bounds $|\mathsf{Y}_a| \le \Lambda_T \alpha^{-6} r_T^3 |\mathfrak{s}_a|_\infty$ and $|\mathsf{Y}_{12}| \le \Lambda_T \alpha^{-6} r_T^6 \mathsf{d}^{-9/2} |\mathfrak{s}_1|_\infty |\mathfrak{s}_2|_\infty$, with a number $\Lambda_T \ge 1$ formed from the constants. With the moments of α^{-1} on the side ℓ, $\int \alpha^{-24} d\mathbb{P} \le \bar{\mathsf{M}}_\ell := 1 + 4L^{24} M^{-3} \ell^3 e^{\mathsf{B}(X_g)\ell^3} \mathsf{C}_{\mathrm{ag}}(25, \eth)$ (Lemma 7.20(e)), which grows with ℓ, this member is at most $3\Lambda_T^2 \bar{\mathsf{M}}_\ell^2 \bar{\mathsf{b}}^2 \mathsf{d}^{3/2}\, (r_T/\mathsf{d})^6 \mathsf{b}^{-2} |\mathfrak{s}_1|_\infty |\mathfrak{s}_2|_\infty$.

(ii) *The induction.* The Gaussian step of Lemma 7.14(c) with $\mathsf{W}_{\mathfrak{s}}$ in place of w gives at the top the value $g_{K;12} = \frac{3}{2} \operatorname{Tr}(\mathsf{W}_{\mathfrak{s}_1} \mathcal{S}_K \mathsf{W}_{\mathfrak{s}_2} \mathcal{S}_K)$, $\mathcal{S}_K = \sum_{\mathsf{k}(\mathsf{d}) < j \le K} \upsilon_j \mathcal{C}_{(j)}$, Wick's rule for two quadratic forms of the photon field. Proposition 7.16 and Lemma 7.9(d), as in step 6 of the proof of Proposition 7.19, bound $|\mathsf{J}_2 - g_{K;12}|$ by $\mathsf{E}_{\mathrm{J}}(g, \mathsf{d})(r_T/\mathsf{d})^6 \mathsf{b}^{-2} |\mathfrak{s}_1|_\infty |\mathfrak{s}_2|_\infty$, with a function E_{J} of (g, d) alone that is at most $C(g)(\log \frac{1}{\mathsf{d}})^{19\mathfrak{p}_0} \mathsf{d}^{1/2}$ for $\mathsf{d} \le t_{\mathrm{N}}(g)$.

(iii) *The free kernel.* For p, q in the two hulls, $\mathsf{r} = |x(p) - x(q)|_\infty \in [\mathsf{d}/\sqrt{3}, \mathsf{d}^+]$ and $t = \mathsf{r}/a_{K-\mathsf{k}(\mathsf{d})} \ge \hat{\mathsf{d}}_{\mathsf{k}(\mathsf{d})}/\sqrt{3}$, the floor of the working level, at which the condition of Lemma 7.17(b) holds by the conditions that fix $t_{\mathrm{N}}(g)$ (as condition (ii) of step 5 of the proof of Proposition 7.19). So Lemma 7.17(b) at $k = \mathsf{k}(\mathsf{d})$, multiplied by r^3, gives $|\mathcal{S}_K - \mathsf{b}^{-1} C_K^{\mathrm{free}}|(p, q) \le \mathsf{b}^{-1} a_K^3 \mathsf{r}^{-3}\, \mathsf{e}_{\mathrm{fr}}(g; \mathsf{d}, \mathsf{d}^+)$, with $\mathsf{b}^{-1} < g^2$ and

$$\mathsf{e}_{\mathrm{fr}}(g; \mathsf{d}, \mathsf{d}^+) = \tfrac{5}{4} C_{\mathrm{tp}} c_L^{(2)} \bar{B} g^2\, \mathsf{d}^+ + C_{\mathrm{tp}}^{\mathrm{bg}} (\mathsf{d}^+)^3 + 2L^3 C_{\mathrm{tp}} \sup_{t \ge \hat{\mathsf{d}}_{\mathsf{k}(\mathsf{d})}/\sqrt{3}} t^3 e^{-\delta_{\mathrm{tp}} L t}.$$

Telescoping the two kernels in $\operatorname{Tr}(\mathsf{W}_{\mathfrak{s}_1} \cdot \mathsf{W}_{\mathfrak{s}_2} \cdot)$, with Lemma 7.17(a), $|C_K^{\mathrm{free}}(p, q)| \le (1 + 3C_{\mathrm{lat}}) a_K^3 |u|^{-3}$, $\mathsf{r}^{-3} \le 3^{3/2} \mathsf{d}^{-3}$ and the second bound of clause (3) of the lemma on bond sources for $\sum_{p,q} |\mathsf{W}_{\mathfrak{s}_a}(p, q)|$, this member is at most $C\, \mathsf{e}_{\mathrm{fr}}(g; \mathsf{d}, \mathsf{d}^+)(r_T/\mathsf{d})^6 \mathsf{b}^{-2} |\mathfrak{s}_1|_\infty |\mathfrak{s}_2|_\infty$: a member polynomial in d^+, besides the far term at the floor.

The members (i) and (ii), which carry the renormalisation group, read of the distances the floor d alone; the largest distance d^+ enters the one explicit member (iii), the comparison of the sum of the slices with the free kernel, through a bound polynomial in d^+.

The case $r \ge r_g$. Then $\rho = r_g$ and $s(r_g) \le K$. Tile the lift by the half-open cubes Q of side r_g and cut $\mathfrak{s}_a = \sum_Q \mathfrak{s}_a^Q$, $\mathfrak{s}_a^Q$ the restriction of $\mathfrak{s}_a$ to the plaquettes and the bonds whose barycentres or midpoints lie in Q; $|\mathfrak{s}_a^Q|_\infty \le |\mathfrak{s}_a|_\infty$, and at most $(2r/r_g + 2)^3 \le 64(r/r_g)^3$ pieces of each source are not 0. The hull of a piece is a part of the hull of $\mathfrak{s}_a$ and has its barycentres within $\frac{\sqrt{3}}{2} r_g + \frac{1}{2} a_K \le r_g$ of the centre of its cube; so every pair of pieces, neither 0, is in the data of the first case at the widths (r_g, d), with $r_g \le \mathsf{d}$, $s(r_g) \le K$, $r_g \le r_1(\mathsf{b})$, the centres of the cubes in the place of x_1, x_2, and the same bounds $\frac{6}{7}\mathsf{d}' \le |x(p) - x(q)| \le \mathsf{d}^+$ on the hulls. Both members of the display are bilinear in $(\mathfrak{s}_1, \mathfrak{s}_2)$, as $\mathcal{O}^T$ and $\mathsf{W}_{\mathfrak{s}}$ are linear in $\mathfrak{s}$, and the sum over the pairs of pieces costs $64^2 (r/r_g)^6 (r_g/\mathsf{d})^6 = 4096 (r/\mathsf{d})^6$.

Together. $(\mathsf{d}'/\mathsf{d})^6 = (\frac{7}{6})^6 \max\{1, 6\mathsf{d}'/7t_{\mathrm{N}}(g)\}^6$ and $4096 (\frac{7}{6})^6 (\frac{105}{104})^6 \le 11060$ give the display with

$$\epsilon_\sharp^{\mathrm{ev}}(g, \ell, \mathsf{d}') = 11060 \max\Big\{1, \frac{6\mathsf{d}'}{7t_{\mathrm{N}}(g)}\Big\}^6 \Big[\mathsf{E}_{\mathrm{J}}(g, \mathsf{d}) + C\, \mathsf{e}_{\mathrm{fr}}(g; \mathsf{d}, \tfrac{8}{7}\mathsf{d}') + 3\Lambda_T^2 \bar{\mathsf{M}}_\ell^2 \bar{\mathsf{b}}^2 \mathsf{d}^{3/2}\Big], \qquad \mathsf{d} = \min\{\tfrac{6}{7}\mathsf{d}', t_{\mathrm{N}}(g)\},$$

a finite function on $(0, \frac{1}{8}\ell]$ formed from the constants, g and ℓ. For $\mathsf{d}' \le \frac{7}{6} t_{\mathrm{N}}(g)$ one has $\mathsf{d} = \frac{6}{7}\mathsf{d}'$ and $\mathsf{d}^+ = \frac{4}{3}\mathsf{d}$, and each of the three members is at most $C(g, \ell)(\log \frac{1}{\mathsf{d}'})^{19\mathfrak{p}_0} \mathsf{d}'^{1/2}$: the first by step 6 of

the proof of Proposition 7.19, the second as the member br of its step 4 under the conditions of its step 5, the third as $\mathsf{d}^{3/2} \le \mathsf{d}^{1/2}$.

The plane and the bond forms. For Lipschitz bumps the lattice form is turned into the integrals of (D.1) by Lemma 7.33, whose data hold: $4a_K \le r$, $16r \le \mathsf{d}'$, $8\mathsf{d}' \le \ell$. For the plane fields take $\mathfrak{s}_a = (\mathbf{1}_{\{\lambda(\cdot)=\lambda_a\}}\varphi_a \circ x, 0)$, $\lambda_1 = \lambda$, $\lambda_2 = \mu$, so that $|\mathfrak{s}_a|_\infty \le \|\varphi_a\|_\infty$ and the main term is $\frac{3}{2}\mathsf{b}^{-2}\sum_{p,q} w_1(p)w_2(q)C_K^{\mathrm{free}}(p,q)^2$; Lemma 7.33(a) times $\frac{3}{2}\mathsf{b}^{-2}$ gives the second display of (D.1). For the bond form take $\mathfrak{s}_1 = (0, \mathsf{w})$, $\mathsf{w}(b) = \varphi_1(x_b)\mathbf{1}_{\{\mu_b=\mu\}}$, so that $Y[\mathsf{w}] = \mathcal{O}^{\mathrm{od}}_{\lambda\lambda'}(\varphi_1)$ and $|\mathfrak{s}_1|_\infty \le 8\|\varphi_1\|_\infty$, and $\mathfrak{s}_2 = (\mathbf{1}_{\{\lambda(\cdot)=\gamma\}}\varphi_2 \circ x, 0)$.

For the symmetric matrix $C = C_K^{\mathrm{free}}$, $\mathrm{Tr}(\mathsf{W}_{\mathfrak{s}_1}C\mathsf{W}_{\mathfrak{s}_2}C) = -2\sum_{b,q}\mathsf{w}(b)w_2(q)C_\lambda(b,q)C_{\lambda'}(b,q)$ with $C_\alpha(b,q) = \sum_p u_{b,\alpha}(p)C(p,q)$, so the main term is $-3\mathsf{b}^{-2}\sum_{b,q}\mathsf{w}(b)w_2(q)C_\lambda(b,q)C_{\lambda'}(b,q)$, and Lemma 7.33(b) times $3\mathsf{b}^{-2}$ gives the first display, with $8\epsilon_\sharp^{\mathrm{ev}}$ in the place of $8\epsilon^{\mathrm{cl}}$. □

Pair minus tensor field.

Lemma 7.35 (A regular gauge on a cube; the curvature is Hölder continuous)**.** Fix $\beta_{\mathrm{H}} \in (0,1)$. There are numbers $\epsilon_{\mathrm{G}} \in (0,1]$ and $C_{\mathrm{G}}^\sharp, C_{\mathrm{H}} \ge 1$, formed from the constants and β_{H}, such that the following holds for $1 \le n \le K$; lengths are in level-n units, $\xi = \eta_n$, and $Q_s(x_0)$ is the set of the bare sites at the sup distance at most s from a bare site x_0.

(a) Let $12a_{K-n} \le \ell$ and let A be a real $\mathfrak{su}(2)$-valued 1-form on the bonds of $Q_2(x_0)$ such that $|A|$, $|\nabla^\xi A|$ and the current of $e^{i\xi A}$ are at most $\mathsf{r}_\circ \le \frac{1}{120}$ there. Then the linear angles $F_p = \xi(\mathrm{d}A)(p)$ satisfy $|F_p| \le 2\xi^2\mathsf{r}_\circ$ and $|F_{p_{\mu\nu}(x)} - F_{p_{\mu\nu}(x')}| \le C_{\mathrm{H}}\,\xi^2\mathsf{r}_\circ|x-x'|^{\beta_{\mathrm{H}}}$ for the plaquettes $p_{\mu\nu}(x)$, $p_{\mu\nu}(x')$ of one orientation with $x, x' \in Q_{1/2}(x_0)$.

(b) Let $W \in \mathcal{V}_n^\chi$, $U = U_n(W)$, and let $\varrho \ge 1$ with $(8\varrho+2)a_{K-n} < \ell$ and $(4\varrho)^2(1+4\varrho)\,4B_3\varepsilon_n \le \epsilon_{\mathrm{G}}$. Then there are $\mathsf{g}\colon Q_{4\varrho}(x_0) \to SU(2)$ and a real 1-form A on the bonds of $Q_{2\varrho}(x_0)$ with $\mathsf{g}(b_-)U(b)\mathsf{g}(b_+)^{-1} = e^{i\xi A(b)}$ there and, on $Q_\varrho(x_0)$, $|A| \le 80C_{\mathrm{G}}^\sharp B_3\varrho^2\varepsilon_n$ and $|\nabla^\xi A| \le 80C_{\mathrm{G}}^\sharp B_3\varrho\,\varepsilon_n$; the plaquette variables and the current of $e^{i\xi A}$ are those of U conjugated by g, and the current has a modulus $< 2B_3\varepsilon_n$.

None of these numbers depends on n, K, ℓ, the spacing, x_0 or the configuration. ■

Proof. (a) The 2-form $f_{\mu\nu} = \xi^{-2}F_{p_{\mu\nu}} = \nabla^\xi_\mu A_\nu - \nabla^\xi_\nu A_\mu$ is antisymmetric and closed, $\mathrm{d}f = 0$, and its lattice codifferential differs from the current of $e^{i\xi A}$ by at most $40|A||\nabla^\xi A| + 32|A|^3$ in the sup bounds, by the expansion of the lattice current; so $|f| \le 2\mathsf{r}_\circ$ and $|\mathrm{d}^*f| \le 2\mathsf{r}_\circ$. For an antisymmetric lattice 2-form f on a cube $Q_R(x_0)$, $R \ge 8\xi$, with $|f| \le m_0$ and $|\mathrm{d}f|, |\mathrm{d}^*f| \le m_1$, the lattice Hodge identity $\Delta(\chi f) = \mathrm{d}^*\mathrm{d}(\chi f) + \mathrm{d}\mathrm{d}^*(\chi f)$, for a cut-off χ equal to 1 on $Q_{R/2}(x_0)$ and written as $\chi f = G_\xi * \Delta(\chi f)$ with the lattice Green function G_ξ of $\xi\mathbb{Z}^3$, and the bounds $|\nabla G_\xi(z)| \le C(|z|+\xi)^{-2}$, $|\nabla^2 G_\xi(z)| \le C(|z|+\xi)^{-3}$, which are uniform in ξ, give $|f(x) - f(x')| \le C(\beta_{\mathrm{H}})(m_0 + Rm_1)(|x-x'|/R)^{\beta_{\mathrm{H}}}$ for $x, x' \in Q_{R/2}(x_0)$. At $R = 1$, $m_0 = m_1 = 2\mathsf{r}_\circ$ this is (a). (b) Put $\alpha = 4B_3\varepsilon_n$ and lift the sites of $Q_{4\varrho}(x_0)$ to the box $\Omega = x_0 + \xi\{-M, \dots, M\}^3$, $M = \lfloor 4\varrho/\xi \rfloor$, of side $s = (2M+1)\xi \le 9\varrho$. The room hypothesis makes the lift injective. By Lemma 7.20(d), U is regular of level n at radius $\alpha_0 = 2B_3\varepsilon_n$. The current-to-matrix-divergence calculation in Lemma YMM1:9.4 gives $|D_U^{\mathsf{T}}\partial U| \le \xi^{-1}(\alpha_0\xi^2)^2 + \xi^2\alpha_0 < \alpha\xi^2$ at every full box bond; its plaquette bound is also $< \alpha\xi^2$. Choose $\epsilon_{\mathrm{G}} \le \min\{1, c_\square\}$ and $C_{\mathrm{G}}^\sharp \ge \max\{1, B_\square\}$, where $c_\square, B_\square$ are the box-gauge constants in the proof of Theorem YMM1:F. The stated smallness implies $s\alpha \le c_\square$.

That box estimate gives a real gauge and potential on Ω with $|A| < B_\square s\alpha \le 36B_\square B_3\varrho\varepsilon_n$, and the same bound for first differences at base sites of depth at least $3/2$. Every positive bond with an endpoint in Q_ϱ has base depth at least $3\varrho - 2\xi > 3/2$. Restricting the potential to $Q_{2\varrho}$ gives both displayed bounds, since $\varrho \ge 1$. Plaquette and current moduli are preserved by the real gauge. □

In Lemmas 7.36–7.41 the data are those of Theorem AB; one progression holds the sources w_1, w_2, w_T, w_3, so that by multilinearity the objects of the two lists (w_1, w_2, w_3) and (w_T, w_3) are

obtained from it. We write $\Delta_n = \mathsf{c}G_{n;12} - G_{n;T}$ and $\Gamma_n = \mathsf{c}G_{n;123} - G_{n;T3}$, functions of the configurations of the level n whose pairs lie in the cores, and $\mathrm{nat}_n^{\mathcal{W}} = \varepsilon_n^2 a_{K-n}^{-4}$.

Lemma 7.36 (Pair minus tensor field on all small-field backgrounds)**.** Let $r \le r_\alpha(g,\mathsf{b})$; let n_1 and n_0 be the least levels with $a_{K-n_1} \ge (\frac{r}{2})^{3/4}$ and $a_{K-n_0} \ge r^{1/2}$, $N_0 = n_0 + m_1$, where $m_1 \ge 1$ is the least integer with $L^{m_1/2} \ge C_7 A_0/(0.85\,\mathsf{c}_\mathfrak{h} A_1)$, $C_7 = 2B_3 + 69\cdot 1280\, C_{\mathrm{G}}^\sharp B_3$, an integer formed from the constants and β_{H} (through $C_{\mathrm{G}}^\sharp$ of the lemma on a regular gauge on a cube, which precedes this lemma), $\epsilon = r^{\beta_{\mathrm{H}}/36} + (a_K/r)^{1/9}$, and let $x_\sharp \ge e^{2\mathfrak{p}_0}$ be the least number such that every $x \ge x_\sharp$ has $17408 B_3 \varepsilon(x) \le \epsilon_{\mathrm{G}}$ and $1280 C_{\mathrm{G}}^\sharp B_3 \varepsilon(x) \le \frac{1}{100}$, with the numbers ϵ_{G}, $C_{\mathrm{G}}^\sharp$ of the lemma on a regular gauge on a cube.

Let $L^{N_0-n_1} \ge 2M$, and let $\epsilon_i^{\mathrm{e}} = C_\omega[1.45\gamma_{i-1} + \frac{1}{2}\mathsf{c}^\flat\theta^{[0]}] \le 1$ for $\mathsf{k}(\frac{r}{2}) \le i < n_1$; this number bounds the single-source arrays of the near pair at the level i, $\mathfrak{n}[\dot{\mathfrak{e}}_{a,i}] \le 2\epsilon_i^{\mathrm{e}}\varsigma_i \mathsf{m}_{i,a}$ ($a = 1,2$, ς_i formed at the width $\frac{r}{8}$), as in Lemma 7.9(a). For $N_0 \le n^\sharp < K$ with $x_{n^\sharp} \ge x_\sharp$ there are real numbers c_n, $N_0 \le n \le n^\sharp$, such that for m_n-almost every $W \in \mathcal{V}_n^\chi$

$$|\Delta_n(U_n(W)) - \mathsf{c}_n| \le \varepsilon^{\mathcal{W}}\,\mathrm{nat}_n^{\mathcal{W}}, \qquad |\mathsf{c}_n - \mathsf{c}_{n'}| \le 2.01\,\tilde{\varepsilon}\,\mathrm{nat}_n^{\mathcal{W}} \quad (n \le n' \le n^\sharp),$$

with $\varepsilon^{\mathcal{W}} \le \tilde{\varepsilon} \le C(g,\mathsf{b})\,\epsilon$. ∎

Proof. (i) We use the regular-field estimate of Lemma B.22 and the insertion identity of Lemma B.23 on the small-field backgrounds. The first is the evaluation of a local term at a configuration that is regular of a level, with the factor ε_n^2: for $1 \le i \le n \le K$, $W \in \mathcal{V}_n^\chi$ and a pointed family f of level i that vanishes unless one of N given cubes of π_i is a cube of the domain, and on the domains with $d_i(X) < D$,

$$\sum_{(X,z)} |\mathsf{f}(X, U_n(W), z) - \mathsf{f}(X, \mathbf{1}, z)| \le C\,\mathsf{N}\,\|\mathsf{f}\|_{i,\lambda_{\mathrm{out}}}\,\varepsilon_n^2\,L^{-4(n-i)}e^{-D/2}.$$

It is (230) at the radius $\varepsilon = 2B_3\varepsilon_n$ at which $U_n(W)$ is regular of the level n (Lemma 7.20(d), $4M\varepsilon \le c_{\mathrm{A}}\alpha_0$), which gives for one domain of size d the factor $(\varepsilon/\alpha_0)^2 L^{-4(n-i)} M^2(1+d)^2$, together with the tails of the proof of Lemma 7.8(a): the domains beyond the depth $d_* = \min\{c_{\mathrm{A}}\alpha_0 L^{2(n-i)}/M\varepsilon, (L^{m+K-i} - 4)/2M\} - 1$ have $e^{-[d_*]_+/2} \le C\varepsilon_n^2 L^{-4(n-i)}$, by $e^{-s/2} \le 8s^{-2}$, by $L^{m+K-n} \ge 13 M y_n$ on the sides $\ell = 2L^m$ of $\mathfrak{L}(g)$ (from $L^m \ge L M y_K$ and Lemma 7.3(a)) and by $x_n^{-1} \le \varepsilon_n^2/A_0^2$; no ceiling beyond those of the data is read. (Lemma 7.8(b) is the same count without the factor ε_n^2.) The second is the averaging identity of one step: the quotient Qt_{j+1} of one step, a positive normalised mean that takes bounded Borel functions of the block fields of the level j to functions of those of the level $j+1$, takes the action $S[\mathfrak{g}](U_j(\cdot))$ of a bare array $\mathfrak{g}$ of the level j to $(S[\mathfrak{g}] + \mathsf{Sum}[\mathsf{DSt}^{[j]}(\mathfrak{f}_{0,j})[\mathfrak{g}]])(U_{j+1}(\cdot))$, m_{j+1}-almost everywhere; so the seminorm $\inf_c \operatorname{ess\,sup}_{\mathsf{m}_n} |\Phi(U_n(W)) - c|$ of such actions does not grow from one level to the next. (ii) *The split.* For $n_0 \le j < K$ let $\mathfrak{x}_j$ be the bare array whose families are c times the kernel families $\mathsf{K}^{(i)}$ of the near pair at the levels $\mathsf{k}(\frac{r}{2}) < i \le n_1$ and whose slot holds minus the weight member of w_T; its action $X^{\mathrm{fz}} = S[\mathfrak{x}_j]$, the frozen part, does not depend on j.

Let $\mathfrak{r}_j$ hold all the other families of Δ of the levels $\le n_0$. Then $\Delta_n = \Delta_n(\mathbf{1}) + X_n + S_n$, where X_n adds to X^{fz} the families that the first derivatives of the steps above n_0 make from $\mathfrak{x}$ alone, and S_n is the action of $\mathfrak{r}_n$ together with the families $\mathsf{s}^{(i)}$, $n_0 < i \le n$, that the first derivatives of the steps make from $\mathfrak{r}$ and from the $\mathsf{s}^{(i')}$ of the lower levels, and with the second derivatives $\mathsf{c}\,\mathsf{B}_{i-1}(\mathfrak{f}_{\{1\},i-1}, \mathfrak{f}_{\{2\},i-1})$ of the steps (Lemma 7.7). The evaluation of (i), the lags of Lemma 7.6(c) and the sizes of Lemma 7.9 give $|S_n| \le C\varepsilon_S\,\mathrm{nat}_n^{\mathcal{W}}$ at every small-field background of the level n, with $\varepsilon_S = 2\varepsilon_{\mathfrak{r}} + C(r/a_{K-n_0})^3$ and the number $\varepsilon_{\mathfrak{r}}$ of step (i) of the proof of the lemma on the chain classes, which follows this lemma; that step uses the same split on the chain classes. (iii) The explicit parts cancel.

With $D(n) = 3n \otimes n - 1$, the pair, multiplied by c, carries the explicit form with the kernel $\mathsf{b}^{-1}C_K^{\mathrm{free}} \approx \mathsf{b}^{-1}a_K^3\mathbb{K}_3(re_\lambda) = \mathsf{b}^{-1}a_K^3(4\pi r^3)^{-1}D(e_\lambda)$, while the tensor source carries $\frac{1}{2a_K}\sum_p w_T(p)|F_p|^2$ with $\delta_{\lambda(p)\lambda} - \frac{1}{3} = \frac{1}{3}D(e_\lambda)_{\lambda(p)\lambda(p)}$; the moment condition $\sum_k \mathsf{a}_k D(n_k) = \mathsf{a}_T D(e_\lambda)$, here with one pair of direction e_λ and $\mathsf{a}_1 = \mathsf{a}_T = 1$, makes them equal. (iv) *The frozen part on the backgrounds.* Let $N_0 \le n \le n^\sharp$, $W \in \mathcal{V}_n^\chi$, $U = U_n(W)$, x_0 a bare site with $|x_0 - c|_\infty \le a_K$, and let lengths be in level-n units, $\xi = \eta_n$.

The gauge. As $x_n \ge x_\sharp$ and $34a_{K-n} < \ell$, clause (b) of the lemma on a regular gauge on a cube, which precedes this lemma, applies at $\varrho = 4$ and gives g on $Q_{16}(x_0)$ and a potential A on the bonds of $Q_8(x_0)$ with $\mathsf{g}(b_-)U(b)\mathsf{g}(b_+)^{-1} = e^{i\xi A(b)}$, and on $Q_4(x_0)$ the bounds $|A|, |\nabla^\xi A| \le C_6\varepsilon_n \le \frac{1}{100}$, $C_6 = 1280C_{\mathrm{G}}^\sharp B_3$, and a current of modulus $< 2B_3\varepsilon_n$. *The cut-off.* Let $h = \prod_\mu \chi(|x_\mu - x_{0,\mu}|)$ with $\chi = 1$ on $[0,3]$, $\chi = 0$ on $[\frac{15}{4}, \infty)$, $|\chi'| \le 2$ and $\operatorname{Lip}\chi' \le 11$; put $\hat{A} = hA$ on the bonds of $Q_4(x_0)$, $\hat{A} = 0$ on all other bonds of T_ℓ, and $\hat{U} = e^{i\xi\hat{A}}$.

Then $\hat{U}$ is the transform of U by g on every bond with an end in $Q_3(x_0)$, and the product rules for hA with the expansion of the lattice current give

$$\max\{\sup|\hat{A}|,\ \sup|\nabla^\xi\hat{A}|,\ \sup|J(\hat{U})|\} \le (2B_3 + 69\,C_6)\,\varepsilon_n = C_7\varepsilon_n \qquad \text{on all of } T_\ell.$$

The shift of the level. Seen from the level $n^\flat = n - m_1 \ge n_0$, the same configuration has the potential $\hat{A}^\flat = L^{-m_1}\hat{A}$, with $|\hat{A}^\flat| \le L^{-m_1}C_7\varepsilon_n$, differences $\le L^{-2m_1}C_7\varepsilon_n$ and current $\le L^{-3m_1}C_7\varepsilon_n$ in level-$n^\flat$ units; with $\varepsilon_n = (A_0/A_1)\delta_n$, $\delta_n \le (\frac{5}{4})^{1/2}L^{m_1/2}\delta_{n^\flat}$ (Lemma 7.3(a)) and the choice of m_1,

$$L^{-m_1}C_7\varepsilon_n \le (\tfrac{5}{4})^{1/2}\cdot 0.85\,\mathsf{c}_\mathfrak{h}\delta_{n^\flat} < \tfrac{11}{10}\mathsf{c}_\mathfrak{h}\delta_{n^\flat} \le r_{n^\flat}.$$

This is the norm clause of the chain class of radius $r_{n^\flat}$, and it is all that the steps below read of the field. *The pair.* Step (ii) of the proof of the lemma on the chain classes is read at the level $n^\flat$ with U in the place of $\tilde{U}$, with two changes. (1) The gauge $u = e^{iX}$ of Lemma 7.12 at the pair is formed for $\hat{A}^\flat$ on the bonds within two level-$n^\flat$ units of x_0, where $\hat{U}$ is the transform of U; it gives the angles F', Hölder continuous as in that step, through the estimate of the proof of clause (a) of the lemma on a regular gauge on a cube on $Q_1(x_0)$ at $m_0 = 2.08\,r_{n^\flat}$ and $m_1 = 3.7\,r_{n^\flat}$, and the plaquette term of the weight member of w_T in this gauge, as $a_p(U) = a_p(\hat{U})$ at the plaquettes of $\operatorname{supp} w_T$, which lie in $Q_{1/2}(x_0)$. (2) For the kernel families of the levels $\mathsf{k}(\frac{r}{2}) \le i < n_1$, $m = n^\flat - i - 1$: Lemma 7.12 for the real pair of the level $i+1$ that $\hat{A}^\flat$ and its current give on all of T_ℓ (the potential multiplied by L^{-m}, the current by L^{-3m}), on the box $N_{\rho'}$ about x_0, $\rho' = \min\{\mathsf{h}_i, 3L^{n-i-1} - 1\}$, with the same u, gives a real point v' of the chart with $\|v'\| \le \mathsf{h}_i L^{-2m}r_{n^\flat}(6 + 19r_{n^\flat}) \le \delta_i/2\Lambda_i$, by ($\alpha$2) at $n^\flat \ge n_0$, the pair having $|L^{-m}\hat{A}^\flat| \le L^{-m}r_{n^\flat}$ and differences and current $\le L^{-2m}r_{n^\flat}$.

A domain X of the level $i+1$ with all its sites within $\rho' - 1$ of x_0 lies in $Q_3(x_0)$, where $\hat{U}$ is the transform of U, so that $\mathsf{K}^{(i+1)}(X, U, z) = \mathsf{K}^{(i+1)}(X, P[v']|_X, z)$ by the gauge invariance and the locality of a local term; the other domains have $d_{i+1}(X) \ge 2L^{n-i-1}/M - 2$, or the depth of step 5 of the proof of Proposition 7.13 if $\rho' = \mathsf{h}_i$, and are paid by the norm (Lemma 7.8(b) at U and at $P[v']$). Steps 2–4 of the proof of Proposition 7.13 (holomorphy, the real ball, two constants), which read of the field only the real point v' and its norm, give at v' the kernel step with the angles F'. As $L^{n-i-1} \ge L^{N_0-n_1} \ge 2M$ and $\epsilon_i^{\mathrm{e}} \le 1$, the domains that leave the box cost at most $C\mathsf{b}\,r\,\mathrm{nat}_n^{\mathcal{W}}$ together.

With $r_{n^\flat}^2 a_{K-n^\flat}^{-4} \le C\,\mathrm{nat}_n^{\mathcal{W}}$ (Lemma 7.3(a), $a_{K-n^\flat} = L^{-m_1}a_{K-n}$) this bounds the frozen part: $|X^{\mathrm{fz}}(U)| \le \varepsilon_X^{\mathcal{W}}\mathrm{nat}_n^{\mathcal{W}}$, with $\varepsilon_X^{\mathcal{W}} \le C[\varepsilon_X + \mathsf{b}\,r]$ and the number ε_X of step (ii) of the proof of the lemma on the chain classes. (v) Carried upward with (i) and the lags of Lemma 7.6(c), $\|X_n\| \le [\varepsilon_X^{\mathcal{W}} + C\gamma_{N_0-1} + C\gamma_n^{8/9}(\varepsilon_X^{\mathcal{W}})^{1/9}]\mathrm{nat}_n^{\mathcal{W}}$; the exponents $\frac{8}{9}$, $\frac{1}{9}$, and $\frac{1}{2}$ below, come from interpolations between the oscillation bound and the bound of the sizes, and the choice of the levels, $\mathsf{k}(\frac{r}{2}) < n_1 < n_0$ with $a_{K-n_1} \ge (\frac{r}{2})^{3/4}$, costs the exponent $\frac{1}{4}$.

Together $\varepsilon^{\mathcal{W}} \le \tilde{\varepsilon} \le C(g,\mathsf{b})[r^{\beta_{\mathrm{H}}/36} + (a_K/r)^{1/9}]$ for $r \le r_\alpha(g,\mathsf{b})$, the levels being ordered by $(\alpha1)$–$(\alpha5)$ of Definition 7.1(5); the constants c_n of two levels differ by at most these oscillations plus the part of the steps between that the sizes of the sources at those levels bound, which is of the same order. □

Lemma 7.37 (Pair minus tensor field on the chain classes)**.** Let $r \le r_\alpha(g,\mathsf{b})$, let n_1 and n_0 be the levels of Lemma 7.36, and $\epsilon = r^{\beta_{\mathrm{H}}/36} + (a_K/r)^{1/9}$. There are numbers c'_n, $n_0 \le n \le K$, and a number $\varepsilon_\alpha \le C(g,\mathsf{b})\,\epsilon$ such that

$$\sup_{A\in\mathsf{Cc}_n(r_n)} \bigl|\Delta_n(e^{i\eta_n A}) - \mathsf{c}'_n\bigr| \le \varepsilon_\alpha\, r_n^2 a_{K-n}^{-4} \qquad (n_0 \le n \le K).$$

■

Proof. (i) *The split* is that of step (ii) of the proof of Lemma 7.36. For $n_0 \le j < K$, $\mathfrak{x}_j$ is the array whose families are c times the kernel families $\mathsf{K}^{(i)}$ of the near pair at the levels $\mathsf{k}(\frac{r}{2}) < i \le n_1$ and whose slot holds minus the weight member of w_T; its action X^{fz}, the frozen part, does not depend on j. $\mathfrak{r}_j$ holds all the other families of Δ of the levels $\le n_0$. Lemma 7.6 and the sizes of Lemma 7.9 give $\mathfrak{n}[\mathfrak{x}_j] \le C a_{K-j}^{-4}$ and $\mathfrak{n}[\mathfrak{r}_j] \le \varepsilon_{\mathfrak{r}} a_{K-j}^{-4}$, where $\varepsilon_{\mathfrak{r}}$ is a constant times $\gamma_{n_0} + s(\frac{r}{2})\theta^{[0]} + (r/a_{K-n_1})^3$ and terms exponentially small in $\hat{r}_{\mathsf{k}(r/2)}$ and in r/a_{K-1}, so that $\varepsilon_{\mathfrak{r}} \le C(g,\mathsf{b})[r^{1/4} + (a_K/r)^{1/4}]$.

On the chain classes $\Delta_n = \Delta_n(\mathbf{1}) + X_n + S_n$, where X_n adds to X^{fz} the families that the first derivatives of the steps above n_0 make from $\mathfrak{x}$ alone, and S_n collects the rest: the action of $\mathfrak{r}_n$, the families that the first derivatives make from $\mathfrak{r}$ and from them, and the second derivatives of the steps; Lemma 7.8(a), in the frame at $\mathsf{k}(\frac{r}{2})$ in which Lemma 7.5(a) puts the near pair, a test pair of the scale $\frac{r}{2}$, under the conditions $3 \le s(\frac{r}{2}) \le K$ and $\mathsf{Lm}_{s(r/2)} \le L^{s(r/2)-3}$ of the data (and $\mathsf{k}(\frac{r}{2}) < n_1 < n_0 \le n < K$ by $(\alpha1)$), and the lags of Lemma 7.6(c) give $|S_n| \le C\varepsilon_S r_n^2 a_{K-n}^{-4}$ with $\varepsilon_S = 2\varepsilon_{\mathfrak{r}} + C(r/a_{K-n_0})^3$. (ii) *The frozen part.* Let $n_0 \le n \le K$, $A \in \mathsf{Cc}_n(r_n)$, x_0 a bare site with $|x_0 - c|_\infty \le a_K$, let $u = e^{iX}$, X linear, be the gauge of Lemma 7.12 at the pair, about x_0, A' the potential of $\tilde{U} = e^{i\eta_n A}$ in this gauge and $F' = \eta_n \mathrm{d}A'$ its angles. Near the pair $|A'|$, $|\nabla A'|$ and the current are at most a constant times r_n (Lemma 7.12, at $\alpha = \gamma_\circ = r_n$, in the units of the level n): on N_2, $|A'| \le 6r_n + 18.7r_n^2 \le 6.2\,r_n$ and $|\nabla^{\eta_n} A'| \le \frac{100}{99}(r_n + 3r_n^2) \le 1.04\,r_n$, and the current, conjugated by the gauge, is at most r_n. So the 2-form $f = \eta_n^{-2}F'$ is closed, $|f| \le 2.08\,r_n$, and, as its codifferential differs from the current by at most $40|A'||\nabla^{\eta_n}A'| + 32|A'|^3$, $|\mathrm{d}^* f| \le 3.7\,r_n$ on $Q_1(x_0)$, since $2r_n \le \varrho_{\mathrm{ch}}$ (Lemma 7.3(b)) and $\varrho_{\mathrm{ch}} \le \frac{1}{60}$ by equation YMM1:(2285).

The lemma on a regular gauge on a cube, which precedes Lemma 7.36, is read through the estimate of the proof of its clause (a) on $Q_1(x_0)$, at $m_0 = 2.08\,r_n$ and $m_1 = 3.7\,r_n$: it makes F' Hölder continuous with the exponent β_{H} on $Q_{1/2}(x_0)$, on the scale of the pair. Proposition 7.13, in the frame of step (i), at the levels $\mathsf{k}(\frac{r}{2}) \le i < n_1$, where $(\alpha2)$ of Definition 7.1(5) gives its condition in (ii), taken before the last replacement of step 5 of its proof, so that $\mathcal{Q}_i$ stands at F' and the last term of (ii) does not occur, replaces $\mathsf{c}\sum_i(\mathsf{Sum}[\mathsf{K}^{(i+1)}](\tilde{U}) - \mathsf{Sum}[\mathsf{K}^{(i+1)}](\mathbf{1}))$ by $\mathsf{c}\,q_{n_1}(F')$ with an error at most $C\sum_i \hat{r}_i^3 \mathsf{b}_i^2(\delta_i + \epsilon_i^{\mathrm{cu}})\Lambda_i^2 \mathsf{h}_i^2\, r_n^2 a_{K-n}^{-4} \le C(g,\mathsf{b})\, r^{1/4} r_n^2 a_{K-n}^{-4}$; the weight member of w_T is expanded in the gauge u at the pair.

With $\xi = \eta_n$, the plaquette angles of $\tilde{U}$ in this gauge are $F'_p + \Psi_p$ with the commutator part $|\Psi_p| \le 24\xi^2|A'|^2$; Lemma 7.12 at $\alpha = \gamma_\circ = r_n$ gives $|A'(b)| \le 3sr_n + (9s + 8\xi)r_n^2 \le 4sr_n + 8\xi r_n^2$ at the bonds with base point within s of x_0, and $|F'_p| \le 2.08\,\xi^2 r_n$; as $a_p = \frac{1}{2}|\theta|^2 + O(|\theta|^4)$ in the plaquette angle θ,

$$|a_p(\tilde{U}) - \tfrac{1}{2}|F'_p|^2| \le |F'_p||\Psi_p| + \tfrac{1}{2}|\Psi_p|^2 + C|F'_p + \Psi_p|^4 \le C\xi^4 r_n^3 (s+\xi)^2$$

at the plaquettes within $s \le \frac{1}{2}$ of x_0. The plaquettes of $\operatorname{supp} w_T$ lie within $s \le r/a_{K-n}$ of x_0, so $s + \xi \le 2r/a_{K-n_0}$; summed against w_T, with $\sum_p |w_T(p)| \le C a_K^{-3}$, this replaces the tensor source by $\frac{1}{2a_K}\sum_p w_T(p)|F'_p|^2$ up to $C(r/a_{K-n_0})^2 r_n^2 a_{K-n}^{-4} \le C\,r\,r_n^2 a_{K-n}^{-4}$, as $a_{K-n_0} \ge r^{1/2}$: in the gauge at

the pair the angles are small at the scale $s+\xi$ of the tensor source. By the Hölder continuity and the comparison of $\mathcal{S}_{n_1}$ with $\mathsf{b}^{-1}C_K^{\mathrm{free}}$ and of C_K^{free} with $a_K^3\mathbb{K}_3$ (Lemma 7.17(b), with $(\alpha 5)$), both main terms equal $\frac{1}{6a_K^4}\sum_{\mu,\nu}D(e_\lambda)_{\mu\nu}\langle F_\mu^\circ,F_\nu^\circ\rangle$, F_μ° the angle of the orientation μ at the centre, up to $C[(r/a_{K-n_1})^{\beta_{\mathrm{H}}}+a_K/r]\,r_n^2a_{K-n}^{-4}$ and terms of the same order; the moment condition of step (iii) of the proof of Lemma 7.36 cancels the main terms. So $\sup_{\mathsf{Cc}_n(r_n)}|X^{\mathrm{fz}}|\le\varepsilon_X r_n^2a_{K-n}^{-4}$ with $\varepsilon_X\le C(g,\mathsf{b})[r^{\beta_{\mathrm{H}}/4}+a_K/r]$. (iii) *Carrying upward.* On the chain classes the averaging identity of one step holds at every point: for $n_0\le m<K$, $A'\in\mathsf{Cc}_{m+1}(r_{m+1})$, the measure $\nu=\nu_{m,A'}$ of the step and every bare array $\mathfrak{g}$ of the level m of size below $N_\star^{[m]}$,

$$\int S[\mathfrak{g}](e^{i\eta_m A^{\mathrm{lw}}(B)})\,d\nu(B)=\big(S[\mathfrak{g}]+\mathsf{Sum}[\mathsf{DSt}^{[m]}(\mathfrak{f}_{0,m})[\mathfrak{g}]]\big)(e^{i\eta_{m+1}A'})+c_{\mathfrak{g}},$$

with a number $c_{\mathfrak{g}}$ that does not depend on A'. It is the first derivative, in the direction of $\mathfrak{g}$, of the exact step integral in Lemma B.23 at the real chart point A', which writes the action of the level $m+1$ through the mean under $\nu_{m,A'}$ of the exponential of the action of the level m at the lowered configurations; the measure $\nu_{m,A'}$ and the lowering map name no array, and the step takes any bare array of that size in its fourth place (Lemma 7.6(b)). As $A^{\mathrm{lw}}(B)\in\mathsf{Cc}_m(r_m)$ and ν is a probability measure, the oscillation of the right member over $\mathsf{Cc}_{m+1}(r_{m+1})$ is at most the oscillation of $S[\mathfrak{g}]$ over $\mathsf{Cc}_m(r_m)$.

A family that the steps above n_0 make from $\mathfrak{x}$, first created at the level $m+1$, is bounded in two ways: by the norm of the calculus, with the factor γ_m (Lemma 7.6(b), (c)), and, through this identity at $\mathfrak{g}=\mathfrak{x}_m$, by the oscillation of X^{fz} at the levels m and $m+1$, at most $2\varepsilon_X L^{4(n-m)}r_n^2a_{K-n}^{-4}$. The smaller of the two, summed over m with $\sum_{l\ge0}\min\{aL^{-l/2},bL^{4l}\}\le 2.4a^{8/9}b^{1/9}$ ($L\ge13$), bounds the oscillation of X_n by $[\varepsilon_X+C\gamma_{K-1}^{8/9}\varepsilon_X^{1/9}]r_n^2a_{K-n}^{-4}$. Together the oscillation of Δ_n on $\mathsf{Cc}_n(r_n)$ is at most $\varepsilon_\alpha r_n^2a_{K-n}^{-4}$ with $\varepsilon_\alpha=\varepsilon_X+C\gamma_{K-1}^{8/9}\varepsilon_X^{1/9}+C\varepsilon_S\le C(g,\mathsf{b})\,\epsilon$, as $\gamma_{K-1}\le1$; c'_n is the centre of this oscillation.

At $n=K$ the chain class is $\{0\}$ and $r_K=0$. □

Lemma 7.38 (Pair minus tensor field up to the last level)**.** Let g satisfy besides (Γ3) of Definition 7.1(6), let $r\le r_\alpha^{\mathcal{W}}(g,\mathsf{b})$, let n_0 be the level of Lemma 7.36, and $\varepsilon^{\mathcal{W}}=C(g,\mathsf{b})[r^{\beta_{\mathrm{H}}/72}+(a_K/r)^{1/18}]$ with a suitable number $C(g,\mathsf{b})\ge1$. There are numbers c_n, $n_0\le n\le K$, such that for m_n-almost every $W\in\mathcal{V}_n^\chi$

$$|\Delta_n(U_n(W))-\mathsf{c}_n|\le\varepsilon^{\mathcal{W}}\,\mathrm{nat}_n^{\mathcal{W}},\qquad|\mathsf{c}_n-\mathsf{c}_K|\le\varepsilon^{\mathcal{W}}\,\mathrm{nat}_n^{\mathcal{W}},$$

and, for $w_3\not\equiv0$ and $\mathsf{d}'=|c-z|$, $|\Gamma_n(U_n(W))|+|\Gamma_K(\mathbf{1})|\le C(\mathsf{b})\,\mathsf{d}'^{-5/2}\varepsilon^{\mathcal{W}}\mathsf{b}^{-2}\mathsf{d}'^{-6}\mu_3$. ■

Proof. The proof of Lemma 7.36 is made at every level $n_0\le n\le K$, with the radius $C_{\mathcal{W}}\varepsilon_n$ of the backgrounds in the place of the radius of a chain class and without the shift of the level. (i) By the first two members of (Γ3) the domains that leave the cores at the radius $2B_3\varepsilon_n$ have a depth that makes the tails of Lemma 7.8(b) at most $C\varepsilon_n^2L^{-4(n-i)}$; so a pointed family of level i that vanishes off a set of sites changes on the backgrounds of the level n by at most a constant times its norm, the number of the cubes that hold a site of the set, $L^{-4(n-i)}$ and $\mathrm{nat}_n^{\mathcal{W}}$. (ii) Lemma 7.35(b) at $\varrho=3$, which applies as $7488B_3\varepsilon_n\le\epsilon_{\mathrm{G}}$ by (Γ3) and $26a_{K-n}<\ell_g$ (as $\ell_g\ge2LMy_K\ge338$), gives about a bare site x_0 next to c a gauge g on $Q_{12}(x_0)$ and a potential A on the bonds of $Q_6(x_0)$ with $\mathsf{g}(b_-)U(b)\mathsf{g}(b_+)^{-1}=e^{i\eta_nA(b)}$ there, $U=U_n(W)$; on $Q_3(x_0)$ the potential, its differences and the current are at most $\mathsf{r}_\circ:=C_{\mathcal{W}}\varepsilon_n\le\frac{1}{120}$.

Lemma 7.12 is used in a local form, with data on $N_{\rho+1}$: *in the units of a level, with the bare spacing $\xi\le\frac{1}{13}$, let $\rho\ge2$ with $4\rho+4$ at most the side of the torus, and let* $\mathsf{g}\colon N_{\rho+1}\to SU(2)$ *and a real* 1*-form A on the bonds with both end points in $N_{\rho+1}$ satisfy $\mathsf{g}(b_-)U(b)\mathsf{g}(b_+)^{-1}=e^{i\xi A(b)}$, $|A|\le\alpha\le\frac{1}{60}$ and $|\nabla^\xi A|\le\gamma_\circ$ there, the current of U being at most ι there; with $c_\mu=A_\mu(x_0)$, $X(x)=\sum_\mu(x-x_0)_\mu c_\mu$ and $h=e^{iX}\mathsf{g}$ on $N_{\rho+1}$ there is a real pair v' on all the bare bonds which, at*

the bonds with base point in N_ρ, is the image of U and of its current under the gauge transformation h, and which obeys the three bounds of Lemma 7.12; if $\|v'\|$ is less than the radius of the ball of the chart, every local term of the level on a domain $X \subset N_{\rho-1}$ that is formed at U has the same value at $P[v']|_X$. Its proof is that of Lemma 7.12, with the transformed potential formed on $N_{\rho+1}$ and the cut-off $\chi(x) = \min\{1, \max\{0, (\rho+1-2\xi-|x-x_0|_\infty)/(1-2\xi)\}\}$, of the width $1-2\xi$ and equal to 1 on N_ρ, in the place of the cut-off of the width ρ: as $|\chi(x+\xi e_\nu)-\chi(x)| \le \frac{13}{11}\xi$, $|\nabla^\xi A'| \le \frac{100}{99}(\gamma_\circ + 3\alpha^2) + \frac{13}{11}[3(\rho+1)\gamma_\circ + (9\rho+9.62)\alpha^2] \le \rho(6\gamma_\circ + 19\alpha^2)$ for $\rho \ge 2$; and the bonds that a local term on $X \subset N_{\rho-1}$ reads have their end points in N_ρ, where $P[v']$ is the image of U under h, while a local term is a gauge invariant function of the pair on its domain.

Viewed from the level $i+1$, $\mathsf{k}(\frac{r}{2}) \le i < n_1$, $m = n-i-1$, the data on $Q_3(x_0)$ have $|A| \le \alpha = L^{-m}\mathsf{r}_\circ$, $|\nabla A| \le \gamma_\circ = L^{-2m}\mathsf{r}_\circ$ and a current at most $L^{-3m}\mathsf{r}_\circ \le \gamma_\circ$, and the cube N_{h_i+1} of the level $i+1$ lies in $Q_3(x_0)$, as $(\mathsf{h}_i+1)L^{-m} \le 3$ (Definition 7.1(6)). The local form at $\rho = \mathsf{h}_i$, where $(4\mathsf{h}_i+4)a_{K-i-1} \le \ell_g$, gives a real point v' of the chart with $\|v'\| \le \mathsf{h}_i\gamma_\circ(6+19\mathsf{r}_\circ) \le 7\mathsf{h}_i L^{-2m} C_{\mathcal{W}}\varepsilon_n \le \delta_i/2\Lambda_i$ (Definition 7.1(6)), inside the ball of the chart; the linear gauge X is the same function at all the levels i, so that one h serves them all.

Steps 2–4 of the proof of Proposition 7.13 at the real point v', the domains in N_{h_i-1} taking the same values at U and at $P[v']$, and the others, of a linear size at least $D_* = (\mathsf{h}_i - 1 - R_w)/M - 2$, costing $2\mathsf{M}_i^{\mathsf{K}} e^{-[D_*]_+} \le \bar{\mathsf{e}}\gamma_\circ^2/\delta_i^2$ by the choice of h_i, replace $\mathsf{c}\sum_i(\mathsf{Sum}[\mathsf{K}^{(i+1)}](U) - \mathsf{Sum}[\mathsf{K}^{(i+1)}](\mathbf{1}))$ by $\mathsf{c}\, q_{n_1}(F')$, F' the linear angles in the gauge h, up to $C\sum_i \hat{r}_i^3 \mathfrak{b}_i^2(\delta_i + \epsilon_i^{\mathrm{cu}})\Lambda_i^2 \mathsf{h}_i^2\, C_{\mathcal{W}}^2 \mathrm{nat}_n^{\mathcal{W}}$. In the gauge h, in the units of the level n, $|A'| \le 4s\mathsf{r}_\circ + 8\eta_n \mathsf{r}_\circ^2$ at the bonds with base point within $s \le 2$ of x_0, $|\nabla A'| \le 1.04\,\mathsf{r}_\circ$ and $|F_p'| \le 2.08\,\eta_n^2 \mathsf{r}_\circ$ there, and $|a_p(U) - \frac{1}{2}|F_p'|^2| \le C\eta_n^4 \mathsf{r}_\circ^3 (s+\eta_n)^2$ at the plaquettes within $s \le \frac{1}{2}$ of x_0; this replaces the tensor source by $\frac{1}{2a_K}\sum_p w_T(p)|F_p'|^2$ up to $C(r/a_{K-n_0})^2 C_{\mathcal{W}}^2 \mathrm{nat}_n^{\mathcal{W}}$.

Lemma 7.35(a) is read through the estimate of its proof on $Q_1(x_0)$, at $m_0 = 2.08\,\mathsf{r}_\circ$ and $m_1 = 3.7\,\mathsf{r}_\circ$ (on N_2, $|A'| \le 6.2\,\mathsf{r}_\circ$, and the codifferential of $\eta_n^{-2}F'$ differs from the current by at most $40|A'||\nabla A'| + 32|A'|^3$): it makes F' Hölder continuous with the exponent β_{H} on the scale of the pair. The comparison of $\mathcal{S}_{n_1}$ with $\mathfrak{b}^{-1}C_K^{\mathrm{free}}$ and of C_K^{free} with $a_K^3 \mathbb{K}_3$ (Lemma 7.17(b), with (α5)) brings both main terms to $\frac{1}{6a_K^4}\sum_{\mu\nu} D(e_\lambda)_{\mu\nu}\langle F_\mu^\circ, F_\nu^\circ\rangle$, F° the angles at the centre, up to $C[(r/a_{K-n_1})^{\beta_{\mathrm{H}}} + a_K/r]C_{\mathcal{W}}^2 \mathrm{nat}_n^{\mathcal{W}}$; the moment condition cancels them, and the frozen part on the backgrounds is at most $\varepsilon_X^{\mathcal{W}} \mathrm{nat}_n^{\mathcal{W}}$. (iii) From one level to the next the averaging identity of one step, written for arbitrary bare arrays, gives m_{n+1}-almost everywhere $\Delta_{n+1} = \mathsf{Qt}_{n+1}[\Delta_n] + \mathsf{b}_n$, where Qt_{n+1} is the quotient of the step, a positive normalised mean, and b_n is c times the covariance, under the step, of the quotients of the two single sources of the near pair.

The one-source bound $|G_{n;a} - G_{n;a}(\mathbf{1})| \le Cr^3|w_a|_\infty \mathrm{nat}_n^{\mathcal{W}}$ on the backgrounds gives $|\mathsf{b}_n| \le CA_0^2 y_{n_0}^{2\mathfrak{p}_0}(r/a_{K-n_0})^3 \mathrm{nat}_n^{\mathcal{W}} \le C(\mathsf{b})\, r\, \mathrm{nat}_n^{\mathcal{W}}$. A quotient does not increase the oscillation, so the centres c_n of the oscillations of two consecutive levels differ by at most twice the oscillation bound plus $C(\mathsf{b})\, r\, \mathrm{nat}_n^{\mathcal{W}}$; as $\mathrm{nat}^{\mathcal{W}}$ falls by the factor $\frac{5}{4}L^{-3}$ from one level to the next, the sum over the levels gives the second bound. (iv) For Γ_n the averaging identity of one step, in its form for two and for three arrays, gives m_{i+1}-almost everywhere, for $n_0 \le i < K$, $\Gamma_{i+1} = \mathsf{Qt}_{i+1}[\Gamma_i] + \mathsf{Qt}_{i+1}[\Delta_i; G_{i;3}] + \mathsf{c}\,\mathsf{Sum}[\mathsf{C}^{(i+1)}]$; here $\mathsf{Qt}_{i+1}[\,\cdot\,;\cdot\,]$ is the covariance of the quotients of the step, and the family $\mathsf{C}^{(i+1)}$ is made of the mixed second derivatives of the step in the arrays of the sets $\{1,3\}$ and $\{2\}$ and in those of $\{2,3\}$ and $\{1\}$, and of its third derivative in the arrays of the three single sources.

A quotient does not raise the essential supremum, so the bound of Γ_n is that of Γ_{n_0} plus the sum over $n_0 \le i < n$ of the bounds of the two other terms. The covariance is at most the smaller of the bound by the oscillations of Δ_i and of the far source on the backgrounds and the bound by the norms, $\mathsf{C}^{(i+1)}$ is bounded by the norms, and Γ_{n_0} by the first display of Lemma 7.39 at $U_{n_0}(W)$, whose pairs of all levels $\le n_0$ lie in the cores (Lemma 7.20(d)); the sum over the levels is that of the proof of Lemma 7.40, with the bound of the oscillation of Δ on the backgrounds in the place of ε_α.

All the numbers so formed are at most $C(g,\mathsf{b})[r^{\beta_{\mathrm{H}}/36}+(a_K/r)^{1/9}]$ for $r\le r_\alpha^{\mathcal{W}}$; with $(\frac{\mathsf{b}}{\mathsf{d}'})^{3/2}(\frac{r}{\mathsf{d}'})^3\le \mathsf{b}^{3/2}\mathsf{d}'^{-2}r^{1/2}$ and $(\frac{\mathsf{b}}{\rho_0})^{3/2}e^{-\mathsf{d}'/8M\rho_0}\le C\mathsf{b}^{3/2}\mathsf{d}'^{-5/2}r^{1/2}$, $\rho_0=a_{K-n_0}$, the claims follow. □

Lemma 7.39 (Crossing functionals at levels below the distance)**.** For $\beta\in\{13,23,123\}$ of the list (w_1,w_2,w_3) and $\beta=T3$ of the list (w_T,w_3), $m=|\beta|$, $1\le i\le K$, and every configuration U whose pairs of the level i lie in the cores,

$$\sum_{(X,z)}|E_\beta^{(i)}(X,U,z)|\le C_\times(\tfrac{8r}{3\mathsf{d}})^6\bar\nu_{i-1;\beta}\,e^{-D_i^\sharp/2},\qquad D_i^\sharp=[\mathsf{d}/2Ma_{K-i}-2]_+.$$

So if $8Ma_{K-n}\le\mathsf{d}$, then for every such U of the level n:

$$|G_{n;\beta}(U)|\le C'_\times\mathsf{b}^{-m/2}a_{K-n}^{-m/2}e^{-\mathsf{d}/4Ma_{K-n}}(\frac{8r}{3\mathsf{d}})^6\prod_{a\in\beta}|w_a|_\infty.$$

■

Proof. By the support rule (Lemma 7.6(d)) a crossing family lives on domains that reach from the pair to the piece, of linear size at least $D_i^\sharp$; the near supports lie in $\mathbb{B}(c,\frac58 r)$, the piece in $\mathbb{B}(z,\frac14 r)$, so the corners of the two kinds are at least $\frac12\mathsf{d}$ apart in the sup distance; its norm is bounded by the sizes of Lemma 7.9(e), in the form (f), at the width r and a crossing distance $\mathsf{d}_\times\ge\frac38\mathsf{d}$, with $(r/\mathsf{d}_\times)^6\le(\frac{8r}{3\mathsf{d}})^6$; Lemma 7.8(b) at U gives the sum with the factor $e^{-D_i^\sharp/2}$, and $\bar\nu_{i-1;\beta}\le\bar c_m(5L/4\mathsf{b})^{m/2}a_{K-i}^{-m/2}\prod|w_a|_\infty$; the sum over $i\le n$ is led by $i=n$. □

Lemma 7.40 (The difference of the jets)**.** Let $w_3\not\equiv 0$. Then the centre z of its cube has $(1-\frac{1}{64})\mathsf{d}\le|c-z|\le 6\mathsf{d}$, and

$$\big|\mathsf{c}\,\mathsf{J}_3(w_1,w_2,w_3)-\mathsf{J}_2(w_T,w_3)\big|\le C(g,\mathsf{b})\,\mathsf{d}^{-12}[r^{\beta_{\mathrm{H}}/72}+(a_K/r)^{1/18}]\mathsf{b}^{-2}\mathsf{d}^{-6}\mu_3.$$

■

Proof. A barycentre in the cube lies in $\operatorname{supp}\varphi_2$, at a distance $\ge\mathsf{d}$ from c and $\le\frac{\sqrt3}{8}r\le\frac{1}{64}\mathsf{d}$ from z, as $r\le(\mathsf{d}/5LM)^2$. Put $\mathsf{d}'=|c-z|$ and $\rho_0=a_{K-n_0}$; the data give $16r\le\mathsf{d}'\le\min\{1,\mathsf{b}\}$, $4M\rho_0\le\mathsf{d}'$ and $64\mathsf{d}'\le\ell_g$ ($\mathsf{d}'\le 6\mathsf{d}$, $r\le(\mathsf{d}/5LM)^2$, $\rho_0<Lr^{1/2}$, $\ell_g\ge 2LMy_K\ge 338$). The corners of the plaquettes of the near supports and of the piece are at least $\frac12\mathsf{d}'$ apart in the sup distance, so Lemma 7.39 holds with d' in the place of d. Lemma 7.9 is used in its form (f), which bounds the crossing distance by 1 in the place of the bound $e^{-2\sqrt3}$ of the placing: at the width r and the crossing distance $\mathsf{d}_\times=\frac38\mathsf{d}'\in[6r,1]$, with the corners of the two kinds at least $\frac12\mathsf{d}'\ge\mathsf{d}_\times/\sqrt3$ apart, its conditions hold as in the proof of Lemma 7.39. By the support rule (Lemma 7.6(d)) a domain of the level $i+1$ that holds corners of both kinds has a linear size at least $D_{i+1}=[\mathsf{d}'/2Ma_{K-i-1}-2]_+$.

The tower. Let $n_0\le i<K$, $A'\in\mathsf{Cc}_{i+1}(r_{i+1})$ and $\nu=\nu_{i,A'}$. The tower identity at several sources (step 1 of the proof of Proposition 7.16; the two clusters, the near sources and the piece, lie in the frame at the level n_0-1, as $4M\rho_0\le\mathsf{d}'$), at the five partitions of $\{1,2,3\}$ and the two of $\{T,3\}$, with every $G_{i;\beta}$ taken at $A^{\mathrm{lw}}(B)$, gives

$$\Gamma_{i+1}(A')=\int\Gamma_i\,d\nu+\kappa_\nu(\Delta_i,G_{i;3})+\mathsf{c}\big[\kappa_\nu(G_{i;13},G_{i;2})+\kappa_\nu(G_{i;23},G_{i;1})+\kappa_\nu(G_{i;1},G_{i;2},G_{i;3})\big].$$

As $A^{\mathrm{lw}}(B)\in\mathsf{Cc}_i(r_i)$ and ν is a probability measure, the mean is at most $\sup_{\mathsf{Cc}_i(r_i)}|\Gamma_i|$; as $\mathsf{Cc}_K(r_K)=\{0\}$, $|\Gamma_K(\mathbf{1})|=|\mathsf{c}\mathsf{J}_3-\mathsf{J}_2|$ is at most $\sup_{\mathsf{Cc}_{n_0}(r_{n_0})}|\Gamma_{n_0}|$ plus the sum over $n_0\le i<K$ of the suprema of the four cumulants.

The covariance of Δ and of the far source. By the oscillations: the explicit parts of Δ_i cancel by the moment condition of step (iii) of the proof of Lemma 7.36, and Lemma 7.37 bounds the oscillation of Δ_i on $\mathsf{Cc}_i(r_i)$ by $2\varepsilon_\alpha r_i^2a_{K-i}^{-4}$; Lemma 7.10 and $|\mathsf{ang}_p^{[i]}|\le 2\eta_i^2r_i$ bound that of $G_{i;3}$ by $C\mu_3r_i^2a_{K-i}^{-4}$; with $x_ir_i^2\le C\mathfrak{b}_i^2$ and $a_{K-i}x_i\ge\frac45\mathsf{b}$, $|\kappa_\nu(\Delta_i,G_{i;3})|\le C\varepsilon_\alpha\mathfrak{b}_i^4\mathsf{b}^{-2}a_{K-i}^{-6}\mu_3$. By the norms:

$\kappa_\nu(\Delta_i, G_{i;3})$ is the value of Sum of the mixed second derivative of the step in the array of Δ_i, of the size at most Ca_{K-i}^{-4} (Lemma 7.6, and Lemma 7.9 in the form (f)), and in the array of the far source; this family vanishes on the domains with $d_{i+1}(X) < D_{i+1}$, and Lemma 7.6(b), the sizes of Lemma 7.9(a), in the form (f), and Lemma 7.8(b) give $|\kappa_\nu(\Delta_i, G_{i;3})| \le C\mathsf{b}^{-1}a_{K-i}^{-7}e^{-D_{i+1}}\mu_3$.

The smaller of the two bounds is at most their geometric mean, $C\varepsilon_\alpha^{1/2}\mathfrak{b}_i^2\mathsf{b}^{-3/2}a_{K-i}^{-13/2}e^{-D_{i+1}/2}\mu_3$; with $\mathfrak{b}_i = A_1 y_i^{\mathfrak{p}_0}$ and $y_i \le \log(4\mathsf{b}/3a_{K-i})$ the sum over i is led by the levels with a_{K-i} about d' and gives the first term below.

The crossing terms. $\kappa_\nu(G_{i;1}, G_{i;2}, G_{i;3})$ is the value of Sum of the third derivative of the step in the arrays of the three single sources, and $\kappa_\nu(G_{i;13}, G_{i;2})$, $\kappa_\nu(G_{i;23}, G_{i;1})$ are the values of Sum of its mixed second derivatives in the arrays of a crossing set and of a single source; these families vanish on the domains with $d_{i+1}(X) < D_{i+1}$. Lemma 7.6(b) at $q = 3$, the sizes of Lemma 7.9(a), in the form (f), and Lemma 7.8(b) give $\mathsf{c}|\kappa_\nu(G_{i;1}, G_{i;2}, G_{i;3})| \le C\mathsf{c}\,\bar\nu_{i;123}\varsigma_i^3 e^{-D_{i+1}} \le C\mathsf{b}^{-1/2}r^3 a_{K-i}^{-21/2}e^{-D_{i+1}}\mu_3$, the widths of the three sources being of the order of r; the two others are smaller, by a factor γ_i (Lemma 7.9(e), in the form (f)). The sum over i, led by the levels with a_{K-i} about d', gives the second term below.

The start. At the configurations of $\mathsf{C}\mathsf{c}_{n_0}(r_{n_0})$, whose pairs lie in the cores,

$$\Gamma_{n_0} = \sum_{i \le n_0} \mathsf{Sum}[\mathsf{c}E_{123}^{(i)} - E_{T3}^{(i)}];$$

the first display of Lemma 7.39, with

$$\bar\nu_{i-1;\beta} \le \bar c_m (5L/4\mathsf{b})^{m/2} a_{K-i}^{-m/2} \prod_{a\in\beta} |w_a|_\infty$$

and

$$e^{-D_i^\sharp/2} \le e \cdot e^{-\mathsf{d}'/4Ma_{K-i}},$$

summed over $i \le n_0$, where the quotient of two consecutive terms is at most $L^{3/2}e^{-(L-1)} < 1$ as $4M\rho_0 \le \mathsf{d}'$, gives

$$|\Gamma_{n_0}| \le C(\mathsf{b}/\rho_0)^{3/2} e^{-\mathsf{d}'/4M\rho_0}\mathsf{b}^{-2}\mathsf{d}'^{-6}\mu_3,$$

at most the third term below.

The result is

$$|\Gamma_K(\mathbf{1})| \le C\Big[\Big(\frac{\mathsf{b}}{\mathsf{d}'}\Big)^{1/2}\mathsf{L}_{\mathsf{d}'}\varepsilon_\alpha^{1/2} + \Big(\frac{\mathsf{b}}{\mathsf{d}'}\Big)^{3/2}\Big(\frac{r}{\mathsf{d}'}\Big)^3 + \Big(\frac{\mathsf{b}}{\rho_0}\Big)^{3/2} e^{-\mathsf{d}'/8M\rho_0}\Big]\mathsf{b}^{-2}\mathsf{d}'^{-6}\mu_3, \qquad \mathsf{L}_{\mathsf{d}'} = \Big(1 + \log^+\frac{\mathsf{b}}{\mathsf{d}'}\Big)^{2\mathfrak{p}_0},$$

where $\varepsilon_\alpha \le C(g,\mathsf{b})\epsilon$ is the number of Lemma 7.37. Then $\varepsilon_\alpha^{1/2} \le C(g,\mathsf{b})[r^{\beta_{\mathrm{H}}/72} + (a_K/r)^{1/18}]$, $(r/\mathsf{d}')^3 \le \mathsf{d}'^{-3}r^{\beta_{\mathrm{H}}/72}$, $e^{-s} \le 2s^{-2}$ at $s = \mathsf{d}'/8M\rho_0$ with $\rho_0 < Lr^{1/2}$, and $(1 - \frac{1}{64})\mathsf{d} \le \mathsf{d}' \le 6\mathsf{d} \le 1$ give the claim. □

Lemma 7.41 (Uniformity in the label)**.** Let $0 < g \le \gamma_{\mathrm{R}}$ and let $\mathcal{K} \subset (g^{-2}, \bar{\mathsf{b}}]$ be compact. Then $C_{\mathrm{A}}(g,\mathsf{b})$, $\mathsf{C}_{\mathrm{R}}(g,\mathsf{b};\mathsf{d})$ and $\mathsf{C}(\mathsf{d})$ of Theorem AB are bounded, and $r_\alpha(g,\mathsf{b})$, $r_{\mathcal{W}}(g,\mathsf{b},\mathsf{d})$, $r_\sharp$, $r_0(\mathsf{b})$, $r_1(\mathsf{b})$ are bounded away from 0, uniformly in $\mathsf{b} \in \mathcal{K}$; here $r_\sharp$ and $\mathsf{C}(\mathsf{d})$ are the numbers that steps 2 and 3 of the proof of (E.3) form at a first-passage datum at g with the label b, for every $\mathsf{b} \in (g^{-2}, \bar{\mathsf{b}}]$. ■

Proof. The thresholds. r_1 does not increase in b, so $r_1(\mathsf{b}) \ge r_1(\bar{\mathsf{b}}) > 0$, and the infimum of r_0 over the labels at g is positive by (B.1). The threshold $r_\alpha(g,\mathsf{b})$ is the largest number below which the inequalities (α1)–(α5) of Definition 7.1(5) hold, and the bound $r \le r_\alpha(g,\mathsf{b})$ enters Lemma 7.36 and the lemma on the chain classes through these inequalities; by the bounds given there each of them holds as soon as r is below a number formed from the constants and g, or, for (α3), below $2\min\{\inf_{\mathsf{b}'} r_0(\mathsf{b}'), r_1(\bar{\mathsf{b}})\}$; so $r_\alpha(g,\mathsf{b}) \ge r_\alpha^-(g) > 0$ for every label at g. $r_{\mathcal{W}}(g,\mathsf{b},\mathsf{d})$ adds to r_α the

inequalities of step 0 of the proof of (E.2), which depend on b only through $a_\sharp = 4\mathsf{b}/5x_\sharp \geq 4g^{-2}/5x_\sharp$; and $r_\sharp$ is the least of these thresholds and of those of the data. So all the thresholds are bounded below by positive numbers formed from the constants, β_{H}, g and d, for all labels in $(g^{-2}, \bar{\mathsf{b}}]$.

The constants. The label enters the proofs of Lemmas 7.36–7.40 and of Theorem AB through five kinds of quantities. (1) The run: by Lemma 7.3(a), $\frac{4}{5}\mathsf{b} \leq a_{K-j}x_j \leq \frac{4}{3}\mathsf{b}$, so that x_j, y_j, δ_j, ε_j, $\mathfrak{b}_j$, $\gamma_j = c_\gamma x_j^{-1/2}$, $\theta^{[j]}$ and r_j lie between two functions of b/a_{K-j}, each continuous in b, and $\frac{3}{4\mathsf{b}} \leq \upsilon_j \leq \frac{5}{4\mathsf{b}}$. (2) The prefactor $\mathsf{c} = \frac{2\pi}{3}\mathsf{b}r^3$ and the units $\mathsf{u}_a = \mathsf{b}^{-1}|w_a|_\infty$. (3) The slices, through b^{-1} and $\bar{B}/\mathsf{b}$ (Lemma 7.17). (4) The number $a_\sharp = 4\mathsf{b}/5x_\sharp$, through $a_*^{-1} \leq L\max\{8M, 5x_\sharp/4\mathsf{b}\}\ell_\epsilon/\mathsf{d}$. (5) The thresholds, bounded below as above.

Member by member: $\gamma_{n_0} \leq c_\gamma(5Lr^{1/2}/4\mathsf{b})^{1/2}$; $s(\frac{r}{2})\theta^{[0]}$, with $x_0 = \mathsf{b}/a_K$; $\sum_i \hat{r}_i^3\mathfrak{b}_i^2(\delta_i + \epsilon_i^{\mathrm{cu}})\Lambda_i^2\mathsf{h}_i^2$, with $x_i \geq \frac{4}{5}\mathsf{b}/a_{K-i}$, while $\Lambda_i \leq C(1 + Y_{r/2})$ and $\mathsf{h}_i \leq C(1 + Y_{r/2})^{2\mathfrak{p}_0}$ are formed with g and r; the cost, at most $C\mathsf{b}\, r\, \mathrm{nat}_n^{\mathcal{W}}$, of the domains that leave the cube of the gauge, and the part of the steps between two levels, of the same order (proof of Lemma 7.36); $y_{n_0} \leq \log(4\mathsf{b}/3\rho_0)$; the bracket of the proof of Lemma 7.40, through $(\mathsf{b}/\mathsf{d}')^{1/2}$, $(\mathsf{b}/\mathsf{d}')^{3/2}$, $(\mathsf{b}/\rho_0)^{3/2}$ and $\mathsf{L}_{\mathsf{d}'}$; the size $b_\Delta = (C\mathsf{b} + C)\Lambda_3$ of Y_Δ, the terms T_1–T_4 and the moments M_b of the proof of (E.2); the number $\epsilon_0(g, \mathsf{b})$, the reciprocal of the constant in $\sum_i \epsilon_i^{\mathrm{e}} \leq C(g, \mathsf{b})\,\epsilon$; the quotients that form C_{R}; and the constant $C(\mathsf{b}, \mathsf{d})$ of step 3 of the proof of (E.3).

Each majorant so formed is a sum of products of a factor that does not contain b and of a function of b made by finitely many products, powers, logarithms and maxima from b, b^{-1}, the constants, β_{H}, g, d and the lower bounds of the thresholds; such a function is continuous on the compact interval $[g^{-2}, \bar{\mathsf{b}}]$, where $g^{-2} \geq e^{2\mathfrak{p}_0} > 1$, and so bounded there. Hence $C_{\mathrm{A}}(g, \mathsf{b})$, $\mathsf{C}_{\mathrm{R}}(g, \mathsf{b}; \mathsf{d})$ and $\mathsf{C}(\mathsf{d})$ are bounded on all of $(g^{-2}, \bar{\mathsf{b}}]$ by numbers formed from the constants, β_{H}, g, d and $\mathsf{d}\,\mathrm{Lip}\,\varphi_1/\|\varphi_1\|_\infty$, in particular on $\mathcal{K}$. □

Proofs of the theorems.

Proof of Theorem Y. (B.2). 1. *The data.* By Lemma 7.5(b) the tents put the pair in the frame at $k_0 = \mathsf{k}(r)$; (Γ1) gives $g \leq \gamma_{\mathrm{jt}}$ and $g^{-2} \geq x_{\mathrm{J}}$, so Lemma 7.6 applies, with (P1)–(P3), and $\rho \leq r_1(\mathsf{b})$ gives $\rho \geq 4Ma_K$ and $E_\sigma(\hat{\rho}_1/2) \leq \varkappa_0^4$; the smallness holds at all heights (Lemma 7.3(b)). At $n = K$, $A = 0$ and both members vanish; let $\mathsf{k}(r) \leq n < K$.

2. *The decomposition.* Differentiate the defining formula for D_n^λ twice: the source term is linear in λ, so $\mathsf{F}_n = \sum_{i\leq n}\mathsf{Sum}[E_{12}^{(i)}]$; with Lemma 7.7 and $q_n = \sum_{i=\mathsf{k}(r)}^{n-1}\mathcal{Q}_i$, $q_{\mathsf{k}(r)} = 0$,

$$\mathsf{F}_n(\tilde{U}) - \mathsf{F}_n(\mathbf{1}) - q_n(\mathsf{ang}^{[n]}(A)) = \underbrace{\sum_{i=1}^{\mathsf{k}(r)}\Delta[E_{12}^{(i)}]}_{\mathrm{I}} + \underbrace{\sum_{j=\mathsf{k}(r)}^{n-1}\Delta[\mathsf{R}^{(j+1)}]}_{\mathrm{II}} + \underbrace{\sum_{i=\mathsf{k}(r)}^{n-1}\left(\Delta[\mathsf{K}^{(i+1)}] - \mathcal{Q}_i(\mathsf{ang}^{[n]}(A))\right)}_{\mathrm{III}}.$$

3. *The passage to the yardstick* $\mathsf{Y}_n = (\rho/r)^6\hat{r}_n^3\mathsf{u}_1\mathsf{u}_2$. For a pointed family f of level $j+1$ that vanishes off Cr_1 and on the domains with $d_{j+1}(X) < D'$, with $\|\mathsf{f}\| \leq \Phi\bar{\nu}_j$, Lemma 7.8(a) in the frame at $k_0 = \mathsf{k}(r)$ of step 1, $\bar{\nu}_j \leq \frac{25}{16}\bar{c}_2 x_j\mathsf{u}_1\mathsf{u}_2$, $x_j \leq \frac{5}{3}L^{n-j}x_n$ and $x_n r_n^2 \leq C\mathfrak{b}_n^2$ give

$$|\Delta[\mathsf{f}]| \leq C_{\mathrm{U}}\,\mathfrak{b}_n^2\,\mathsf{N}_{j+1}(w_1)\,\Phi\,u_j^{-3}e^{-D'/2}\,u_n^3\mathsf{u}_1\mathsf{u}_2.$$

4. *I, the levels at and below the working level, are cut by the distance.* By the support rule $D' = \mathsf{D}(u_i)$; Lemma 7.9(b) and (P2) give $\mathsf{N}_i\bar{\Psi}_{i-1;12} \leq Cq^6(1 + u_i^6)$; with $u_i = L^l u_{\mathsf{k}(r)}$ and $u_{\mathsf{k}(r)}/\sqrt{3}M \geq \frac{4}{\sqrt{3}}Y_r^{2\mathfrak{p}_0}$ the sum is led by $i = \mathsf{k}(r)$: $|\mathrm{I}| \leq C\mathfrak{b}_n^2 e^{-Y_r^{2\mathfrak{p}_0}/\sqrt{3}}\mathsf{Y}_n$.

5. *II, the rest families.* Step 3 with $D' = 0$ and Lemma 7.9(c); $\mathsf{N}_{j+1}\varsigma_j^2 u_j^{-3} \leq 216L^3q^6u_{j+1}^3$, $\mathsf{N}_{j+1}\Xi_j^r u_j^{-3} \leq 216q^6$, $\sum_{j<n}\gamma_j \leq 0.45\gamma_n \leq C\delta_n/\mathfrak{b}_n$, and $u_{\mathsf{k}(r)}^3[\gamma_{\mathsf{k}(r)} + \theta^{[0]}] \leq CY_r^{6\mathfrak{p}_0}\delta_{\mathsf{k}(r)}$, $\delta_{\mathsf{k}(r)} \leq$

$A_1 Y_r^{\mathfrak{p}_0}(r/\mathsf{b})^{1/2}$ (Lemma 7.3(c)):

$$|\mathrm{II}| \le \{C\mathfrak{b}_n\delta_n + C\mathfrak{b}_n^2 Y_r^{7\mathfrak{p}_0}(r/\mathsf{b})^{1/2}\}\mathsf{Y}_n.$$

6. *III, the kernel families.* Proposition 7.13, narrow form; $\mathsf{c}_i \le Ce^{-\delta_{\mathrm{tp}}u_i/\sqrt{3}}$, so $\sum_i \mathsf{c}_i(1+u_i)^2u_i^3 \le C$, and $\sum_{i\ge \mathsf{k}(r)} \mathfrak{b}_i^4\delta_i u_i^3 \le 1.12\,\mathfrak{b}_{\mathsf{k}(r)}^4 u_{\mathsf{k}(r)}^3\delta_{\mathsf{k}(r)}$:

$$|\mathrm{III}| \le \{CY_r^{15\mathfrak{p}_0+2}(r/\mathsf{b})^{1/2} + C\mathfrak{b}_n^2 r_n\}\mathsf{Y}_n.$$

7. *The sum.* $\mathfrak{b}_n \le \mathfrak{b}_{\mathsf{k}(r)} \le A_1 Y_r^{\mathfrak{p}_0}$, $r_n \le \frac{8}{5}\mathsf{c}_{\mathfrak{h}}\delta_n$ and $(r/\mathsf{b})^{1/2} \le g\,r^{1/2}$ give the bound. The factor $(\rho/r)^6$ costs nothing: F_n is bilinear in (w_1, w_2), every estimate depends on the weights only through $\sum_p |w_a(p)|$ or through a norm that (P1) bounds, and the one place where a sup norm could enter, Λ_i, sees a quotient (Proposition 7.13, step 6). By Lemma 7.3(c), $\log\frac{1}{r} \le Y_r \le 2\log\frac{1}{r} + C(g)$, whence $\epsilon'_{\mathrm{N}}(r)(\log\frac{1}{r})^N \to 0$.

(B.1). 1. Lemma 7.5(a) and its proof put the test pair in all six conditions of Definition 7.4 at $k_0 = \max\{K-s, 2\}$, under $3 \le s \le K$ and $\mathsf{Lm}_s \le L^{s-3}$, as required in (B.1); there the number $\theta^{[j]}/K_{\mathbf{M}}$ of every step is at most half of the largest value that the one-step theorem admits, $\hat r_{k_0} \ge M$, so $\varsigma_i = 1$ for $i \le k_0$, and $\mathsf{D}_i^{12} \ge \hat r_i/\sqrt{3} - 1$. 2. Below k_0, Proposition YMM1:122.2 gives $\|E_{12}^{(j)}\| \le C\nu_{j-1}$, with ν_j defined in (199); its running, half-ceiling and separation hypotheses are those verified in the pair frame of Lemma 7.5(a); from k_0 on, Lemma 7.6(b), (c) and the start at k_0 give the rest families with $\|\mathsf{R}^{(j+1)}\|_{j+1,\lambda_{\mathrm{out}}} \le \epsilon_j^{(2)}\varsigma_j\bar\nu_j$,

$$\epsilon_j^{(2)} \le C\big[x_j^{-1/2}(1+\mathsf{e}_\downarrow) + \theta^{[k_0]}\big], \qquad \mathsf{e}_\downarrow = \sum_{i\le k_0} e^{-4\beta_{\mathrm{s}}\kappa[\mathsf{D}_i^{12}/M-2]_+}\varkappa_{i-1}^{-2}\,:$$

no number in it grows with $\log\frac{1}{r}$ or with $n-k_0$, as the derivatives of the step gain the factor $1/\mathfrak{b}_j$ per order in the sources (Lemma 7.6(b)) and the lags of Lemma 7.6(c) fall like L^{-4l} and sum geometrically over the levels. 3. The decomposition of step 2 above, over the base level k_0, with Lemma 7.8(a), in the frame at k_0, for I and II and Proposition 7.13 at the test pair for III, both in the form stated after them, whose conditions are the frame, the smallness at the heights concerned ($2r_n \le \varrho_{\mathrm{ch}}$, so that $r_n \le \frac{1}{120}$ as $\varrho_{\mathrm{ch}} \le \frac{1}{60}$; $\epsilon_i^{\mathrm{cu}} \le 1$; $x_n^{-1} \le r_n^2$) and the side bound $\ell \ge 2LMy_K$: for a test pair at $k_0 = \max\{K-s, 2\}$ these hold for $g \le \min\{\gamma_{\mathrm{jt}}, \gamma_{\mathrm{O}}\}$ and $r \le r_0(\mathsf{b})$, the frame by Lemma 7.5(a), the side bound as $\ell \in \mathfrak{L}(g)$, and the smallness at the heights $\ge k_0$ being among the conditions that fix γ_{O} and $r_0(\mathsf{b})$.

The shape ϑ does not enter, since any $\bar{\mathsf{e}} \ge 2\mathsf{w}_1\mathsf{w}_2\mathsf{E}_i$ is admissible. 4. In the yardstick $\hat r_n^3\mathsf{u}_1\mathsf{u}_2$ the main part of II is $\le C\mathfrak{b}_n^2[\gamma_n(1+\mathsf{e}_\downarrow) + (n-k_0)\theta^{[k_0]}]$, III is $\le C\hat r_{k_0}^3\mathfrak{b}_{k_0}^4(\delta_{k_0} + \epsilon_{k_0}^{\mathrm{cu}})\Lambda^2\mathsf{h}^2 + C\mathfrak{b}_n^2 r_n$, by the bound $\mathsf{E}_i \le C_{\mathsf{E}}\delta_i^4(\delta_i + \epsilon_i^{\mathrm{cu}})$ of Proposition 7.13, and I is $\le C\mathfrak{b}_n^2 e^{-c'Y_s^{2\mathfrak{p}_0}}$. With $\theta^{[k_0]} \le C(r/\mathsf{b})^{1/2}y_{k_0}^{\mathfrak{p}_0}$, $K - k_0 \le s \le Cy_{k_0}$ and $\mathsf{e}_\downarrow \le Cy_{k_0}^{2\mathfrak{p}_0}e^{-c'Y_s^{2\mathfrak{p}_0}}$, and the smallness that the recursions need holding for $g \le \gamma_{\mathrm{O}}$ and $r \le r_0(\mathsf{b})$, this is the bound of (B.1); its last term $C\mathfrak{b}_n^2 r_n \le C\mathfrak{b}_n^2\delta_n$ is the price of writing the form with the linear angles of one chart. 5.

The conditions that fix $r_0(\mathsf{b})$ depend on b through $(r/\mathsf{b})^{1/2}$, through $y_{k_0} \le \log\frac{\mathsf{b}}{r} + C\log\log\frac{\mathsf{b}}{r}$ and through $x_{k_0} \le \frac{24}{23}\mathsf{b}\hat r_{k_0}/r$; on $(g^{-2}, \bar{\mathsf{b}}]$ these are bounded by their values at the two ends, so r_0 has a positive infimum over the labels at g.

(B.3). $|\mathsf{ang}_p^{[n]}(A)| \le 2\eta_n^2 r_n$, Lemma 7.17(a) with $\mathsf{r} \ge r/\sqrt{3}$, and (P1):

$$|q_n(\mathsf{ang}^{[n]}(A))| \le C\,r_n^2\,\mathsf{b}\,a_{K-n}^{-4}\rho^6 r^{-3}\mathsf{u}_1\mathsf{u}_2 = C\,r_n^2\,\mathsf{b}\,a_{K-n}^{-1}(\rho/r)^6\hat r_n^3\mathsf{u}_1\mathsf{u}_2 \le C\mathfrak{b}_n^2(\rho/r)^6\hat r_n^3\mathsf{u}_1\mathsf{u}_2,$$

as $\mathsf{b}\,a_{K-n}^{-1} \le \frac{5}{4}x_n$ and $x_n r_n^2 \le C\mathfrak{b}_n^2$. □

Proof of Theorem X. 1. *(A.1).* Proposition 7.19(a) bounds J_3 against the lattice ring ($64\mathsf{d} \le \ell_g$ as $\ell_g \ge 26$ and $\mathsf{d} \le e^{-34}$; $\rho \le r_1(\mathsf{b})$ by $\mathsf{d} \le \mathsf{d}_4(g) \le r_1(\bar{\mathsf{b}}) \le r_1(\mathsf{b})$), and Lemma 7.21 bounds $S_3^T - \mathsf{J}_3$ by $13\Lambda_3^3\mathsf{M}'^3\mathsf{b}^3\mathsf{d}^{3/2}\mathrm{nat}_3$ (all supports lie within $20\mathsf{d} \le \frac{1}{8}\ell_g - 1$ of x_1).

2. *The geometry of (A.2).* For a triple $(z_1,z_2,z_3)=(x,y,z)$ of $\mathcal{D}$ put $r=\frac12 r_*$, $\mathsf{d}=\frac12\mathsf{d}_*$; bumps f_a with supports in balls of radius $\rho<\min\{\frac14 r_*, r_1(\bar{\mathsf{b}})\}$ inside the open balls of radius $\frac14 r_*$ about the z_a are placed at (ρ,r,d): their supports are $\ge r_*-\frac12 r_*=r$ apart in the pair and $\ge \mathsf{d}_*-\frac12 r_*\ge\mathsf{d}$ across, with $|x_1-x_2|\le 3r$, $|x_a-x_3|\le 5\mathsf{d}$, all in $\mathbb{B}(z_1,\frac94\mathsf{d}_*)$; this holds for every ratio $r_*/\mathsf{d}_*\in(0,1]$, and $\mathsf{d}_*\le\mathsf{d}_5(g)$ gives $\mathsf{d}\le\mathsf{d}_4(g)$.

3. *Lattice to continuum.* Lemma 7.22(a) with $\mathsf{d}^+=5\mathsf{d}_*$ and a Lipschitz number ϑ of the f_a:

$$|3\,\mathrm{Tr}\prod_a((f_a\circ x)\mathsf{b}^{-1}C_K^{\mathrm{free}})-3\mathsf{b}^{-3}\int k_3\prod f_a|\le 3C^{(3)}[a_K/\vartheta\rho+(5\mathsf{d}_*/\ell_g)^3]\mathrm{nat}_3.$$

4. *The limit.* Along first-passage data with $K_j\to\infty$ and labels $\to\mathsf{b}$, $S_3^T(f)\to S_3^{(\ell_g,\mathsf{b})}(f)$ (Theorem YMM1:A), $a_{K_j}/\vartheta\rho\to 0$, and the brackets are bounded with $\bar{\mathsf{b}}$ and $\bar{\mathsf{M}}^{(24)}$ (Lemma 7.20(e)); with $r^{-3}\mathsf{d}^{-6}=512\,r_*^{-3}\mathsf{d}_*^{-6}$ this is the bound of the form in (A.2).

5. *Kernels.* Lemma 7.23(a) on $\prod_a U_a$, with $(\frac{3}{\pi})^3\le 1$: a Borel kernel, bounded at its Lebesgue points by the bound of the form at the centre; the cover of $\mathcal{D}$ by such products and the glueing of Lemma 7.30 give one kernel on $\mathcal{D}$; the closest pair of a triple is (x,y) after a relabelling. *(A.3)* is Lemma 7.23(b).

6. *(A.4).* (i) is Proposition 7.28(a) at $n=3$. (ii) For a triple with $\mathsf{d}_*\le\mathsf{d}_5(g)$, the bumps of Lemma 7.29(c) about it are in the data of (i) at every large j (the cube of side $\frac92\mathsf{d}_*\le\frac12\ell_g$ about x holds them, so the projection keeps all distances and the integrals of k_3); (i), step 4 at the label b, and $S_3^T[\nu_j]\to S_3^{\sigma'}$ give $|\int(\mathsf{s}_3-3\mathsf{b}^{-3}k_3)\prod f_a^\rho|\le[\epsilon_{\mathrm{A}}+512C_3^{\mathrm{tr}3}\mathsf{b}^3\mathsf{d}_*^{3/2}]\mathsf{b}^{-3}r_*^{-3}\mathsf{d}_*^{-6}\cdot 0.102\le\mathsf{E}_3(g,\mathsf{d}_*)\mathsf{b}^{-3}r_*^{-3}\mathsf{d}_*^{-6}$, and Lemma 7.29(c) gives the bound at the point. (iii) is Lemma 7.29(a).

7. *(A.5).* Let (K_j,β_j,ν_j) be a Gibbs sequence at g_0; its members are periodic Gibbs states, $\nu_j\in\mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$. For large j, β_j exceeds $L(g^{-2}+B_\sharp)$; let K_j' be the first-passage index of β_j at g and $z_j=K_j-K_j'$; as $g\le g_0$, $0\le z_j\le z_+$ with z_+ formed from g_0, g and the constants. (1) *The states.* For $0\le z<K$ the dilation $U\mapsto U^{(z)}$, $U^{(z)}(L^z b)=U(b)$, maps the bonds, the plaquettes and the finite sets of bonds of $\mathbb{L}_K$ onto those of $\mathbb{L}_{K-z}$, with $a_{L^zp}(U^{(z)})=a_p(U)$. The Gibbs kernel of a finite set of bonds has the exponent $-\beta\sum_p a_p$ over the plaquettes that contain a bond of the set, which reads β and the lattice and not its spacing; so the image $\nu^{(z)}$ of a Gibbs state at (a_K,β) satisfies the equations of the kernels at (a_{K-z},β), and invariance under a subgroup Γ' of finite index of $a_K\mathbb{Z}^3$ becomes invariance under $L^z\Gamma'$, of finite index in $a_{K-z}\mathbb{Z}^3$.

So the dilation carries $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ onto $\mathcal{G}^{\mathrm{per}}_{K-z,\beta}$ (equation YMM1:(1819) and the definition of periodic states following it), and $\nu_j^{(z_j)}$ is a periodic Gibbs state at the first-passage datum (K_j',β_j) at g, with the label $L^{z_j}a_{K_j}\beta_j$. (2) *The fields.* At every configuration U of $\mathbb{L}_K$, $x(L^zp)=L^zx(p)$ and $a_{K-z}=L^za_K$ give $\mathcal{O}(f)(U)=L^z\mathcal{O}'(f^{(z)})(U^{(z)})$, $f^{(z)}=f(L^{-z}\cdot)$, the prime marking the field at the cutoff $K-z$, as in Lemma 7.31(d), which is the dilation; so in every law ν on $\mathbb{L}_K$, $S_3^T[\nu](f)=L^{3z}S_3^T[\nu^{(z)}](f^{(z)})$. (3) *The approximants* of a component of a canonical decomposition of the limit are periodic Gibbs states at the same data, by the definition of the components and their approximants in Lemma 7.29(a); (1) and (2) apply to them. (4) *The limit.* On a subsequence $z_j=z$ is constant and the labels converge, to b_0 say; along it $S_3^T[\nu_j^{(z)}](f)=L^{-3z}S_3^T[\nu_j](f(L^z\cdot))\to L^{-3z}S_3^\sigma(f(L^z\cdot))$ on separated triples, σ the limit, and this functional has the continuous kernel $\mathsf{s}_3^{(z)}=L^{-12z}\mathsf{s}_3(L^{-z}\cdot)$; likewise for a component and its approximants.

The proof of (A.4)(ii) uses of the law σ' the convergence $S_3^T[\nu_j]\to S_3^{\sigma'}$ on separated triples and the continuity of the kernel of $S_3^{\sigma'}$ at the triple (Lemma 7.29(c)); so (A.4)(ii) at g applies to the dilated sequence, whose labels tend to $L^z\mathsf{b}_0$, at the triples with $L^z\mathsf{d}_*\le\mathsf{d}_5(g)$. In kernels $\mathsf{s}_3(x)=L^{12z}\mathsf{s}_3^{(z)}(L^zx)$, and the natural size is invariant: $L^{12z}(L^z\mathsf{b}_0)^{-3}(L^zr_*)^{-3}(L^z\mathsf{d}_*)^{-6}=\mathsf{b}_0^{-3}r_*^{-3}\mathsf{d}_*^{-6}$, $k_3(L^z\cdot)=L^{-9z}k_3$. The approximants of a component are periodic Gibbs states at the same couplings and are dilated alike. □

Proof of Theorem Z. 1. *(C.1).* At $x, y = c \pm \frac{r}{2}n$: $r_* = r$; the two distances $|c - z \pm \frac{r}{2}n|$ lie in $[\mathsf{d} - \frac{r}{2}, \mathsf{d} + \frac{r}{2}]$ and the sum of their squares is $2\mathsf{d}^2 + \frac{1}{2}r^2$, so $\mathsf{d}_* \in [\frac{3}{4}\mathsf{d}, \frac{17}{16}\mathsf{d}]$, $r \le \mathsf{d}_* \le \mathsf{d}_5(g)$. (A.2) multiplied by $\frac{2\pi}{3}\mathsf{b}r^3$ gives $\frac{2\pi}{3}(\frac{4}{3})^6 \le 12$ times $\bar{\epsilon}_{\mathrm{A}}\mathsf{b}^{-2}\mathsf{d}^{-6}$, and Lemma 7.24(c) gives $2.66 \le 2.7$; "almost everywhere" is in (c, h, z), a linear change of the variables (x, y, z). (ii) (A.3) at every triple; k_3 is continuous off the diagonals, so its means tend to its values; with tents, (A.3) in the tent form and the second part of Lemma 7.24(c). (iii) (A.4)(ii) at every triple and Lemma 7.24(c).

2. *(C.2)(i).* Proposition 7.19(b) bounds J_2; Lemma 7.21 at two sources gives $|S_2^T - \mathsf{J}_2| \le 3\Lambda_3^2\mathsf{M}'^2\mathsf{b}^2\mathsf{d}^{3/2}(\rho/\mathsf{d})^6\mathsf{b}^{-2}|w_1|_\infty|w_2|_\infty$; at the plane weights $w_1 = \mathbf{1}_{\{\lambda(p)=\lambda\}}\varphi_1 \circ x$, $w_2 = \mathbf{1}_{\{\lambda(p)=\mu\}}\varphi_2 \circ x$, Lemma 7.22(c) turns the lattice square into $\mathcal{K}_{\lambda\mu}$ ($8a_K \le \rho$ by $s(\rho) \le K$; the assumption $|x_1 - x_2| \le 18\mathsf{d}$ is the one that this step and the rings need).

3. *(C.2)(ii).* For $(x_0, y_0) \in \Omega_{\mathrm{P}}$ and bounded Borel f, h supported in the closed balls of radius $\frac{1}{8}\mathsf{d}_0$ about x_0, y_0, the jets, the remainder, $|C_K^{\mathrm{free}}(p, q)| \le (1 + 3C_{\mathrm{lat}})a_K^3|u|^{-3}$ and the count of plaquettes give

$$|\langle \mathcal{O}_\lambda(f); \mathcal{O}_\mu(h)\rangle_{K_j,\ell_g,\beta_j}| \le \mathsf{B}(g, \mathsf{d}_0)\|f\|_\infty\|h\|_\infty, \qquad \mathsf{B} = 4^{-6}g^4[\tfrac{3}{2} \cdot 729(1 + 3C_{\mathrm{lat}})^2 + \mathsf{E}_2(g, \tfrac{1}{2}\mathsf{d}_0)],$$

with no Lipschitz number (the Riemann sums of step 2 involve $a_K/\vartheta\rho$ and give no bound in the sup norms). Lemma 7.30 gives one subsequence for all pairs of balls; along it step 2, with $a_{K_j}/\vartheta\rho \to 0$, gives the bump form at every centre: the balls of radius $\frac{1}{8}\mathsf{d}_0$ are $\ge \frac{1}{2}\mathsf{d}_0 =: \mathsf{d}$ apart, $|x_1 - x_2| \le \frac{5}{2}\mathsf{d}$, and $(\rho/\mathsf{d})^6 = 64(\rho/\mathsf{d}_0)^6$. Lemma 7.23 at $p = 2$ gives the kernels and the almost everywhere bound, and Lemma 7.24(a) gives $t_\lambda - \mathsf{t}^\circ(e_\lambda, \cdot) = \sum_\mu(\delta_{\lambda\mu} - \frac{1}{3}\sum_{\lambda'}\delta_{\lambda'\mu})$ with $\delta_{\lambda\mu} = \tau_{\lambda\mu} - \frac{3}{2}\mathsf{b}^{-2}[\mathbb{K}_{3,\lambda\mu}]^2$: three terms and a third of nine, so the factor 6.

4. *(C.3).* Along the subsequence of the limit point $S_3^T \to S_3^{(\ell_g,\mathsf{b})}$, since that limit is taken along all data with labels $\to \mathsf{b}$. By (A.3) and by Lemma 7.23(b) applied to the bump form of (C.2)(ii) at the centre (c, z), the means over balls of radius ρ of $\mathsf{s}_3 - 3\mathsf{b}^{-3}k_3$ and of $\tau_{\lambda\mu} - \frac{3}{2}\mathsf{b}^{-2}[\mathbb{K}_{3,\lambda\mu}]^2$ are bounded at every centre, with the factors $(\frac{3}{4\pi})^3, (\frac{3}{4\pi})^2 \le 1$; k_3 and $[\mathbb{K}_3]^2$ are continuous off the diagonals; adding with Lemma 7.24(a), (c) gives the display, and the tents likewise. The cone form: (C.1)(i) at n, (C.2)(ii) at (c, z) almost everywhere (a null set of (c, z) is a null set of (c, h, z)), and $|\mathsf{t}^\circ(n, X) - \mathsf{t}^\circ(e_\lambda, X)| \le 0.057|n - e_\lambda|\mathsf{b}^{-2}|X|^{-6}$.

5. *(C.4).* (d) is Proposition 7.28(b) with step 2 on the least torus (the projection is injective and keeps distances on $\mathbb{B}(x_0, \frac{3}{2}\mathsf{d}_0)$, so the integrals and the norms are those of the periodised functions); it gives the bound $\bar{\mathsf{B}}(g, \mathsf{d}_0)$ of step 3 along ν_j for j large. (a) Lemma 7.30 on Ω_σ. (b) The bump form at every centre of Ω_σ with $64\mathsf{E}_2(g, \frac{1}{2}\mathsf{d}_0)\mathsf{b}^{-2}\mathsf{d}_0^{-6}\rho^6$; Lemma 7.23; the bound at a point by centres $\zeta_m \to (x, y)$ of distances $\mathsf{d}_{\zeta_m} < |x - y|$, whence the supremum in ϵ_σ. Every ν_j is invariant under the translations of $\mathbb{L}_{K_j}$ by Proposition YMM1:103.4, so the limit forms are invariant under all translations, and by Fubini's theorem $\tau_{\lambda\mu}^\sigma(x, y)$ is a function of $x - y$ almost everywhere. $\sum_{\lambda,\mu}\langle \mathcal{O}_\lambda; \mathcal{O}_\mu\rangle = S_2^T$, which converges along the whole sequence to $S_2^{\sigma'}$ with the continuous kernel s_2^T; with Lemma 7.24(a) this gives the bound of s_2^T almost everywhere, and at every point by continuity, $\epsilon_\sigma(g, \cdot)$ being nondecreasing. (c) Let $\mathcal{N}$ be the union of the null sets of (b); it is fixed before r is named.

Off $\mathcal{N}$, (b) and Lemma 7.24(a) give $|t_\lambda^\sigma - \mathsf{t}^\circ(e_\lambda, \cdot)| \le 6(\frac{3}{\pi})^2\epsilon_\sigma\mathsf{b}^{-2}\mathsf{d}^{-6} \le 6\epsilon_\sigma\mathsf{b}^{-2}\mathsf{d}^{-6}$, and (C.1)(iii) at $n = e_\lambda$ holds at every point, since s_3 is continuous; $12\sup\mathsf{E}_3 + 6\epsilon_\sigma = \epsilon'_\sigma$. With tents of radius $\rho < \frac{1}{8}\mathsf{d}$ at (c, z): the bump form of (b) at the centre (c, z), and Lemma 7.24(d) times $\frac{3}{2}$, six times, give $21\rho/\mathsf{d}$. □

Proof of Theorem AA. 1. *(D.1) below* γ_{N} is Proposition 7.34. 2. *(D.1) at every* $g \le \gamma$. Let z, g'_1, g'_2 be as in Lemma 7.31 and $K_\circ(g) = z + \max_\iota s'_\iota(r_{g'_\iota})$. For $K \ge K_\circ(g)$, $(K - z, \beta)$ is a first-passage datum at some $g'_\iota \le \gamma_{\mathrm{N}}$, on the side $L^z\ell \in \mathfrak{L}(g'_\iota)$, and the conditions of Proposition 7.34 hold at $(L^z r, L^z\mathsf{d}')$; by Lemma 7.31(d) each display at (K, ℓ, β) is that display at $(K - z, L^z\ell, \beta)$. So (D.1)

holds with

$$\epsilon^{\mathrm{cl}}(g,\ell,\mathsf{d}')=\max_{\iota=1,2}\epsilon_\sharp^{\mathrm{ev}}(g'_\iota,L^z\ell,L^z\mathsf{d}'),\qquad \mathsf{d}_{\mathrm{cl}}(g)=\tfrac{7}{6}L^{-z}\min_\iota t_{\mathrm{N}}(g'_\iota),$$

a finite function of (g,ℓ,d'), with the rate for $\mathsf{d}'\le\mathsf{d}_{\mathrm{cl}}(g)$. On the dilated torus, at the distance $L^z\mathsf{d}'$, the members of $\epsilon_\sharp^{\mathrm{ev}}$ that carry the renormalisation group, the remainder and the induction, read the distances through the floor $\min\{\frac{6}{7}L^z\mathsf{d}',t_{\mathrm{N}}(g'_\iota)\}$ alone; the largest distance $\frac{8}{7}L^z\mathsf{d}'$ enters the one explicit member, the comparison of the sum of the slices with the free kernel (Lemma 7.17(b)), which is polynomial in that distance; and the passage from the floor to $L^z\mathsf{d}'$ costs the factor $\max\{1,6L^z\mathsf{d}'/7t_{\mathrm{N}}(g'_\iota)\}^6$ of $\epsilon_\sharp^{\mathrm{ev}}$ (proof of Proposition 7.34). 3.

(D.2). The forms are bounded in the sup norms at every pair of small balls in Ω°, as in step 3 of the proof of Theorem Z; Lemma 7.30 gives one subsequence for the plane and the bond forms; (D.1) with $a_{K_j}/\vartheta r\to 0$ gives the bump forms at every centre; Lemma 7.23, with centres in the window $[\frac{7}{9}t,\frac{9}{7}t]$ and $(\frac{3}{\pi})^2(\frac{9}{7})^6\le 4.2$, gives the kernels. For T_n: the kernel of $\langle T_\lambda;\mathcal{O}\rangle$ is within $3(4.2+4.2)\bar\epsilon^{\mathrm{cl}}=25.2\,\bar\epsilon^{\mathrm{cl}}$ of $\mathsf{t}^\circ(e_\lambda,\cdot)$, that of $\langle\mathcal{O}^{\mathrm{od}}_{\lambda\lambda'};\mathcal{O}\rangle=\sum_\gamma\langle\mathcal{O}^{\mathrm{od}}_{\lambda\lambda'};\mathcal{O}_\gamma\rangle$ within $12.6\,\bar\epsilon^{\mathrm{cl}}$ of $3\mathsf{b}^{-2}[\mathbb{K}_3^2]_{\lambda\lambda'}$; with $\sum_\lambda n_\lambda^2=1$, $\sum_{\lambda<\lambda'}|n_\lambda n_{\lambda'}|\le 1$ and Lemma 7.24(a), $25.2+12.6\le 38$.

The kernel t_n is a quadratic polynomial in n whose coefficients are the nine kernels, so one null set serves all n. 4. *(D.3)* is (C.1) and (D.2) by the triangle inequality: almost everywhere in (c,h,z) by Fubini's theorem; for the means and the tents, the bump forms of (D.1) at the centre (c,z) itself, extended to indicators of balls by Lemma 7.23(b), bound the means of the kernels with factors below those of the almost everywhere bound. □

Proof of Theorem AB. (E.2). 0. *The stopping level.* Let $\epsilon=r^{\beta_{\mathrm{H}}/36}+(a_K/r)^{1/9}$, $\ell_\epsilon=\max\{1,\log\frac{1}{\epsilon}\}$, $a^\flat=\min\{\mathsf{d}/8M\ell_\epsilon,a_\sharp\}$ with $a_\sharp=4\mathsf{b}/5x_\sharp$, so that $a_{K-n}\le a_\sharp$ gives $x_n\ge x_\sharp$ (Lemma 7.3(a)), n_* the largest level with $a_{K-n_*}\le a^\flat$, and $a_*=a_{K-n_*}\in(a^\flat/L,a^\flat]$. The conditions that define $r_{\mathcal{W}}(g,\mathsf{b},\mathsf{d})$, namely $r\le\min\{r_\alpha,(\mathsf{d}/5LM)^2,e^{-1}\}$, $8ML^{m_1+2}r^{1/2}(1+\log\frac{1}{r})\le\mathsf{d}$, $L^{m_1+2}r^{1/2}\le a_\sharp$ and $r^{-1/4}\ge 2M$, secure $N_0<n_*$, $x_{n_*}\ge x_\sharp$ and $L^{N_0-n_1}\ge 2M$, as $L^{N_0-n_1}=L^{m_1}a_{K-n_0}/a_{K-n_1}\ge r^{-1/4}$ (so Lemma 7.36 holds with $n^\sharp=n_*$ when $\epsilon_i^{\mathrm{e}}\le 1$), $8Ma_*\le\mathsf{d}$, $e^{-\mathsf{d}/4Ma_*}\le\epsilon^2$ and $a_*^{-1}\le C\ell_\epsilon/\mathsf{d}$.

1. *The identity.* Lemma 7.20(c) at $k=n_*$, $\mathbb{P}_*=\mathbb{P}_{n_*}$, for the two lists, G_3 being the same function in both:

$$\mathsf{c}S_3^T(w_1,w_2,w_3)-S_2^T(w_T,w_3)=\int\Gamma\,d\mathbb{P}_*+\kappa_{\mathbb{P}_*}(\Delta,G_3)+\mathsf{c}[\kappa_{\mathbb{P}_*}(G_{13},G_2)+\kappa_{\mathbb{P}_*}(G_{23},G_1)]$$
$$+\mathsf{c}\,\kappa_{\mathbb{P}_*}(G_1,G_2,G_3)=:T_1+T_2+T_3+T_4,$$

with Δ, Γ, G_β taken at $U_{t'}(W)$.

2. *Sizes.* $r^3|w_{1,2}|_\infty\le 489$, $|w_T|_\infty\le\frac{2}{3}|w_1|_\infty$, $\mathsf{c}|w_1|_\infty|w_2|_\infty r^3\le C\mathsf{b}$, $|w_3|_\infty\le\mu_3 r^{-3}$; the bounds of Lemma 7.21 hold at every point of the small-field region, as their proof uses of W only that the background is regular.

3. *T_1, T_3: the crossings.* At $t'\le n_*$, $8Ma_{K-t'}\le\mathsf{d}$, and Lemma 7.39 with $e^{-\mathsf{d}/4Ma_*}\le\epsilon^2$ gives $|T_1|\le C(\mathsf{b})a_*^{-3/2}\mathsf{d}^{-6}\epsilon^2\mu_3$ and $|T_3|\le Ca_*^{-1}r^3\mathsf{d}^{-6}\epsilon^2\mu_3\mathsf{M}_6$, $\mathsf{M}_b=\int\alpha^{-b}d\mathbb{P}_*$: no negative power of r is left.

4. T_4. $|T_4|\le C\mathsf{b}r^3\Lambda_3^3\mathsf{M}_{18}\mu_3$.

5. *T_2: pair minus tensor field.* $T_2=\int(\Delta-\mathsf{c}_{n_*})(G_3-\int G_3)d\mathbb{P}_*$, and $|G_3-\int G_3|\le\Lambda_3\mu_3(\alpha^{-6}+\mathsf{M}_6)$ by step 2. On the parts with $t'\ge N_0$ each measure is absolutely continuous with respect to $\mathsf{m}_{t'}$, and Lemma 7.36 gives $|\Delta-\mathsf{c}_{n_*}|\le 3.01\,\tilde\varepsilon\,\alpha^{-4}$ almost everywhere. The number c_{n_*}: the first part of $\mathbb{P}_*$, on which $t'=n_*$ and $\alpha=a_*$, has positive mass, as the density of m_{n_*} on $\mathcal{V}_{n_*}^\chi$ is a positive exponential by (224) and (225). This region is open, its defining tests are strict, and they hold at the trivial field, where all curvature and fluctuation defects vanish. It therefore has positive Haar measure; at almost every point of it $|\Delta-\mathsf{c}_{n_*}|\le\varepsilon^{\mathcal{W}}a_*^{-4}$ (Lemma 7.36) and $|\mathsf{Y}_\Delta|=|\Delta-\Delta_K(\mathbf{1})|\le b_\Delta a_*^{-6}$, $b_\Delta=(C\mathsf{b}+C)\Lambda_3$ (Lemma 7.21 at every point, step 2), so that $|\mathsf{c}_{n_*}-\Delta_K(\mathbf{1})|\le(\varepsilon^{\mathcal{W}}+b_\Delta)a_*^{-6}$.

On the parts with $t' < N_0$, $\alpha < a_{K-N_0} = L^{m_1} a_{K-n_0} < L^{m_1+1} r^{1/2} < a_*$, so that there $|\Delta - \mathsf{c}_{n_*}| \le |\mathsf{Y}_\Delta| + |\Delta_K(\mathbf{1}) - \mathsf{c}_{n_*}| \le (2b_\Delta + \varepsilon^{\mathcal{W}})\alpha^{-6}$ and $\mathsf{M}_6 \le (1+\mathsf{M}')\alpha^{-6}$; and $\int_{\{\alpha<\varrho\}} \alpha^{-12} d\mathbb{P}_* \le \varrho^{12}\mathsf{M}'$ (Lemma 7.20(e)) at $\varrho = a_{K-N_0}$ gives a factor Cr^6.

6. *Together.* $\mathsf{M}_b \le a_*^{-b} + \mathsf{M}' \le C(g,\mathsf{b})\ell_\epsilon^b \mathsf{d}^{-b}$, $\epsilon^{1/2}\ell_\epsilon^{10} \le C$ and $r^{3-\beta_{\mathrm{H}}/72}(1+\log\frac{1}{r})^{18} \le C$ give $|\mathsf{c}S_3^T - S_2^T| \le C_{\mathrm{A}}(g,\mathsf{b})\mathsf{d}^{-18}[r^{\beta_{\mathrm{H}}/72} + (a_K/r)^{1/18}]\mu_3$. If the smallness $\epsilon_i^{\mathrm{e}} \le 1$ of the single-source arrays of the near pair, which Lemma 7.36 asks at the levels $\mathsf{k}(\frac{r}{2}) \le i < n_1$, fails, then, as $\sum_{\mathsf{k}(r/2)\le i<n_0} \epsilon_i^{\mathrm{e}} \le C_\omega[2.2\gamma_{n_0} + \frac{1}{2}s(\frac{r}{2})\mathsf{c}^\flat\theta^{[0]}] \le C(g,\mathsf{b})\,\epsilon$ (with $\gamma_{n_0} \le C(\mathsf{b})r^{1/4}$ and $s(\frac{r}{2})\theta^{[0]} \le C(\mathsf{b})(a_K/r)^{1/4}$), the number ϵ exceeds a number $\epsilon_0(g,\mathsf{b}) > 0$, the bracket is $\ge (\frac{1}{2}\epsilon_0)^{1/2}$, and the bounds of Lemma 7.21 give the claim with a larger C_{A}.

(E.1). By Lemma 7.20(c) for the two lists,

$$[\mathsf{c}S_3^T - S_2^T] - [\mathsf{c}\mathsf{J}_3 - \mathsf{J}_2] = \int \mathsf{Y}_{\Delta 3}\, d\mathbb{P} + \kappa_{\mathbb{P}}(\mathsf{Y}_\Delta, \mathsf{Y}_3) + \mathsf{E}, \qquad \mathsf{E} = \mathsf{c}[\kappa_{\mathbb{P}}(\mathsf{Y}_{13}, \mathsf{Y}_2) + \kappa_{\mathbb{P}}(\mathsf{Y}_{23}, \mathsf{Y}_1) + \kappa_{\mathbb{P}}(\mathsf{Y}_1, \mathsf{Y}_2, \mathsf{Y}_3)],$$

and Lemma 7.21 gives $|\mathsf{E}| \le C\Lambda_3^3 \mathsf{M}'\mathsf{b}^3\mathsf{d}^{3/2}r^3 \cdot \mathsf{b}^{-2}\mathsf{d}^{-6}\mu_3$. For $r \le r_{\mathcal{W}}$ the first bracket is bounded by (E.2) and the second by Lemma 7.40 (if $w_3 \equiv 0$ all members vanish): together $C(g,\mathsf{b})\mathsf{d}^{-12}[r^{\beta_{\mathrm{H}}/72} + (a_K/r)^{1/18}]\mathsf{b}^{-2}\mathsf{d}^{-6}\mu_3$, and $|\mathsf{E}|$ is of this form as $r^3 \le r^{\beta_{\mathrm{H}}/72}$. For $r > r_{\mathcal{W}}$, Lemma 7.21 bounds the left member of (E.1) by $C(\mathsf{b})\bar{\mathsf{M}}^{(24)}[\mathsf{d}^{-9/2}+1]\mu_3$, while the bracket is $\ge r_{\mathcal{W}}^{\beta_{\mathrm{H}}/72}$; the larger of the two quotients so formed is $\mathsf{C}_{\mathrm{R}}(g,\mathsf{b};\mathsf{d})$.

(E.1) under (Γ3). The stronger bounds stated in (E.1) are Lemma 7.38, at the levels $n \ge n_0$, that is at the levels with $a_{K-n} \ge r^{1/2}$, with $\mathsf{d}' = |c-z| \in [(1-\frac{1}{64})\mathsf{d}, 6\mathsf{d}]$. Let $r \le r_\alpha^{\mathcal{W}}(g,\mathsf{b})$. On the part of Ω with $t' = n \ge n_0$ the measure $\mathbb{P}$ is absolutely continuous with respect to m_n, $\mathsf{Y}_{\Delta 3} = \Gamma_n(U_n(W)) - \Gamma_K(\mathbf{1})$ and, with $\mathsf{c}_* = \mathsf{c}_K - \Delta_K(\mathbf{1})$, $\mathsf{Y}_\Delta - \mathsf{c}_* = \Delta_n(U_n(W)) - \mathsf{c}_K$, so that Lemma 7.38 bounds both by $\varepsilon^{\mathcal{W}}$ times their natural sizes, $\mathrm{nat}_n^{\mathcal{W}} \le \alpha^{-4}$; $\kappa_{\mathbb{P}}(\mathsf{Y}_\Delta, \mathsf{Y}_3) = \int(\mathsf{Y}_\Delta - \mathsf{c}_*)(\mathsf{Y}_3 - \int \mathsf{Y}_3 d\mathbb{P})\, d\mathbb{P}$, and $|\mathsf{c}_*| \le C(g,\mathsf{b})$, since $\mathbb{P}(\alpha < \alpha_1) \le \frac{1}{2}$ for $\alpha_1 = (2\bar{\mathsf{M}}^{(24)})^{-1/24}$ (Lemma 7.20(e)), while $a_{K-n_0} < Lr^{1/2} \le \alpha_1$, so that on the set $\{\alpha \ge \alpha_1\}$, of positive measure, both $|\mathsf{Y}_\Delta - \mathsf{c}_*| \le 2\varepsilon^{\mathcal{W}}\alpha_1^{-4}$ and the bound of Y_Δ by Lemma 7.21 hold.

The parts with $t' < n_0$ have $\alpha < a_{K-n_0} < Lr^{1/2}$, where nothing cancels and the moments of Lemma 7.20(e) give the factors r^6 and r^9; for $r > r_\alpha^{\mathcal{W}}$ Lemma 7.21 bounds the left member while the bracket is $\ge (r_\alpha^{\mathcal{W}})^{\beta_{\mathrm{H}}/72}$. Together the left member of (E.1) is at most $C(g,\mathsf{b})\mathsf{d}^{-5/2}[r^{\beta_{\mathrm{H}}/72} + (a_K/r)^{1/18}]\mathsf{b}^{-2}\mathsf{d}^{-6}\mu_3$.

(E.3). 1. For $\mathsf{b} \in I(g)$ every $(K, L^K\mathsf{b})$ is a first-passage datum at g with the label b. 2. *The pieces.* Cut φ_2 by the indicators of the cubes of side $\frac{r}{4}$; at most $9^3(\mathsf{d}/r)^3$ of them meet its support, and as $|y_1 - y_2| \le 3\mathsf{d}$ the centre z of each has $|c-z| \le 5\mathsf{d} + \frac{\sqrt{3}}{8}r \le 6\mathsf{d}$ for $c \in \operatorname{supp}\varphi_1$, so every piece is a w_3 of the data. By (E.2), summed over the pieces and integrated against $\varphi_1(c)\,dc$, $\int|\varphi_1| \le \frac{4\pi}{3}\mathsf{d}^3\|\varphi_1\|_\infty$:

$$\Big|\mathsf{A}_{r,K} - \int dc\,\varphi_1(c)\, S_2^T(w_T^c, \varphi_2)\Big| \le C(g,\mathsf{b})\mathsf{d}^{-12}[r^{\beta_{\mathrm{H}}/72} + (a_K/r)^{1/18}]\|\varphi_1\|_\infty\|\varphi_2\|_\infty.$$

3. *The smeared tensor.* $\int dc\,\varphi_1(c)\mathcal{O}(w_T^c) = T_\lambda(\varphi_1 * \chi^{r/8})$ exactly, $\|\varphi_1 * \chi^{r/8} - \varphi_1\|_\infty \le \frac{r}{8}\operatorname{Lip}\varphi_1$, and the two-point bound of Lemma 7.21 in the sup norms (supports at a distance $\ge \frac{1}{2}\mathsf{d}$, after cutting $\varphi_1 * \chi^{r/8} - \varphi_1$ into pieces) gives $|\langle T_\lambda(\varphi_1 * \chi^{r/8} - \varphi_1); \mathcal{O}(\varphi_2)\rangle| \le C(\mathsf{b},\mathsf{d})\, r \operatorname{Lip}\varphi_1 \|\varphi_2\|_\infty$; this is (i), with $r_\sharp$ the least of the thresholds of (E.2) and of the data. Steps 2 and 3 read the datum through (E.2) and Lemma 7.21 at it; so (i) holds, with the same proof, at every first-passage datum (K,β) at g whose label $\mathsf{b}' = a_K\beta$ lies in $(g^{-2}, \bar{\mathsf{b}}]$, with $\mathsf{A}_{r,K}$ formed at (K,β) with the prefactor $\frac{2\pi}{3}\mathsf{b}'r^3$ and with the numbers $r_\sharp$ and $\mathsf{C}(\mathsf{d})$ formed at b'. 4.

(ii). At a fixed r, $\mathsf{A}_{r,K} \to \mathsf{A}_r$ as $K \to \infty$: for each c, $S^T_{3;K,\ell_g,\beta_K}(f_+^c, f_-^c, \varphi_2) \to S_3^{(\ell_g,\mathsf{b})}(f_+^c, f_-^c, \varphi_2)$ by Theorem YMM1:A (Lipschitz functions with disjoint supports), with a bound uniform in c and

K (Lemma 7.21 and Proposition 7.19), and dominated convergence in c. Hence, by (i),

$$\limsup_{K,K'\to\infty} \big|\langle T_\lambda(\varphi_1);\mathcal{O}(\varphi_2)\rangle_{K,\ell_g,\beta_K} - \langle T_\lambda(\varphi_1);\mathcal{O}(\varphi_2)\rangle_{K',\ell_g,\beta_{K'}}\big| \le 2\mathsf{C}(\mathsf{d})r^{\beta_{\mathrm{H}}/72}\mathsf{b}^{-2}\|\varphi_1\|_\infty\|\varphi_2\|_\infty,$$

and $r\to 0$ shows that the sequence is a Cauchy sequence; $s(\frac{r}{2})\le K$ and $128a_K\le r$ hold for all large K, so the conditions of (i) on the cutoff hold along the sequence. 5. *(iii)*: $K\to\infty$ in (i). As g satisfies (Γ), the limit points of (C.2) along data with $\beta_j = L^{K_j}\mathsf{b}$ all give the form t_λ on these pairs.

(E.4). Let $\mathsf{b}_j = a_{K_j}\beta_j \to \mathsf{b}\in I(g)$, and let $\mathsf{A}_r^{(j)}$ be $\mathsf{A}_{r,K}$ formed at (K_j,β_j) with $\frac{2\pi}{3}\mathsf{b}_j r^3$. As $g^{-2}<\mathsf{b}<\bar{\mathsf{b}}$, for j large the labels lie in a compact subset of $(g^{-2},\bar{\mathsf{b}}]$. The bound (i), in its form at every label of $(g^{-2},\bar{\mathsf{b}}]$ (step 3 above; a label b_j may lie outside $I(g)$), holds at (K_j,β_j) with the prefactor $\frac{2\pi}{3}\mathsf{b}_j r^3$, and by Lemma 7.41 its constants and thresholds are uniform in j. At a fixed r, $\mathsf{A}_r^{(j)}\to\mathsf{A}_r$: the prefactor $\frac{2\pi}{3}\mathsf{b}_j r^3$ tends to $\frac{2\pi}{3}\mathsf{b}r^3$; for each c, $S^T_{3;K_j,\ell_g,\beta_j}(f_+^c,f_-^c,\varphi_2)\to S_3^{(\ell_g,\mathsf{b})}(f_+^c,f_-^c,\varphi_2)$ by Theorem YMM1:A, one limit along all data whose labels tend to b; and the bounds of Lemma 7.21 on $|S_3^T-\mathsf{J}_3|$ and on $|\mathsf{J}_3|$, summed over the pieces of φ_2, are uniform in c and in j, as $\mathsf{b}_j\le\bar{\mathsf{b}}$, so that dominated convergence applies in c. So

$$\limsup_j \big|\langle T_\lambda(\varphi_1);\mathcal{O}(\varphi_2)\rangle_{K_j,\ell_g,\beta_j} - t_\lambda(\varphi_1,\varphi_2)\big| \le \limsup_j\big(|\langle T_\lambda;\mathcal{O}\rangle_j - \mathsf{A}_r^{(j)}| + |\mathsf{A}_r^{(j)}-\mathsf{A}_r|\big) + |\mathsf{A}_r - t_\lambda| \le C\, r^{\beta_{\mathrm{H}}/72},$$

and $r\to 0$. □

Proof of Theorem AC. (a) Proposition 7.19(c), Lemma 7.21 at $n=4$, and Proposition 7.28(a) at $n=4$. (b) The assumptions of (b) give $\operatorname{supp} f_a\subset\mathbb{B}(x_a,\rho)$, with the balls $\mathbb{B}(x_a,\rho)$ at least r apart in each pair and at least d apart across, as Lemma 7.22(b) asks; the $w_a = f_a\circ x$ form two pairs at (ρ,r,d) with the centres x_a, with the bounds $|x_1-x_2|,|x_3-x_4|\le 8r$ and $|x_a-x_b|\le 18\mathsf{d}$, $a\le 2<b$, of the data; and $8a_K\le\rho$ by $s(\rho)\le K$ (Lemma 7.5(b)) and $\mathsf{d}\le\mathsf{d}^+$, as (b) notes. The bounds of (a) on $|S_4^T-\mathsf{J}_4|$ and on $|\mathsf{J}_4-\frac{3}{2}\sum_\varsigma \operatorname{Tr}\prod_l(w_{\varsigma(l)}\mathsf{b}^{-1}C_K^{\mathrm{free}})|$, the identity $\frac{3}{2}\sum_\varsigma\operatorname{Tr}\prod_l(w_{\varsigma(l)}\mathsf{b}^{-1}C_K^{\mathrm{free}}) = 3\mathsf{b}^{-4}\cdot\frac{1}{2}\sum_\varsigma\operatorname{Tr}\prod_l((f_{\varsigma(l)}\circ x)C_K^{\mathrm{free}})$ and Lemma 7.22(b) give (b). (c) For a point of $\mathcal{D}_4$ take the open balls of radius $\frac{1}{4}r_*$ about the x_a, $r=\frac{1}{2}r_*$, $\mathsf{d}=\frac{1}{2}\mathsf{d}_*$, and bumps f_a supported in balls $\mathbb{B}(x'_a,\rho)$ of radius ρ that lie inside them: these balls are $\ge r$ apart in a pair and, since $r_*\le\mathsf{d}_*$, $\ge\mathsf{d}$ apart across, as (b) asks, and the $f_a\circ x$ form two pairs at (ρ,r,d) with the centres x'_a (in a pair the centres are $\le\frac{5}{2}r_*=5r$ apart, across $\le 11\mathsf{d}$), all inside a ball of radius $6\mathsf{d}_*=\frac{1}{2}\mathsf{d}^+$; then (b), the limit $K\to\infty$ at the label b (Theorem YMM1:A), Lemma 7.23 at $p=4$ with $(\frac{3}{\pi})^4<1$, and $r^{-6}\mathsf{d}^{-6}=4096\,r_*^{-6}\mathsf{d}_*^{-6}$.

The rings (1234), (1243) of k_4 have the size $r_*^{-6}\mathsf{d}_*^{-6}$, the ring (1324) the size d_*^{-12}. □

7.5. **Scope.** Every statement of this section is made at short distances, on one torus or in states at a cutoff and in their limits, and the constants that depend on the side grow with it. The side of the torus enters through conditions that ask it to be large against the lengths in play, and through constants that grow with it, among them: the conditions that the supports lie in a ball small against it; the conditions that the boxes and the cubes of the local gauges do not wrap around the torus, namely $4\rho+4$ at most the side in Lemma 7.12, in the units of the level, the case distinction of step 5 of the proof of Proposition 7.13 on whether its box fits in the torus, which reads $\ell\ge 8$, $(4\mathsf{h}_i+4)a_{K-i-1}\le\ell_g$ in (α2) and in Definition 7.1(6), and $12a_{K-n}\le\ell$, $(8\varrho+2)a_{K-n}<\ell$ for the regular gauge on a cube, read at $\varrho=4$ in Lemma 7.36 and at $\varrho=3$ up to $n=K$ in the proof of the bounds of (E.1) under (Γ3), where $26<\ell_g$; the bound $L^m\ge LMy_K$ of the sides of $\mathfrak{L}(g)$, which gives $\ell_g\ge 338$, in the tails of Lemma 7.8, in Proposition 7.13, in Lemma 7.40 and for $26<\ell_g$; the distance $\frac{1}{4}\ell_g\ge 6.5$ of two mirror copies in Lemma 7.27; the membership $\ell\in\mathfrak{L}(g)$ wherever the objects of the theory are entered, as in the frame of Lemma 7.5; the terms in d/ℓ of the comparison of C_K^{free} with $\mathbb{K}_3$; the moments of Lemma 7.20(e); and the constant Q_0 of Lemma 7.25.

In the bond forms the members that carry the renormalisation group, the remainder and the induction of the proof of Proposition 7.34, read the distances through the floor $\min\{\frac{6}{7}\mathsf{d}', t_{\mathrm{N}}(g)\}$; the largest distance $\frac{8}{7}\mathsf{d}'$ enters the one explicit member, the comparison of the sum of the slices with C_K^{free} (Lemma 7.17(b)), which is polynomial in that distance and a part of $\epsilon_\sharp^{\mathrm{ev}}$. Theorems YMM1:AJ and YMM1:AD enter through the two-sided stability bound of the torus measures and the chessboard bound of Lemma 7.25, in (A.4), (A.5), (C.1)(iii), (C.4) and for the states of Theorem AC(a); Theorem AB, like every statement of this section, uses Theorems YMM1:D, YMM1:AJ and YMM1:AD.

The crossing functionals of Lemma 7.39 are joint cumulants of the steps given the block fields of a scale below d. The comparisons with t° and with the kernels t_λ and t_n are additive, in the unit $\mathsf{b}^{-2}\mathsf{d}^{-6}$; $\mathsf{t}^\circ(n, X)$ vanishes on the cone $3(n \cdot \hat{X})^2 = 1$. On a torus a kernel is a class modulo null sets, while at fixed (c, z) the triples $(c \pm \frac{r}{2}n, z)$ form a null set; there (C.1)–(C.3) and (D.3) are statements almost everywhere, or through means, tents and cones of directions. For the laws on $\mathbb{R}^3$ satisfying the continuity hypotheses in (A.4)(ii) and (C.4), including the periodic-Gibbs limits and their canonical components, s_3 and s_2^T are continuous, and the kernels $\tau_{\lambda\mu}^\sigma$ and t_λ^σ are classes modulo null sets: (C.1)(iii) holds at every point and for every unit vector n; (C.4)(c) holds for s_3 itself, without means, for every $0 < r \le \frac{1}{2}\mathsf{d}$ and every λ, at every (c, z) off one null set fixed before r is named, and at every (c, z) with the limit forms at the tents χ_c^ρ, χ_z^ρ, $0 < \rho < \frac{1}{8}\mathsf{d}$, in the place of $t_\lambda^\sigma(c, z)$ and $21\rho/\mathsf{d}$ added in the bracket.

The kernels $\tau_{\lambda\mu}$, t_λ, t_n of (C.2)–(C.4) and (D.2) belong to limit points, each chosen once for all pairs of bumps; at a label of $I(g)$, for $g \le \gamma_{\mathrm{R}}$ and on the least torus, the forms $\langle T_\lambda(\varphi_1); \mathcal{O}(\varphi_2)\rangle$ of (E.3) have one limit along all cutoffs.

8. Plane fields, stress and anisotropic variations

We compare the curvature bilinears with plane insertions and the stress tensor obtained from anisotropic changes of the lattice action. Uniform estimates permit the removal of the cutoff; the collapse and remainder estimates identify the conserved stress insertion.

The Ward identities retain their boundary terms and quantitative hypotheses. The two-scale comparisons use the results of Section 7; they do not identify arbitrary coincident-point products without a specified extension.

8.1. **Notation and hypotheses.** *Model, constants and data.* We work in the common real and sourced construction setting of Proposition YMM1:69.1 and Section YMM1:82: the Wilson action of SU(2) on $T_\ell = \mathbb{R}^3/\ell\mathbb{Z}^3$, $\ell = 2L^m$, at the spacing $a = a_K = L^{-K}$, $L \ge 13$ odd; $a_p = 1 - \frac{1}{2}\mathrm{tr}\,\partial U(p)$ and $A = \sum_p a_p$; $\langle\cdot\rangle_{K,\ell,\beta}$ and $\langle\cdot\,;\ldots;\cdot\rangle_{K,\ell,\beta}$ are the means and the joint cumulants of $Z_{K,\ell,\beta}^{-1} e^{-\beta A} dU$, and $S_{n;K,\ell,\beta}^T$ are the connected functions of $\mathcal{O}$. For a plaquette p, $x(p)$ is its barycentre, $\lambda(p)$ its normal direction and $P(p)$ the set of its two directions; for a bond b, x_b is its midpoint and μ_b its direction.

The constants are those of the list of constants and conditions among the construction results, fixed in its order, γ last. For a reference coupling $0 < g \le \gamma$, $\mathfrak{L}(g)$ is the set of the sides at g (equation YMM1:(1528)), ℓ_g the least of them, and $\mathfrak{D}(g)$ the set of the first-passage data (K, β) at g (Corollary YMM1:74.2), with the label $\mathsf{b} = a_K\beta$; $X_g = L(g^{-2} + B_\sharp)$, $\bar{B} = B_\sharp L/(L-1)$, $I(g) = (g^{-2} + \bar{B}, X_g - \bar{B}]$. Every label of $\mathfrak{D}(g)$ lies in $[\gamma^{-2}, X_g + \bar{B}]$; $MR(X_g + \bar{B}) \le L^m$ on every side $2L^m$ in $\mathfrak{L}(g)$, $R(x)$ being the least power of L above $(\log x)^r$ with the exponent r among the construction results; and for $\mathsf{b} \in I(g)$ every pair $(K, L^K\mathsf{b})$, $K \in \mathbb{N}$, is a first-passage datum at g.

The bounds $\gamma_W^{\mathrm{sd}} \le \gamma_W^{\mathrm{ref}} = x_W^{-1/2} \le \gamma$ on the reference coupling (the choices in equations YMM1:(2326)–(2327)), the threshold x_{J}, the radii α_0, α_1 of the cores, the numbers $\mathfrak{p}_0$, A_0, A_1, c', κ, M, C_{lat} and the function $B(\cdot)$ are those among the construction results, and so is the depth function: $s(\rho)$ is the least integer $s \ge 0$ with $L^s\rho \ge C_W(s)$, where $C_W(s) = C_{W,0}A_0^2 Y_s^{2\mathfrak{p}_0}$ and $Y_s = (s+1)\log L + \log(g^{-2} + \bar{B})$. The choice preceding equation YMM1:(2326) satisfies every

inequality defining x_{J} in (228). Since x_{J} is the least such threshold, $x_W \geq \max\{\gamma^{-2}, x_{\mathrm{J}}\}$, and hence $g^{-2} \geq x_{\mathrm{J}}$ for $0 < g \leq \gamma_W^{\mathrm{ref}}$. $\mathcal{G}_{K,\beta}^{\mathrm{per}}$ is the set of the periodic Gibbs states at (a_K, β); a *state* at (K, β) is one of them or the measure of a torus with a side in $\mathfrak{L}(g)$; for a state ν we write $A^\nu[F] = F - \nu(F)$.

We write $p_\ell = \ell^{-3} \log Z_{K,\ell,\beta}$ for the pressure of T_ℓ per unit of physical volume, formed with the plain partition function $Z_{K,\ell,\beta}$ of the measure above (Section YMM1:86); at zero source Theorems YMM1:AJ and YMM1:AD write $Z_{K,\ell,\beta} = e^{E_{(K)}[\ell]} \widetilde{Z}_\ell(0)$, with the vacuum constant $E_{(K)}[\ell]$ of the side ℓ and the normalised partition function $\widetilde{Z}_\ell(0)$ among the construction results. For $(K, \beta) \in \mathfrak{D}(g)$ and $\ell \geq \ell'$ in $\mathfrak{L}(g)$, $0 \leq p_{\ell'} - p_\ell \leq G_g$, with the number $G_g = C_{\mathrm{S}} + C_g + C_{\mathrm{gap}}$ among the construction results.

The lower bound is reflection positivity: $Z_{K,\ell,\beta} \leq Z_{K,\ell',\beta}^{(\ell/\ell')^3}$, Corollary B.1(e). The upper bound follows from $|E_{(K)}[\ell]\ell^{-3} - E_{(K)}[\ell']\ell'^{-3}| \leq C_{\mathrm{gap}}$, $\widetilde{Z}_{\ell'}(0) \leq e^{C_{\mathrm{S}}\ell'^3}$ and $\widetilde{Z}_\ell(0) \geq e^{-C_g\ell^3}$ (Propositions YMM1:74.4 and YMM1:74.5, through Corollary B.1, Proposition YMM1:89.2 and Lemma N.1, which compare two sides; C_{S} and $C_{\mathrm{gap}} = 2C_{\mathrm{tt}}C'_{\mathrm{tt}}E_0$ are the numbers of Section N, and C_g that of (288)). Distances are Euclidean unless they are called sup distances; Lip_∞ is the Lipschitz constant for the sup distance, $\|f\|_\sharp = \max\{\sup|f|, 40M\,\mathrm{Lip} f\}$, $\|\eta\|_{C^2}$ is the sum of the suprema of $|\eta|$, $|\nabla\eta|$, $|\nabla^2\eta|$, and $\|\varphi\|_{C^{1,1}} = \max\{\sup|\varphi|, \sup|\nabla\varphi|, \mathrm{Lip}\,\nabla\varphi\}$.

Constants in the statements depend only on the constants among the construction results and on the arguments shown, never on K, β, the state or the test functions.

Lemma 8.1 (A bound on separated torus cumulants)**.** Fix the common construction choice and $0 < g \leq \gamma$. Put $\delta_e = \kappa - \log 9216 > 0$ and

$$S(\kappa) = \frac{2^{12}}{1 - e^{-\delta_e}}, \qquad C'_\Sigma = \frac{27}{26}\,5^3 + \left(\frac{6}{e\delta_e}\right)^3 \frac{e^{2\delta_e}}{1 - e^{-\delta_e}}, \qquad c_V = C_{\mathrm{S}}(2 + \log g^{-2}) + 1.$$

For $n \geq 2$ and $d > 0$, define

$$C_n(d) = \left(\frac{n}{2\varrho}\right)^n \left[4^n \log 2 + 81\sqrt{3}\, C_{\mathrm{S}} S(\kappa) C'_\Sigma d^{-3}\right].$$

At every first-passage datum (K, β) at g, on every $\ell \in \mathfrak{L}(g)$, real Lipschitz functions $f_1, \dots, f_n$ with two supports at Euclidean distance at least d satisfy

$$|S^T_{n;K,\ell,\beta}(f_1, \dots, f_n)| \leq C_n(d) e^{nc_V\ell^3} \prod_i \|f_i\|_\sharp. \tag{27}$$

The constants are independent of K, β, ℓ and the functions; $C_n(d)$ depends only on n, d, ϱ and the fixed construction constants, while c_V may also depend on g. If each support is in a sup-ball of radius $R > 0$ and $\ell \geq 16n(R + 1)$, Proposition YMM1:89.4 instead gives a bound independent of ℓ. ■

Proof. Proposition YMM1:88.3, with $Q_\ell = \exp[C_{\mathrm{S}}(2 + \log g^{-2})\ell^3]$, gives

$$|S^T_n(f)| \leq \left(\frac{n}{2\varrho}\right)^n \left[\log 2\,(2Q_\ell + 2)^n + 81\sqrt{3} C_{\mathrm{S}} S(\kappa) C'_\Sigma \ell^3 d^{-3}\right] \prod_i \|f_i\|_\sharp.$$

Here C'_Σ is the scale-sum constant in equation YMM1:(1776). Since $Q_\ell \geq 1$, $(2Q_\ell + 2)^n \leq 4^n Q_\ell^n$; and $\ell^3 \leq e^{n\ell^3}$. Absorbing these two factors proves (27). Symmetry of a cumulant allows the separated pair to occupy any two positions. The per-ball assertion is exactly Proposition YMM1:89.4, under the additional support and side assumptions stated above. □

In this section c_V denotes the displayed enlarged constant. Every use below is through (27); no identity with a pressure or a vacuum-energy coefficient is used.

Plane fields and rings. A *weight* is a real or complex function w of the plaquettes; $\mathcal{O}(w) = a^{-1}\sum_p w(p)a_p$, $\mathcal{O}(f) = \mathcal{O}(f \circ x)$, $\mathcal{O}_\lambda(f) = a^{-1}\sum_{\lambda(p)=\lambda} f(x(p))a_p$, so that $\mathcal{O} = \mathcal{O}_1 + \mathcal{O}_2 + \mathcal{O}_3$,

and $\check{D}_m = \mathcal{O} - 2\mathcal{O}_m$. $C_K^{\mathrm{free}}(p,q)$ is the matrix of the orthogonal projection onto the exact lattice curvatures, and

$$\mathcal{K}_K^{(n)}(w_1,\dots,w_n) = \tfrac{1}{2}\sum_{\varsigma}\sum_{p_1,\dots,p_n}\prod_a w_a(p_a)\prod_{i\in\mathbb{Z}/n} C_K^{\mathrm{free}}(p_{\varsigma(i)},p_{\varsigma(i+1)}),$$

the sum over the $(n-1)!$ cyclic orders ς; $\mathcal{K}_{K,\ell'}^{(n)}$ is the same sum on $T_{\ell'}$. With $\mathbb{K}_3(u) = (3\hat{u}\hat{u}^{\mathrm{T}} - \mathbf{1})/(4\pi|u|^3)$, the continuum ring $\mathcal{K}_\lambda^{(n)}(\phi)$ is the same expression with $\int\prod_a \phi_a(y_a)\,dy_a$ for the sum over the plaquettes and $\mathbb{K}_3(y_{\varsigma(i)} - y_{\varsigma(i+1)})_{\lambda_{\varsigma(i)}\lambda_{\varsigma(i+1)}}$ for C_K^{free}. We put $\mathcal{K}_{\lambda\mu}(\phi_1,\phi_2) = \iint \phi_1(x)\phi_2(y)[\mathbb{K}_3(x-y)_{\lambda\mu}]^2\,dx\,dy$, $k_3(x,y,z) = \mathrm{tr}[\mathbb{K}_3(x-y)\mathbb{K}_3(y-z)\mathbb{K}_3(z-x)]$ and, for a unit vector n, $\mathsf{t}^\circ(n,X) = \frac{3}{32\pi^2}\mathsf{b}^{-2}|X|^{-6}(3(n\cdot\hat{X})^2 - 1)$.

Since $\mathbb{K}_3(X)^2 = (16\pi^2|X|^6)^{-1}(3\hat{X}\hat{X}^{\mathrm{T}} + \mathbf{1})$, we have $\frac{3}{2}\mathsf{b}^{-2}\sum_{\lambda,\mu}[\mathbb{K}_3(X)_{\lambda\mu}]^2 = \frac{9}{16\pi^2}\mathsf{b}^{-2}|X|^{-6}$, the free two-point kernel of $\mathcal{O}$, and $\frac{3}{2}\mathsf{b}^{-2}\sum_\mu\{[\mathbb{K}_3(X)_{\lambda\mu}]^2 - \frac{1}{3}\sum_{\lambda'}[\mathbb{K}_3(X)_{\lambda'\mu}]^2\} = \mathsf{t}^\circ(e_\lambda,X)$. For plaquettes $p \neq q$ and u a least lift of $x(p) - x(q)$, equations YMM1:(2245)–(2246) bound the lattice kernel by $|C_K^{\mathrm{free}}(p,q)| \le (1 + 3C_{\mathrm{lat}})a^3|u|^{-3}$ and compare it with $\mathbb{K}_3$, $|\epsilon_p\epsilon_q C_K^{\mathrm{free}}(p,q) - a^3\mathbb{K}_3(u)_{\lambda(p)\lambda(q)}| \le C_{\mathrm{lat}}a^3(a^2|u|^{-5} + \ell^{-3})$, $\epsilon_p = \pm 1$ the orientations (YMM1:(2246) and YMM1:(2245) of equations YMM1:(2245)–(2246)).

Its differences along one plane obey

$$|C_K^{\mathrm{free}}(p,q) - C_K^{\mathrm{free}}(p',q)| \le C_\nabla\, a^3|x(p) - x(p')|\,|u|^{-4} \qquad \text{for parallel, equally oriented } p,\ p' \text{ with } |x(p)-x(p')| \le \tfrac{1}{4}|u| \text{ and } |u| \ge 8a,$$

$C_\nabla = 256\sqrt{3}\,C_{\mathrm{h}}(1 + 3C_{\mathrm{lat}})$, C_{h} the constant of the interior gradient estimate for discrete harmonic functions on $\mathbb{Z}^3$. Indeed the Laplacian $dd^* + d^*d$ of the cubic lattice acts on 2-forms plane by plane as the scalar lattice Laplacian, and it commutes with the projection; so it carries the column $C_K^{\mathrm{free}}(\cdot,q)$, the projection of the unit form δ_q, to $dd^*\delta_q$, which vanishes at every plaquette that shares no bond with q, in particular at every plaquette whose barycentre is more than a away from $x(q)$. On each plane the column is therefore discrete harmonic at the distance $\ge 2a$ from $x(q)$. A lattice path from $x(p)$ to $x(p')$ of length $\le \sqrt{3}|x(p) - x(p')|$ keeps the distance $\frac{1}{2}|u|$ from $x(q)$; on the balls of radius $\frac{1}{4}|u|$ about its points the first bound bounds the column by $4^3(1 + 3C_{\mathrm{lat}})a^3|u|^{-3}$, and the gradient estimate on these balls bounds each step by $4^4 C_{\mathrm{h}}(1 + 3C_{\mathrm{lat}})a^4|u|^{-4}$.

Lattice calculus. $\mathbf{w}(V) = (V - V^{-1})/2i$ and $\langle X, Y\rangle = \frac{1}{2}\mathrm{tr}XY$. For a positively oriented bond b and a plaquette $p \ni b$, $W_{b,p}$ is the holonomy of p from the initial point of b, along b; $p(b,\pm\rho)$, $\rho \neq \mu_b$, are the plaquettes through b in the directions $\pm\rho$; $\mathbf{u}_{b,\rho} = -\frac{1}{2}[\mathbf{w}(W_{b,p(b,\rho)}) - \mathbf{w}(W_{b,p(b,-\rho)})]$, $\mathbf{u}_{b,\mu_b} = 0$, the displacement of b, and $\mathfrak{d}_{b,p,\rho} = \langle \mathbf{u}_{b,\rho}, \mathbf{w}(W_{b,p})\rangle$, the elementary densities; $\mathbf{u}_{b,\rho}$ is the half sum of the field strengths of the two plaquettes at b on the sides $\pm e_\rho$, and $G_\rho(b) = \mathbf{w}(W_{b,p(b,\rho)}) + \mathbf{w}(W_{b,p(b,-\rho)})$ is the transported difference of these field strengths. With $p_\pm = p \pm a e_\rho$,

$$\mathfrak{r}_\rho(p) = \sum_{b\subset\partial p}\mathfrak{d}_{b,p,\rho} - \tfrac{1}{2}(a_{p_+} - a_{p_-}), \qquad \mathfrak{s}_{l\rho}(p) = \sum_{b\subset\partial p}\frac{(x_b - x(p))_l}{a}\,\mathfrak{d}_{b,p,\rho}, \qquad \mathfrak{r}_\rho^\sharp(p) = \mathfrak{r}_\rho(p) - \Psi_\rho(p) + \Psi_\rho(p_-),$$

the orbital remainder, the spin densities and the cubic remainder, where the orbital potential is $\Psi_\rho(p) = \frac{1}{2}a_{p\cup p_+} - a_p - a_{p_+} + \frac{1}{2}a_p a_{p_+}$ for $\rho \in P(p)$, $a_{p\cup p_+}$ being the plaquette term of the 1×2 rectangle, and $\Psi_\rho(p) = -\frac{1}{16}\sum_y\langle Y_y, Y_y\rangle$, $Y_y = \mathbf{w}(W_p^y) - \mathrm{Ad}(U(y, y + ae_\rho))\mathbf{w}(W_{p_+}^{y+ae_\rho})$, for $\rho = \lambda(p)$, the sum running over the corners y of p and W_p^y being the holonomy of p from y. For a weight v and a vector field η the stress insertion is

$$\Theta_v[\eta] = \sum_p v(p)\,a^{-1}\sum_{b\subset\partial p}\sum_\rho(\eta^\rho(x_b) - \eta^\rho(x(p)))\mathfrak{d}_{b,p,\rho},$$

and $\Theta_\beta[\eta]$ is its value at $v \equiv \beta$. A *field* is a triple η of real functions on the barycentres; $\mathsf{H}(\eta) = \max_\rho \sup|\eta^\rho| + \max_\rho \mathrm{Lip}_\infty \eta^\rho$, and

$$\mathfrak{K}^{\mathrm{v}}[\eta] = a^{-1}\sum_p \sum_\rho \eta^\rho(x(p))\,\mathfrak{r}_\rho(p), \qquad \mathfrak{K}^\sharp[\eta] = a^{-1}\sum_p \eta^{\lambda(p)}(x(p))\,\mathfrak{r}^\sharp_{\lambda(p)}(p)$$

are the orbital insertion and the cubic insertion. We write $\mathrm{div}^s\eta(y) = \sum_\rho (2a)^{-1}[\eta^\rho(y+ae_\rho) - \eta^\rho(y-ae_\rho)]$, $\nabla^+_\rho\varphi(y) = a^{-1}[\varphi(y+ae_\rho)-\varphi(y)]$, $\nabla^c_\rho\varphi(y) = a^{-1}[\varphi(y+\frac{a}{2}e_\rho)-\varphi(y-\frac{a}{2}e_\rho)]$, $e^\eta(p) = [\nabla^c_\mu\eta^\mu + \nabla^c_\nu\eta^\nu](x(p))$ with $\{\mu,\nu\} = P(p)$, and $\mathrm{St}_K[\eta] = \Theta_\beta[\eta] - \mathsf{b}\,\mathcal{O}(\mathrm{div}^s\eta)$. With v_η the derivation that displaces U along η and $\mathrm{div}\,v_\eta$ its divergence, the identities (Lemma J.1, with the integration by parts J.1) are $v_\eta A(\beta,\cdot) = \mathfrak{K}^{\mathrm{v}}[\beta\eta] - \mathsf{b}\,\mathcal{O}(\mathrm{div}^s\eta) + \Theta_\beta[\eta]$ and $\mathrm{div}\,v_\eta = -\frac{3}{2}a\,\mathcal{O}(e^\eta)$. So the null term $N_\beta[\eta] = v_\eta A(\beta,\cdot) - \mathrm{div}\,v_\eta$ of Lemma 8.10(a) is $\mathrm{St}_K[\eta] + \mathfrak{K}^{\mathrm{v}}[\beta\eta] + \frac{3}{2}a\,\mathcal{O}(e^\eta)$; and since, identically in U, $\mathfrak{K}^{\mathrm{v}}[\beta\eta] = -\beta\sum_{p,\rho}(\nabla^+_\rho\eta^\rho)(x(p))\Psi_\rho(p) + \beta\mathfrak{K}^\sharp[\eta]$ (Lemma 8.10(b)), $N_\beta[\eta] = \mathbb{T}_\beta[\eta] + \beta\mathfrak{K}^\sharp[\eta]$ with the *stress functional*

$$\mathbb{T}_\beta[\eta] = \mathrm{St}_K[\eta] - \beta\sum_{p,\rho}(\nabla^+_\rho\eta^\rho)(x(p))\,\Psi_\rho(p) + \tfrac{3}{2}a\,\mathcal{O}(e^\eta),$$

which reads η through its differences alone and vanishes at a constant field; the cubic insertion $\beta\mathfrak{K}^\sharp[\eta]$, which completes it to the null term, is its *cubic part*.

Tensor entries. $V = \mathrm{Sym}_3(\mathbb{R})$ and $|H|_\infty = \sup_x \max_{l,r}|H_{lr}(x)|$. For $H \in C_c(\mathbb{R}^3;V)$ we put $\mathcal{T}_K(H) = \mathcal{O}(w_H) - a^{-1}\sum_b H_{\lambda_b\lambda'_b}(x_b)\langle \mathbf{u}_{b,\lambda_b}, \mathbf{u}_{b,\lambda'_b}\rangle$, $w_H(p) = H_{\lambda(p)\lambda(p)}(x(p))$, $\lambda_b < \lambda'_b$ being the directions normal to b; formally $\mathcal{T}_K(H) = \frac{1}{2}\int \mathrm{Tr}(HT)$ with $T_{lr} = \mathrm{tr}B_lB_r$, and $\mathcal{T}_K(f\mathbf{1}) = \mathcal{O}(f)$, $\mathcal{T}_K(f(\mathbf{1}-2E_{mm})) = \check{D}_m(f)$. We put $H^{\mathrm{cons}}[\eta] = (\mathrm{div}\,\eta)\mathbf{1} - \nabla\eta - (\nabla\eta)^{\mathrm{T}}$ and $\Delta_K[\eta] = \mathrm{St}_K[\eta] - \mathsf{b}\,\mathcal{T}_K(H^{\mathrm{cons}}[\eta])$.

At smooth fields the density of $\mathrm{St}_K[\eta]$ against $\partial_l\eta^r$ is $\mathsf{b}[\frac{1}{2}\delta_{lr}|B|^2 - \langle B_l, B_r\rangle]$, so that of $\mathsf{b}\,\mathcal{T}_K(H^{\mathrm{cons}}[\eta])$ is the same and the classical density of $\Delta_K[\eta]$ vanishes. A *tensor limit* at g along (K_j,β_j,ρ_j), with $(K_j,\beta_j) \in \mathfrak{D}(g)$, $K_j \to \infty$ and $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$, is a functional with $\sigma(H_1,\dots,H_n) = \lim_j \rho_j(\prod_a A^{\rho_j}[\mathcal{T}_{K_j}(H_a)])$ for all $H_a \in C_c(\mathbb{R}^3;V)$ with pairwise disjoint supports; the labels need not converge. The stress entries are $T_{lr}(\varphi) = \beta\sum_p \varphi(x(p))[\mathfrak{s}_{lr}(p) - \delta_{lr}a_p]$.

Rotations. For $\omega \in \mathfrak{so}(3)$, $|\omega| = \max|\omega_{\rho\lambda}|$, and ωy is taken in the chart $(-\frac{\ell}{2},\frac{\ell}{2})^3$; $\nabla^s_\omega\varphi(y) = \sum_\rho(\omega y)_\rho(2a)^{-1}[\varphi(y+ae_\rho)-\varphi(y-ae_\rho)]$, and $\mathfrak{S}_\omega[v] = \sum_p v(p)\sum_{\rho,\lambda}\omega_{\rho\lambda}\mathfrak{s}_{\lambda\rho}(p)$ is the spin insertion. A cut-off function at K is a real function χ on $\mathbb{R}^3$ that vanishes outside $(-\frac{\ell}{2}+2a,\frac{\ell}{2}-2a)^3$, regarded as a function on T_ℓ (Section YMM1:112); it has the margin $\delta_0 \geq 2a$ if it vanishes outside $(-\frac{\ell}{2}+\delta_0,\frac{\ell}{2}-\delta_0)^3$; it covers $f_1,\dots,f_n$ if $\chi = 1$ at the barycentre and at the bond midpoints of every plaquette at which some $f_i \neq 0$; $\mathrm{Var}(\chi)$ is the closed set of the points near which χ is not constant. The cut-off variation density and the flux insertion of Section YMM1:112 are

$$h_{\omega,\chi}(p) = a^{-1}\sum_{b\subset\partial p}\sum_\rho [\chi(x_b) - \chi(x(p))](\omega x_b)_\rho\,\mathfrak{d}_{b,p,\rho}, \qquad \mathfrak{B}_{\omega,\chi} = \mathsf{b}\,\mathcal{O}(\nabla^s_\omega\chi) - \beta\sum_p h_{\omega,\chi}(p) - \tfrac{3}{2}a\,\mathcal{O}(v_\chi),$$

with $v_\chi(p) = \sum_{\rho\in P(p)}(\omega x(p))_\rho\nabla^c_\rho\chi(x(p))$; $\mathfrak{B}_{\omega,\chi}$ depends on U near $\mathrm{Var}(\chi)$ only, and $\beta\sum_p h_{\omega,\chi}(p) = \Theta_\beta[\chi\,\omega y] - \beta\,\mathfrak{S}_\omega[\chi]$. With $\mathcal{O}(f.) = \mathcal{O}(f_1);\dots;\mathcal{O}(f_n)$, the bulk term and the cubic remainder are

$$\mathfrak{U}_{\omega,\chi}(f) = -\beta\langle \mathfrak{S}_\omega[\chi] + \mathfrak{K}^{\mathrm{v}}[\chi\,\omega y]; \mathcal{O}(f.)\rangle + a^{-1}\sum_i \langle \mathfrak{S}_\omega[f_i] + \mathfrak{K}^{\mathrm{v}}[f_i\,\omega y]; (\mathcal{O}(f_l))_{l\neq i}\rangle,$$

$$\mathfrak{U}^\sharp[\eta](f) = -\beta\langle \mathfrak{K}^\sharp[\eta]; \mathcal{O}(f.)\rangle + a^{-1}\sum_i \langle \mathfrak{K}^\sharp[f_i\eta]; (\mathcal{O}(f_l))_{l\neq i}\rangle,$$

and, for χ covering the f_i, the rotational Ward identity at finite cutoff is

$$\sum_i \langle \mathcal{O}(f_1);\dots;\mathcal{O}(\nabla^s_\omega f_i);\dots;\mathcal{O}(f_n)\rangle = \mathfrak{U}_{\omega,\chi}(f) + \langle \mathfrak{B}_{\omega,\chi}; \mathcal{O}(f.)\rangle.$$

The spread of sets $S_0,\dots,S_n$ is $\inf\max_{i<i'}|y_i-y_{i'}|_\infty$ over $y_i\in S_i$; it is at least the sup distance of any two of them.

8.2. **Principal results.**

Definition 8.2 (Additional quantitative torus-law hypothesis)**.** For a fixed integer $n\ge 2$, hypothesis $(\mathrm{Q_n})$ is the following assertion about the interacting Wilson measure. There exist a coupling threshold γ_n, depth thresholds $s_n(g)$ and $\mathsf{d}_n(g,\ell)$, and errors $\varepsilon_n(g,s)$ and $\omega_n(g,s;c)$, uniform in the cutoff, label, position and weights, with the properties below. We require $\varepsilon_n(g,s)\to 0$ as $s\to\infty$ and use the explicit large-field majorant

$$\omega_n(g,s;c)=L^{3s}(\mathsf{Z}_s^\vee)^n\big[L^{4n}c_\Sigma+s\big]\exp\big[-cA_0^2(Y_s^*)^{2\mathfrak{p}_0}\big],\qquad c_\Sigma=\sum_{l\ge 0}L^{-2l}(l+2)^{2n\mathfrak{p}_0},$$

$Y_s^*=\log(\frac45 L^{-t_1(s)}x_s^-)$, $x_s^-=\frac45 L^{s-2}g^{-2}(L^2C_W(s)Y_s^{3\mathfrak{p}_0})^{-1}$, $Y_s=\log\bar{x}_s$, and $\mathsf{Z}_s^\vee\ge 1$, $t_1(s)\ge 1$ are numbers formed with the basic constants, n, g and s: $\mathsf{Z}_s^\vee$ bounds, in the units of the levels above the working level of depth s, the sizes of the n sources carried there by Theorem YMM1:D, and is at most a power of $\bar{x}_s$ times a polynomial in Y_s, and $L^{t_1(s)}$ is at most a polynomial in Y_s; so $\mathsf{L}_w\omega_n(g,s;c)$ bounds the large-field histories summed against their weights w_t, each with the n-th power of the sizes of the sources at its level.

Let $n\ge 2$, $0<g\le\gamma_n$, $(K,\beta)\in\mathfrak{D}(g)$, $\ell\in\mathfrak{L}(g)$, $0<\mathsf{d}<1$, $s_n(g)\le s=s(\mathsf{d})\le K$, and let $c,\mathsf{L}_w>0$ satisfy $\mathsf{w}_t\le\mathsf{L}_wL^{3(K-t)}e^{-cp_0(g_t)^2}$ $(1\le t\le K)$, $\varsigma_K(c)\ge 4n+5$ and $\mathsf{L}_w\omega_n(g,s;c)\le\frac18$; here w_t is the probability of a first creation of a large field at level t, $p_0(g_t)=A_0(\log g_t^{-2})^{\mathfrak{p}_0}$, and $\varsigma_K(c)=2c\mathfrak{p}_0A_0^2(\log g_K^{-2})^{2\mathfrak{p}_0-1}$. For real weights w_a and points x_a with $|x(p)-x_a|<\mathsf{d}$ where $w_a(p)\ne 0$ and $|x(p)-x(q)|\ge\mathsf{d}$ where $w_a(p)\ne 0\ne w_b(q)$, $a\ne b$,

$$\big|\langle\mathcal{O}(w_1);\dots;\mathcal{O}(w_n)\rangle_{K,\ell,\beta}-3\mathsf{b}^{-n}\mathcal{K}_K^{(n)}(w)\big|\le\mathsf{e}_n\,\mathsf{b}^{-n}\prod_a\sup|w_a|,\qquad \mathsf{e}_n=\varepsilon_n(g,s)+2(1+\bar{B}g^2L^{2-s})^n\mathsf{L}_w\omega_n(g,s;c).$$

The hypotheses hold with $c=c'$ and $\mathsf{L}_w=2M^{-3}\ell^3e^{B(X_g)\ell^3}$ for $\mathsf{d}\le\mathsf{d}_n(g,\ell)$ and every $K\ge s(\mathsf{d})$, and then $\mathsf{e}_n\to 0$ as $\mathsf{d}\to 0$ (for $n\ge 6$ provided $\log g^{-2}\ge(\frac{4n+5}{2c'\mathfrak{p}_0A_0^2})^{1/(2\mathfrak{p}_0-1)}$). ∎

The arbitrary-order small-field remainder in Definition 8.2 is an additional hypothesis. The Gaussian cyclic calculation and the large-field majorant alone do not establish it. The clauses below that use $(\mathrm{Q_n})$ are stated conditionally; the other clauses retain their own hypotheses.

Theorem AD (Plane fields)**.** Let $0<g\le\gamma_W^{\mathrm{ref}}$ and $\ell'\in\mathfrak{L}(g)$.

(a) *One torus.* For $r\ge 2$ and $0<\mathsf{d}<1$ there are $K_0(r,\mathsf{d})$, depending on g,r,d, and $k(r,\mathsf{d})$, depending besides on ℓ', such that

$$|\langle\mathcal{O}(w_1);\dots;\mathcal{O}(w_r)\rangle_{K,\ell',\beta}|\le k(r,\mathsf{d})\prod_a\sup|w_a|$$

for all $(K,\beta)\in\mathfrak{D}(g)$ with $K\ge K_0(r,\mathsf{d})$ and all real weights whose sets of barycentres are mutually at distance $\ge\mathsf{d}$; the weights need no regularity and no sign, and they may depend on the plane; with $2^rk(r,\mathsf{d})$ the same holds for complex weights. For every $p>7$, $k(r,\mathsf{d})\le C_{r,p}\mathsf{d}^{-pr}$. Besides, the growth in the order is controlled: for every $0<g\le\gamma$ with $g^{-2}\ge x_{\mathrm{J}}$, every side $\ell\in\mathfrak{L}(g)$, every $q\ge 2$, every $\mathsf{d}\ge a_K$, all planes and all bounded complex functions $u_1,\dots,u_q$ on T_ℓ whose supports are at pairwise sup distances $\ge 2\mathsf{d}$, and for K above a threshold depending on g,q,d,

$$|\langle\mathcal{O}_{\lambda_1}(u_1);\dots;\mathcal{O}_{\lambda_q}(u_q)\rangle_{K,\ell,\beta}|\le A_\ell^q\,(q!)^{\frac{21}{2}+\mathfrak{p}_0}\,e^{36c_Lq^2}\max\{1,\mathsf{d}^{-4q}\}\prod_a\sup|u_a|,\qquad c_L=\frac{(\log L)^2}{2c'A_0^2(\log\frac{L}{2})^2},$$

with A_ℓ depending on g and ℓ.

(b) *Every state.* For $n \geq 2$ and $\mathsf{d}_0, R > 0$ there is $C_n(\mathsf{d}_0; R)$, depending on $g, \ell', n, \mathsf{d}_0, R$, such that for every $(K, \beta) \in \mathfrak{D}(g)$, all planes and all bounded real f_i supported in closed balls of radius R at mutual distances $\geq \mathsf{d}_0$,

$$|\langle \mathcal{O}_{\lambda_1}(f_1); \dots; \mathcal{O}_{\lambda_n}(f_n)\rangle_s| \leq C_n(\mathsf{d}_0; R) \prod_i \sup|f_i|,$$

where s is any member of $\mathcal{G}^{\mathrm{per}}_{K,\beta}$, or the measure of T_ℓ with $\ell = 2L^m \geq L\ell'$ in $\mathfrak{L}(g)$ and the supports in $(-\frac{\ell}{4}, \frac{\ell}{4})^3$. The same holds for bounded weights, and $|\nu'(\mathcal{O}_\lambda(f)) - \nu(\mathcal{O}_\lambda(f))| \leq C_1(R)\sup|f|$ for any two such states ν, ν'.

(c) *Limit points.* Let $(K_j, \beta_j) \in \mathfrak{D}(g)$, $K_j \to \infty$, and let s_j be either any periodic Gibbs state at (K_j, β_j), or the measure of T_{ℓ_j} with $\ell_j \in \mathfrak{L}(g)$, $\ell_j \geq L\ell'$, $\ell_j \to \infty$, the cumulants being formed once the supports lie in $(-\frac{\ell_j}{4}, \frac{\ell_j}{4})^3$. Every subsequence has a further subsequence along which the cumulants of (b) converge for all $n \geq 2$, all planes and all real $f_i \in C^1_c(\mathbb{R}^3)$ with disjoint supports. The limits S_n are real, multilinear and symmetric; they obey the bound of (b) and $|S_n| \leq B^n (n!)^{4+p} \prod_i \sup|f_i|$ for every $p > 7$, with B depending on $g, \ell', \mathsf{d}_0, R, p$ and not on n; they are invariant under $x \mapsto rx + v$, $r \in W_3$, $v \in \mathbb{R}^3$, the planes being permuted as the axes, and their sum over the planes is the limit of S_n^T.

With $\Pi(J) = \sum_\pi \prod_{I \in \pi} S_{\#I}(I)$, π running over the partitions of a finite family J of pairs (plane, function) into blocks of at least two members, $\sum_{\alpha,\alpha'} \bar{z}_\alpha z_{\alpha'} \Pi(\theta J_\alpha \cup J_{\alpha'}) \geq 0$ for families J_α on one side of a mirror θ: at every coordinate mirror, the planes being fixed, in both cases; and, for limits of periodic Gibbs states, also at the diagonal mirrors with normal $e_\mu \pm e_\nu$, which exchange the planes μ, ν in the reflected entries.

(d) *The full sequence on a torus.* Let $0 < g \leq \gamma$ with $g^{-2} \geq x_{\mathrm{J}}$, $\mathsf{b} \in I(g)$, $\ell \in \mathfrak{L}(g)$, $n \geq 2$, $\mathsf{d} > 0$ and $\theta_n = 1/(1260n(8n+3))$. There are C, depending on n and b, and K_1, depending on $g, \ell, \mathsf{d}, \mathsf{b}, n$, such that for $K \geq K_1$, all planes and all real ϕ_a with $\mathrm{Lip}_\infty \phi_a < \infty$ and supports at pairwise sup distances $\geq \mathsf{d}$, $G_K = \langle \mathcal{O}_{\lambda_1}(\phi_1); \dots; \mathcal{O}_{\lambda_n}(\phi_n)\rangle_{K,\ell,L^K\mathsf{b}}$ obeys

$$|G_{K+1} - G_K| \leq C\, \ell^{3(n+1)} K^{2\mathfrak{p}_0+2} L^{-\theta_n K} \prod_a (\sup|\phi_a| + \mathrm{Lip}_\infty \phi_a).$$

So $\lim_K G_K$ exists with the summed rate; for continuous ϕ_a with supports at pairwise sup distances $\geq 2\mathsf{d}$ it exists without a rate; and the same holds with $\mathsf{b}\check{D}_m$ for an entry. With one plane field among action densities the rate is better: for real Lipschitz $k, f_1, \dots, f_n$ with supports pairwise $\geq \mathsf{d}$ apart, $K \geq K_1$ and a C depending on $g, \ell, n, \mathsf{d}, \mathsf{b}$,

$$\big|\langle \mathcal{O}_\lambda(k); \mathcal{O}(f_\cdot)\rangle_{K+1,\ell,L^{K+1}\mathsf{b}} - \langle \mathcal{O}_\lambda(k); \mathcal{O}(f_\cdot)\rangle_{K,\ell,L^K\mathsf{b}}\big| \leq C K^{2\mathfrak{p}_0(n+2)+2} L^{-K/80} \|k\|_\sharp \prod_i \|f_i\|_\sharp.$$

The Lipschitz constants cannot be dropped from the bound on $|G_{K+1} - G_K|$: it fails with $\prod_a \sup|\phi_a|$ alone for bounded functions sampled at the barycentres, for instance for the indicator of the points of a ball that are barycentres at an even cutoff and at no smaller cutoff, whereas the bound on $|G_K|$ itself needs sup norms only, by (a). One pair (C, K_1) serves a compact interval of labels in $I(g)$; every $\mathsf{b} \geq 2\max\{\gamma^{-2}, x_{\mathrm{J}}\}$ is admitted at $g = (\mathsf{b}/2)^{-1/2}$, and by the dilation $G_K(\phi; \mathsf{b}, \ell) = L^{zn} G_{K-z}(\phi(L^{-z}\cdot); L^z\mathsf{b}, L^z\ell)$ the same holds at every label $\mathsf{b} > 0$ on every side $2L^m$.

(e) *Two points at one scale.* Let $0 < g \leq \gamma^{\mathrm{sd}}_W$, $\ell = \ell_g$, $\vartheta \in (0,1)$, $(K, \beta) \in \mathfrak{D}(g)$, $0 < \mathsf{d} \leq \mathsf{d}_0^{\mathrm{ref}}(g, \vartheta)$ with $s(\mathsf{d}) \leq K$, $\mathsf{d}_0^{\mathrm{ref}}(g, \vartheta)$ being the threshold in equation YMM1:(2335), and let (f, h) be a test pair of $\mathfrak{T}_{T_\ell}(\mathsf{d}; \vartheta)$ (Lemma I.1). Then, uniformly in K,

$$\Big|\langle \mathcal{O}_\lambda(f); \mathcal{O}_{\lambda'}(h)\rangle_{K,\ell,\beta} - \tfrac{3}{2}\mathsf{b}^{-2}\mathcal{K}_{\lambda\lambda'}(f,h)\Big| \leq C(g,\vartheta)\big(\log\tfrac{1}{\mathsf{d}}\big)^{-2\mathfrak{p}_0}\mathsf{b}^{-2}\|f\|_\infty\|h\|_\infty.$$

Since $\mathcal{K}_{\lambda\lambda'}(f,h) \geq \frac{6}{175}(\frac{\vartheta}{20})^{10}\|f\|_\infty\|h\|_\infty$, the nine two-point functions are positive for small d. So is the two-point function of $\mathcal{O}_1 - \mathcal{O}_2$ at the test pairs with $\hat{u}_1^2 + \hat{u}_2^2 \leq \frac{1}{4}$ for all $u \in \operatorname{supp} f - \operatorname{supp} h$, for instance at those carried by balls of radius d whose centres are $4\mathsf{d}e_3$ apart: there

$$\begin{aligned}&[\mathbb{K}_3(u)]_{11}^2 - 2[\mathbb{K}_3(u)]_{12}^2 + [\mathbb{K}_3(u)]_{22}^2\\ &\quad = \frac{9(\hat{u}_1^2 - \hat{u}_2^2)^2 - 6(\hat{u}_1^2 + \hat{u}_2^2) + 2}{16\pi^2|u|^6} \geq \frac{1}{32\pi^2|u|^6},\end{aligned}$$

and, since $|u| \leq 10\mathsf{d}$ on $\operatorname{supp} f - \operatorname{supp} h$ (Lemma I.1(a)) and the masses of f, h are at least $\vartheta\mathsf{d}^3\|f\|_\infty$, $\vartheta\mathsf{d}^3\|h\|_\infty$ (Lemma I.1), its main term is at least

$$\frac{3}{2}\mathsf{b}^{-2}(32\pi^2)^{-1}10^{-6}\vartheta^2\|f\|_\infty\|h\|_\infty,$$

against 4 times the error of the display; so no plane field is a multiple of $\mathcal{O}$. The law holds with 9 times the error for $\mathcal{O} - 2\mathcal{O}_m$. For two entries $\mathsf{b}[\mathcal{O} - 2\mathcal{O}_m]$, both the main term and the error are multiplied by b^2. The two-point law on a torus of small side, Theorem YMM1:AU in the form of Proposition YMM1:126.4 against the lattice kernel, holds for all complex weights w_1, w_2 carried by balls of radius $\mathsf{d} - a_K$ about points x_0, y_0 with $3\mathsf{d} \leq |x_0 - y_0| \leq 4\mathsf{d}$, with 16 times its tolerance (4 times for real weights), whatever the dependence of the weights on the plane.

(f) *Free photons and the conditional continuum comparison.* For three free lattice photon fields the cyclic expression $3\mathsf{b}^{-n}\mathcal{K}_K^{(n)}(w)$ is the exact cumulant. For the interacting plane fields, assume $(\mathrm{Q_n})$ of Definition 8.2, with its stated data and error e_n. For real Lipschitz ϕ_a with $\operatorname{supp}\phi_a \subset B(x_a, \mathsf{d}) \subset B(c, \frac{\ell}{4})$, $\operatorname{Lip}\phi_a \leq \|\phi_a\|_\infty/(\vartheta_0\mathsf{d})$, $0 < \vartheta_0 \leq 1$, and supports $\geq \mathsf{d}$ apart, the plane fields $\mathcal{O}_{\lambda_a}(\phi_a)$ obey the law with $\mathcal{K}_\lambda^{(n)}(\phi)$ for $\mathcal{K}_K^{(n)}(w)$ and with the bracket $\mathsf{e}_n + C_n'(\frac{a_K}{\vartheta_0\mathsf{d}} + \frac{\mathsf{d}^3}{\ell^3})$, where $C_n' = \frac{3}{2}n![6^nC_{\mathrm{lat}}(1+3C_{\mathrm{lat}})^{n-1} + 43\cdot 11^n]$; with $3^nC_n'$ the same holds for the combinations $\sum_\lambda k_{a\lambda}\mathcal{O}_\lambda$, $k_a \in [-1,1]^3$, such as $\mathcal{O} - 2\mathcal{O}_m$. Multiplying any of these entries by b multiplies both the main term and its error by b for that entry.

(g) *The law in every state.* (i) Let $0 < g \leq \gamma_W^{\mathrm{sd}}$, $n \geq 1$ and $\sigma \in (0,1)$. There are $\mathsf{d}_2 > 0$ and C, c, depending on g, n, σ, such that for $(K,\beta) \in \mathfrak{D}(g)$, $0 < \mathsf{d} \leq \mathsf{d}_2$ with $s(\mathsf{d}) \leq K$, all bounded real f_a vanishing outside closed balls of radius d inside one ball of radius $9\mathsf{d}$, at mutual distances $\geq \mathsf{d}$, and every state s at (K,β),

$$|S_n^T[s](f) - S_{n;K,\ell_g,\beta}^T(f)| \leq \mathsf{e}_n'(g,\mathsf{d})\,\mathsf{b}^{-n}\prod_a \|f_a\|_\infty, \qquad \mathsf{e}_n'(g,\mathsf{d}) \leq C(\log\tfrac{1}{\mathsf{d}})^{cn}\mathsf{d}^{3(1-\sigma)-[\frac{n}{2}-1]_+};$$

If $(\mathrm{Q_n})$ holds on T_{ℓ_g} and $g \leq \min\{\gamma_n, \gamma_W^{\mathrm{sd}}\}$, the preceding comparison and (f) give the free law in every state for $2 \leq n \leq 7$, under the depth hypotheses of $(\mathrm{Q_n})$. (ii) Assume $(\mathrm{Q_m})$ on $T_{\ell'}$ for every $2 \leq m \leq 8n$. Let $n \geq 2$, $0 < g \leq \min_{2\leq m\leq 8n}\gamma_m$ with $\log g^{-2} \geq (\frac{32n+5}{2c'\mathfrak{p}_0A_0^2})^{1/(2\mathfrak{p}_0-1)}$, and $\ell' \in \mathfrak{L}(g)$. For $0 < \mathsf{d} \leq \min_{2\leq m\leq 8n}\mathsf{d}_m(g,\ell')$, every $(K,\beta) \in \mathfrak{D}(g)$ with $K \geq s(\mathsf{d})$, every $s \in \mathcal{G}_{K,\beta}^{\mathrm{per}}$ and the measure s of every torus T_ℓ, $\ell \geq \ell'$ in $\mathfrak{L}(g)$, and real plaquette weights with the support and separation conditions of Definition 8.2, inside a cube of side $\frac{1}{4}\ell'$,

$$|\kappa_s(\mathcal{O}(w_1),\dots,\mathcal{O}(w_n)) - 3\mathsf{b}^{-n}\mathcal{K}_{K,\ell'}^{(n)}(w)| \leq \mathsf{e}_n^\sharp(g,\ell',\mathsf{d})\,\mathsf{b}^{-n}\prod_a \sup|w_a|,$$

where $\mathsf{e}_n^\sharp$ depends on no state, side or cutoff and tends to 0 with d. Under the same hypotheses, the following comparison holds for every non-empty $B \subset \{1,\dots,n\}$. It also holds for $n = 1$ assuming $(\mathrm{Q_m})$ for $2 \leq m \leq 8$ and their coupling and depth conditions:

$$|\kappa_s((\mathcal{O}(w_a))_{a\in B}) - \kappa_{T_{\ell'}}((\mathcal{O}(w_a))_{a\in B})| \leq \eta^\sharp(1+\eta^\sharp)^{n-1}\mathsf{b}^{-\#B}\prod_{a\in B}\sup|w_a|,$$

$\kappa_{T_{\ell'}}$ being the joint cumulant under the measure of $T_{\ell'}$, with $\eta^\sharp \to 0$ as $\mathsf{d} \to 0$. The same holds for the plane fields and their combinations $\mathcal{O} - 2\mathcal{O}_m$, with the corresponding three-plane coefficient factors. For $\mathsf{b}[\mathcal{O} - 2\mathcal{O}_m]$, multiply the comparison bound by b for every such entry.

(h) *Short distance in every state and in every limit.* Let $0 < g \le \gamma_\sigma$, where $\gamma_\sigma \le \gamma_W^{\mathrm{sd}}$ is a constant formed with the constants, $\mathsf{d}_\sigma(g) > 0$ a threshold and $\Omega_\sigma = \{(x,y) : 0 < |x-y| < \mathsf{d}_\sigma(g)\}$; put $E_2(g,t)$, $E_3(g,t)$ for the tolerances at the distance t of the laws of two and of three points at narrow bumps, which Step 4 proves on the least torus and (i) and (iii) below state, functions of g and t formed with the constants, $E_2(g,t) \le C(g)(\log \frac{1}{t})^{19\mathfrak{p}_0} t^{1/2}$, $E_3(g,t) \le C(g)[(\log \frac{1}{t})^{39\mathfrak{p}_0+2} t^{1/2} + (t/\ell_g)^3]$.

(i) At a cutoff, in every state: for $(K,\beta) \in \mathfrak{D}(g)$, every state s at (K,β), points x_0, y_0 with $\mathsf{d}_0 = |x_0 - y_0| \le \mathsf{d}_\sigma(g)$, $\rho > 0$ with $s(\rho) \le K$, and bounded real f_1, f_2 supported in balls of radius ρ inside $B(x_0, \frac{1}{8}\mathsf{d}_0)$, $B(y_0, \frac{1}{8}\mathsf{d}_0)$,

$$\Big|\langle \mathcal{O}_\lambda(f_1); \mathcal{O}_\mu(f_2)\rangle_s - \tfrac{3}{2}\mathsf{b}^{-2} \sum_{\lambda(p)=\lambda} \sum_{\lambda(q)=\mu} f_1(x(p)) f_2(x(q)) C_K^{\mathrm{free}}(p,q)^2 \Big| \le E_2(g, \tfrac{1}{2}\mathsf{d}_0) \Big(\frac{2\rho}{\mathsf{d}_0}\Big)^6 \mathsf{b}^{-2} \|f_1\|_\infty \|f_2\|_\infty,$$

C_K^{free} being that of T_{ℓ_g}; for real Lipschitz ϕ_a with $\operatorname{Lip}\phi_a \le \|\phi_a\|_\infty/(\vartheta\rho)$ the same holds with $\frac{3}{2}\mathsf{b}^{-2}\mathcal{K}_{\lambda\mu}(\phi_1,\phi_2)$ and with the bracket $E_2 + C\frac{a_K}{\vartheta\rho}$. By the change of units $x \mapsto L^z x$ this narrow form holds at every $0 < g \le \gamma$, on every side of $\mathfrak{L}(g)$, for distances d_0 below a threshold depending on g.

(ii) Let $(K_j, \beta_j) \in \mathfrak{D}(g)$, $K_j \to \infty$, with labels $\mathsf{b}_j \to \mathsf{b}$, and let s_j be states at (K_j, β_j). Along a subsequence $\langle \mathcal{O}_\lambda(\phi_1); \mathcal{O}_\mu(\phi_2)\rangle_{s_j}$ converges for all real Lipschitz ϕ_a with $\operatorname{supp}\phi_1 \times \operatorname{supp}\phi_2 \subset \Omega_\sigma$, and every such limit has Borel kernels $\tau_{\lambda\mu}(x,y) = \hat\tau_{\lambda\mu}(x-y)$ with

$$\begin{aligned} &|\tau_{\lambda\mu}(x,y) - \tfrac{3}{2}\mathsf{b}^{-2}[\mathbb{K}_3(x-y)_{\lambda\mu}]^2| \\ &\qquad \le (\tfrac{3}{\pi})^2 \epsilon_\sigma(g, |x-y|)\, \mathsf{b}^{-2}|x-y|^{-6} \\ &\qquad\qquad \text{almost everywhere,} \end{aligned}$$

$$\epsilon_\sigma(g,t) = 64 \sup_{0<t'\le t} E_2(g, \tfrac{1}{2}t') \le C(g)(\log \tfrac{1}{t})^{19\mathfrak{p}_0} t^{1/2};$$

before a kernel is named, at every centre and for bumps of radius ρ in $B(x_0, \frac{1}{8}\mathsf{d}_0)$, $B(y_0, \frac{1}{8}\mathsf{d}_0)$, the limit differs from $\frac{3}{2}\mathsf{b}^{-2}\mathcal{K}_{\lambda\mu}(\phi_1,\phi_2)$ by at most

$$64 E_2(g, \frac{1}{2}\mathsf{d}_0)\mathsf{b}^{-2}\mathsf{d}_0^{-6}\rho^6 \|\phi_1\|_\infty \|\phi_2\|_\infty.$$

If besides, for all $n \ge 2$, the $S_n^T[s_j]$ converge on separated tuples to the connected functions $S_n^{\sigma'}$ of reconstruction data σ' on $\mathbb{R}^3$, let s_n^T be the continuous kernel of $S_n^{\sigma'}$ $(n = 2, 3)$: with the continuous kernels $\mathsf{s}_1, \mathsf{s}_2, \mathsf{s}_3^{\mathrm{m}}$ of the moments of σ' (Proposition YMM1:108.3), $\mathsf{s}_2^T = \mathsf{s}_2 - \mathsf{s}_1 \otimes \mathsf{s}_1$ and

$$\begin{aligned} \mathsf{s}_3^T(x,y,z) = \mathsf{s}_3^{\mathrm{m}}(x,y,z) - \mathsf{s}_2(x,y)\mathsf{s}_1(z) - \mathsf{s}_2(x,z)\mathsf{s}_1(y) - \mathsf{s}_2(y,z)\mathsf{s}_1(x) \\ + 2\mathsf{s}_1(x)\mathsf{s}_1(y)\mathsf{s}_1(z). \end{aligned}$$

Then $\sum_{\lambda,\mu} \tau_{\lambda\mu} = \mathsf{s}_2^T$ almost everywhere on Ω_σ, so that $|\mathsf{s}_2^T(x,y) - \frac{9}{16\pi^2}\mathsf{b}^{-2}|x-y|^{-6}| \le 9\epsilon_\sigma(g,|x-y|)\mathsf{b}^{-2}|x-y|^{-6}$ on Ω_σ.

(iii) Three points at two scales: in the latter case, at every (x,y,z) with $0 < |x-y| = r_* \le \mathsf{d}_* = \operatorname{dist}(z, \{x,y\}) \le \mathsf{d}_\sigma(g)$,

$$|\mathsf{s}_3^T(x,y,z) - 3\mathsf{b}^{-3}k_3(x,y,z)| \le E_3(g, \mathsf{d}_*)\, \mathsf{b}^{-3} r_*^{-3} \mathsf{d}_*^{-6},$$

uniformly in $r_*/\mathsf{d}_* \in (0,1]$.

(iv) Point splitting: off one null set of pairs (c,z) with $0 < \mathsf{d} = |c-z| \le \frac{1}{2}\mathsf{d}_\sigma(g)$, for all $0 < r \le \frac{1}{2}\mathsf{d}$ and all λ,

$$\big|\tfrac{2\pi}{3}\mathsf{b}r^3\mathsf{s}_3^T(c+\tfrac{r}{2}e_\lambda, c-\tfrac{r}{2}e_\lambda, z) - t_\lambda(c,z)\big| \le \big[\epsilon'_\sigma(g,\mathsf{d}) + 2.7(r/\mathsf{d})^2\big]\mathsf{b}^{-2}\mathsf{d}^{-6}, \qquad \epsilon'_\sigma(g,\mathsf{d}) \le C(g)\big(\log\tfrac{1}{\mathsf{d}}\big)^{39\mathfrak{p}_0+2}\mathsf{d}^{1/2},$$

$t_\lambda = \sum_\mu(\tau_{\lambda\mu} - \frac{1}{3}\sum_{\lambda'}\tau_{\lambda'\mu})$ being the kernel of the limit of $\langle \mathcal{O}_\lambda - \frac{1}{3}\mathcal{O}; \mathcal{O}\rangle$; and at every such (c,z), for every unit vector n,

$$|\frac{2\pi}{3}\mathsf{b}r^3\mathsf{s}_3^T(c+\frac{r}{2}n, c-\frac{r}{2}n, z) - \mathsf{t}^\circ(n, c-z)| \le [12 \sup_{\frac{3}{4}\mathsf{d}\le t\le\frac{17}{16}\mathsf{d}} E_3(g,t) + 2.7(r/\mathsf{d})^2]\mathsf{b}^{-2}\mathsf{d}^{-6}.$$

(v) On the least torus at a fixed label $\mathsf{b} \in I(g)$, for g small enough in terms of the constants. For real Lipschitz ϕ_1, ϕ_2 with disjoint supports, $\lim_K \langle \mathcal{O}_\lambda(\phi_1) - \frac{1}{3}\mathcal{O}(\phi_1); \mathcal{O}(\phi_2)\rangle_{K,\ell_g,L^K\mathsf{b}}$ exists. Let moreover $\mathsf{d} > 0$ with $6\mathsf{d} \le \min\{1, \mathsf{b}\}$ and $0 < \vartheta_0 \le 1$, let ϕ_1, ϕ_2 be real Lipschitz functions each carried by a ball of radius d, with supports $\ge \mathsf{d}$ apart, $|c-z| \le 6\mathsf{d}$ for $c \in \operatorname{supp}\phi_1$ and $z \in \operatorname{supp}\phi_2$, and $\operatorname{Lip}\phi_1 \le \|\phi_1\|_\infty/(\vartheta_0\mathsf{d})$; for $r > 0$ put $\rho = \frac{r}{8}$ and let $f_\pm^c(y) = \frac{3}{\pi\rho^3}(1 - |y - c \mp \frac{r}{2}e_\lambda|/\rho)_+$ be the radial tents of radius ρ and mass 1 about $c \pm \frac{r}{2}e_\lambda$, of sup norm $\frac{3}{\pi\rho^3} = \frac{1536}{\pi r^3}$. There are $r_* > 0$, depending on $g, \mathsf{b}, \mathsf{d}$, and $C(g, \mathsf{b}, \mathsf{d}, \vartheta_0)$ such that for $0 < r \le r_*$ and every K with $128a_K \le r$, that is $16a_K \le \rho$, and $s(\rho) \le K$

$$\Big|\tfrac{2\pi}{3}\mathsf{b}r^3\int \phi_1(c)\, S^T_{3;K,\ell_g,L^K\mathsf{b}}(f_+^c, f_-^c, \phi_2)\, dc - \big\langle \mathcal{O}_\lambda(\phi_1) - \tfrac{1}{3}\mathcal{O}(\phi_1); \mathcal{O}(\phi_2)\big\rangle_{K,\ell_g,L^K\mathsf{b}}\Big| \le C(g,\mathsf{b},\mathsf{d},\vartheta_0)\big[r^{\beta_H/72} + (a_K/r)^{1/18}\big]\mathsf{b}^{-2}\|\phi_1\|_\infty\|\phi_2\|_\infty,$$

β_H being the Hölder exponent. As the depth function is non-increasing, $s(\rho) \le K$ gives $s(\frac{r}{2}) \le K$; and r_* is taken so that for $0 < r \le r_*$ the depth $s = s(\frac{r}{2})$ obeys $s \ge 3$ and $L^2 C_W(s) Y_s^{3\mathfrak{p}_0} \le L^{s-3}$ (both hold for small r, since $s(\frac{r}{2}) \to \infty$ as $r \to 0$ and the second holds at all large s) and $\frac{r}{2} \le \min\{r_0(\mathsf{b}), r_1(\mathsf{b})\}$, the radii, depending on g and b, up to which Step 4 forms the induction over the levels and the frame of the pair. Here $C(g,\mathsf{b},\mathsf{d},\vartheta_0) = C(g,\mathsf{b},\vartheta_0)\mathsf{d}^{-9/2}$, of which the part of the three-point function beyond its explicit Gaussian part takes $C(g,\mathsf{b})\mathsf{d}^{-5/2}$.

The explicit Gaussian parts of the two members, which take the rest, are compared on the lattice of T_{ℓ_g}: the near leg, between the two tents, against $a_K^3\mathbb{K}_3(re_\lambda)$, by the comparison of the lattice kernel with $\mathbb{K}_3$ in the setting, at the cost $(a_K/r)^2 + (r/\ell_g)^3$, the mean of $\mathbb{K}_3$, whose entries are harmonic off 0, over the two radial tents being its value at re_λ, and $\frac{2\pi}{3}r^3 \cdot 3\mathbb{K}_3(re_\lambda) = \frac{3}{2}(E_{\lambda\lambda} - \frac{1}{3}\mathbf{1})$; the far legs by the bound on the differences of C_K^{free} along one plane of the setting; and the shift of the argument of ϕ_1 by at most r costs $r\operatorname{Lip}\phi_1 \le r\|\phi_1\|_\infty/(\vartheta_0\mathsf{d})$.

Hence, at this fixed d, the limit in K is the limit as $r \to 0$ of

$$\frac{2\pi}{3}\mathsf{b}r^3\int \phi_1(c)\, S_3^{(\ell_g,\mathsf{b})}(f_+^c, f_-^c, \phi_2)\, dc.$$

The limit in K exists for all real Lipschitz ϕ_1, ϕ_2 with disjoint supports, and it is identified in this way for all ϕ_1, ϕ_2 as above.

■□

Theorem AE (One stress insertion; stress entries; conservation)**.** (a) *Bounds in every geometry.* Let $0 < g \le \gamma_W^{\text{ref}}$, $\ell' \in \mathfrak{L}(g)$, $n \ge 1$, $0 < \rho < 1$, $\omega \in \mathfrak{so}(3)$, and let χ be a cut-off function

at K, Lipschitz on $\mathbb{R}^3$. For every $(K,\beta)\in\mathfrak{D}(g)$,

$$\Big|\Big\langle \beta\sum_p h_{\omega,\chi}(p);\mathcal{O}(f.)\Big\rangle_{K,\ell',\beta}\Big| \le \mathsf{b}\,C_n^\flat(\rho)\,|\omega|\,\mathrm{Lip}_\infty(\chi)\prod_i \|f_i\|,$$

(i) with $\|f_i\|=\sup|f_i|$ for bounded real f_i (or real weights), $\mathrm{Var}(\chi)$ and the $\mathrm{supp}\,f_i$ being pairwise $\ge\rho$ apart; (ii) with $\|f_i\|=\|f_i\|_\sharp$ for real Lipschitz f_i in any mutual position, $\mathrm{Var}(\chi)$ being at distance $\ge\rho$ from each $\mathrm{supp}\,f_i$. $C_n^\flat(\rho)=468\ell' k_n^\flat(\rho)$, where $k_n^\flat(\rho)$ depends on g,ℓ',n,ρ, not on χ, on the f_i or on the place of the shell. In (ii) the number may be taken free of the side and of the state: on every torus T_ℓ, $\ell\ge\ell'$ in $\mathfrak{L}(g)$, and in every $\nu\in\mathcal{G}^{\mathrm{per}}_{K,\beta}$, for K above a threshold depending on g,ℓ',n,ρ, the left member is at most $156\,\mathsf{b}\,C_n^e(\rho)|\omega|\,\mathrm{Lip}(\chi)R_1(\chi)N_\chi\prod_i N_i\|f_i\|_\sharp$, where $R_1(\chi)\le\frac12+\frac32\ell$ is the largest $|x_b|_1$ at the bonds where χ varies, N_χ and N_i are the numbers of the cubes of a mesh $h(n,\rho)$ that meet the shell and the supports, and $C_n^e(\rho)$ depends on g,ℓ',n,ρ; at every label $\mathsf{b}>0$ on every side $2L^m$ the same holds for all K with a number depending on b,ℓ,n,ρ.

Both bounds are cases of one rule for a rough entry F of Lemma 8.8 whose carrier lies, with respect to the f_i, as $\mathrm{Var}(\chi)$ in (i), resp. (ii): the left member with F in the place of $\beta\sum_p h_{\omega,\chi}(p)$ is at most $k_n^\flat(\rho)\|F\|\prod_i\|f_i\|$ on $T_{\ell'}$, and, in (ii), at most $C_n^e(\rho)N_F\|F\|\prod_i N_i\|f_i\|_\sharp$ free of the side and of the state, N_F being the number of the cubes of the mesh that meet the carrier of F; here $-\beta\sum_p h_{\omega,\chi}(p)=\mathsf{b}\,\mathrm{Pf}(k^h)$ with $\|\mathrm{Pf}(k^h)\|\le 156|\omega|\,\mathrm{Lip}(\chi)R_1(\chi)\le 468\ell'|\omega|\,\mathrm{Lip}_\infty(\chi)$. The same rule gives the bounds for the whole flux insertion $\mathfrak{B}_{\omega,\chi}=\mathsf{b}\,\mathrm{Pf}(k^h)+\mathcal{O}(v^{\mathfrak{B}})$, of norm $\le(158\mathsf{b}+3a)|\omega|\,\mathrm{Lip}(\chi)R'(\chi)$, $R'(\chi)=\max\{R_1(\chi),R_1'(\chi)\}$, where $R_1'(\chi)\le\frac32\ell$ is the number of Lemma 8.8, the largest $|x(p)|_1$ at the plaquettes at which χ is not constant on the points $x(p)\pm ae_\mu$, $x(p)\pm\frac a2 e_\mu$, $\mu=1,2,3$, among which are those where $\nabla^s_\omega\chi$ or v_χ does not vanish, which hold every plaquette at which $v^{\mathfrak{B}}\ne0$, so that the largest $|x(p)|_1$ at these may stand for $R_1'(\chi)$ throughout: on $T_{\ell'}$ with $\frac{158\mathsf{b}+3a}{156}C_n^\flat(\rho)$ in the place of $\mathsf{b}\,C_n^\flat(\rho)$, and free of the side and of the state with $(158\mathsf{b}+3a)C_n^e(\rho)|\omega|\,\mathrm{Lip}(\chi)R'(\chi)N_\chi$ in the place of $156\,\mathsf{b}\,C_n^e(\rho)|\omega|\,\mathrm{Lip}(\chi)R_1(\chi)N_\chi$.

For $\mathrm{supp}\,\eta$ at distance $\ge\rho$ from each $\mathrm{supp}\,f_i$ (and, in (i), the $\mathrm{supp}\,f_i$ pairwise $\ge\rho$ apart) it gives them for $\Theta_\beta[\eta]=\mathsf{b}\,\mathrm{Pf}(k^\eta)$, of norm $\le 156\,\mathsf{b}\max_\rho\mathrm{Lip}\,\eta^\rho$, and for $\mathfrak{K}^{\mathrm{v}}[\beta\eta]$, which beside fields that do not read the bonds within $2a$ of $\mathrm{supp}\,\eta$ is the rough entry $-\Theta_\beta[\eta]+\mathsf{b}\,\mathcal{O}(\mathrm{div}^s\eta)-\frac32 a\,\mathcal{O}(e^\eta)$ of norm $\le(159\mathsf{b}+3a)\max_\rho\mathrm{Lip}\,\eta^\rho$ (the null term of Lemma 8.10(a) drops): on $T_{\ell'}$ with $156\,\mathsf{b}\,k_n^\flat(\rho)\max_\rho\mathrm{Lip}_\infty\eta^\rho$, resp. $(159\mathsf{b}+3a)k_n^\flat(\rho)\max_\rho\mathrm{Lip}_\infty\eta^\rho$, in the place of $\mathsf{b}\,C_n^\flat(\rho)|\omega|\,\mathrm{Lip}_\infty(\chi)$, and free of the side and of the state with $156\,\mathsf{b}\,C_n^e(\rho)\max_\rho\mathrm{Lip}\,\eta^\rho N_\eta$, resp. $(159\mathsf{b}+3a)C_n^e(\rho)\max_\rho\mathrm{Lip}\,\eta^\rho N_\eta$, in the place of $156\,\mathsf{b}\,C_n^e(\rho)|\omega|\,\mathrm{Lip}(\chi)R_1(\chi)N_\chi$, N_η being the number of the cubes of the mesh that meet the $\frac\rho2$-neighbourhood of $\mathrm{supp}\,\eta$.

Bounded fields, or real weights that depend on the plane, may be added in sup norms if they are $\ge\rho$ apart from the shell, from one another and from all the other fields.

(b) *Stress entries.* $T_{lr}(\varphi)$ is b times a rough entry (Lemma 8.8) of norm at most an absolute constant times $\sup|\varphi|$. So for $0<g\le\gamma_W^{\mathrm{ref}}$ the joint cumulants on one torus of r entries $T_{l_ar_a}(\varphi_a)$ and $\mathcal{O}(w_a)$ with supports pairwise $\ge\mathsf{d}$ apart are bounded uniformly in $K\ge K_0'(r,\mathsf{d})$, for merely bounded φ_a,w_a; for two entries this holds at every $0<g\le\gamma$: $|\langle T_{lr}(\varphi);\mathcal{O}(f)\rangle|\le C\mathsf{b}\sup|\varphi|\sup|f|$ and $|\langle T_{lr}(\varphi);T_{l'r'}(\varphi')\rangle|\le C\mathsf{b}^2\sup|\varphi|\sup|\varphi'|$, C depending on g, the side and the distance. Along subsequences $\langle T;\mathcal{O}\rangle$ and $\langle T;T\rangle$ converge for continuous entries with disjoint supports, and the limits are symmetric in (l,r), translation invariant, covariant under W_3 with the signs of a tensor, and reflection positive.

(c) *The value, Lipschitz norms.* Let $\mathsf{b}\ge 2x_W$, $g=(\mathsf{b}/2)^{-1/2}$, $\ell'\in\mathfrak{L}(g)$, $\beta=L^K\mathsf{b}$, $n\ge1$, $0<\mathsf{d}<1$ and $c<\frac{1}{14}$. There are C,p,K_*, depending on $\mathsf{b},\ell',n,\mathsf{d},c$, such that for $K\ge K_*$, every real C^2 vector field η and all real Lipschitz f_i, the $n+1$ supports being pairwise at

sup distance $\geq \mathsf{d}$,

$$|\langle \mathfrak{K}^{\mathrm{v}}[\beta\eta]; \mathcal{O}(f.)\rangle| + |\langle \Theta_\beta[\eta] - \mathsf{b}\,\mathcal{O}(\mathrm{div}^s\eta); \mathcal{O}(f.)\rangle| \leq CK^pL^{-cK}\|\eta\|_{C^2}\prod_i \|f_i\|_\sharp.$$

By $x \mapsto L^z x$ the same holds at every label $\mathsf{b} > 0$ on every side $2L^m$.

(d) *The value, sup norms.* In the setting of (c): for every field η and all real weights w_a, the $n+1$ carriers being pairwise at sup distance $\geq \mathsf{d}$, $|\beta\langle \mathfrak{K}^\sharp[\eta]; \mathcal{O}(w_1); \dots; \mathcal{O}(w_n)\rangle| \leq CK^pL^{-cK}\mathsf{H}(\eta)\prod_a \sup|w_a|$, and the same with rough entries or block forms (Lemmas 8.8 and 8.10) in the places of the $\mathcal{O}(w_a)$; for C^2 fields η vanishing within sup distance d of the carriers, the two members of (c) with $\mathcal{O}(w_a)$ for $\mathcal{O}(f_a)$ are $\leq CK^pL^{-cK}\|\eta\|_{C^2}\prod_a \sup|w_a|$. At $n = 1$, for every real vector field η, Lipschitz for the sup distance, and every bounded real h (a function or a weight) with $\eta = 0$ within sup distance d of $\{x(p) : h(p) \neq 0\}$,

$$|\langle \Theta_\beta[\eta]; \mathcal{O}(h)\rangle - \mathsf{b}\langle \mathcal{O}(\mathrm{div}^s\eta); \mathcal{O}(h)\rangle| + |\langle \mathfrak{K}^{\mathrm{v}}[\beta\eta]; \mathcal{O}(h)\rangle| \leq CK^pL^{-K/200}(\mathsf{H}(\eta) + \max_\rho \mathrm{Lip}_\infty\eta^\rho)\sup|h|.$$

For two fields with carriers $\geq \mathsf{d}$ apart, $|\beta^2\langle \mathfrak{K}^\sharp[\eta]; \mathfrak{K}^\sharp[\eta']\rangle| \leq CK^{2p}L^{-2cK}\mathsf{H}(\eta)\mathsf{H}(\eta')$, and, with $\mathsf{H}^+ = \mathsf{H} + \max_\rho \mathrm{Lip}_\infty$,

$$|\langle \mathfrak{K}^{\mathrm{v}}[\beta\eta]; \mathfrak{K}^{\mathrm{v}}[\beta\eta']\rangle| \leq CK^pL^{-K/200}\mathsf{H}^+(\eta)\mathsf{H}^+(\eta')$$

and

$$|\langle \mathrm{St}_K[\eta]; \mathrm{St}_K[\eta']\rangle| \leq CK^pL^{-K/200}\mathsf{b}\,\mathsf{H}^+(\eta)\max_\rho \mathrm{Lip}_\infty\eta'^\rho.$$

All this holds at every fixed label $\mathsf{b} > 0$ on every side $2L^m$. At every first-passage datum $(K,\beta) \in \mathfrak{D}(g)$ on every side of $\mathfrak{L}(g)$, with numbers that depend on g and on no label, the clauses on the cubic insertion alone (one $\beta\mathfrak{K}^\sharp[\eta]$ beside n weights, rough entries or block forms, and two of them) hold for $0 < g \leq \gamma$ with $g^{-2} \geq x_{\mathrm{J}}$, and the other clauses, which also read the bilinear half of the orbital insertion and the term $a\,\mathcal{O}(e^\eta)$, for $0 < g \leq \gamma_W^{\mathrm{ref}}$, where $g^{-2} \geq x_{\mathrm{J}}$ holds of itself.

(e) *Conservation and collapse in every periodic Gibbs state.* Let $0 < g \leq \gamma$ and $R, \mathsf{d} > 0$. There are C, p, K_0, depending on g, d, R, such that for all $(K,\beta) \in \mathfrak{D}(g)$ with $K \geq K_0$, all $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, all $\eta, \eta' \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ and $H' \in C_c(\mathbb{R}^3; V)$ supported in a ball of radius R, with $\mathrm{supp}\,\eta$ at sup distance $\geq \mathsf{d}$ from $\mathrm{supp}\,\eta'$ and from $\mathrm{supp}\,H'$, and with $A = A^\nu$:

$$|\nu(A[\mathrm{St}_K[\eta']]A[\mathrm{St}_K[\eta]])| \leq CK^pL^{-K/14}\|\eta'\|_{C^2}\|\eta\|_{C^2}, \qquad |\nu(\mathfrak{K}^{\mathrm{v}}[\beta\eta])| \leq CK^pL^{-K/28}\|\eta\|_{C^2},$$

$$|\nu(A[\mathcal{T}_K(H^{\mathrm{cons}}[\eta'])]A[\mathcal{T}_K(H^{\mathrm{cons}}[\eta])])| \leq CK^pL^{-K/20}\|\eta'\|_{C^2}\|\eta\|_{C^2},$$

$$|\nu(A[\mathcal{T}_K(H^{\mathrm{cons}}[\eta])]A[\mathcal{T}_K(H')])| \leq CK^pL^{-K/60}\|\eta\|_{C^2}|H'|_\infty,$$

and $|\nu(A[\Delta_K[\eta]]A[Z])| \leq CK^pL^{-K/60}\|\eta\|_{C^2}\mathsf{z}$ for $Z = \mathcal{T}_K(H')$, $\mathsf{z} = |H'|_\infty$, and for $Z = \mathrm{St}_K[\eta']$ or $\Delta_K[\eta']$, $\mathsf{z} = \|\eta'\|_{C^2}$. The last bound says that the stress insertion collapses onto $\mathsf{b}\,\mathcal{T}_K(H^{\mathrm{cons}}[\eta])$ in every periodic Gibbs state.

(f) *Any number of entries.* Let $0 < g \leq \gamma$, $n \geq 2$, $1 \leq n_1 \leq n$, $R > 0$, $0 < c < \frac{1}{28}$ and $u = \lceil \frac{1/28 - c}{4n-1}K \rceil$. There are C, p, depending on g, n, R, c, and K_0, depending on g, n, c, such that for all $(K,\beta) \in \mathfrak{D}(g)$ with $K \geq K_0$, all $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, every d with $\mathsf{d}L^u \geq K^2$, all $\eta_a \in C^2_c(\mathbb{R}^3;\mathbb{R}^3)$ $(a \leq n_1)$ and $H_a \in C_c(\mathbb{R}^3; V)$ $(a > n_1)$ with supports in a ball of radius R at pairwise sup distances $\geq \mathsf{d}$, and for X_a any of $\mathcal{T}_K(H^{\mathrm{cons}}[\eta_a])$, $\mathrm{St}_K[\eta_a]$, $\Delta_K[\eta_a]$, $\mathrm{Rm}_K[\eta_a]$ (Lemma 8.10(c)), $\mathfrak{K}^{\mathrm{v}}[\beta\eta_a]$ $(a \leq n_1)$ and $X_a = \mathcal{T}_K(H_a)$ $(a > n_1)$,

$$\Big|\nu\Big(\prod_a A^\nu[X_a]\Big)\Big| \leq CK^pL^{-cn_1K}\prod_{a\leq n_1}\|\eta_a\|_{C^2}\prod_{a>n_1}|H_a|_\infty,$$

and the same holds for the joint cumulant under ν; with $H_a = h_a\mathbf{1}$ the spectators are action densities. At $n_1 = 1$, $c = \frac{1}{56}$ and a fixed $\mathsf{d} > 0$ this holds for $K \geq K_0(\mathsf{d})$.

(g) *Every tensor limit is conserved.* Let $0 < g \leq \gamma$ and let σ be a tensor limit at g. Then $\sigma(H^{\mathrm{cons}}[\eta], H_2, \dots, H_n) = 0$ for every $n \geq 2$, $\eta \in C^2_c(\mathbb{R}^3; \mathbb{R}^3)$ and $H_a \in C_c(\mathbb{R}^3; V)$ whose supports are pairwise disjoint and disjoint from $\operatorname{supp}\eta$. In particular $\sigma(H^{\mathrm{cons}}[\theta\eta], H^{\mathrm{cons}}[\eta]) = 0$ for $\operatorname{supp}\eta \subset \{x_3 > 0\}$, $\theta\eta = \theta \circ \eta \circ \theta$, θ the mirror $x_3 \mapsto -x_3$, so that in the reconstruction of σ the vector of $\mathcal{T}(H^{\mathrm{cons}}[\eta])$ vanishes; and along the sequence $\mathsf{b}_j^2\rho_j(A[\mathcal{T}(H^{\mathrm{cons}}[\theta\eta])]A[\mathcal{T}(H^{\mathrm{cons}}[\eta])]) - \rho_j(A[\mathfrak{K}^{\mathrm{v}}[\beta_j\theta\eta]]A[\mathfrak{K}^{\mathrm{v}}[\beta_j\eta]]) \to 0$.

For $0 < g \leq \gamma_W^{\mathrm{sd}}$ tensor limits exist: by Theorem C(a) of Section 2, the centred products of any number of tensor entries at separated supports are bounded in every periodic Gibbs state by numbers that depend on no cutoff, side, state or position, so every sequence of first-passage data at g with $K_j \to \infty$ and of periodic Gibbs states has a subsequence along which all of them converge. Tensor limits are covariant as tensors under the translations and W_3, reflection positive at the nine families of mirrors, and their trace part is the scalar limit, $\sigma(f_1\mathbf{1}, \dots, f_n\mathbf{1})$ being the limit of the centred products of the $\mathcal{O}(f_a)$.

■□

Remark 8.3 (Normalisation; the role of the collapse). Conservation at disjoint supports does not fix the normalisation of a tensor: $X_{lr} = |x|^{-2}[F_l n_r + F_r n_l - \delta_{lr} F\cdot n + n_l n_r F\cdot n]$, $n = x/|x|$, is symmetric, traceless and conserved off 0, with the flux $\frac{16\pi}{3}F$. And Theorem AE(g) rests on the collapse in (e): the decorrelation of the orbital insertion alone (the second bound of (e)) does not make the six tensor fields conserved; it is the identification of the stress insertion with $\mathsf{b}\,\mathcal{T}_K(H^{\mathrm{cons}}[\eta])$, up to $\Delta_K[\eta]$, that does.

Theorem AF (Ward identities on tori)**.** Let $0 < g \leq \gamma$, $\ell \in \mathfrak{L}(g)$, $n \geq 1$, $\mathsf{d} > 0$, $0 < \delta_0 < \frac{\ell}{2}$ and $c < \frac{1}{14}$.

(a) *Rotations on a fixed torus.* There are C, p, depending on $g, \ell, n, \mathsf{d}, \delta_0, c$, such that for all K, $\mathsf{b}' \in I(g)$, $\beta = L^K\mathsf{b}'$, $\omega \in \mathfrak{so}(3)$, every cut-off function χ at K of class $C^{1,1}$ with the margin δ_0, and all real f_i vanishing outside $(-\frac{\ell}{2} + \delta_0, \frac{\ell}{2} - \delta_0)^3$ and covered by χ:

(i) if $n \geq 2$, $f_i \in C^{1,1}$ and the spread of the supports is $\geq \mathsf{d}$ (the supports may touch if no point is common to all of them), $|\mathfrak{U}_{\omega,\chi}(f)| \leq C|\omega|K^pL^{-cK}\|\chi\|_{C^{1,1}}\prod_i \|f_i\|_{C^{1,1}}$;

(ii) if $n = 1$, f_1 is Lipschitz and $\chi = 1$ on the sup d-neighbourhood of $\operatorname{supp} f_1$, $|\mathfrak{U}_{\omega,\chi}(f_1)| \leq C|\omega|K^pL^{-cK}\|\chi\|_{C^{1,1}}\|f_1\|_\sharp$;

(iii) whatever the supports, if χ and χ' both equal 1 on the d-neighbourhood of $\bigcup_i \operatorname{supp} f_i$, $|\langle\mathfrak{B}_{\omega,\chi} - \mathfrak{B}_{\omega,\chi'}; \mathcal{O}(f_\cdot)\rangle| \leq C|\omega|K^pL^{-cK}(\|\chi\|_{C^{1,1}} + \|\chi'\|_{C^{1,1}})\prod_i \|f_i\|_\sharp$.

If $n \geq 2$, the f_i are of class C^3, $\operatorname{dist}_\infty(\operatorname{supp} f_1, \operatorname{supp} f_2) \geq \mathsf{d}$ and a fixed χ covers the f_i at all large K, then $\mathfrak{U}_{\omega,\chi}(f) + \langle\mathfrak{B}_{\omega,\chi}; \mathcal{O}(f_\cdot)\rangle \to \sum_i S_n^{(\ell,\mathsf{b}')}(f_1, \dots, (\omega y)\cdot\nabla f_i, \dots, f_n)$ at the rate $K^pL^{-K/10} + L^{-K}$, and the flux alone converges to the same limit at the rate K^pL^{-cK}; the limit does not depend on χ. With nothing asked of the bulk term, for $\omega = \omega_{13}$, the generator of the turns in the plane of e_1, e_3, $f^t = f \circ e^{-t\omega}$, $f_i \in C^3$ supported in a ball inside the margin with $\operatorname{dist}(\operatorname{supp} f_1, \operatorname{supp} f_2) \geq \sqrt{3}\mathsf{d}$, and χ covering all the f^t, $0 \leq t \leq \frac{\pi}{2}$:

$$\Big|\int_0^{\pi/2}[\mathfrak{U}_{\omega,\chi}(f^t) + \langle\mathfrak{B}_{\omega,\chi}; \mathcal{O}(f^t_\cdot)\rangle]\,dt\Big| \leq Ca_K\prod_i\|f_i\|_{C^3}, \qquad \int_0^{\pi/2}\sum_i S_n^{(\ell,\mathsf{b}')}(f_1^t, \dots, (\omega y)\cdot\nabla f_i^t, \dots, f_n^t)\,dt = 0.$$

(b) *Rotations along growing tori.* Let $n \geq 2$, $R, \mathsf{d}_0 > 0$, $\chi_R(y) = \chi_1(|y|/R)$ with $\chi_1 \in C^\infty$, $\chi_1 = 1$ on $[0, \frac{4}{3}]$ and $\chi_1 = 0$ on $[\frac{5}{3}, \infty)$. There are C, p, K_0, depending on g, n, R, d_0, c and on no side, such that

$$|\mathfrak{U}_{\omega,\chi_R}(f)_{K,\ell,\beta}| \leq C|\omega|K^pL^{-cK}\prod_i\|f_i\|_{C^{1,1}}$$

for all $(K,\beta)\in\mathfrak{D}(g)$ with $K\ge K_0$, every $\ell\in\mathfrak{L}(g)$ with $2R+2a<\frac{\ell}{2}$ and all smooth f_i supported in $\{|y|<\frac{R}{2}\}$ at mutual distances $\ge \mathsf{d}_0$; without its cubic member $\mathfrak{U}^\sharp[\chi_R\,\omega y](f)$ the bulk term is $\le C|\omega|K^{1+\mathfrak{p}_0}L^{-c_*K}\prod_i\|f_i\|_{C^{1,1}}$ for every $c_*<\frac12$. The same bounds hold under the weak limit points of the torus laws. Along every sequence (K_j,ℓ_j,β_j) with $K_j,\ell_j\to\infty$ along which the connected functions converge to S_n, $\langle\mathfrak{B}_{\omega,\chi_R};\mathcal{O}(f.)\rangle\to-\frac{d}{dt}S_n(f(e^{-t\omega}\cdot))|_{t=0}$ for every R; so the limit is invariant under rotations if and only if this flux tends to 0.

For the volume-first scalar limits, which are invariant under O(3), the flux through every shell tends to 0. With the limits taken one after the other: at a label $\mathsf{b}'\in I(g)$, on each torus T_ℓ, $\ell\in\mathfrak{L}(g)$, the limit in K of the flux is $\sum_i S_n^{(\ell,\mathsf{b}')}(\dots,(\omega y)\cdot\nabla f_i,\dots)$ through every enclosing shell, by (a). If along sides $\ell_k\in\mathfrak{L}(g)$, $\ell_k\to\infty$, the limits $S_n^\circ(X)=\lim_k S_n^{(\ell_k,\mathsf{b}')}(X)$ exist for all $n\ge2$ and all tuples X of real Lipschitz functions with compact supports at positive distances, then for smooth f_i with compact supports at positive mutual distances and all cut-off functions χ_k on T_{ℓ_k} of class $C^{1,1}$ that vanish near the seam and cover the f_i (for instance χ_R at a fixed R, or χ_{R_k} with $R_k\to\infty$ and $2R_k<\frac12\ell_k-1$, a far shell)

$$\lim_k\lim_K\langle\mathfrak{B}_{\omega,\chi_k};\mathcal{O}(f.)\rangle_{K,\ell_k,L^K\mathsf{b}'}=\sum_i S_n^\circ(f_1,\dots,(\omega y)\cdot\nabla f_i,\dots,f_n)=-\tfrac{d}{dt}S_n^\circ(f(e^{-t\omega}\cdot))\big|_{t=0},$$

through any shell; and there are integers K_k^* such that S_n° is the limit of the connected functions along $(K_k,\ell_k,L^{K_k}\mathsf{b}')$ for every sequence $K_k\ge K_k^*$. For each fixed order $n\ge2$, there is $c_\ell(n,g)>0$ such that the same limit is obtained by taking the spacing limit first on each torus whenever $\ell_j\to\infty$ and $\ell_j\le c_\ell(n,g)K_j^{2\mathfrak{p}_0/3}$. Thus $S_n=\lim_j S_n^{(\ell_j,\mathsf{b}_j)}$ at any first-passage labels, and raising the cutoffs at fixed sides and labels does not change this limit. The constant is specified in the proof. For every $K\ge1$, the labels of the first-passage data satisfy

$$I(g)\subset\{L^{-K}\beta:(K,\beta)\in\mathfrak{D}(g)\}\subset\big(g^{-2}+B_\sharp-L^{-1}\bar B,\,L(g^{-2}+\bar B)\big].$$

(c) *One stress entry: trace and diagonal.* Let $0<\mathsf{b}_-\le\mathsf{b}\le\mathsf{b}_+$, $\beta=L^K\mathsf{b}$, $\ell=2L^m$ any side, and let two of the $n+1$ supports be $\ge\mathsf{d}$ apart, the others may touch; $\lambda_L=\log(L/2)/\log L$ and $c_n=\lambda_L/(4(6+3n))$. For γ small enough in terms of the other constants, and with C,p depending on $\ell,\mathsf{b}_\pm,n,\mathsf{d}$,

$$|\langle T_{mm}(\varphi)-\mathsf{b}\check D_m(\varphi);\mathcal{O}(f.)\rangle|+|\langle(T_{11}+T_{22}+T_{33})(\varphi)-\mathsf{b}\,\mathcal{O}(\varphi);\mathcal{O}(f.)\rangle|\le CK^pL^{-c_nK}\|\varphi\|_\sharp\prod_i\|f_i\|_\sharp,$$

so that $-T_{33}=\mathsf{b}[\mathcal{O}_3-\mathcal{O}_1-\mathcal{O}_2]$ inside these functions. For every $\epsilon>0$, $\langle(T_{lr}-T_{rl})(\varphi);\mathcal{O}(f.)\rangle=O(a^{1-\epsilon})\mathrm{Lip}\,\varphi$ and $|\langle T_{lr}(\varphi);\mathcal{O}(f.)\rangle|\le C_\epsilon a^{-\epsilon}\sup|\varphi|\prod_i\|f_i\|_\sharp$; and $\langle\mathfrak{K}^{\mathrm{v}}[\beta\eta]-\beta\mathfrak{K}^\sharp[\eta];\mathcal{O}(f.)\rangle=O(K^pL^{-c_nK})\mathrm{Lip}\,\eta$ for Lipschitz vector fields η, in contact with the f_i or not. At pairwise separated supports and a fixed label $\lim_K\langle T_{mm}(\varphi);\mathcal{O}(f.)\rangle$ exists.

(d) *All Ward identities with one stress entry.* Let γ be as in (c), $\gamma^{-2}\le\mathsf{b}_-\le\mathsf{b}\le\mathsf{b}_+$, $MR(\mathsf{b}_+)\le L^m$, $\ell=2L^m$; let $\xi=e_r$, ωy or y, where for $\xi=\omega y$ and $\xi=y$, taken in $(-\frac{\ell}{2},\frac{\ell}{2})^3$, the functions χ and f_i vanish within a fixed distance of $\partial(-\frac{\ell}{2},\frac{\ell}{2})^3$; and either $n\ge2$, $f_i\in C^2$ with pairwise disjoint supports, $I\subset\{1,\dots,n\}$ and $\chi\in C^2$ equal to 1 near $\operatorname{supp}f_i$ for $i\in I$ and to 0 near the others, or $n=1$, $I=\emptyset$ and $\chi=0$ near $\operatorname{supp}f_1$. Then

$$\lim_K\Big\langle\sum_{l,r}T_{lr}(\xi^r\partial_l\chi);\mathcal{O}(f.)\Big\rangle_{K,\ell,L^K\mathsf{b}}=-\sum_{i\in I}S_n^{(\ell,\mathsf{b})}(f_1,\dots,\xi\cdot\nabla f_i,\dots,f_n)\\+\delta_{\xi,y}(|I|S_n^{(\ell,\mathsf{b})}(f)-\mathsf{b}\,S_{n+1}^{(\ell,\mathsf{b})}(\chi,f)),$$

and at the cutoff the two members differ by $\mathfrak{U}^\sharp[\chi\xi](f)$ up to $O(K^pL^{-c_nK})$ and up to the convergence of the right member. Since $|\mathfrak{U}^\sharp[\chi\xi](f)|\le CK^pL^{-cK}$ for every $c<\frac{1}{14}$ (Lemma 8.12, the spread of $\{\chi\xi\ne0\}$ and of the supports being positive), the right

member converges at the rate $K^p L^{-K/10}$ and $c_n < \frac{1}{36}$, the left member converges at the rate $K^p L^{-c_n K}$, the slowest of the three. For $I = \emptyset$ this is the conservation of the stress tensor beside action densities; for $\xi = e_r$ and χ a periodic function of y_3 alone, $\langle T_{3r}(\chi'); \mathcal{O}(f.)\rangle \to -\sum_{i\in I} S_n^{(\ell,\mathsf{b})}(\dots, \partial_r f_i, \dots)$. Thus, inside these cumulants on one torus, T_{3r} integrated over the planes $\{y_3 = \text{const}\}$ acts on the enclosed entries as $-\partial_r$, so that $-T_{33}$, the Euclidean energy density, acts as ∂_3.

(e) *Translations.* Let $(K,\beta) \in \mathfrak{D}(g)$, $n \geq 2$, ρ a direction and $\mathsf{d}' > 0$. For real $f_i \in C^2$ with Lipschitz $\partial_\rho^2 f_i$ and $\operatorname{dist}(\operatorname{supp} f_1, \operatorname{supp} f_2) \geq \mathsf{d}' + 2a$,

$$\Big|\beta\langle \mathfrak{K}^\sharp[e_\rho]; \mathcal{O}(f.)\rangle - a^{-1}\sum_i \langle \mathfrak{K}^{\mathrm{v}}[f_i e_\rho]; (\mathcal{O}(f_l))_{l\neq i}\rangle\Big| = \Big|\sum_i S^T_{n;K,\ell,\beta}(f_1, \dots, \nabla^s_\rho f_i, \dots, f_n)\Big| \\ \leq (n+1)2^n C_n(\mathsf{d}') e^{n c_V \ell^3} a_K^2 \prod_i N_i,$$

$N_i = \max\{\|f_i\|_\sharp, \|\partial_\rho f_i\|_\sharp, \frac{1}{2}\|\partial_\rho^2 f_i\|_\sharp\}$, with $C_n(\mathsf{d}')$ and c_V as in Lemma 8.1; at $n = 2$ the left member vanishes identically. For $I \subset \{1, \dots, n\}$, the f_i with $i \in I$ of class C^3 with Lipschitz $\partial_\rho^3 f_i$, the others Lipschitz, $\operatorname{dist}(\operatorname{supp} f_1, \operatorname{supp} f_2) \geq \mathsf{d}' + a$, and χ a real function on T_ℓ with $\chi(x(p)) = \chi(x_b) = 1$ at every plaquette p at which some f_i, $i \in I$, does not vanish and at its four bonds b, and $\chi(x(p)) = \chi(x_b) = 0$ at every plaquette p at which some f_i, $i \notin I$, does not vanish and at its four bonds b,

$$\langle N_\beta[\chi e_\rho]; \mathcal{O}(f.)\rangle - a^{-1}\sum_{i\in I}\langle \mathfrak{K}^{\mathrm{v}}[f_i e_\rho]; (\mathcal{O}(f_l))_{l\neq i}\rangle = -\sum_{i\in I} S^T_{n;K,\ell,\beta}(f_1, \dots, \partial_\rho f_i, \dots, f_n) + \mathsf{r},$$

$|\mathsf{r}| \leq \frac{a_K^2}{6} C_n(\mathsf{d}') e^{n c_V \ell^3} \sum_{i\in I} \|\partial_\rho^3 f_i\|_\sharp \prod_{l\neq i} \|f_l\|_\sharp$, $N_\beta[\chi e_\rho] = \mathbb{T}_\beta[\chi e_\rho] + \beta\mathfrak{K}^\sharp[\chi e_\rho]$ the null term of Lemma 8.10(a). Thus the stress functional $\mathbb{T}_\beta[\chi e_\rho]$ of a cut-off translation, taken together with its cubic part $\beta\mathfrak{K}^\sharp[\chi e_\rho]$ and with the contact terms $-a^{-1}\sum_{i\in I}\langle \mathfrak{K}^{\mathrm{v}}[f_i e_\rho]; (\mathcal{O}(f_l))_{l\neq i}\rangle$, generates the translation of the enclosed entries up to $O(a^2)$, with connected functions bounded uniformly in K. If the closed a-neighbourhoods of the supports lie in balls of radius R and $\ell \geq 16n(R+1)$, the numbers may be taken free of ℓ.

■□

Remark 8.4 (The spread is needed). For $n \geq 3$ the bound (a)(i) fails at supports with a common point. The symmetric difference is no derivation: by the invariance of the measure under the lattice translations, $\sum_i S_n^T(\dots, \nabla^s_\rho f_i, \dots)$ is a^2 times connected functions of difference quotients of the f_i, at $n = 3$ exactly

$$\sum_{i=1}^3 S_3^T(\dots, \nabla^s_\rho f_i, \dots) = \tfrac{a^2}{2}\, S_3^T(\nabla^+_\rho f_1, \nabla^+_\rho f_2, \nabla^+_\rho f_3),$$

and connected functions of action densities at coinciding points are of the order a^{-3} (Proposition 8.19(c)). For free photons, let the real f_i have compact supports inside the margin and bounded derivatives through order five, and let $\chi = 1$ on a neighbourhood of their supports. Then $a\,\mathfrak{U}_{\omega,\chi}(f) \to 3\mathsf{b}^{-3}\int \sum_\rho (\omega y)_\rho\, \partial_\rho f_1\, \partial_\rho f_2\, \partial_\rho f_3$ at $n = 3$, while the identity with the true generator survives at supports with a common point: $\sum_i S_n^T(\dots, (\omega y)\cdot\nabla f_i, \dots) - \langle \mathfrak{B}_{\omega,\chi}; \mathcal{O}(f.)\rangle$ is $O(a)$ at $n = 2$ and $O(a\log\frac{1}{a})$ at $n = 3$. For SU(2), at every $g \leq \gamma$, on every side $\ell \in \mathfrak{L}(g)$ and for every $n \geq 3$ there are smooth $f_1, \dots, f_n$ with a common point, a rotation ω and a cut-off function χ such that

$$450\,(n-1)!\,\mathsf{b}'^{-n} \leq a_K |\mathfrak{U}_{\omega,\chi}(f)| \leq 2.3\cdot 10^5\,(n-1)!\,\mathsf{b}'^{-n}$$

for all large K, uniformly in the labels $\mathsf{b}' \in I(g)$. At $n = 1$ the neighbourhood in (a)(ii) is needed: there are a real Lipschitz f_1, a rotation ω and a cutoff $\chi \in C^{1,1}$ covering f_1, equal to one on its support but on no neighbourhood of it, for which the free-photon model has $\liminf_K \mathfrak{U}_{\omega,\chi}(f_1) > 0$.

Theorem AG (One plane field between two times)**.** Let $0 < g \le \gamma_W^{\mathrm{ref}}$, $\ell' \in \mathfrak{L}(g)$, $(K_j, \beta_j) \in \mathfrak{D}(g)$ with $K_j \to \infty$, $\nu_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$, and $(X)_j = \prod_i [\mathcal{O}_{K_j}(f_i) - \nu_j(\mathcal{O}_{K_j}(f_i))]$. Every subsequence has a further subsequence along which the following hold.

(i) $\sigma(X) = \lim_j \nu_j((X)_j)$ and $\sigma^{(m)}(u; X) = \lim_j \nu_j((X)_j[\check{D}_{m,j}(u) - \nu_j(\check{D}_{m,j}(u))])$ exist for all real $u, f_i \in C^1_c(\mathbb{R}^3)$ with disjoint supports; they are real and multilinear, $\sum_m \sigma^{(m)}(u; X) = \sigma(u \cdot X)$, the product with one more scalar factor, they are translation invariant and covariant under W_3: a quarter turn that carries e_3 to e_i carries $\sigma^{(3)}$ to $\sigma^{(i)}$.

(ii) On the Hilbert space $\mathcal{H}(\sigma)$ of the reconstruction data of the limit, with the Hamiltonian $H \ge 0$, the reflection θ, the translations $U(\vec{x})$, whose generators P_1, P_2 commute with H, and the classes $[G]$, the joint spectrum lies in the cones $H \ge |P_k|$, $k = 1, 2$: every periodic Gibbs state obeys the five-point inequality (241) of Lemma F.5 at the mirror normal to e_3 and the direction e_k, which passes to the limit and puts the spectral measure of every class on $\{\cosh(tE) + \cos(tq_k) \ge 2\}$ for a dense set of $t > 0$, hence on $\{E \ge |q_k|\}$. So $H \ge 0$ and $H \ge |P_k|$ are the hypotheses of Lemma 8.14 in the direction x_3 and, in its last sentence, in the directions x_1, x_2; and there is a unique family of bounded operators $B^{(m)}(s, s')$, $s, s' > 0$, with $B^{(m)}(s, s')^* = B^{(m)}(s', s)$, $e^{-tH} B^{(m)}(s, s') e^{-t'H} = B^{(m)}(s + t, s' + t')$ and

$$\sigma^{(m)}(u; \theta\overline{\tau_{se_3} G'} \cdot \tau_{s'e_3} G) = \int u(x) \, \langle [G'], U(\vec{x}) B^{(m)}(s + x_3, s' - x_3) U(-\vec{x}) [G] \rangle \, dx$$

for u supported in $\{-s < x_3 < s'\}$ and G, G' supported in $\{x_3 > 0\}$.

(iii) $\|B^{(m)}(s, s')\|$ is bounded by a finite function of $\min\{s, s', 1\}$, g and ℓ', and for u supported in $\{\gamma' - s \le x_3 \le s' - \gamma'\}$ the left member of (ii) is at most $c(\gamma') \|u\|_{L^1} \|[G']\| \, \|[G]\|$. For $0 < g \le \gamma_W^{\mathrm{sd}}$ every such limit with converging labels arises, along a further subsequence, from a tensor limit σ_T (Theorem AE(g)): $\sigma(X) = \sigma_T(f_1 \mathbf{1}, \dots, f_n \mathbf{1})$ and $\sigma^{(m)}(u; X) = \sigma_T(u(\mathbf{1} - 2E_{mm}), f_1 \mathbf{1}, \dots, f_n \mathbf{1})$. Let $\mathcal{H}(\sigma_T)$ be the reconstruction of σ_T at θ, spanned by the classes $[F]$ of the tuples F of entries in $C_c(\{x_3 > 0\}; V)$ with $\langle [F'], [F] \rangle = \sigma_T(\theta \bar{F}' \cdot F)$, with its Hamiltonian and its translations, whose joint spectrum lies in the same cones by the same five-point inequality; its *scalar subspace* $\mathcal{H}_0$, the closed span of the classes of the tuples of scalar entries $f_a \mathbf{1}$, is $\mathcal{H}(\sigma)$ and reduces the Hamiltonian and the translations, and Π_0 is the projection onto it.

For $e \in V$ the *point operator* of the tensor entry at e is the family $B^e(s, s')$ of bounded operators on $\mathcal{H}(\sigma_T)$ that Lemma 8.14 gives for $u \mapsto \sigma_T(ue, \cdot)$, with $\sigma_T(ue, \theta\overline{\tau_{se_3} F'} \cdot \tau_{s'e_3} F) = \int u(x) \langle [F'], U(\vec{x}) B^e(s + x_3, s' - x_3) U(-\vec{x}) [F] \rangle \, dx$ as in (ii); it is linear in e, and $\|B^e(s, s')\| \le C|e| \min\{s, s', 1\}^{-p}$ for every $p > \frac{17}{2}$, $|e|$ the Euclidean norm of e and C depending on g, p and the limit label and not on the side, by the bound on the chessboard seminorm of a centred tensor entry. Then $B^{(m)}(s, s') = \Pi_0 B^{\mathbf{1} - 2E_{mm}}(s, s') \Pi_0$ on $\mathcal{H}_0$, the compression to the scalar subspace of the point operator at $\mathbf{1} - 2E_{mm}$, so that $\|B^{(m)}(s, s')\| \le C \min\{s, s', 1\}^{-p}$; and for $Z = (u; X)$ and R_α the turn by the angle α in the plane of e_i, e_3,

$$\sigma^{(3)}(Z \circ R_\alpha) + \sigma^{(3)}(Z \circ R_{-\alpha}) = 2 \cos^2 \alpha \, \sigma^{(3)}(Z) + 2 \sin^2 \alpha \, \sigma^{(i)}(Z).$$

Thus the $\check{D}_m$ behave under turns as the diagonal of a symmetric tensor; moreover $\alpha \mapsto \sigma^{(3)}(Z \circ R_\alpha)$ is of the form $c_0 + c_1 \cos 2\alpha + c_2 \sin 2\alpha$ with numbers c_0, c_1, c_2, and its second derivative at $\alpha = 0$ is $2[\sigma^{(i)}(Z) - \sigma^{(3)}(Z)]$.

■□

One step of the renormalisation group, at every level and with its never-large term, runs with three complex plane couplings, about its prescribed background with free centres (Theorem AH); on the labels of histories with large-field regions the moved backgrounds, the centres of the steps and the counterterms are those of Theorem AI. For a triple $P = (U, A', J)$ at the level n, $\mathbf{U}_P = e^{i\eta_n A'} U$, $\eta_n = L^{-n}$, is its complex configuration (Definition YMM1:49.1); on a region X let $\mathrm{hol}_n(P; X)$ be

the Hölder-$\frac{1}{2}$ number, transports included, of $L^{2n}(\partial\mathbf{U}_P - 1)$ at distances ≤ 1 in level-n units; the *core with the third radius* $\mathcal{U}_n(X)$ is the set of triples in the hereditary core of Definition YMM1:49.1 at the radii (α_0, α_1), with all the tower conditions retained as in Section P, with $\mathrm{hol}_n(P; X) < \alpha_2$; $\rho_Z^{k\to j}(U, A', J) = (U, \lambda A', \lambda^3 J)|_Z$, $\lambda = L^{-(k-j)}$; $\mathcal{D}_n$ and d_n are as in Section YMM1:45.

A region $Z \in \mathcal{D}_j$ is *short* at k if $d_j(Z) + 4 \le L^{k-j}$. The *box* Z^{box} of a short Z is the least box of level-j cubes that holds a lift of Z (a wall-connected union of cubes of the covering that the covering map carries one to one, cube by cube, onto Z; such unions exist, Z being wall-connected, and any two of them differ by a period), enlarged by one level-j cube on each of its six sides and carried back by the covering map: it does not depend on the lift, its sides are at most $d_j(Z) + 4 \le L^{k-j}$ level-j cubes, it lies in $\mathcal{D}_j$, holds Z, and holds both end points of every bond with an end point in Z. Then X_Z is the union of the level-k cubes that hold a level-j cube of Z^{box}: one or two along each axis, so at most eight, with $X_Z \in \mathcal{D}_k$ and $d_k(X_Z) = 0$.

For every $Z \in \mathcal{D}_j$, Z^{up} is the union of the level-k cubes that hold a level-j cube of Z. A *term* on $\mathcal{U}_j(Z)$ is a bounded function on it that is holomorphic on its slices, a function of the pair $(\mathbf{U}_P, J)$, and gauge invariant.

The extended list. Theorems AH and AI are stated at the choices of the following extension of the list $\mathcal{T}^{\mathrm{S}}[2\varrho]$ of Theorems YMM1:AJ and YMM1:AD (the common real and sourced choice of Section YMM1:82, including (211)). The base choice also retains (194) and the radius, decay and block-number conditions of Lemma Q.7. These are imposed when choosing the response parameters in the proof of Proposition YMM1:69.1, before the polymer-window size M: the finitely many local constants here depend only on L, so the response block number $\mathfrak{M}$ can be raised and its radii and decay rate reduced at that stage. For Lemma 8.20 take this same response block number at least M_{ps} and M_H, the floors in Theorem YMM1:I and Lemma Q.7. Enlarge w_{lin} to at least $\max\{g_{\mathrm{p}}, w_S\}$, where w_S is from Proposition YMM1:29.1, and reduce α_{lin} so that $2\alpha_{\mathrm{lin}} \le a_Q$ and the four local-system radii are at most a_H. These choices depend only on L. The separated setting has $R_1 \ge L$ and terminal torus side at least $6R_1\mathfrak{M}$, hence at least $6LM_{\mathrm{ps}}$. On a real regular label, $F'(0) = J(U)$ at full bonds; the scalar part of $D_U^{\mathsf{T}}\partial U$ is bounded by $\xi^{-1}\max_{p\ni b}|\partial U(p) - I|^2$. Thus equation YMM1:(579) gives the full matrix-divergence bound at twice the regularity radius. The ceiling on $C_m\varepsilon$ in part (c) supplies this radius and the four local-system radii, while its width ceiling supplies the enlarged w_{lin}. These are conditions on the common response choice; they are not new analytic assumptions. It adds 108 entries, in this order: four lower bounds on chosen constants among the construction results, each by a function of earlier constants; 85 further determined constants, each a positive explicit formula in earlier constants, placed before γ (four abbreviations are used among the formulas); and 15 further upper bounds on γ. No condition is laid on L, on E_0 or on a window constant.

The following constants retain their meanings in the real construction and its sourced extension (the proof of Proposition YMM1:69.1 and Section YMM1:82):

$$\mathsf{C}_{\mathrm{ex}}, \mathsf{C}_{\mathrm{cs}}, \mathsf{C}_{\mathrm{mn}}, \lambda_{\mathrm{s}}, \gamma_{\mathrm{r}}, c_{\mathrm{r}}, \mathsf{u}_{\mathrm{G}}, \lambda_{\mathrm{r,gs}}, \bar{c}_{\mathrm{P}}, \beta_{\mathrm{s}}, \kappa, \kappa'', \bar{r}_H, \bar{\kappa}, \lambda_V, \vartheta_*, \mathsf{c}_{\mathrm{os}}, \mathsf{c}_{\mathfrak{h}}, \varepsilon_{\mathfrak{h}}, r_P^{\circ}, \mathsf{C}_{\mathcal{A}}, \mathsf{s}^{\star}, K_\Lambda, N_\star, K_P,$$
$$w_\star, \varepsilon_{\mathcal{W}}, \mathsf{o}, B^{(\mathrm{cg})}, A_0, A_1, \mathfrak{p}_0, \alpha_0, \alpha_1, B_3, E_0, M, L'$$

the plaquette constant $\mathsf{c}_{\mathrm{pl}} = 600$ and the number C_P of equation YMM1:(799), $K_{\mathrm{c}} = 96(1+2\mathsf{c}_{\mathrm{pl}})^2 C_{\mathrm{E}}$, $C_{\mathrm{E}} = 4096$, the numbers b_{D}, $\mathsf{B}_\sharp(0)$, $\mathsf{B}_\sharp(1/2)$ and $\mathsf{B}_\sharp = \mathsf{B}_\sharp(0)$ of Proposition Q.8, and $a^\sharp$, $K^\sharp$ of the tower hypotheses of Section P.

Here $\lambda_{\mathrm{r,gs}}$ denotes the canonical history Gaussian gap, written λ_{r} in equation YMM1:(1137) with the specialization of equation YMM1:(1161):

$$\lambda_{\mathrm{r,gs}} = \min\left\{\frac{\gamma_0}{2}, \left(1 + 2(B_{\mathrm{nm}}^2/\gamma_0)^2\right)^{-1}\right\}.$$

The symbols B_{nm} and γ_0 have the values in that specialization. This history gap is distinct in notation from the plain-step gap $\lambda_{\mathrm{r}}^{\mathrm{pv}}$ defined below.

The entries are:

1. the lower bound $\mathsf{C}_{\mathrm{ex}} \geq \max\{2\mathsf{C}_{\mathrm{cs}}, 8\}$;
2. directly behind $\bar{c}_{\mathrm{P}}$: $\lambda_{\mathrm{r}}^{\mathrm{pv}} := \min\{\frac{1}{2}\gamma_{\mathrm{r}}, (1+2c_{\mathrm{r}}^2)^{-1}\}$ and $c_q := \max\{\bar{c}_{\mathrm{P}}+\mathsf{C}_{\mathrm{mn}}^3/\lambda_{\mathrm{r,gs}}+2,\ \mathsf{C}_{\mathrm{mn}}^3(\frac{1}{2}\mathsf{u}_{\mathrm{G}}+c_{\mathrm{r}}+3)/\lambda_{\mathrm{r}}^{\mathrm{pv}}+2\}$;
3. with the abbreviation $E_q := 1+2\lambda_{\mathrm{s}}+\mathsf{C}_{\mathrm{cs}}(c_q+2)$, the lower bounds $(1+4\beta_{\mathrm{s}})\kappa \geq E_q$ and $\frac{1}{2}\kappa \geq 2\lambda_{\mathrm{s}}+8\log 2+\frac{\mathsf{C}_{\mathrm{cs}}}{L}E_q$;
4. directly behind $\bar{r}_H$: $r_H^q := \kappa''+\lambda_{\mathrm{s}}+\mathsf{C}_{\mathrm{cs}}(c_q+2)$, $\kappa' := \kappa''+1$, $r_{\mathrm{w}}^q := \max\{\frac{\mathsf{C}_{\mathrm{cs}}}{L}r_H^q+\lambda_{\mathrm{s}}, \frac{8\kappa'}{L}\}$, $r_t := \lambda_{\mathrm{s}}$, $r^q := r_{\mathrm{w}}^q+\lambda_{\mathrm{s}}$, $r_1 := \kappa''-8\log 2$, $r_1' := \kappa''-16\log 2$;
5. the lower bounds $\bar{\kappa} \geq 1+\mathsf{C}_{\mathrm{cs}}r_H^q+\log\mathsf{C}_{\mathrm{cs}}$ and $\bar{\kappa} \geq 3+16\kappa'+2\lambda_{\mathrm{s}}+2\lambda_V$;
6. the lower bound $\mathsf{C}_{\mathrm{mn}}(LM)^3 \geq c_q$;
7. directly before γ, in this order: $c_K := 2/\gamma_{\mathrm{r}}+4(c_{\mathrm{r}}+\frac{1}{2})^2/\gamma_{\mathrm{r}}^2$; $B' := 6\cdot 10^5 c_K(LM)^3 e^{16\kappa'}$; $S' := 4096e^{8\kappa'}$; $b_A := 6.1201^2M^3$; $K_T^{\mathrm{pl}} := \max\{12L^4M^3K_{\mathrm{c}}, 2b_A, 112b_A+\frac{1}{2}M^3\}$; $a_Z := \mathsf{c}_{\mathrm{os}}\alpha_0$; $r^{\mathrm{pl}} := \min\{r_P^\circ, \varepsilon_{\mathfrak{h}}/\sqrt{2}, 1/(3\mathsf{c}_{\mathfrak{h}}), a_Z/(2\mathsf{c}_{\mathfrak{h}})\}$; $\delta' := \min\{1, \varepsilon_{\mathfrak{h}}/\mathsf{C}_{\mathcal{A}}, \mathsf{s}^\star\alpha_0/(1+\beta_{\mathrm{s}}), A_1(2\mathfrak{p}_0/e)^{\mathfrak{p}_0}\}$; $r_2^{\mathrm{pl}} := \mathsf{C}_{\mathcal{A}}\delta'$; $r_3^{\mathrm{pl}} := \min\{r^{\mathrm{pl}}, r_2^{\mathrm{pl}}\}$; $\bar{u}_f := K_\Lambda \mathsf{s}^\star N_\star$; $\varrho^{\mathrm{pl}} := \min\{\frac{1}{4}r^{\mathrm{pl}}, (r^{\mathrm{pl}})^3/(256B'K_T^{\mathrm{pl}}S')\}$; $\sigma_3 := \min\{(r^{\mathrm{pl}})^2/(64B'K_T^{\mathrm{pl}}S'),\ r^{\mathrm{pl}}\varrho^{\mathrm{pl}}/(4B'K_T^{\mathrm{pl}}S')\}$; $\varepsilon_1 := [8\mathsf{C}_{\mathrm{cs}}^2L^3e^{\mathsf{C}_{\mathrm{cs}}(\kappa''+c_q+r_H^q)}]^{-1}$; $v_0 := (2^{17}L^3)^{-1}$; $v_d := (2^{17}L^3)^{-1}$; $\hat{\rho} := \varepsilon_1/(8e)$; $\eta := 1$; $\gamma_2^q := (LM)^{-3}$; $\theta_m := \frac{1}{2}\vartheta_*$; $\varepsilon_m^{\mathrm{pl}} := \min\{\frac{1}{2}\vartheta_*, (LM)^{-3/2}\}$; $\theta_1' := \frac{1}{2}\theta_m$; $\theta_1'' := \frac{1}{4}(1/\varepsilon_m^{\mathrm{pl}}+4\varepsilon_m^{\mathrm{pl}}/\theta_m^2)^{-1}$; $v_{\mathrm{ce}} := \mathsf{C}_{\mathcal{A}}$; $v^+ := \sqrt{2}\,\mathsf{C}_{\mathcal{A}}+1$; $a_{\mathrm{cap}} := \varepsilon_1 v_0/(96e)$; $c_1^+ := \min\{\frac{1}{4}r_3^{\mathrm{pl}},\ a_{\mathrm{cap}}(r^{\mathrm{pl}})^3/(128K_T^{\mathrm{pl}}M^3)\}$; $K_Z := 4B'K_T^{\mathrm{pl}}S'/r^{\mathrm{pl}}$; $B_0 := 6\cdot 10^5 c_K(LM)^3$; $K_6 := 1296M^3\max\{1, 2C_P\}B_3L^{-2}$; with the abbreviation $\theta_* := \min\{\theta_1', \theta_1''\}$,

9. fifteen upper bounds on γ, each of the form $\sup_{x\geq\gamma^{-2}} F(x) \leq \Phi$ with $F(x)\to 0$ as $x\to\infty$ and $\Phi > 0$ formed with earlier constants; with the thresholds $\delta(x) = A_1x^{-1/2}(\log x)^{\mathfrak{p}_0}$, $\varepsilon(x) = A_0x^{-1/2}(\log x)^{\mathfrak{p}_0}$ of YMM1:(634) and

$$\xi(x) := \exp(-\mathsf{C}_{\mathrm{mn}}^{-1}\gamma_2^q(1-\theta_m)^2A_1^2(\log x)^{2\mathfrak{p}_0})$$

they are: $3K_P\delta(x)\leq a_{\mathrm{cap}}$; $\bar{u}_f^c\mathsf{C}_{\mathcal{A}}\delta(x)/r_3^{\mathrm{pl}}\leq a_{\mathrm{cap}}$; $\frac{64}{3}(7M^3+\bar{u}_f^c)c_1^+\mathsf{C}_{\mathcal{A}}\delta(x)/(r_3^{\mathrm{pl}})^2\leq\frac{1}{3}a_{\mathrm{cap}}$; $\mathsf{C}_{\mathcal{A}}\delta(x)\leq\frac{1}{2}r_3^{\mathrm{pl}}$; $(\theta_1'+\theta_1'')\delta(x)\leq\frac{1}{2}c_1^+$; $6(LM)^3\xi(x)\leq 1$; $2(LM)^3\xi(x)^{1/2}\leq\varepsilon_1L^3$; $[(1-\theta_m)A_1(\log x)^{\mathfrak{p}_0}]^{-1}\leq 1$; $2Q^{\mathrm{pl}}Q'L^{-2c^{\mathrm{pl}}\log(x/2)}\leq 1$; $Q'\bar{K}_{\mathrm{w}}e^{-c^{\mathrm{pl}}(\log(x/2))^2}\leq\hat{\rho}v_d$; $\mathsf{c}_{\mathfrak{h}}v^+\delta(x)\leq\frac{1}{2}a_Z'$; $2B_3\varepsilon(x)\leq 1$; $2\varepsilon(x)\leq\varepsilon_{\mathcal{W}}\alpha_0$; $K_H\varepsilon(x)\leq\frac{1}{2}\alpha_2^{\mathrm{pl}}$; $8K_\Lambda N_\star(1+\beta_{\mathrm{s}})\delta(x)/\alpha_0\leq w_\star$.

Each formula names only constants that stand before it, and none reads K, m, a level, a sequence of couplings, a weight or a field. The list so extended is an order table of admissible shape; choices of it exist; the restriction of a choice to the constants of $\mathcal{T}^{\mathrm{S}}[2\varrho]$ is a choice of that list, and its restriction to the constants of the list $\mathcal{T}^{\mathrm{F}+}$ of Theorem YMM1:D (the real choices in Proposition YMM1:69.1) is a choice of that list. Theorem AI lowers γ further where it says so.

Theorem AH (Three plane couplings)**.** Let the constants be a choice of the extended list stated before this theorem, which adds to the list of Theorems YMM1:AJ and YMM1:AD four lower bounds on chosen constants, each by a function of earlier constants, further determined constants placed before γ and further upper bounds on γ, and no new condition on L itself; its choices exist, they restrict to choices of the lists of Theorems YMM1:D, YMM1:AJ and YMM1:AD, and at each of them the standing conditions of the frame of Definition B.14 hold, as do the locality for all pairs of regions and the gauge covariance at all decoupling parameters of the Gaussian structure among the construction results, the tower hypotheses of Section P and the inequality $\alpha_0+\alpha_1\leq a^\sharp$ with the constant $a^\sharp$ in the radius conditions YMM1:(867). At every choice $L > 4\cdot 10^{19}$, as a consequence of the condition $L\geq 2\mathsf{C}_{\mathrm{ex}}$ among the construction results and of the lower bound $\mathsf{C}_{\mathrm{ex}}\geq 2\mathsf{C}_{\mathrm{cs}}$ of the extended list, with $\mathsf{C}_{\mathrm{cs}}\geq 24C_{\mathrm{E}}^2e^{24}$.

(a) *Lifted local terms.* For all K, m and $1\leq j<k<K$ with $2L^{m+K-k}\geq C_LM$, that is, for which the lattice (ℓ, K), $\ell = 2L^m$, is allowed at the height k (Section YMM1:50.4), $C_L\geq 8\mathsf{n}_{\mathrm{e}}L$ being the room and $\mathsf{n}_{\mathrm{e}}\geq 1$ the halo width of Section YMM1:50.4, so that $m+K-k\geq m'+2$, $\mathcal{D}_j$ and $\mathcal{D}_k$ are defined and a box of at most two cubes of the level k along each axis does not wrap around the torus, which has at least $8L$ such cubes along each axis, every $Z\in\mathcal{D}_j$ short at k, every $P'\in\mathcal{U}_k(X_Z)$ and every term E on $\mathcal{U}_j(Z)$,

$$|E(\rho_Z^{k\to j}P') - E(\mathbf{1})| \leq C_Q\sup|E|\,(d_j(Z)+2)^4L^{-4(k-j)},$$

and the same with $(d_j(Z)+2)^2$ in the place of $(d_j(Z)+2)^4$ and with $72M^2\bar{C}_2^2(c_3^Q)^{-2}\leq C_Q$ in the place of C_Q when $L^{-(k-j)}\leq\lambda_Q$ and $(d_j(Z)+4)L^{-(k-j)}\leq c_s$, with the constants λ_Q, $c_s = c_s^Q$, $\bar{C}_2$ and c_3^Q of item 8 of the list; C_Q is a function of constants placed before γ, it lays no condition on any constant, and it depends on no j, k, K, m, Z, P', E. The same holds on every larger base in $\mathcal{D}_k$ that holds the box of Z, for cores at any positive radii, and on the plain cores for its local terms of level j. The power 4 is attained: for every short Z and every plaquette with its bonds in the boundary of Z there are a term E with $\sup|E|\leq\frac{1}{2}$ and a triple P' with $E(\rho_Z^{k\to j}P') - E(\mathbf{1})\geq c_QL^{-4(k-j)}$, $c_Q>0$ a constant. For the abelian group $\mathrm{U}(1)^3$ the inequality fails.

(b) *The lift.* Let K, m and $1 \le k < K$ be as in (a), $2L^{m+K-k} \ge C_L M$, and let $\kappa_{\rm lf} \ge 4\log 18432$ be a rate. For terms $g^{(j)}(Z,\cdot)$ on $\mathcal{U}_j(Z)$, $1 \le j \le k$, $Z \in \mathcal{D}_j$, with $B_j = \sup_Z e^{\kappa_{\rm lf} d_j(Z)} \sup|g^{(j)}(Z,\cdot)| < \infty$, the lift

$$\mathrm{Lf}[g](X;P') = \sum_{j\le k} \sum_{Z\in\mathcal{D}_j:\, X_Z = X} [g^{(j)}(Z;\rho_Z^{k\to j}P') - g^{(j)}(Z;\mathbf{1})], \qquad X \in \mathcal{D}_k,\ P' \in \mathcal{U}_k(X),$$

($X_Z = Z^{\rm up}$, the union of the cubes of the level k that hold a cube of Z, for the Z that are not short, among them all $Z \in \mathcal{D}_k$, for which $Z^{\rm up} = Z$) is a term on $\mathcal{U}_k(X)$, linear in g, depending on g at the Z in X alone, and

$$|\mathrm{Lf}[g](X;P')| \le 2C_E(140C_Q+1)\sum_{j\le k} L^{-(k-j)} B_j\, e^{-\kappa_{\rm lf} d_k(X)}, \qquad C_E = 4096,$$

a bound that is uniform in the level.

(c) *One step at all levels.* Let K, m with $L^m \ge MR(x_K)$ and let $x_0 > \cdots > x_K \ge \gamma^{-2}$ be an admissible sequence of couplings in the frame of Definition B.14; by (215) the frame has $C_L \le 2LR(\gamma^{-2}) \le 2LR(x_K)$, so that $2L^{m+K-k} \ge 2LMR(x_K) \ge C_L M$ at every $k < K$, and (a) and (b) apply at every level. Let $\sigma, \tau \ge 0$ with $\sigma + 2\tau \le c_{\rm w}$, $c_{\rm w} = w_6 > 0$ the constant of item 8, placed before γ, and let ω be a complex plaquette function whose plane weights w_κ, $\kappa \in \{12, 13, 23\}$, obey $\sup|w_\kappa| \le \sigma(x_K - \bar B)$ and $M\mathrm{Lip}_\infty w_\kappa \le \tau x_K$, with no tie between the planes.

Put $v_n = -L^{K-n}\omega/x_n$, $g_n = x_n^{-1/2}$, $y_n = \log(x_n/2)$, $\mathsf{b}_n = A_1(\log x_n)^{\mathfrak{p}_0}$ the threshold of the level n (equation YMM1:(634)), and, for a weight w, $A_n(w;U) = A^{\eta_n}(w,U) = L^n \sum_p w(p) a_p(U)$, the weighted action of (216). For $1 \le n \le K$, $X \in \mathcal{D}_n$ and $\mathsf{a} = (\mathsf{a}_1, \mathsf{a}_2) \in (0, \alpha_0] \times (0, \alpha_2]$, $\alpha_2 = \alpha_2^{\rm pl}$ the third radius of item 8, the *core of the size* a, $\mathcal{U}_n(X;\mathsf{a})$, is the set of triples P in the same hereditary core of Definition YMM1:49.1 at the radii (α_0, α_1) with $|\partial \mathbf{U}_P(p) - \mathbf{1}| < \mathsf{a}_1 L^{-2n}$ at the plaquettes formed on X and $\mathrm{hol}_n(P;X) < \mathsf{a}_2$; $\mathcal{U}_n(X) = \mathcal{U}_n(X;(\alpha_0,\alpha_2))$ is the core with the third radius, and $N_n(\mathsf{a}) = \sigma\mathsf{a}_2/\alpha_2 + 2\tau L^{-(K-n)}\mathsf{a}_1/\alpha_0$.

The following objects are formed by recursion on the step $k = 0, 1, \dots, K-1$, which integrates the fluctuation field of the level k at the coupling x_k over the fibre of a block field W of the level $k+1$, at the triple $Q = P_W$. *The classical action and the trees:* the classical action $\Psi^{(k)}(Q;\cdot)$ of the step is its Gaussian form, with the covariance $C_*(Q)$ of the step, together with its linear term and its higher potentials, the weight v_k and the earlier trees being entered as potentials, so that the action of the step carries no explicit weight; $c_*^{(k)}$ is its stationary point; the tree $\mathrm{ta}_k(Z';\omega,\cdot)$, $Z' \in \mathcal{D}_{k+1}$, is the value $\Psi^{(k)}(Q;c_*^{(k)})$, written as a sum of local terms and re-sorted into terms on the cores $\mathcal{U}_{k+1}(Z')$; and the sum of the trees is $\mathrm{Tr}_n(P) = \sum_{j=1}^n (x_{j-1}/x_n) \sum_{Z\in\mathcal{D}_j} \mathrm{ta}_{j-1}(Z;\omega,\rho_Z P)$, $\mathrm{Tr}_0 = 0$, so that $x_{k+1}\mathrm{Tr}_{k+1}(Q) = x_k[\mathrm{Tr}_k(\rho Q) + \Psi^{(k)}(Q;c_*^{(k)})]$.

The non-classical array: the non-classical term $\delta_{k+1}(Z';\omega,\cdot)$ consists of the potential V^J of the Jacobians of the chart (the localised exponent J_W of the Jacobians in the weight wt_W of the chart integral below, one of the potentials of the step) and of the potential V' of the arrays of the step, both taken at $c_*^{(k)}$, and of the ideal term $E_k^{\rm id}$ below at the centre $g_k^{-1}c_*^{(k)}$ less the same object at $\omega = 0$, all re-sorted in the same way; $\mathrm{Lf}_k = \mathrm{Lf}[g]$ is the lift of (b) at $g^{(j)} = \delta_j$; $S_n^c[\omega](U) = S[\mathfrak{f}_n](U) + \sum_{j\le n}\sum_{Z\in\mathcal{D}_j}[\delta_j(Z;\omega,p_Z^{(j)}(U)) - \delta_j(Z;\omega,\mathbf{1})]$, where $S[\mathfrak{f}_n]$ is the action of the bare arrays of the never-large term at the zero source (Proposition B.15, at $w = 0$) and $p_Z^{(j)}(U)$ the plain pair of U on Z, the configuration and its current of the level j on $\mathrm{Bd}(Z)$; and $E_n[\omega] = E_{(n)} + \sum_{i\le n}\sum_{X\in\mathcal{D}_i}\delta_i(X;\omega,\mathbf{1})$, $E_{(n)}$ the number of that term.

The centres, the ideal term and the tiny terms: the true centres are $\nu_j^{(n)}(V) = g_j^{-1}c_*^{(j)}$, read at the triple ρP_V of the level $j+1$, $0 \le j < n$, and the centre of the step is $\mathsf{m} = \nu_k^{(k+1)}(W)$;

for a system V of potentials $V^o(Y;\cdot)$, $Y\in\mathcal{D}_k$, and a centre n, $\Xi_{\mathsf{n}}[V](Q)=\int d\mathsf{G}_{\mathsf{n}}(B)\,\mathbf{1}\{B\in \mathrm{Rg}_{x_k}\}\exp\sum_{Y,o}V^o(Y;B-\mathsf{n})$, G_{n} being the Gaussian measure of the covariance $C_*(Q)$ and the mean n; V_{m} is the system of the three potentials of the step about the centre m (the potentials of the step, the potential of the arrays, and the remainder of the shift of the centre), without the carried tiny terms; $E_k^{\mathrm{id}}(X';Q,\mu)$, $X'\in\mathcal{D}_{k+1}$, is the cluster sum at the centre 0 of the system V_μ on X', so that $\Xi_0[V_\mu](Q)=\exp\sum_{X'}E_k^{\mathrm{id}}(X';Q|_{X'},\mu|_{X'})$; and $\mathrm{Rf}^{(k+1)}(X';Q,\nu)$ is the cluster sum at the centre ν_k of the system V_{ν_k} enlarged, for $k\ge1$, by the carried term $\mathrm{Rf}^{(k)}$ as one further potential, less the cluster sum at the centre 0 of V_{ν_k} without it.

The classical factor of the step: $c_k(W)=n_k(W)\exp\big[\mathcal{E}_k(W)-x_k\Psi^{(k)}(Q;c_*^{(k)})+\sum_{Y\in\mathcal{D}_k}(V^J+V')(Y;Q|_Y;c_*^{(k)}|_Y)\big]$, where $\mathcal{E}_k(W)$ is the exponent of $\Phi_k[\omega]$ below at $V_W(0)$ ($\Phi_0[\omega]=\rho_0$), V^J and V' are the potential of the Jacobians of the chart and the potential of the arrays of the step, as in δ_{k+1}, and $n_k(W)=\mathsf{pf}_k(x_k)\,\mathsf{Z}^{(k)}$ is the normalisation of the step, with the prefactor equation YMM1:(907) and the Gaussian integral in Proposition YMM1:50.2 at the triple of W; so $\mathrm{wt}_W(B)\Phi_k[\omega](V_W(B))$ is $c_k(W)$ times the density of G_{m} at B times $\exp\sum_{Y,o}V^o_{\mathsf{m}}(Y;B-\mathsf{m})$.

Then for $1\le n\le K$ the never-large term of $\rho_0=\exp[-A(x_0-L^K\omega,\cdot)]$ at the level n has the density

$$f_n(V)=\Phi_n[\omega](V)\exp\sum_{X\in\mathcal{D}_n}\mathrm{Rf}^{(n)}(X;P_V,\nu^{(n)}(V))\quad\text{on }\mathcal{V}_n^\chi,\qquad f_n=0\quad\text{off it},$$

$\mathcal{V}_n^\chi$ being the set of the configurations of the level n that pass all the small-field tests (Definition B.14), and

$$\Phi_n[\omega]=\exp\big[E_n[\omega]-x_nA_n(1+v_n;U_n(V))-x_n\mathrm{Tr}_n(P_V)+S_n^c[\omega](U_n(V))\big],\qquad v_n=-L^{K-n}\omega/x_n,$$

where Tr_n, the sum of the trees (the classical remainders) of the earlier steps, the non-classical array $S_n^c[\omega]$ and the number $E_n[\omega]$ are those above, and P_V is the frozen triple of the background $U_n(V)$ of Proposition B.15 and Theorem YMM1:E in the setting of Section YMM1:52.7. Each step $0\le k<K$, at every $W\in\mathcal{V}_{k+1}^\chi$ and with $f_0=\rho_0$, is the identity

$$\int_{\mathrm{Rg}_{x_k}}\mathrm{wt}_W(B)f_k(V_W(B))\,dB=c_k(W)\,\Xi_0[V_{\mathsf{m}}](Q)\exp\sum_{X'\in\mathcal{D}_{k+1}}\mathrm{Rf}^{(k+1)}(X';Q,\nu^{(k+1)}(W)),\qquad c_k(W)\,\Xi_0[V_{\mathsf{m}}](Q)=\Phi_{k+1}[\omega](W),$$

whose left member is $f_{k+1}(W)$, the chart integral $\mathsf{I}[f_k](W)$ at $\mathsf{t}=x_k$ (Definition B.2 and equation (191), (191)): Rg_{x_k} is the set of the scaled fields below the threshold $\mathfrak{b}(x_k)$ (Section B.2), $V_W(B)$ the chart of the fibre over W (Lemma B.3), and $\mathrm{wt}_W(B)=\mathsf{pf}_k(x_k)\,z_{V_0}^{(k)}(\Gamma)\exp[-x_kG_W(B)+\mathsf{J}_W(B)]$, $V_0=V_k^{\mathrm{bf}}(W)$, the weight of the chart integral; $Q=P_W$, $\mathsf{m}=\nu_k^{(k+1)}(W)$ is the centre of the step, and $c_k(W)$, Ξ_0 and V_{m} are those above; so each step is classical, times ideal, times the exponential of a tiny term.

The ideal term is $\exp\sum_{X'}E_k^{\mathrm{id}}(X';\cdot)$ with $|E_k^{\mathrm{id}}|\le\frac14e^{-\kappa''d_{k+1}(X')}$, so it does not vanish. $\mathrm{Rf}^{(n)}(X;P,\nu)$ is holomorphic on $\mathcal{U}_n(X)$ times the polydisc of the centres, one 1-form ν_j for every earlier level $j<n$, with $|\mathrm{Re}\,\nu_j(b)|<\vartheta_{j,n}\theta_1'\mathsf{b}_j$ and $|\mathrm{Im}\,\nu_j(b)|<\vartheta_{j,n}\theta_1''\mathsf{b}_j$, $\vartheta_{j,n}=\frac12(1+2^{-(n-j-1)})$, gauge invariant when the centres are carried along, and $|\mathrm{Rf}^{(n)}|\le\bar K_{\mathrm{w}}e^{-c^{\mathrm{pl}}y_n^2}e^{-\kappa d_n(X)}$, $y_n=\log(x_n/2)$, with the constants $\bar K_{\mathrm{w}}$ and c^{pl} of item 7; the true centres obey $|\nu_j^{(n)}(V)(b)|\le\frac{\theta_*}{2}L^{-2(n-j-1)}\mathsf{b}_j$, $\mathsf{b}_j=A_1(\log x_j)^{\mathfrak{p}_0}$ the threshold of the level j (equation YMM1:(634)); the trees obey $e^{r_1d_n(Z)}|\mathrm{ta}_{n-1}(Z;\omega,P)|\le K_{\mathrm{ta}}N_n(\mathsf{a})^2$ on the cores $\mathcal{U}_n(Z;\mathsf{a})$ of the size a, at every $\mathsf{a}\in(0,\alpha_0]\times(0,\alpha_2]$, with one K_{ta} and one rate r_1 at all

levels; the non-classical terms obey $e^{r_1 d_n(Z)}|\delta_n(Z;\omega,P)| \le 129\min\{1,(\sigma+2\tau)/c_{\mathrm{w}}\}$ on $\mathcal{U}_n(Z)$; and the lift of the non-classical array, which is (b) at $g^{(j)} = \delta_j$, $B_j \le 129$ and the rate $\kappa_{\mathrm{lf}} = r_1$, obeys $e^{r_1 d_k(X)}|\mathrm{Lf}_k(X;\omega,P')| \le 129 K_{\mathrm{Lf}} L/(L-1)$, $K_{\mathrm{Lf}} = 2C_E(140C_Q+1)$, as $\sum_{j\le k} L^{-(k-j)} \le L/(L-1)$.

The rate r_1 is admissible in (b): $r_1 = \kappa'' - 8\log 2$ with $\kappa'' = (1+4\beta_{\mathrm{s}})\kappa + 1 + \lambda_{\mathrm{s}}$ and $\lambda_{\mathrm{s}} \ge 1$ (Section YMM1:82, where $\lambda_{\mathrm{s}} = \log 18432$ and the formula for κ'' is recalled), so that by item 3, $r_1 \ge E_q + 2 - 8\log 2 > \mathsf{C}_{\mathrm{cs}} > 4\log 18432$. Every number is a constant placed before γ or an absolute constant. Everything is holomorphic in ω on the open set of the plaquette functions that lie, for some $\sigma,\tau \ge 0$ with $\sigma + 2\tau \le c_{\mathrm{w}}$, in the class with strict inequalities $|v_n|_\infty < \sigma$ and $\mathrm{sw}_n(v_n) < 2\tau L^{-(K-n)}$ at every $0 \le n \le K$, $\mathrm{sw}_n(v)$ being the largest difference $|v(p_{\mu\nu}(x')) - v(p_{\mu\nu}(x))|$ over the parallel plaquettes with $x' - x$ along e_μ or e_ν and of length at most one spacing of the level n.

At $\omega = 0$ the trees, the δ_n and Tr_n vanish, the true centres are $\nu_j^{(n)}(V) = 0$, and $\mathrm{Rf}^{(n)}(X;P,0) = 0$ for every $P \in \mathcal{U}_n(X)$, at the zero centres; hence $f_n = \Phi_n[0]$ is the never-large term. The background is $U_n(V)$ from Proposition B.15, and the centres of the Gaussian integrals are free arguments; the cores with the third radius coincide with the plain cores at the levels $n \le (\frac{L}{2} + 29.39)/\log L$, so at the levels $n \le 13$ for every odd $L \ge 13$, and are proper subsets of them from some level on; at $k = 0$, where the step is written with bond labels, its centre is at most $K_Z\sigma$ on the whole plain core, K_Z a constant placed before γ.

■□

Theorem AI (Weighted backgrounds)**.** In the setting of Theorem AH, part (a) uses the regular-reference and geometric setting of Definition 8.5; its analytic response and Hessian estimates are proved in Proposition 8.6. Parts (c) and (d) additionally assume the complex scalar gauge-transfer estimate of Definition 8.22. Evaluation of the algebraic identity in (e) on those moved backgrounds has the same assumptions; the identity and its bounds for already given families do not require it.

(a) *Critical backgrounds.* Use the real regular reference, natural-pair and separated-region setting of Definition 8.5. For the plane and symmetric corner weights $\mathbf{h} = (h,v)$, Proposition 8.6 gives a unique critical background in the slice $RD^{\mathsf{T}}A = 0$, $\mathcal{Q}(A) = b$, among fields with $\sup_y \|A\|_y^{\beta_H} \le r_*$, where this norm includes the scaled first-gradient Hölder seminorm defined there. It is holomorphic in the row datum and the weights on $\sup|b| < \rho_*$, $\|\mathbf{h}\| < z_*$, real at real data, and obeys the localized response bounds (28)–(29). Its Hessian in the block datum satisfies (30) on $Y_0 + iY_0$, with the longer-sequence hypotheses in that proposition. The unweighted comparison is at the same reference background. The Hölder norm of the weights cannot be replaced by their supremum in a uniform Hölder estimate for this response. There is a separate finite-lattice assertion at $U_0 = 1$, when all regions are the whole torus. For real plane weights $v_{\mu\nu} = \epsilon k_{\mu\nu}$, $|k| \le 1$, or for a single real mixed tensor term $\epsilon\varkappa\langle f_{\mu\nu}, f_{\mu\lambda}\rangle$, $|\varkappa| \le 1$, with $0 \le \epsilon < 1$, the critical backgrounds near the zero block datum form a real-analytic family and their block Hessian at that datum obeys $(1-\epsilon)Z_0 \le Z_\epsilon \le (1+\epsilon)Z_0$. This assertion uses each of these two perturbations separately.

A common constant $c \ne -1$ in the plane weights factors out: the weights $(h, v+c)$ have the same critical fields as $\mathbf{h}' = (h,v)/(1+c)$ and their multipliers and Hessians are multiplied by $1+c$. The smallness conditions are those on $\mathbf{h}'$. For real $c > -1$ the positive Hessian floor is multiplied by $1+c$ as well.

After lowering γ by the ceilings specified in the proof, the following holds on every history. At each step $t \ge 2$, the background and row datum of the run satisfy the hypotheses above, and for real weights with $\|\mathbf{h}\| \le z_N^+$ the block Hessian is at least $\frac{1}{2}\gamma^{\mathrm{pc}}\|B\|^2$ on real $B \in Y_0$. At the first step the real part of the second variation of the action itself is at least that amount for $B \in Y_0 + iY_0$ and complex weights with $\|h\|_\infty + \sup|v| \le z_N^1$. The latter assertion

uses the two-region natural-pair hypothesis and the explicit background and block-field ceilings in the proof.

(b) *Walk terms.* Under the natural-pair and separated-region hypotheses of Proposition Q.10, there are numbers $r_\tau, r'_\tau > 0$ and a power M^τ of L, depending only on L, such that all four weighted systems are invertible for $|v|_\infty < r_\tau$, radii at most r'_τ, and block number at least M^τ. Their inverses satisfy the mean-square divergence-source estimate (343), and their local walk terms satisfy (344), at a common exponential rate. The Hessian changes by the local plaquette form of Lemma Q.9. Grouping a walk by its visited pieces gives zero for a disconnected set S and a bound with the factor $\epsilon_*^{\#S-1}$ for a connected set, after a further increase of M^τ for the prescribed ϵ_*, as proved after Proposition Q.10. The pieces and their adjacency are those specified there.

(c) *The moved background on a label.* On the label of a history with large-field regions, in every frame of Theorems YMM1:AJ and YMM1:AD (every such frame satisfies the standing conditions under which these labels are formed), after lowering γ by three further upper bounds of the shape of the list, $\sup_{x\ge\gamma^{-2}} \max\{w_{\mathrm{G}}, w_{\mathrm{lin}}(L)\}(\log x)^{-r} \le 1$ with $w_{\mathrm{G}} = 4c_U^{-1}(7\log L + \log 2)$, which gives $MR(\gamma^{-2}) \ge \max\{w_{\mathrm{G}}, w_{\mathrm{lin}}(L)\}$, $\sup_{x\ge\gamma^{-2}} C_m\varepsilon(x) \le \alpha_\star$ and $\sup_{x\ge\gamma^{-2}} 2K'_5 C_m\varepsilon(x) \le b_2$, where C_m is fixed before γ and depends on L and the previously chosen construction constants, including B_3, and is the constant with which a label supplies its background, regular at the radius $C_m\varepsilon_k$ with the envelope $e(x) = C_m\varepsilon_{j(x)}$, ε_j being the radius of regularity of the layer j; $\alpha_\star$ is a positive number of L with $\alpha_\star \le \min\{\alpha_{\mathrm{lin}}(L), e_0(L)\}$, the numbers of Lemma 8.20, so that the second ceiling gives the radius of regularity $\alpha \le \alpha_{\mathrm{lin}}(L)$ and the bound $\sup e \le e_0(L)$ on the envelope under which Lemma 8.20 applies; K'_5 is a positive number formed with L through the constant K_{lin} of Lemma 8.20 and the constant K_5 below; and $b_2 > 0$ is the radius with which the substitution with three pairs of radii among the construction results (Proposition P.2) carries the cores at half their radii into the cores at three quarters of them, and for anisotropies an of the plaquettes with $t(\mathrm{an}) < t_0$, $t_0 > 0$ a number of L with $t_0 \le t_{\mathrm{lin}}(L) \le \frac14$, $t_{\mathrm{lin}}(L)$ the number of Lemma 8.20, t being the supremum plus the scaled Hölder-$\frac12$ quotients: the moved background $W = e^{i\eta_k A}U$, $\eta_k = L^{-k}$ the spacing of the level, exists, is critical for $\sum_p(1+\mathrm{an}(p))a_p$ on the surface of the prescribed block averages up to a complex gauge, and is holomorphic in an; if $U = \tilde U$ at the bonds with an end point within the weighted distance R of a point x_1, then, with $e'(x) = e(x)\exp[-c_U(\mathsf{R} - d_B(x,x_1))_+]$,

$$l(b)\,|\eta_k A[U](b) - \eta_k A[\tilde U](b)| \le K_U\, t(\mathrm{an})\, e'(b_-) \qquad \text{at every bond } b,$$

b_- the initial point of b, with no gauge transformation between; the same bound holds, at every plaquette p, site x and row c of the block constraints, for the curvatures, $l(p)^2\eta_k^2|D_U A[U](p) - D_{\tilde U}A[\tilde U](p)| \le K_U t(\mathrm{an})e'(x_p)$, x_p the base point of p, for the divergences, $l(x)^2\eta_k^2|D_U^* A[U](x) - D_{\tilde U}^* A[\tilde U](x)| \le K_U t(\mathrm{an})e'(x)$, and for the multipliers ω of the pair, $|\omega[U](c) - \omega[\tilde U](c)| \le K_U t(\mathrm{an})e'(c_-)$, c_- the base point of c; if $\mathsf{R} \ge w_*$, then at every point x_* of a layer $n \ge 2$ with $d_B(x_*, x_1) \le \mathsf{R} - w_*$, in one gauge that is a member of gauge systems of both U and $\tilde U$, the Hölder-$\frac12$ quotients of $\eta_k^2(D_U A[U] - D_{\tilde U}A[\tilde U])$, over the plaquettes of one orientation in the cube of the bare sites within $\frac14 l_n$ bare spacings of x_*, and of $\eta_k(A[U] - A[\tilde U])$, over the bonds of one direction based within $\frac18 l_n - 2$ bare spacings of x_*, obey $(\frac14 l_n)^{1/2}[\cdot]_{1/2} \le K_U t(\mathrm{an})e'(x_*)l_n^{-2}$, resp. $l_n^{1/2}[\cdot]_{1/2} \le K_U t(\mathrm{an})e'(x_*)l_n^{-1}$; and the multiplier ω_0 of the plain background obeys $|\omega_0[U](c) - \omega_0[\tilde U](c)| \le K_O e'(c_-)$.

Here $l(b), l(p), l(x)$ are the scales of the layers, $l_n = L^n$, D_U is the covariant lattice exterior derivative and D_U^* its adjoint, and d_B is the weighted distance of Definition YMM1:12.3; c_U, K_U, K_O depend on L alone, $c_U \le 1/(6L)$, $K_U = 7K_{\mathrm{lin}}^2(1+2L^3)^2 e^{c_U w_*}$ with the constant

K_{lin} of Lemma 8.20 and $w_* = w + 21L$, $w = w(L)$ being the width of the cut-off used in the proof. The map $(\mathrm{an}, U) \mapsto A$ is jointly continuous, and the moved background, its triples and its currents are Borel functions of the configuration; every critical point on the fibre of norm $\le r_2(L)$ is carried to W by a unique small gauge transformation that induces the identity at every top of the sequence; the full covariant gradient obeys $l(x)^2|\eta_k^2(\nabla_\kappa A_\nu)(x)| \le K_5\, t(\mathrm{an})\, e(x)$; W lies in the cores at three quarters of their radii; the construction commutes with the translations by vectors of the coarsest lattice; and $\sum_p |(1+\mathrm{an}(p))a_p(W) - a_p(U)| \le K|\mathrm{an}|_\infty \sum_p a_p(U)$.

(d) *The centres on a label.* Let $0 < \theta_3 \le 1$ be fixed before γ. In the setting of (c), let γ be lowered further by upper bounds of the shape of the list formed with θ_3, A_0, A_1, $\mathfrak{p}_0$, r, ε_{v} and numbers of L, among them $C_\chi(1+2\theta_3)\delta(x) < \frac{1}{8}r_c$ for $x \ge \gamma^{-2}$, with two numbers C_χ, r_c of L; this keeps the box $|\mathrm{Re}\, B_1(b)| + |\mathrm{Im}\, B_1(b)| < (1+2\theta_3)\mathsf{b}_k$ of the complex block data of the step, of the unscaled radius $(1+2\theta_3)\delta(x_k)$, and with it the polydisc $|\mathsf{n}(b)| < \theta_3\mathsf{b}_k$ below, of the unscaled radius $\theta_3\delta(x_k)$, inside the ball, of a radius of L alone, in which the system of the centre has exactly one solution.

Let the envelope of (c) be taken with C'/L in the place of C_m, $C' = \max\{LC_m, 2LC_\chi(1+2\theta_3)A_1/(\rho_{\mathrm{u}}A_0)\}$, $\rho_{\mathrm{u}} = \rho_{\mathrm{u}}(L)$ being the radius of that ball; C' is the one number that is enlarged. Among the upper bounds on γ above are the ceilings $\sup_{x\ge\gamma^{-2}} C'\varepsilon(x) \le c(L)$, $c(L) > 0$ numbers of L, and the block-number and small-radius conditions of Proposition Q.10, under which Corollary Q.11 gives the global energy bound for the linear system; the nonlinear field-energy bound is supplied by Lemma 8.21. Let the anisotropies obey moreover $t(\mathrm{an}) < t_\theta$, where $t_\theta = \min\{t_0, t_{\mathrm{u}}(L), c_{\mathrm{ce}}\theta_3 A_1/A_0\}$, $t_{\mathrm{u}}(L)$ being the number of L below which the moved backgrounds with a complex block datum are formed and $c_{\mathrm{ce}} > 0$ a number formed with L and C'; so $t_\theta \in (0, t_0]$ is formed with θ_3 and with constants placed before γ.

At every step $0 \le k < K$ and every regular base of the step (a regular background of the coarser level together with its block datum), the *centre* of the step is defined by two conditions: it is a complex stationary point n of the weighted action on the fibre of the block field, and it is in the block axial gauge. There is exactly one n with $|\mathsf{n}(b)| < \theta_3\mathsf{b}_k$ at all bonds b of the step that obeys the two conditions; it is $\mathsf{n} = g_k^{-1}a''$, a'' the 1-form, in the axial gauge, of the finer block average of $W[\mathrm{an}; b_0]$ read about the finer block average of $W[0; b_0]$. Here both backgrounds are formed over the same regular reference background U_{b} on the longer sequence, with the same complex block datum b_0 obtained from the base of the step; $|\mathsf{n}(b)| \le C_\theta t(\mathrm{an})\mathsf{b}_k \le \frac{1}{2}\theta_3\mathsf{b}_k$, C_θ depending on L, θ_3, A_1/A_0 and C_m. At $b_0 = 0$, the base being U_{b} with its own block averages, $\sum_b |\mathsf{n}(b)|^2 \le C^2|\mathrm{an}|_\infty^2 A(\beta_t, U_{\mathrm{b}})$, C a number of L, the sum running over all the bonds of the step for $1 \le k < K$ and over its external bonds at $k = 0$, $A(\beta_t, U_{\mathrm{b}})$ being the action of the reference background with the couplings of the step; and n is holomorphic in an, real at real an and real b_0, and 0 when an is constant.

The linearised system of the centre (the second variation of the constrained weighted action with its multipliers, the averaging constraint and the block axial gauge) is invertible, in ℓ^2 and in a weighted maximum norm, with bounds depending on L alone. The centres $\mathsf{n}^{(i)}$ of the earlier steps $0 \le i < k$, formed by the same rule about the moved background of the label, vanish at an $= 0$, are holomorphic in an and obey $|g_i\mathsf{n}^{(i)}(b)| \le Ct(\mathrm{an})\varepsilon_i$, that is $|\mathsf{n}^{(i)}(b)| \le Ct(\mathrm{an})(A_0/A_1)\mathsf{b}_i \le \frac{1}{2}\theta_3\mathsf{b}_i$, with one number C of L for all levels, $\varepsilon_i = \varepsilon(x_i)$ the radius of regularity of the level i and $g_i = x_i^{-1/2}$; and their squares, summed over the stored bonds, which are the external bonds of these steps, obey $\sum_{i<k}\sum_b |\mathsf{n}^{(i)}(b)|^2 \le C^2|\mathrm{an}|_\infty^2 A(\beta_k, U)$, $A(\beta_k, U)$ being the action of the background with the couplings of the level k.

(e) *The counterterms on a label.* On the label of a history with large-field regions the part of every coupling counterterm among the construction results that sees the anisotropy moves

exactly into the local terms and the boundary terms (Lemma 8.23): the anisotropy stands in the main weight and the local terms, and in the moved background whenever (c) is applied, and in no counterterm; the counterterms, the values at the trivial triple and the trivial values of the sums are unchanged; at a fixed triple, with the original families and counterterms held fixed, the changes in the re-filed local and boundary entries are linear in an with explicit Lipschitz constants. The following size bounds require a margin. Let $0 < \theta < 1$; let the families $E^{(j)}$ before the re-filing obey $\|E^{(j)}\|_{j,\kappa+1} \le (1-\theta)E_0$ at every level and every source; let $\|\mathrm{an}\|$ be the norm of the anisotropies in the format of the families, with $|\mathrm{an}|_\infty \le \sigma_3\|\mathrm{an}\|$, the anisotropies ranging over $\|\mathrm{an}\| < 1$, and, if $B_\sharp > 0$, let $\sigma_3 \le \theta E_0 e^{-7(\kappa+1)}/(\frac{3}{2}B_\sharp\alpha_0^2)$.

Then the re-filed families $\hat{E}^{(j)}$ obey $\|\hat{E}^{(j)}\|_{j,\kappa+1} \le E_0$ and $\|\hat{E}^{(j)} - E^{(j)}\|_{j,\kappa+1} \le \theta E_0\|\mathrm{an}\|$; if $\|E^{(j)} - E_0^{(j)}\|_{j,\kappa+1} \le D$, $E_0^{(j)}$ the family at zero source, then $\|\hat{E}^{(j)} - E_0^{(j)}\|_{j,\kappa+1} \le D + \theta E_0\|\mathrm{an}\|$, and for the re-filed families this bound stands in the place of the quadratic bound among the construction results; in a frame of Theorems YMM1:AJ and YMM1:AD the added parts of the boundary entries are at most $\theta M^3 E_0 e^{-7}\|\mathrm{an}\|e^{-\kappa d_j(X)}$; the trivial values are unchanged.

■□

Definition 8.5 (Weighted critical backgrounds)**.** Fix $0 < \beta_H < 1$. Use a separated sequence through level $1 \le k < K$, with bare spacing $\eta = L^{-k}$, the interior and outward determining rows, and no inward or edge rows. Retain the natural-pair, block-number, separation and torus-size hypotheses of the regular response construction in Propositions YMM1:31.1 and YMM1:34.2. In particular the terminal torus has at least $6R_1\mathfrak{M}$ sites per direction. The common block number and width are chosen large enough for the ordinary Hölder kernels and the positive fluctuation form used below: $\mathfrak{M} \ge M^{\mathrm{pc}}$, $R_1\mathfrak{M} \ge \mathfrak{r}^{\mathrm{pr}}$ and $\delta_* R_1\mathfrak{M} \ge 512\log L$. Here M^{pc} is enlarged to make the cutoff defect in the proof at most $1/8$, and the regularity ceiling a^{pc} is decreased to give the local inverse comparison there.

Let U_0 be real, critical for the unweighted action on the fibre of its block averages. Write $\mathcal{Q}$ for the straightened row map and $a_{\mathcal{Q}}$ for its fixed analytic potential radius, chosen so that this map and its local Taylor bounds hold on $\sup_y \|A\|_y < 2a_{\mathcal{Q}}$. Write $K_A = \mathcal{Q}'(A)$, $K_0 = K_A|_{A=0}$, and

$$F(A) = \eta^{-1}\sum_p a_p(e^{i\eta A}U_0), \qquad F'(0) = K_0^{\mathsf{T}}\omega_0.$$

The fine pairing has weight η^3, and the dimensionless row pairing has weight ξ_c^{-1}. Suppose U_0 is regular at radius α: its plaquette defects are at most $\alpha\eta^2\xi_y^{-2}$ and $\xi_y^3|F'(0)| \le \alpha$. Require the pair $(U_0, F'(0))$ to belong to the natural class of that sequence with radii (α,α,α) and real factor U_0. This retains the local real gauges in that class.

The weights are $\mathbf{h} = (h, v)$. The plane weight v is a function of inner plaquettes. At each bare site x, the symmetric matrix $h_{ww'}(x)$ is indexed by the 24 oriented corners $w = (\iota,\iota')$, $|\iota| \ne |\iota'|$, with $\iota,\iota' \in \{\pm1,\pm2,\pm3\}$. If f_w is the field strength of the corresponding plaquette loop based at x, put

$$T_{\mathbf{h}}(A) = T_h(A) + T_v(A), \quad T_h(A) = \eta^3\sum_{x,w,w'} h_{ww'}(x)\langle f_w, f_{w'}\rangle, \quad T_v(A) = \eta^{-1}\sum_p v(p)a_p.$$

All loops are contained in the ambient region. Set $|h(x)| = \max_w \sum_{w'} 2|h_{ww'}(x)|$. The norm $\|\mathbf{h}\|$ is the supremum over tops y of the sum of the local suprema of $|h|$ and $|v|$ and their C^{β_H} seminorms multiplied by $\xi_y^{\beta_H}$. The pairs in these seminorms have one base point in the cell of y and distance at most $\xi_y/4$; plane weights are compared in the same plane.

For potentials use

$$\|A\|_y = \max\{\xi_y|A|_y, \xi_y^2|\nabla A|_y\}, \qquad \|A\|_y^{\beta_H} = \max\{\|A\|_y, \xi_y^{2+\beta_H}[\nabla A]_{\beta_H,y}\}.$$

The last seminorm uses the transports of U_0 along inner combs, over the same distances. With N_y denoting the appropriate potential, row or weight norm, write

$$\|u\|_{\theta,y_0} = \sup_y e^{\theta d_{\mathbf{B}}(y,y_0)} N_y(u).$$

For the Hessian assertion add the next region Ω_{k+1} and require the same natural-pair bounds on this longer sequence. Let Y_0 be the real top-layer fields about Ω_{k+1} whose next linearized averages vanish and which vanish on the block axial trees. Its norm and pairing are the top-row ones. ■

Proposition 8.6 (Weighted critical response)**.** In Definition 8.5, there are positive radii a_*, r_*, ρ_*, z_* and constants B_*, Θ, C_T, depending only on L and β_H, with $a_* \le \min\{a^{\mathrm{pc}}, a_{\mathcal{Q}}, L^{-2}/4\}$ and the following property. If $\alpha \le a_*$, $\sup|b| < \rho_*$ and $\|\mathbf{h}\| < z_*$, there is exactly one critical background $e^{i\eta A}U_0$ with

$$RD^{\mathsf{T}}A = 0, \qquad \mathcal{Q}(A) = b, \qquad \sup_y \|A\|_y^{\beta_H} \le r_*.$$

Its pair (A,ω) is holomorphic in $(b,\mathbf{h})$ and real at real data, and equals $(0,\omega_0)$ at $(0,0)$. It satisfies $\sup_y \|A\|_y^{\beta_H} < r_*$. For a row c_0 and a datum e_{c_0} supported there,

$$\begin{aligned} \|d_b A\, e_{c_0}\|_y^{\beta_H} &\le 2B_* e^{-\delta_* d_{\mathbf{B}}(y,y_{c_0})/4}|e|, \\ |d_b\omega\, e_{c_0}|_y &\le 2\Theta B_* e^{-\delta_* d_{\mathbf{B}}(y,y_{c_0})/4}|e|. \end{aligned} \tag{28}$$

For every weight direction $\mathbf{k}$ and $0 \le \theta \le \delta_*/4$,

$$\max\{\|d_{\mathbf{h}}A\,\mathbf{k}\|_{\theta,y_0}^{\beta_H}, \Theta^{-1}\|d_{\mathbf{h}}\omega\,\mathbf{k}\|_{\theta,y_0}\} \le 2C_T(\alpha + \sup_y \|A\|_y^{\beta_H})\|\mathbf{k}\|_{\theta,y_0}. \tag{29}$$

Here δ_* is the fixed propagator rate, with the response kernels taken at rate $3\delta_*/8$ before their weighted summation. With the longer-sequence hypotheses, let $Z = d_b\omega$ be the Hessian of the weighted critical value and put $s = \max\{\sup|b|/\rho_*, \|\mathbf{h}\|/z_*\}$. After decreasing the radii, there are $\gamma^{\mathrm{pc}}, e_0, \kappa_0 > 0$ such that

$$\mathrm{Re}\langle \bar{B}, ZB\rangle \ge (\gamma^{\mathrm{pc}} - e_0\alpha - \kappa_0 s)\|B\|^2, \qquad B \in Y_0 + iY_0. \tag{30}$$

The reference for the perturbation in s is the unweighted Hessian at $b = 0$ over this same U_0. ■

Proof. We keep the exact constrained response at the reference. Its Hessian includes the multiplier correction. Put $\Delta = F''(0)$, and define $W(A,\omega)$ by $\langle X, W(A,\omega)Y\rangle = \langle \omega, \mathcal{Q}''(A)[X,Y]\rangle$. Thus $W_0 = W(0,\omega_0)$. Set

$$G_1 = (\Delta - W_0 + DRD^{\mathsf{T}} + K_0^{\mathsf{T}} a K_0)^{-1}, \quad H = G_1 K_0^{\mathsf{T}}(K_0 G_1 K_0^{\mathsf{T}})^{-1}, \quad \widetilde{G} = G_1 - HK_0G_1.$$

The physical and dimensionless row conversions are those in the proof of Proposition YMM1:34.2; a is the positive row coefficient of that construction, including its boundary extension. This extension cancels on $N(K_0)$. Elimination of the auxiliary variables in Proposition YMM1:31.1 gives

$$K_0H = 1, \quad K_0\widetilde{G} = 0, \quad \widetilde{G}(\Delta - W_0 + DRD^{\mathsf{T}}) = 1 - HK_0, \quad RD^{\mathsf{T}}H = 0.$$

The ordinary response kernels and their first differences decay exponentially. Their Hölder bounds follow as in Lemma Q.7, with the fixed exponents β_H and $(1+\beta_H)/2$ in that proof. The exponent gap in its ordinary-input argument is positive. For a divergence source of exponent β_H, use instead the same-exponent parametrix in the proof of Lemma 8.20, with that exponent in the Green-kernel cancellation estimate of Lemma YMM1:19.4. The local multiplier term W_0 has size $C\alpha$ and is one of the lower-order terms in that parametrix. Thus all constants are uniform in the region sequence and its depth.

Write

$$C(A) = \mathcal{Q}(A) - K_0A, \qquad F'(A) = F'(0) + \Delta A + \mathcal{V}(A).$$

The critical equation with the slice term and its constraint is equivalent to the following two equations:

$$A = H(b - C(A)) + \widetilde{G}(C'(A)^{\mathsf{T}}\omega - F'(0) - \mathcal{V}(A) - W_0 A - T'_{\mathbf{h}}(A)),$$
$$\omega = H^{\mathsf{T}}(F'(A) + T'_{\mathbf{h}}(A) + DRD^{\mathsf{T}}A - C'(A)^{\mathsf{T}}\omega).$$

Denote this map by $\Phi^{\mathbf{h}}$. The exact identities above recover both equations from its fixed point. Conversely a solution gives a fixed point by the same elimination. The slice term vanishes at a real fixed point by gauge invariance and the scalar projection identity; holomorphy extends that identity to the complex parameter domain.

Here is the uniform smallness estimate behind the contraction. The Taylor kernels of the row map are confined to the double block beneath a row. The local action kernels are confined to a plaquette star. In the scaled local norms their bounds are

$$\|C'(A)\| + \|C'(A)^{\mathsf{T}}\| \le Cr, \quad \|\mathcal{V}'(A)\| \le Cr, \quad \|W(A,\omega) - W_0\| \le C(|\omega - \omega_0| + r|\omega_0|)$$

on $\sup \|A\|_y \le r$, while $|\omega_0| \le C\alpha$. These are the local estimates used in Proposition YMM1:33.1; their passage to exponentially weighted norms costs a fixed summation constant. The first component of $\partial_X \Phi^0$ is therefore small. In the second component, the only term without a small factor is $H^{\mathsf{T}}(D^{\mathsf{T}}D + DRD^{\mathsf{T}})\delta A$, which has a fixed bound $K_8\|\delta A\|$. Choose $\Theta \ge 4K_8$ and measure pairs by

$$\|X\|_{\theta,y_0} = \max\{\|A\|^{\beta_H}_{\theta,y_0}, \Theta^{-1}\|\omega\|_{\theta,y_0}\}.$$

First reducing a_*, r_* makes the two remaining derivative bounds at most $1/8$ each. The product inequality $[fg]_{\beta_H} \le |f|[g]_{\beta_H} + [f]_{\beta_H}|g|$ gives the same bounds for the Hölder terms. The added weighted action contributes at most $C\|\mathbf{h}\|$ to the derivative: its leading term is the covariant divergence of the weight times the field strength, and its other terms are the local curvature commutators. The divergence estimate just described uses the C^{β_H} norm of that product. Reduce z_* to absorb this contribution. We obtain

$$\|\partial_X \Phi^{\mathbf{h}}\|_{\theta,y_0} \le \tfrac{1}{2}, \qquad 0 \le \theta \le \delta_*/4. \tag{31}$$

This contraction proves uniqueness in the stated norm, including its first-gradient Hölder term.

At $X_0 = (0, \omega_0)$ the displacement of the map is bounded by $C(\sup|b| + \alpha\|\mathbf{h}\|)$. Reducing ρ_*, z_* puts this displacement within half the chosen ball. Iteration gives the fixed point and its holomorphy, uniformly on smaller parameter balls. Conjugation gives reality. If a critical point in the slice has $\sup \|A\|^{\beta_H}_y \le r_*$, the row equation $K_A H = 1 + C'(A)H$ has an inverse bounded by its Neumann series. It gives the multiplier bound needed to place that point in the same pair ball. Thus it is the fixed point. The actual block field is obtained from the reduced datum by the accumulated averaging gauge, as in Corollary YMM1:41.3.

Differentiate the fixed-point equation in a single row. It gives

$$(1 - \partial_X \Phi^{\mathbf{h}}) d_b X \, e_{c_0} = (He_{c_0}, 0).$$

The right side has norm at most $B_*|e|$ in the exponential norm centred at y_{c_0}. The inverse on the left has norm at most 2, proving (28). In a weight direction the right side is formed from $T'_{\mathbf{k}}(A)$. This first variation is linear in the field strength and is bounded by $C_T(\alpha + \sup\|A\|^{\beta_H}_y)\|\mathbf{k}\|_{\theta,y_0}$. The same inverse gives (29).

We next record the unweighted lower bound used for the Hessian. The longer-sequence hypothesis is needed here. Let T^{ax} be the fluctuation form in nonpivot axial coordinates. In the local inversion proof of Theorem YMM1:L, the flat axial form T^0 has the gap in equation YMM1:(593). The finite support of the pivot-coordinate map and the exponential bound for the row inverse give an upper bound $T^0 \le a_{\mathrm{pc}} I$ by the row and column sum test. Hence

$$a_{\mathrm{pc}}^{-1} I \le (T^0)^{-1} \le \gamma_{\mathrm{c}}^{-1} I.$$

The natural class supplies a real local gauge on each comparison cube in which the potential and its first differences are small. In that gauge, the local system differs from the flat one by the local defect bounded in the proof of Theorem YMM1:L. The resolvent expansion bounds the difference of the inverse blocks by $C\alpha e^{-\delta d(b,b')}$. Summing its rows and columns, and decreasing the regularity radius, gives

$$\|C_\kappa - (T^0)^{-1}\| \le (2a_{\mathrm{pc}})^{-1}.$$

Here C_κ is the block of the local inverse from the nonpivot-field source to the nonpivot field. Elimination of its other components identifies it with the inverse of the local reduced form. At real data it is real and symmetric. The last bound therefore gives

$$(2a_{\mathrm{pc}})^{-1} I \le C_\kappa \le p_{\mathrm{pc}} I, \qquad p_{\mathrm{pc}} = \gamma_{\mathrm{c}}^{-1} + (2a_{\mathrm{pc}})^{-1}.$$

Returning to the original local gauge is unitary and preserves these inequalities. With the partition from that same local inversion proof, put

$$P = \sum_\kappa h_\kappa C_\kappa h_\kappa, \qquad \sum_\kappa h_\kappa^2 = 1.$$

The local inverse bounds give $(2a_{\mathrm{pc}})^{-1} I \le P \le p_{\mathrm{pc}} I$. To compare PT^{ax} with the identity, lift a nonpivot field B to the auxiliary solution Φ in the reduced system. Its equation has only the last source component $T^{\mathrm{ax}} B$, and the ordinary inverse estimate gives $\|\Phi\|_\infty \le C_{\mathrm{pc}} \|B\|_\infty$. On the enlarged comparison cube the local and global equations agree. Multiply by a cutoff which equals one on the support of h_κ and apply the local inverse. The main term is $h_\kappa B$. The error is the inverse applied to the cutoff commutator. Every difference of the cutoff costs $\mathfrak{M}^{-1}$; the enlarged cubes have bounded overlap. Multiplying by h_κ and summing consequently gives

$$PT^{\mathrm{ax}} = 1 - E, \qquad \|E\|_\infty \le 2 N_G B_{\mathrm{pc}} C'_{\mathrm{cut}} C_{\mathrm{cut}} C_{\mathrm{pc}} \mathfrak{M}^{-1} \le \tfrac{1}{8}.$$

Here N_G is the overlap bound of the enlarged comparison cubes, B_{pc} the local inverse bound, C_{cut} the bound for the scaled cutoff differences, and C'_{cut} the commutator bound per such difference. The constant C_{pc} is the lifting bound for Φ above. All depend only on L. The last inequality is imposed by the common block floor. Although PT^{ax} need not be symmetric, it is similar to the real symmetric matrix $P^{1/2} T^{\mathrm{ax}} P^{1/2}$. Its eigenvalues lie in $[7/8, 9/8]$. Consequently $T^{\mathrm{ax}} \ge 7/(8p_{\mathrm{pc}})$. For $B \in Y_0$, the next-average constraint recovers its pivot entries from the nonpivot entries: $B = \mathsf{C}\check{B}$. Here C solves the linear next-average equations for the pivot bonds in the axial gauge. Its entries are bounded by C_K, and each bond shares a coordinate block with at most $n_{\mathrm{pc}} = 36L^3$ positively oriented bonds. The finite block-coordinate estimate gives $\|B\|^2 \le 2(C_K n_{\mathrm{pc}})^2 \|\check{B}\|^2$. Hence the unweighted fluctuation form has a positive floor γ^{pc} on Y_0. The difference between that Lagrangian form and the Hessian of the critical value is the second derivative of the row map paired with the reference current. Its local kernel bound gives a loss at most $e_0 \alpha \|B\|^2$. Thus at $(b, \mathbf{h}) = (0, 0)$,

$$\langle B, Z(0,0;U_0) B \rangle \ge (\gamma^{\mathrm{pc}} - e_0 \alpha) \|B\|^2.$$

The derivative of the multiplier is the block Hessian, because the critical equation cancels the field variation in the first derivative of the critical value. The analytic response and its localized derivative estimates above bound the rows and columns of this Hessian by a summable exponential kernel on the top layer. Cauchy's estimate on the common parameter balls, followed by that same row and column sum, gives

$$\|Z(b,\mathbf{h};U_0) - Z(0,0;U_0)\|_{Y_0^{\mathbb{C}} \to (Y_0^{\mathbb{C}})^*} \le \kappa_0 s.$$

Reducing the stated radii once leaves the larger analytic balls needed for Cauchy's estimate. Taking the real part proves (30). The unweighted comparison throughout is at the same reference U_0. □

8.3. **Construction estimates.** We use the following results among the construction results. Theorem YMM1:D, and Theorems YMM1:AJ and YMM1:AD. The weighted progression and the never-large term with a source, with the statements on one term and on families: Section YMM1:51.9, Proposition YMM1:51.15 and Theorem YMM1:V; and the sections on sources, equation (218) and Proposition B.15. The rarity of a first creation of a large field on one torus, Proposition M.2, and the rarity of the large-field region uniformly in the volume, Proposition L.6. The law of the field and of the history, Proposition YMM1:44.1, with the measures in equation YMM1:(647).

The count of polymers, Lemma O.1, whose extension to any number of sources is Lemma 8.7. The frame, Definition B.14; its background and the history with no large-field region, Proposition B.15; and the local step with a source, Proposition E.7. The hereditary cores, Definition YMM1:49.1 and Section P; the Hölder bound for real backgrounds, Theorem BT; and the ordinary Hölder response, Proposition Q.8. The boards of the lattices, Section B.1; reflection positivity at the site and bond mirrors, which are the walls of the boards, Proposition YMM1:91.4; the chessboard estimate, Proposition YMM1:86.3 and, for the torus measures, Corollary B.1; the domination of periodic Gibbs states by the torus measures through their conditional laws, Proposition YMM1:91.9; and the bound $0 \le p_{\ell'} - p_\ell \le G_g$ of the setting on the pressures formed with the plain partition functions of Section YMM1:86, Corollary B.1 with Proposition YMM1:89.2 and Lemma N.1.

The bound on connected functions of $\mathcal{O}$ on a torus at separated supports, $|S^T_{n;K,\ell,\beta}(f)| \le C_n(\mathsf{d})e^{nc_V\ell^3}\prod_i \|f_i\|_\sharp$ for real Lipschitz f_i two of whose supports are $\ge \mathsf{d}$ apart, as proved in Lemma 8.1, and its per-ball form, Proposition YMM1:89.4, for supports in sup-balls of radius R and $\ell \ge 16n(R+1)$. The two-point law on a torus of small side, Theorem YMM1:AU with Proposition YMM1:126.4, and the kernel bounds $|C^{\mathrm{free}}_K(p,q)| \le (1+3C_{\mathrm{lat}})a^3|u|^{-3}$ and $|\epsilon_p\epsilon_q C^{\mathrm{free}}_K(p,q) - a^3\mathbb{K}_3(u)_{\lambda(p)\lambda(q)}| \le C_{\mathrm{lat}}a^3(a^2|u|^{-5}+\ell^{-3})$, u the least lift of $x(p)-x(q)$ and $\epsilon_p = \pm 1$ the orientations, of equations YMM1:(2245)–(2246).

The comparison of two lattices at equal label, Theorem YMM1:AR; the laws of the block fields, Definition B.29 and Corollary B.30; and the limits $S^{(\ell,\mathsf{b})}_n$ of $S^T_{n;K,\ell,L^K\mathsf{b}}$ at a fixed label, with the rate $K^pL^{-K/10}$, Theorem YMM1:AS, with the all-side extension in Corollary YMM1:119.2. Reflection positivity of the periodic Gibbs states at all the families of mirrors, Proposition YMM1:103.4, and the reconstruction data of the limits of Gibbs sequences, Theorem YMM1:AP. The large-field part: the histories and their labels defined in Section YMM1:44, with the finite exploration in equations YMM1:(643)–(644); the separated layers, physical row spaces and unweighted constrained systems of Sections YMM1:23 and YMM1:27; their weighted mean-square extension in Proposition Q.10 and Corollary Q.11; and the layer-weighted distance of Lemma YMM1:12.3. The same-exponent Hölder estimate for the moved background is proved in Lemma 8.20, with its normed spaces and envelope class.

The lattice calculus of Section J, J and equations YMM1:(2104)–(2105) and YMM1:112, the integration by parts J.1 of Lemma J.1, and the rotational Ward identity at finite cutoff, Proposition YMM1:112.1. For the step with plane couplings and the backgrounds: the lattices allowed at a height, with the room and the width of the halos, Section YMM1:50.4; the scaled fields below the threshold, Section B.2, the chart of the fibre, Lemma B.3, and the chart integral, Definition B.2 and equation (191) with (191), its prefactor equation YMM1:(907) and the Gaussian integral in Proposition YMM1:50.2; the weighted action (216) and the density (217) at zero source; the common real and sourced choices in Proposition YMM1:69.1 and Section YMM1:82; and the substitution with three pairs of radii, Proposition P.2.

For the arbitrary-order short-distance comparison we assume $(\mathrm{Q_n})$ of Definition 8.2. Its uniform interacting small-field remainder is part of that additional input. The free Gaussian contribution is computed by expanding $-\frac{3}{2}\log\det(1-\mathcal{S}W_\lambda)$: the mixed coefficients are the cyclic contractions of the covariance $\mathcal{S}$. The explicit first-creation weights give the large-field term in ω_n. These two calculations do not supply the remaining arbitrary-order interacting error. From the other sections

we use: for $0 < g \le \gamma_W^{\mathrm{sd}}$, the bound on centred products of any number of tensor entries at separated supports in every periodic Gibbs state, uniformly in the cutoff, the side, the state and the position, Theorem C(a), and the bound $\|\mathcal{T}_K(H) - c\|_{\mathrm{ch}} \le 2\mathsf{C}_T Y_i^{\mathsf{q}_T} a_i^{-11/2} \mathsf{b}^{-1} |H|_\infty$, $Y_i = 2[\mathsf{c}_T + \log \frac{1}{a_i}]$, on the chessboard seminorm of a centred tensor entry in a cell of side a_i, (4) of Theorem B(a), with $\mathsf{C}_T, \mathsf{q}_T, \mathsf{c}_T$ the constants C_E, q_E, c_E of that bound (Section 2); and, for $0 < g \le \gamma_W^{\mathrm{sd}}$, the invariance $\sigma(RX) = \sigma(X)$, $R \in \mathrm{O}(3)$, of tensor limits at tuples with one non-scalar entry among scalar ones (Section 5, Theorem U, which gives Theorem R(c) at these tuples).

8.4. **Auxiliary estimates.**

Lemma 8.7 (Several sources)**.** Let $0 < g \le \gamma$ with $g^{-2} \ge x_{\mathrm{J}}$, which holds for every $0 < g \le \gamma_W^{\mathrm{ref}}$; let $(K, \beta) \in \mathfrak{D}(g)$ with $K \ge 3$, $x_0 = \beta > x_1 > \cdots > x_K$ its run, $g^{-2} < x_K \le X_g$, and $\ell = 2L^m$ with $MR(x_K) \le L^m$, which holds on every side $\ell \in \mathfrak{L}(g)$; let $s \ge 1$ be a depth and $k = \max\{K - s, 2\}$ the working level, so that $2 \le k \le K - 1$; and let (F_a, o_a, w_a), $a = 1, \dots, p$, be dominated local sources with the comparison weights w_a. A *dominated local source* (F, o, w) consists of a real function F of the configurations of the bare bonds that is a gauge invariant polynomial in the entries of the bond variables; a local representation o of F, that is, families of local terms at the heights $1 \le j \le k$ whose sums, less their values at the trivial configuration, are F, and a family at the height 0 that sums to the fluctuation variation $F(e^{iB'}\mathbf{U}) - F(\mathbf{U})$ over the background $\mathbf{U}$ of the level-1 block field; and a real weight $w \ge 0$ of the plaquettes with $|F| \le \mathcal{O}(w)$ on all configurations, with sizes of o at most those of a source of the first size $|w|_\infty$, $m_0(o) \le 12\mathsf{c}^\flat M^3 \alpha_0^2 L^K |w|_\infty$ and $m_j(o) \le 12 M^3 \alpha_0^2 L^{K-j} |w|_\infty$ for $1 \le j \le k$, $m_0(o)$ being the size of the family at the height 0, $m_j(o)$ twice the norm $\|\cdot\|_{j,\kappa}$ of the family at the height j and $\mathsf{c}^\flat = 81 C_P^2 \mathsf{C}_{\mathcal{A}}^2 / K_\Lambda$, and such that the corners of the plaquettes of $\operatorname{supp} w$ carry o: its members vanish on the regions that hold none of these corners. Zero sources are omitted before the parameter radii are formed.

(a) Let $\Lambda_0 = \{\lambda \in \mathbb{C}^p : \sum_a |\lambda_a| m_{0,a} < N_\star^{[0]}\}$ and, for $1 \le j \le k$, $\Lambda_j = \{\lambda \in \Lambda_{j-1} : \sum_a |\lambda_a| n_{j,a} < N_\star^{[j]} - (\sum_{n \le j} \omega_n)(E_0 + \frac{3}{2}\alpha_0^2 B_\sharp)\}$, where $m_{j,a} = m_j(o_a)$, $n_{j,a} = m_{j,a} + \sum_{i=1}^{j} \omega_{j+1-i} d_{i,a}$, $d_{1,a} = \theta(x_0) m_{0,a}$, $d_{j+1,a} = \theta(x_j) n_{j,a}$, $\omega_n = (n+1) L^{-(n-1)}$, θ is the size of a source of (b), and $N_\star^{[j]} = w_\star \alpha_0 / (4 K_\Lambda (1 + \beta_{\mathrm{s}}) \delta(x_j))$ is the bound on the size of the bare array that the step of the level j carries (equations (196) and (197)). These are open convex neighbourhoods of 0, decreasing in j; their thresholds read no source and not p, so the sources share the room of each step, and a polydisc $\{|\lambda_a| < \rho_a\}$ lies in Λ_{t-1} when $\sum_a \rho_a m_{0,a} \le N_\star^{[0]}$ and $\sum_a \rho_a n_{j,a}$ is at most the right member of the condition of Λ_j for $1 \le j < t$; in particular $\Lambda_k = \bigcap_{0 \le j \le k} \Lambda_j$ holds the polydisc of the radii $\rho_a = p^{-1} \min_{0 \le j \le k} N_j / n_{j,a}$, N_j being the right member of the condition of Λ_j and $n_{0,a} = m_{0,a}$: these radii are p^{-1} times numbers that depend on the sizes of the sources alone.

For $1 \le t \le k+1$ and $\lambda \in \Lambda_{t-1}$, $\tau_{h_t}[\rho_0 e^{\sum_a \lambda_a F_a}] = e^{D_t^\lambda(U_t(\cdot))} \mathsf{m}_t$ on the small block fields of the level t, with D_t^λ holomorphic in λ and formed from the members $E_\lambda^{(i)}(X)$ of the weighted progression; $\partial_B E_\lambda^{(i)}(X) = 0$ unless X meets the carrier of every F_a, $a \in B$, and the mixed derivatives at $\lambda = 0$ of the level i carry the factor $\exp(-[L^{t-i} \mathsf{D}_t / M - 2]_+)$, D_t the least sup distance of the carriers in level-t units. The centred moments at the never-large history are $\Phi[\prod_{a \in B}(F_a - c_a)] = \sum_\pi \prod_{\beta \in \pi} \kappa_\beta$, π over the partitions of B into blocks β, with $\kappa_\beta = \partial_\beta D_t^\lambda|_{\lambda=0}$ for $\#\beta \ge 2$ and $\kappa_{\{a\}} = \partial_a D_t^\lambda|_{\lambda=0} - c_a$ at the one-element blocks.

Here $\rho_0 = e^{-\beta A}$ is the bare density, h_t the never-large history of the level t and $\tau_{h_t}[\cdot]$ its term, $\mathsf{m}_t = \tau_{h_t}[\rho_0]$ a finite positive measure on the block fields of the level t, U_t the background, c_a the constant of F_a at the level t, and $\Phi[Y]$ the bounded density of $\tau_{h_t}[Y\rho_0]$ with respect to m_t.

(b) Let $p \geq 2$, $0 < g \leq \gamma_W^{\mathrm{ref}}$, $0 < \mathsf{d} < 1$ with $s = s(\mathsf{d}) \leq K$ and $2\mathsf{T}_p(3)\theta(L^{s-2}g^{-2}) \leq 1$, and let the weights $w_a \neq 0$ be carried by balls $B(x_a, \frac{7}{8}\mathsf{d})$ at mutual distances $\geq \frac{5}{4}\mathsf{d}$. Then $|\langle F_1; \dots; F_p\rangle_{K,\ell,\beta}| \leq k_p^{\mathrm{loc}}(g,s;\ell)\,\mathsf{b}^{-p}\prod_a |w_a|_\infty$, with k_p^{loc} depending on g, p, ℓ, s alone. Here $\mathsf{T}_p(u) = \sum_{n\geq 1}(n+1)L^{-(n-1)}\big[(\frac{4}{3})^{1/2}L^{n/2}(1+n)^{\mathfrak{p}_0}\big]^p e^{-4\beta_s\kappa[L^{n-1}u-2]_+}$ is the series of the mixed derivatives of the order p and $\theta(x) = K_{\mathbf{M}}(1+\beta_s)A_1(\log x)^{\mathfrak{p}_0}x^{-1/2}/\alpha_0$ the size of a source at the coupling x, with the constants $\beta_s, K_{\mathbf{M}}$.

(c) In (b), let moreover $2\max\{\tilde{\mathsf{T}}_p(3), (\frac{4}{3})^{1/2}L\,\mathsf{S}_{\mathrm{nat}}\}\,\theta(L^{s-2}g^{-2}) \leq 1$, where $\tilde{\mathsf{T}}_p$ is the series T_p with the further factor $L^{n/4}$ in its n-th term and $\mathsf{S}_{\mathrm{nat}} = \sum_{n\geq 1}(n+1)^{1+\mathfrak{p}_0}L^{-n/4}$; this condition implies that of (b), and $\tilde{s}(p)$ denotes the least integer $s \geq 3$ with it. If the sizes of the local representation of F_1 at the heights $1 \leq j \leq k$, and its values on the backgrounds of the levels $1 \leq t \leq k$, are smaller than those of a source of the weight w_1 by the factors $L^{-j/4}$, resp. $L^{-t/4}$, that is, $m_j(o_1) \leq 12M^3\alpha_0^2L^{K-j}L^{-j/4}|w_1|_\infty$ and $|F_1(U_t(W))| \leq L^{-t/4}\,2B_3^2\varepsilon(x_t)^2L^{K-4t}\sum_p w_1(p)$ at the backgrounds of the configurations $W \in \mathcal{V}_t^\chi$, then

$$|\langle F_1; \dots; F_p\rangle_{K,\ell,\beta}| \leq L^{-(k-1)/4}\,\tilde{k}_p(g,s;\ell)\,\mathsf{b}^{-p}\prod_a |w_a|_\infty,$$

with a number $\tilde{k}_p(g,s;\ell) \geq k_p^{\mathrm{loc}}(g,s;\ell)$ that depends on g, p, ℓ, s alone.

(d) Let $c = \sum_i \kappa_i m_i$ be a block form of Lemma 8.10(b): each monomial m is a product of $n_2(m)$ factors $\langle \mathbf{w}, \mathbf{w}'\rangle$, $n_3(m)$ factors $\det(\mathbf{w}, \mathbf{w}', \mathbf{w}'')$ and $n_a(m)$ factors $1 - \frac{1}{2}\mathrm{tr}\,V$, where V runs over the holonomies of the lassos of the block of 27 sites centred at a site x, the holonomies of its plaquettes carried to x along paths of at most three steps in the block, and $\mathbf{w} = \mathbf{w}(V)$; the order of m is $2n_2(m) + 3n_3(m) + 2n_a(m)$, and $\|c\| = \sum_i |\kappa_i| 2^{n_a(m_i)}$ is the norm of c of that lemma. For a real function k of the sites, the source $\mathrm{Fm}^c(k) = a^{-1}\sum_x k(x)c_x(U)$ of Lemma 8.10(b) is a dominated local source with the comparison weight $\varpi\mathbf{1}_{\mathrm{Pl}(k)}$ for every $\varpi \geq 76\|c\||k|_\infty$, $\mathrm{Pl}(k)$ being the set of the plaquettes of the blocks of the sites with $k \neq 0$, and $|\mathrm{Fm}^c(k)| \leq \mathcal{O}(2\|c\||k|_\infty\mathbf{1}_{\mathrm{Pl}(k)})$ on all configurations; if all its monomials have an order ≥ 3, the hypothesis of (c) holds for it with the comparison weight $\Gamma_c^\circ\|c\||k|_\infty\mathbf{1}_{\mathrm{Pl}(k)}$, $\Gamma_c^\circ = \max\{76,\ 34\max\{1, 5.04\alpha_0\}^{\mathrm{Ord}(c)-2},\ 2\max\{1, 2B_3\}^{\mathrm{Ord}(c)-2}\}$, $\mathrm{Ord}(c)$ the largest order of its monomials, even with L^{-2j} and L^{-2t} in the places of $L^{-j/4}$ and $L^{-t/4}$.

(e) Let $\ell \in \mathfrak{L}(g)$, let (F_a, o_a, w_a), $a = 1, 2$, be two dominated local sources whose carriers are at the sup distance d', and let $2 \leq t \leq k$, k the working level, $s' = K - t$ (so that $1 \leq s' \leq K-2$, as $k \leq K-1$), with $L^{s'}\mathsf{d}' \geq 3M$, so that $\mathsf{D}_t \geq 3M$, and $\mathsf{h}_2(s') \leq 1$, where $\mathsf{h}_2(s') = \frac{4}{3}\mathsf{k}_2 L\,\theta(\frac{3}{4}L^{s'+1}g^{-2})\,\mathsf{T}_2^\circ(L^{s'}\mathsf{d}'/M)$ with the series $\mathsf{T}_2^\circ(u) = \sum_{n\geq 1}(n+1)^{2\mathfrak{p}_0+1}e^{-4\beta_s\kappa[L^{n-1}u-2]_+}$ and the number $\mathsf{k}_2 = \max\{\frac{1}{2}(\mathsf{c}^\flat)^2, 5\}$. Then, with $y_a \leq 4\ell^3L^{4(K-t)}|w_a|_\infty$: the real part of the density $D_{t,2}$ of F_2 at the never-large history differs from the real part of its constant c_2 by at most C_1y_2, and the mixed part $D_{t,12}$ of the density of F_1F_2 is at most $C_2e^{3-\mathsf{D}_t/M}y_1y_2$.

■

Proof sketch. $MR(x_K) \leq L^m$ on the sides of $\mathfrak{L}(g)$:

$$L^{m_{\mathfrak{L}}(g)} \geq LM\,R(X_g + \bar{B})$$

by equation YMM1:(1528), and $x_K \leq X_g + \bar{B}$. (a) is the derivative calculus for the never-large term with one source (Proposition E.7 and equation (218)), carried out in p parameters. Each source enters each step as one more local term, and the p sources share the room of each step, the bound of the step on the size of what it carries: with $m_{0,a}$ the size of F_a at the height 0 and $n_{j,a} = m_{j,a} + \sum_{i=1}^j \omega_{j+1-i}d_{i,a}$ the size at the level j of F_a together with all that the steps below the level j have made of it, as in the statement, the parameter λ ranges at the level t, $1 \leq t \leq k+1$,

over the set $\Lambda_{t-1} = \bigcap_{0\le j<t} \Lambda_j$, the sets Λ_j being those of the statement,

$$\Lambda_0 = \Big\{\lambda : \sum_a |\lambda_a|\, m_{0,a} < N_0\Big\}, \qquad \Lambda_j = \Big\{\lambda \in \Lambda_{j-1} : \sum_a |\lambda_a|\, n_{j,a} < N_j\Big\} \quad (1 \le j \le k),$$

with $N_0 = N_\star^{[0]}$ and $N_j = N_\star^{[j]} - (\sum_{n\le j} \omega_n)(E_0 + \frac{3}{2}\alpha_0^2 B_\sharp)$ for $1 \le j \le k$, $\omega_n = (n+1)L^{-(n-1)}$ as in the statement: $N_\star^{[j]}$ is the bound on the size of what the step of the level j carries, and for $1 \le j \le k$ the array of the level j without the sources has a size at most $(\sum_{n\le j} \omega_n)(E_0 + \frac{3}{2}\alpha_0^2 B_\sharp) \le \frac{1}{2} N_\star^{[j]}$ (the weighted-lag array bound in the proof of Proposition B.8, together with $8K_\Lambda N_\star s_j \le w_\star$ from item 9 before Theorem AH), to which the sources add at most $\sum_a |\lambda_a|\, n_{j,a}$; so $N_j \ge \frac{1}{2} N_\star^{[j]}$ is the room that the step of the level j leaves to the sources, a number that reads no p. The sets Λ_j are open and convex and decrease with j, and Λ_{t-1} holds the polydisc of the radii $\min_{0\le j<t} N_j/(p\, n_{j,a})$, $n_{0,a} = m_{0,a}$, since on it $\sum_a |\lambda_a|\, n_{j,a} < N_j$ for $0 \le j < t$; so Λ_k, which lies in every Λ_{t-1}, holds the polydisc of the radii $\min_{0\le j\le k} N_j/(p\, n_{j,a})$.

These radii are p^{-1} times numbers that depend on the sizes of the sources alone, while the thresholds N_j read no p. On Λ_{t-1} the members of the progression up to the level t are holomorphic in λ; the derivative in λ_a of a member vanishes unless its polymer meets the carrier of F_a, and the count of polymers in Lemma O.1, applied at every level $1 \le j \le k+1$ to the polymers that meet a given set of sites, gives the decay in the distance of the carriers: a polymer of the level i that meets the carriers of all the F_a, $a \in B$, has a linear size at least $L^{t-i}\mathsf{D}_t/M - 2$, whence the factor $\exp(-[L^{t-i}\mathsf{D}_t/M - 2]_+)$ of the statement; the formula for the centred moments is the moment–cumulant formula for the quotient of the never-large term with the sources by the term without them, in which the centring moves the first cumulant alone: $\kappa_{\{a\}} = \partial_a D_t^\lambda|_{\lambda=0} - c_a$, and $\kappa_\beta = \partial_\beta D_t^\lambda|_{\lambda=0}$ for $\#\beta \ge 2$. (b) The cumulant is a mixed derivative at 0 of the logarithm of the normalised partition function with the sources.

The histories with a first creation of a large field at a level t weigh at most w_t. Along the never-large history the mixed derivative families of the order p are bounded in the norm of the rate $\kappa^+ = (1 + 4\beta_s)\kappa$; read at the rate κ they keep the factor $e^{-4\beta_s\kappa[D_j/M-2]_+}$, D_j the least sup distance of the carriers in level-j units. On the way from the finer levels up to the working level k, a family of the level i enters the step of the level $j \ge i$ with the weight $(n+1)L^{-(n-1)}$ of the lag $n = j+1-i$, while the size of a source against the bound of the step is at the level $i-1$ at most $(\frac{4}{3})^{1/2} L^{n/2} (1+n)^{\mathfrak{p}_0}$ times that at the level j; so the series T_p of the statement sums the mixed derivatives of the order p over the levels finer than the working level,

$$\mathsf{T}_p(u) = \sum_{n\ge 1} (n+1) L^{-(n-1)} \Big[\big(\tfrac{4}{3}\big)^{1/2} L^{n/2} (1+n)^{\mathfrak{p}_0} \Big]^p e^{-4\beta_s \kappa [L^{n-1}u - 2]_+},$$

and the induction over the levels up to $k+1$ closes if $\theta(x_j)\, \mathsf{T}_p(D_j/M) \le \frac{1}{2}$ for $1 \le j \le k$. Since $D_j/M \ge 3$, $\theta(x_j) \le \theta(L^{s-2} g^{-2})$ and T_p does not increase, this holds under the condition $2\mathsf{T}_p(3)\theta(L^{s-2}g^{-2}) \le 1$ of the statement. Cauchy's estimates in each parameter then give the factor $\mathsf{b}^{-p} \prod_a |w_a|_\infty$. (c) is a recursion of numbers. If the sizes of F_1 fall like $L^{-j/4}$, the recursion of (a) gives $n_{j,1} \le \Gamma L^{-j/4}$ times the size at the level j of a source of the weight w_1, Γ a number formed with the constants: against the induction hypothesis at the level j, the lag n contributes at most $(\frac{4}{3})^{1/2} L\, \theta(x_j) (n+1)^{1+\mathfrak{p}_0} L^{-n/4}$, and the induction closes with the sum $\mathsf{S}_{\mathrm{nat}} = \sum_{n\ge 1} (n+1)^{1+\mathfrak{p}_0} L^{-n/4}$ of the statement.

In the induction of (b) the falling sizes of the first source compare the level $i-1$ with the level j with the further factor $L^{n/4}$, so that the series $\tilde{\mathsf{T}}_p$ of the statement, which is T_p with the further factor $L^{n/4}$ in its n-th term, takes the place of T_p. Both inductions close under the condition $2\max\{\tilde{\mathsf{T}}_p(3), (\frac{4}{3})^{1/2} L\, \mathsf{S}_{\mathrm{nat}}\}\, \theta(L^{s-2}g^{-2}) \le 1$ of (c), which implies the one of (b) at the same s; then the bound of (b) holds with $L^{-(k-1)/4} \tilde{k}_p(g, s; \ell)$ in the place of $k_p^{\mathrm{loc}}(g, s; \ell)$, $\tilde{k}_p \ge k_p^{\mathrm{loc}}$ a number of

the same kind formed with these series, for the sizes at the levels $1 \le j \le k$ and the values on the backgrounds of the levels $1 \le t \le k$.

So the recursion closes under the condition of (c); the least integer $s \ge 3$ at which it holds with $p = r$ is the number $\tilde{s}(r)$ of the statement, and we write $\tilde{k}_r$ for the number $\tilde{k}_r(g, s; \ell)$ of the bound of (c). (d) Let $c = \sum_i \kappa_i m_i$ be a block form of Lemma 8.10(b), $\|c\| = \sum_i |\kappa_i| 2^{n_a(m_i)}$ its norm as in the statement, with m_i written also for the order of the monomial m_i, and k a real function of the sites; the source is $\mathrm{Fm}^c(k) = a^{-1} \sum_x k(x) c_x(U)$. At a height $j \ge 1$ it is represented by the family $\eta_j^{-1} \sum_x L^{K-j} k(x) c_x$, $\eta_j = L^{-j}$, so that $\eta_j^{-1} L^{K-j} = a^{-1}$, the sum over the sites x whose block lies in a given region of the level j; such a region has at most 8 cubes and the linear size 0, and at most $8M^3\eta_j^{-3}$ sites have one region (each of the at most eight cubes contains $(M/\eta_j)^3$ bare sites).

On the cores of radii (b_0, b_1) in Definition YMM1:49.1 the vector part of the holonomy of a lasso is at most $5.04\, b_0 \eta_j^2$ in level-j units and its plaquette term at most $(5.04\, b_0 \eta_j^2)^2$, so a monomial of the order m is at most $(5.04\, b_0)^m \eta_j^{2m}$, and the family has the size $8M^3 L^{K-j} |k|_\infty \sum_i |\kappa_i| (5.04\, b_0)^{m_i} \eta_j^{2m_i - 4}$. The sizes are taken at $(b_0, b_1) = (\alpha_0, \alpha_1)$: as $5.04\, \alpha_0 L^{-2} \le 1$, $(5.04\, \alpha_0)^{m_i} \eta_j^{2m_i - 4} \le 25.41\, \alpha_0^2$, and with the factor 2 of the size of a representation at a height $j \ge 1$ this is at most $34 \|c\| |k|_\infty$ in the unit $12 M^3 \alpha_0^2 L^{K-j}$ of the size of a source of the weight 1.

At the height 0 the representation is the family in the fourth place $a^{-1} \sum_x k(x) [c_x(e^{iB'} U) - c_x(U)]$, B' the fluctuation field with its values at the pivot bonds, which sums to the fluctuation variation of the source; a lasso has at most ten factors, and telescoping in them gives the size $911\, \mathsf{c}^\flat M^3 \alpha_0^2 L^K \|c\| |k|_\infty$, that is $\frac{911}{12} \|c\| |k|_\infty \le 76 \|c\| |k|_\infty$ in the unit $12 \mathsf{c}^\flat M^3 \alpha_0^2 L^K$ of the height 0. So $76 \|c\| |k|_\infty$ bounds the sizes at all the heights, being at least $34 \|c\| |k|_\infty$ at the heights $j \ge 1$ and $\frac{911}{12} \|c\| |k|_\infty$ at the height 0. On the real configurations one factor of a monomial is at most $a_p + a_{p'}$, p, p' plaquettes of its lassos: a factor $\langle w, w' \rangle$ or $\det(w, w', w'')$, since $|w|^2 \le 2a_p$ and $|w| \le 1$, or a plaquette term itself; every other factor is at most 1, or 2 if it is a plaquette term; so $|\mathrm{Fm}^c(k)| \le \mathcal{O}(2 \|c\| |k|_\infty \mathbf{1}_{\mathrm{Pl}(k)})$, $\mathrm{Pl}(k)$ the plaquettes of the blocks of the sites with $k \ne 0$, and the set $\{k \ne 0\}$ carries all the representations: $\mathrm{Fm}^c(k)$ is a dominated local source with the comparison weight $\varpi \mathbf{1}_{\mathrm{Pl}(k)}$ for every $\varpi \ge 76 \|c\| |k|_\infty$.

If all the orders are ≥ 3, the factor $(5.04\, \alpha_0 \eta_j^2)^{m_i - 2} \le \max\{1, 5.04\, \alpha_0\}^{\mathrm{Ord}(c) - 2} L^{-2j}$, $\mathrm{Ord}(c)$ the largest order, gives the fall L^{-2j} of the sizes; on the backgrounds of the level t the plaquette terms are below $\bar{a} = 2B_3^2 \varepsilon_t^2 L^{-4t}$, ε_t the radius of regularity of the level t, a factor of the order $q \in \{2, 3\}$ is at most $(2\bar{a})^{q/2}$, and the values fall like L^{-2t}. With the comparison weight $\Gamma_c^\circ \|c\| |k|_\infty \mathbf{1}_{\mathrm{Pl}(k)}$ of the statement, $\Gamma_c^\circ = \max\{76,\, 34 \max\{1, 5.04\, \alpha_0\}^{\mathrm{Ord}(c) - 2},\, 2 \max\{1, 2B_3\}^{\mathrm{Ord}(c) - 2}\}$, this is the hypothesis of (c), with L^{-2j} and L^{-2t}. (e) The density of a source at the never-large history of the level t is its first derivative in (a); its oscillation is bounded by the size of the source at that level, which is y_2 up to a constant, and the mixed part is the second mixed derivative, which carries the factor of the distance from (a), with $\mathsf{D}_t \ge L^{s'} \mathsf{d}' \ge 3M$.

The second mixed derivatives are summed over the levels finer than t as in (b) at $p = 2$, $\frac{4}{3} L\, \mathsf{T}_2^\circ$ being the series T_2, and the condition $\mathsf{h}_2(s') \le 1$ closes that induction up to the level t. □

Lemma 8.8 (Rough entries)**.** A petal at a site x is a pair $\pi = (\alpha, \alpha')$ of signed directions with $|\alpha| \ne |\alpha'|$, $W_x(\pi)$ the holonomy from x of the plaquette that it spans, and $q_x(\pi, \pi') = \langle \mathbf{w}(W_x(\pi)), \mathbf{w}(W_x(\pi')) \rangle$. For real $k = (k_{\pi\pi'}(x))$ put $\mathrm{Pf}(k) = a^{-1} \sum_x \sum_{\pi, \pi'} k_{\pi\pi'}(x) q_x(\pi, \pi')$ and $|k|_1 = \sup_x \sum_{\pi, \pi'} |k_{\pi\pi'}(x)|$. A *rough entry* is $F = \mathrm{Pf}(k) + \mathcal{O}(v)$ with a real weight v; its norm is $\|F\| = 13|k|_1 + |v|_\infty$, and it is carried by the barycentres of the plaquettes of $\mathrm{supp}\, v$ and of those with a corner at which $k \ne 0$. Let $0 < g \le \gamma_W^{\mathrm{ref}}$, $\ell' \in \mathfrak{L}(g)$, $r \ge 2$ and $0 < \mathsf{d} < 1$. There are $K_0'(r, \mathsf{d})$ and $k'(r, \mathsf{d}) \le C_{r,p} \mathsf{d}^{-pr}$ $(p > 7)$ such that

$$|\langle F_1; \dots; F_r \rangle_{K, \ell', \beta}| \le k'(r, \mathsf{d}) \prod_a \|F_a\|$$

for all $(K,\beta)\in\mathfrak{D}(g)$ with $K\ge K_0'(r,\mathsf{d})$ and all rough entries whose carriers are pairwise $\ge\mathsf{d}$ apart. Moreover $\Theta_\beta[\eta]=\mathsf{b}\,\mathrm{Pf}(k^\eta)$ with $|k^\eta|_1\le 12\max_\rho \mathrm{Lip}_\infty\eta^\rho$, so $\|\mathrm{Pf}(k^\eta)\|\le 156\max_\rho\mathrm{Lip}_\infty\eta^\rho$; $-\beta\sum_p h_{\omega,\chi}(p)=\mathsf{b}\,\mathrm{Pf}(k^h)$ with $|k^h|_1\le 12|\omega|\,\mathrm{Lip}(\chi)R_1(\chi)\le 36\ell|\omega|\,\mathrm{Lip}_\infty\chi$; $\mathfrak{B}_{\omega,\chi}=\mathsf{b}\,\mathrm{Pf}(k^h)+\mathcal{O}(v^{\mathfrak{B}})$ with $|v^{\mathfrak{B}}|_\infty\le(2\mathsf{b}+3a)|\omega|\,\mathrm{Lip}(\chi)R_1'(\chi)$, where $R_1'(\chi)\le\frac{3}{2}\ell$ is the number of Theorem AE(a), the largest $|x(p)|_1$, taken in the chart $(-\frac{\ell}{2},\frac{\ell}{2})^3$, at the plaquettes where $\nabla^s_\omega\chi$ or v_χ does not vanish (at their barycentres $x(p)$, χ is not constant on the points $x(p)\pm ae_\rho$, $x(p)\pm\frac{a}{2}e_\rho$, $\rho=1,2,3$); the entries $\mathsf{b}\,\mathrm{Pf}(k^\eta)$, $\mathsf{b}\,\mathrm{Pf}(k^h)$ and $\mathfrak{B}_{\omega,\chi}$ are carried within $2a$ of $\mathrm{supp}\,\eta$, resp. $\mathrm{Var}(\chi)$; and $T_{lr}(\varphi)=\mathsf{b}\,(\mathrm{Pf}(k^{lr})+\mathcal{O}(v^{lr}))$ with $13|k^{lr}|_1+|v^{lr}|_\infty\le C_T\sup|\varphi|$, C_T an absolute constant. ■

Proof sketch. A rough entry is a dominated local source in the sense of Lemma 8.7: a gauge invariant polynomial with a local representation at every height, with $|F|\le\mathcal{O}(w)$ for a weight w of size $\|F\|$ on its carrier. Put $\sum_a\lambda_aF_a$ into the weighted progression (Lemma 8.7(a)). Its families are holomorphic in λ near 0 with sizes that depend on the $\sup|w_a|$ alone, and they are local: $\partial_BE^{(i)}_\lambda(X)=0$ unless X meets every carrier in B, so that $d_i(X)\ge D_i/M-2$, D_i being the least sup distance of these carriers in level-i units, and a factor $e^{-\kappa^+[D_i/M-2]_+}$ appears. We split the mean over the level t of the first creation of a large field. Up to that level the history is the never-large one, and

$$\tau_{h_t}\big[\rho_0e^{\sum_a\lambda_aF_a}\big]=e^{D_t^\lambda(U_t(\cdot))}\,\mathsf{m}_t,\qquad \Phi\Big[\prod_{a\in B}(F_a-c_a)\Big]=\sum_\pi\prod_{\beta\in\pi}\kappa_\beta,\quad \kappa_\beta=\partial_\beta D_t^\lambda|_{\lambda=0}\ (\#\beta\ge 2),\quad \kappa_{\{a\}}=\partial_aD_t^\lambda|_{\lambda=0}-c_a,$$

with the signs of Lemma 8.7(a); each κ_β with $\#\beta\ge2$ is bounded by the mixed derivatives above. Behind the level t only a positive weight enters, of the mass $\mathsf{w}_t\le 2M^{-3}\ell'^3e^{B(X_g)\ell'^3}L^{3(K-t)}e^{-c'p_0(g_t)^2}$, which is smaller than every power of $L^{-(K-t)}$, while the centred insertions carried to the level $t-1$ are at most powers of L^{K-t}. The mixed derivatives of the orders $\le r$ converge at the depth $s(\mathsf{d}'')$, $\mathsf{d}''=\min\{\frac{4}{5}\mathsf{d},L^{-\bar s(r)}\}$, where $\bar s(r)$ is the least integer $s\ge3$ with $2\mathsf{T}_r(3)\theta(L^{s-2}g^{-2})\le1$, with the series T_r and the size θ of Lemma 8.7(b); at every $s\ge\bar s(r)$ the condition holds, since θ does not increase.

Apply Proposition 2.10(a′), (b) to the dominated local sources just constructed. Its summability condition is the one defining $\bar s(r)$ above, and it permits the fixed side ℓ': the local cumulant constant may be chosen with $k_r(g,s;\ell')\le C_r(g,\ell')Y_s^{8r\mathfrak{p}_0}$. Cutting every weight into at most $(2\ell'/\mathsf{d}'')^3$ pieces and using $\mathsf{b}^{-r}\le g^{2r}$ therefore gives $k'(r,\mathsf{d})\le C_r(g,\ell')g^{2r}(2\ell'/\mathsf{d}'')^{3r}Y^{8r\mathfrak{p}_0}_{s(\mathsf{d}'')}$. The same proposition bounds $Y_{s(\mathsf{d}'')}\le2\log(1/\mathsf{d}'')+C(g)$; since $\mathsf{d}''=\min\{4\mathsf{d}/5,L^{-\bar s(r)}\}$, this proves the asserted $C_{r,p}\mathsf{d}^{-pr}$ bound for every $p>7$. The same decomposition, at the least depth s with $L^s\mathsf{d}\ge3M$ at which the mixed derivatives of the order q are summable, gives the second bound of Theorem AD(a): $L^s\le\max\{1,LM\mathsf{u}_q/\mathsf{d}\}$ with $\mathsf{u}_q=O(q\log q)$, the sums over partitions are at most $C^q(q!)^{3/2+\mathfrak{p}_0}$, and the rarity of a first creation, at which all the q insertions are bounded by their suprema, costs $\exp[c_L(4q+4)^2]$. The formulas for k^η, k^h and k^{lr} are the definitions written in petals: for $b=\langle x,x+ae_\mu\rangle$ and $p=p(b,\alpha'')$, $\mathfrak{d}_{b,p,\rho}=-\frac{1}{2}[q_x((\mu,\rho),(\mu,\alpha''))-q_x((\mu,-\rho),(\mu,\alpha''))]$, and the shell lies in $|x|_1\le\frac{1}{2}+\frac{3}{2}\ell$.

For the whole flux insertion, $\mathfrak{B}_{\omega,\chi}-\mathsf{b}\,\mathrm{Pf}(k^h)=\mathcal{O}(v^{\mathfrak{B}})$ with $v^{\mathfrak{B}}(p)=\mathsf{b}\,\nabla^s_\omega\chi(x(p))-\frac{3}{2}a\,v_\chi(p)$; as $\sum_\rho|(\omega y)_\rho|\le2|\omega||y|_1$ and the difference quotients of χ in $\nabla^s_\omega\chi$ and in v_χ are at most $\mathrm{Lip}(\chi)$, $|v^{\mathfrak{B}}(p)|\le(2\mathsf{b}+3a)|\omega|\,\mathrm{Lip}(\chi)|x(p)|_1$, and $v^{\mathfrak{B}}(p)\ne0$ only at the plaquettes where $\nabla^s_\omega\chi$ or v_χ does not vanish, at whose barycentres χ is not constant on the points $x(p)\pm ae_\rho$, $x(p)\pm\frac{a}{2}e_\rho$: this gives the factor $R_1'(\chi)$ of Theorem AE(a). □

Lemma 8.9 (Chessboard bound)**.** Let $0<g\le\gamma$, $\ell'\in\mathfrak{L}(g)$, $(K,\beta)\in\mathfrak{D}(g)$, and let a board of cubic cells of side l' dividing $\frac{\ell'}{2}$ be placed on $T_{\ell'}$, on every T_ℓ with $\ell\ge\ell'$ in $\mathfrak{L}(g)$ and on $a_K\mathbb{Z}^3$; $N'=(\ell'/\mathsf{l}')^3$. For a bounded Borel function F of the bonds inside one cell put $\|F\|_{\mathrm{ch}}=|\langle\prod_\kappa F^{[\kappa]}\rangle_{K,\ell',\beta}|^{1/N'}$, the product running over the mirror copies of F, conjugated on odd reflection parity, in the N' cells of

$T_{\ell'}$. Then

$$|s(F_1 \cdots F_q)| \le \prod_i e^{G_g \mathsf{l}'^3} \|F_i\|_{\mathrm{ch}}$$

for functions $F_1, \dots, F_q$ of distinct cells, s being a periodic Gibbs state at (K, β) or the measure of T_ℓ, $\ell \in \mathfrak{L}(g)$, $\ell \ge \ell'$. In particular, for real F_1, F_2 of two distinct cells and real c_1, c_2: $|s(F_1) - c_1| \le e^{G_g \mathsf{l}'^3} \|F_1 - c_1\|_{\mathrm{ch}}$ and $|s(A^s[F_1]A^s[F_2])| \le 2e^{2G_g \mathsf{l}'^3} \|F_1 - c_1\|_{\mathrm{ch}} \|F_2 - c_2\|_{\mathrm{ch}}$. ■

Proof sketch. On T_ℓ, $\ell \ge \ell'$, reflection positivity at the walls gives the chessboard estimate $|\langle F_1 \cdots F_q \rangle_{K,\ell,\beta}| \le \prod_i \langle \prod_\kappa F_i^{[\kappa]} \rangle_{K,\ell,\beta}^{1/N_\ell}$, $N_\ell = (\ell/\mathsf{l}')^3$. The product of the mirror copies over all the cells of T_ℓ is a periodisation of the product over the cells of $T_{\ell'}$, and the chessboard seminorms on the two sides compare by the inequality $\langle \prod_\kappa F^{[\kappa]} \rangle_{K,\ell,\beta}^{1/N_\ell} \le \langle \prod_\kappa F^{[\kappa]} \rangle_{K,\ell',\beta}^{1/N'} e^{\mathsf{l}'^3 (p_{\ell'} - p_\ell)}$ (Corollary B.1(e)). It is reflection positivity at the walls applied once more, to the periodised product: the pattern of the copies has the period $2\mathsf{l}'$, which divides ℓ', so that a slab of that length is a half slab and its mirror image, the transfer operator across it is positive, and $\operatorname{Tr} T^n \le (\operatorname{Tr} T)^n$ in each of the three directions; this bounds the unnormalised N_ℓ-th root by the unnormalised N'-th root, and the ratio $Z_{K,\ell',\beta}^{1/N'} / Z_{K,\ell,\beta}^{1/N_\ell}$ of the plain partition functions per cell is $e^{\mathsf{l}'^3 (p_{\ell'} - p_\ell)} \le e^{G_g \mathsf{l}'^3}$, the pressures $p_\ell = \ell^{-3} \log Z_{K,\ell,\beta}$ being formed with the plain partition functions (Section YMM1:86).

A periodic Gibbs state is dominated by the torus measures through its conditional laws (Proposition YMM1:91.9), and this domination carries the bound to every periodic Gibbs state. The last two bounds are the cases $q = 1$ and $q = 2$, with $s(A^s[F_1]A^s[F_2]) = s((F_1 - c_1)(F_2 - c_2)) - (s(F_1) - c_1)(s(F_2) - c_2)$. □

Lemma 8.10 (Exact identities)**.** (a) Let $\mathbf{X}$ be a polynomial field of directions that vanishes off a finite set Λ of bonds: at each positively oriented bond b a $\mathfrak{g}$-valued polynomial $\mathbf{X}(b)$ in the plaquette variables, 0 for $b \notin \Lambda$; let $v_{\mathbf{X}} F = \sum_b \sum_{\mathsf{a}} \langle \sigma_{\mathsf{a}}, \mathbf{X}(b) \rangle \partial_b^{\mathsf{a}} F$ and $\operatorname{div} v_{\mathbf{X}} = \sum_b \sum_{\mathsf{a}} \partial_b^{\mathsf{a}} \langle \sigma_{\mathsf{a}}, \mathbf{X}(b) \rangle$, $\sigma_1, \sigma_2, \sigma_3$ the Pauli matrices and ∂_b^{a} the derivative along $e^{i\epsilon\sigma_{\mathsf{a}}} U(b)$ at $\epsilon = 0$. Then $\nu((\beta v_{\mathbf{X}} A - \operatorname{div} v_{\mathbf{X}}) Y) = 0$ for every Gibbs state or torus measure ν at (a_K, β) and every bounded Borel Y that does not depend on the bonds of Λ; so every joint cumulant under ν with the entry $\beta v_{\mathbf{X}} A - \operatorname{div} v_{\mathbf{X}}$ and further entries not depending on Λ vanishes. $N_\beta[\eta] = \Theta_\beta[\eta] + \mathfrak{K}^{\mathrm{v}}[\beta\eta] - \mathsf{b}\, \mathcal{O}(\operatorname{div}^s \eta) + \frac{3}{2} a\, \mathcal{O}(e^\eta)$ is such a null term.

With the contact terms, for all weights f_i and every vector field η, $\langle N_\beta[\eta]; \mathcal{O}(f_\cdot) \rangle + \sum_i \langle \mathrm{Ct}[f_i; \eta]; (\mathcal{O}(f_l))_{l \ne i} \rangle = 0$, where $\mathrm{Ct}[f; \eta] = \mathcal{O}(\operatorname{div}^s(f\eta)) - a^{-1} \Theta_f[\eta] - a^{-1} \mathfrak{K}^{\mathrm{v}}[f\eta]$.

(b) Identically in U, $\mathfrak{K}^{\mathrm{v}}[\eta] = -\sum_p \sum_\rho (\nabla_\rho^+ \eta^\rho)(x(p)) \Psi_\rho(p) + \mathfrak{K}^\sharp[\eta]$; for $\rho \in P(p)$, $\mathfrak{r}_\rho^\sharp(p) = 0$ and $-(a_p + a_{p+ae_\rho}) \le \Psi_\rho(p) \le 0$; $\mathfrak{r}^\sharp$ transforms as a vector under the coordinate mirrors of the lattice: $\mathfrak{r}_\rho^\sharp$ is odd under the mirror normal to ρ and even under the two mirrors that contain e_ρ, so that it is odd, for every ρ, under the inversion $y \mapsto 2z - y$ through a site z, the product of the three mirrors through z. Hence $\langle \mathfrak{K}^\sharp[\eta] \rangle_{K,\ell,\beta} = 0$, and by translation invariance also $\langle \mathfrak{K}^{\mathrm{v}}[\eta] \rangle_{K,\ell,\beta} = 0$; and if a field ζ has $\zeta^\rho(y + se_\rho) = \zeta^\rho(y)$ for all y, s and ρ, then $\langle \mathfrak{K}^\sharp[\zeta]; \mathcal{O}(f) \rangle_{K,\ell,\beta} = 0$ for every weight f.

A *block form* is a combination $c = \sum_i \kappa_i m_i$ of monomials in the lassos of the block $\mathrm{Bk}(x) = x + a\{-1, 0, 1\}^3$ of 27 sites centred at a site x: a lasso is a path of at most three steps from x inside the block to a corner y of a plaquette of the block, the holonomy of that plaquette from y, and the path back; with $w = \mathbf{w}(W)$ and $a_{\mathrm{lz}} = 1 - \frac{1}{2} \operatorname{tr} W$ the vector part and the plaquette term of the holonomy W of a lasso, a monomial is a product of n_2 factors $\langle w, w' \rangle$, n_3 factors $\det(w, w', w'')$ and n_a factors a_{lz}, and $2n_2 + 3n_3 + 2n_a$ is its order in the field strength. The same lassos are taken at every site, c_x is the form at the block of x, the order of c is the least order of its monomials, and its norm is the number $\|c\| = \sum_i |\kappa_i| 2^{n_a(m_i)}$ of Lemma 8.7(d).

For a real function k of the sites, $\mathrm{Fm}^c(k) = a^{-1} \sum_x k(x) c_x(U)$ is a dominated local source of size $\le 76 \|c\| |k|_\infty$, carried by $\{k \ne 0\}$, with $|\mathrm{Fm}^c(k)| \le \mathcal{O}(2\|c\| |k|_\infty \mathbf{1}_{\mathrm{Pl}(k)})$, $\mathrm{Pl}(k)$ the

plaquettes of the blocks of the sites with $k \neq 0$; and if all the monomials of c have order ≥ 3, as for the commutator terms, the defects of the linear Bianchi identity, a_p^2 and $a_p a_{p_+}$, its sizes fall like L^{-2j} with the level j and its values on the backgrounds like L^{-2t} with the level t, with the comparison weight $\Gamma_c^\circ \|c\| |k|_\infty \mathbf{1}_{\mathrm{Pl}(k)}$ of Lemma 8.7(d). $\Psi_{\lambda(p)}(p)$ is a block form of order 2 and norm 1, and $\mathfrak{r}_\rho^\sharp(p)$, $\rho = \lambda(p)$, a block form of order 2 and norm ≤ 8, both at the block of the lowest corner of p; so for a real weight k the sums $a^{-1}\sum_p k(p)\Psi_{\lambda(p)}(p)$ and $a^{-1}\sum_p k(p)\mathfrak{r}^\sharp_{\lambda(p)}(p)$ over the plaquettes of one normal are sources $\mathrm{Fm}^c(\tilde{k})$, $\tilde{k}(x)$ the value of k at the plaquette of that normal with the lowest corner x, and they are dominated local sources of the sizes $\leq 76|k|_\infty$ and $\leq 608|k|_\infty$; as a function $|\mathfrak{r}_\rho^\sharp(p)| \leq C\bar{a}^{3/2}$, $\bar{a}$ the largest a_q near p, and $\beta\mathfrak{K}^\sharp$ is treated by parity (Lemmas 8.11, 8.12).

(c) For a vector field k, $\beta\sum_{p,\rho}\mathsf{k}^\rho(x(p))\Psi_\rho(p) = -\frac{1}{4}\mathfrak{N}[\mathsf{k}] + \sum_{v=1}^5 \mathfrak{J}_v[\mathsf{k}] - \frac{1}{4}c_\mathsf{k}$, where $\mathfrak{N}[\mathsf{k}] = \beta v_{\mathbf{X}^\mathsf{k}} A - \operatorname{div} v_{\mathbf{X}^\mathsf{k}}$ is the null term of (a) for the field of directions $\mathbf{X}^\mathsf{k}(b) = \sum_{\rho\neq\mu_b}\mathsf{k}^\rho(x_b)G_\rho(b)$, $c_\mathsf{k} = 6\sum_b\sum_{\rho\neq\mu_b}\mathsf{k}^\rho(x_b)$ is a number, and $\mathfrak{J}_1,\dots,\mathfrak{J}_5$ are sums of local densities of the orders $2,2,2,3,4$ with weights at most $3|\mathsf{k}|_\infty + \frac{3}{2}\mathsf{b}\mathrm{Lip}_\infty\mathsf{k}$, $\frac{1}{8}\mathsf{b}\mathrm{Lip}_\infty\mathsf{k}$, $\frac{1}{2}\mathsf{b}\mathrm{Lip}_\infty\mathsf{k}$, $\frac{1}{4}\beta|\mathsf{k}|_\infty$ and $\beta|\mathsf{k}|_\infty$, vanishing beyond the sup distance a of $\operatorname{supp}\mathsf{k}$. Consequently, with $\mathsf{k}_\eta^\rho = \nabla_\rho^+\eta^\rho$, $\mathrm{St}_K[\eta] = N_\beta[\eta] - \frac{1}{4}\mathfrak{N}[\mathsf{k}_\eta] - \mathrm{Rm}_K[\eta] - \frac{1}{4}c_{\mathsf{k}_\eta}$, where $\mathrm{Rm}_K[\eta] = \beta\mathfrak{K}^\sharp[\eta] - \sum_v \mathfrak{J}_v[\mathsf{k}_\eta] + \frac{3}{2}a\,\mathcal{O}(e^\eta)$ is the remainder of the stress insertion.

(d) $\Delta_K[\eta] = F^0 + F^1$, rough entries carried within $2a$ of $\operatorname{supp}\eta$, with $\|F^0\| \leq 286\mathsf{b}\sup|\nabla\eta|$ and $\|F^1\| \leq 780\mathsf{b}\,a\sup|\nabla^2\eta|$; F^0 is null: its classical density, a quadratic form in the field strength with coefficients linear in $\nabla\eta$, vanishes identically.

(e) For a positively oriented bond b and directions λ,ρ: $\sum_{p\ni b} a^{-1}(x_b - x(p))_\lambda \mathfrak{d}_{b,p,\rho} = \langle \mathbf{u}_{b,\lambda}, \mathbf{u}_{b,\rho}\rangle$, so that $\sum_p \mathfrak{s}_{\lambda\rho}(p) = \sum_b \langle \mathbf{u}_{b,\lambda}, \mathbf{u}_{b,\rho}\rangle$ is a symmetric positive semidefinite matrix; for $\lambda \neq \mu_b$ and $p_\pm = p(b,\pm\lambda)$, $|\mathbf{u}_{b,\lambda}|^2 = (a_{p_+} + a_{p_-}) - \frac{1}{4}(a_{p_+}^2 + a_{p_-}^2) + \Psi_\lambda(p_-)$ and $\Psi_\lambda(p_-) = -\frac{1}{4}|G_\lambda(b)|^2 - \frac{1}{4}(a_{p_+}^2 + a_{p_-}^2)$; for $\nu \in P(p)$, $\mathfrak{s}_{\nu\nu}(p) = \frac{3}{2}a_p + \frac{1}{4}(a_{p+ae_\nu} + a_{p-ae_\nu}) - \frac{1}{2}a_p^2 + \frac{1}{2}(\Psi_\nu(p) + \Psi_\nu(p-ae_\nu))$, and $\mathfrak{s}_{\lambda\rho}(p) = 0$ if $\lambda = \lambda(p)$. Consequently, identically in U,

$$T_{mm}(\varphi) - \mathsf{b}\check{D}_m(\varphi) = \beta \sum_{p:\, m\in P(p)} \varphi(x(p))\Big[\tfrac{1}{2}\big(\Psi_m(p) + \Psi_m(p - ae_m)\big) - \tfrac{1}{2}a_p^2\Big] + \mathsf{b}\,\mathcal{O}(\tilde{\varphi}_m),$$

$\tilde{\varphi}_m(p) = \frac{1}{4}[\varphi(x(p) + ae_m) - 2\varphi(x(p)) + \varphi(x(p) - ae_m)]\mathbf{1}\{m \in P(p)\}$, so $|\tilde{\varphi}_m| \leq \frac{1}{2}a\,\mathrm{Lip}\,\varphi$; and $\sum_m T_{mm}(\varphi) - \mathsf{b}\,\mathcal{O}(\varphi) = \sum_m (T_{mm}(\varphi) - \mathsf{b}\check{D}_m(\varphi))$.

(f) *The null term against sources that meet its carrier.* For a complex vector field k and a complex function f on T_ℓ put $\mathsf{e}^\mathsf{k}(p) = \sum_{\rho\in P(p)}[\mathsf{k}^\rho(x(p) + \frac{a}{2}e_\rho) + \mathsf{k}^\rho(x(p) - \frac{a}{2}e_\rho)]$ and

$$\mathfrak{C}'[\mathsf{k}; f] = \sum_p \sum_{b\subset\partial p} \sum_{\rho\neq\mu_b} a^{-1}(f(x(p)) - f(x_b))\mathsf{k}^\rho(x_b)\,\langle G_\rho(b), \mathbf{w}(W_{b,p})\rangle, \qquad \mathfrak{R}[\mathsf{k}; f] = \mathsf{b}^{-1}\mathrm{div}\, v_{\mathbf{X}^{f\mathsf{k}}} + \mathfrak{C}'[\mathsf{k}; f],$$

with $\mathbf{X}^\mathsf{k}$ and $\mathfrak{N}[\mathsf{k}]$ as in (c). Then: (N1) $v_{\mathbf{X}^\mathsf{k}}\mathcal{O}(f) = \mathsf{b}^{-1}\mathfrak{N}[f\mathsf{k}] + \mathfrak{R}[\mathsf{k}; f]$, identically in U; (N2) $\int \mathfrak{N}[\mathsf{k}]\, e^{\mathcal{O}(w)}e^{-\beta A}dU = \int (v_{\mathbf{X}^\mathsf{k}}\mathcal{O}(w))e^{\mathcal{O}(w)}e^{-\beta A}dU$ for every complex function w on T_ℓ; (N3) for a finite set A and complex functions f_l, $l \in \mathsf{A}$,

$$\big\langle \mathfrak{N}[\mathsf{k}]; (\mathcal{O}(f_l))_{l\in\mathsf{A}}\big\rangle_{K,\ell,\beta} = \sum_{j=1}^{\#\mathsf{A}} \sum_{(q_1,\dots,q_j)} \mathsf{b}^{-(j-1)}\Big\langle \mathfrak{R}\big[f_{q_1}\cdots f_{q_{j-1}}\mathsf{k}; f_{q_j}\big]; (\mathcal{O}(f_l))_{l\in\mathsf{A}\setminus\{q_1,\dots,q_j\}}\Big\rangle_{K,\ell,\beta},$$

the inner sum over the sequences of j distinct elements of A (for $\mathsf{A} = \emptyset$ the left member is the mean, and it is 0); (N4) $\mathfrak{R}[\mathsf{k}; f] = \mathsf{b}^{-1}c_{f\mathsf{k}} - 3\mathsf{b}^{-1}\sum_p a_p\,\mathsf{e}^{f\mathsf{k}}(p) + \mathfrak{C}'[\mathsf{k}; f]$ is a number, the density a_p with weights $\leq 12\,\mathsf{b}^{-1}\sup|f|\sup|\mathsf{k}|$ and the densities $\langle G_\rho(b), \mathbf{w}(W_{b,p})\rangle$ of the order 2 with weights $\leq \frac{1}{2}\mathrm{Lip}_\infty f\,\sup|\mathsf{k}|$: no factor β enters. Its weight at a plaquette p vanishes unless a bond b of p has $\mathsf{k}(x_b) \neq 0$ and $f \neq 0$ at x_b or at $x(p)$, so that its densities

are carried within the sup distance $2a$ of $\operatorname{supp}\mathsf{k}$ and of $\operatorname{supp} f$, and the number vanishes unless $\mathsf{k}(x_b)f(x_b)\neq 0$ at some bond.

Consequently, if the spread D of $\operatorname{supp}\mathsf{k}$ and the $\operatorname{supp} f_l$, $l\in\mathsf{A}$, is $>4a$, the terms of (N3) with $j=\#\mathsf{A}$ vanish, the numbers drop from the other terms, and in each of them the entry is carried by a set whose spread with the supports of the remaining f_l is $\geq D-2a$. This rests on the merging of sets: if $S_0,\dots,S_n$ have the spread D, $Q\subset\{1,\dots,n\}$, $2r<D$, and T lies within the sup distance r of S_0 and of every S_q, $q\in Q$, then $T=\emptyset$ if $Q=\{1,\dots,n\}$, and otherwise the spread of T and the S_l, $l\notin Q$, is $\geq D-r$.

■

Proof sketch. (a) The Haar measure is invariant; with $\partial^{\mathsf{a}}_b\langle\sigma_{\mathsf{a}},\mathbf{w}(W_{b,p})\rangle=1-a_p$, an integration by parts in each bond variable against $e^{-\beta A}$ gives $\nu((\beta v_{\mathbf{X}}A-\operatorname{div}v_{\mathbf{X}})Y)=0$ in finite volume, and in a Gibbs state through its conditional laws. With sources the same integration by parts against $e^{-A(\beta-a^{-1}w_z,\cdot)}$, $w_z=\sum_i z_i f_i$, followed by the mixed derivative in z at 0, gives the contact terms, since $v_\eta A(v,\cdot)$ is linear in the weight v. (b) For $q_\pm=p(b,\pm\rho)$ in one plane, $\langle\mathbf{w}(W_{b,q_-}),\mathbf{w}(W_{b,q_+})\rangle=-2\Psi_\rho(q_-)-a_{q_-}-a_{q_+}$; so $\mathfrak{r}_\rho(p)=\Psi_\rho(p)-\Psi_\rho(p_-)$ in the plane, and the split is a summation by parts.

Under the mirror r normal to ρ, $\mathfrak{d}_{\mathsf{r}b,\mathsf{r}p,\rho}(\mathsf{r}U)=-\mathfrak{d}_{b,p,\rho}(U)$ and $\Psi_\rho(\mathsf{r}p)(\mathsf{r}U)=\Psi_\rho(p_-)(U)$, and the measure of a torus is invariant under r. Under a coordinate mirror that contains e_ρ these quantities are carried to the same quantities at the image bond and plaquette: the holonomy $W_{b,p}$ is taken from the initial point of b along b, and where the mirror reverses the orientation of b both factors of $\mathfrak{d}_{b,p,\rho}$ change their sign together; so $\mathfrak{r}^\sharp_\rho$ is even under it, and the three coordinate mirrors through a site compose to the inversion through it.

For ζ: $\langle\mathfrak{K}^\sharp[\zeta];\mathcal{O}(f)\rangle=a^{-1}\sum_{p'}f(p')\langle\mathfrak{K}^\sharp[\zeta];a_{p'}\rangle$, and for each p' and ρ the mirror normal to ρ through $x(p')$ keeps $a_{p'}$, the measure and ζ^ρ, carries the plaquettes normal to ρ among themselves, and changes the sign of $\mathfrak{r}^\sharp_\rho$ on them. A block form has local representations at every height of size $76\|c\|\|k|_\infty$ (the proof of Lemma 8.7(d), with the lassos from the centre of the block, which reach its 27 sites in at most three steps); the field strength is $O(L^{-2j})$ in level-j units on the backgrounds, which gives the fall for monomials of order ≥ 3, with the comparison weight $\Gamma_c^\circ\|c\|\|k|_\infty\mathbf{1}_{\mathrm{Pl}(k)}$ of Lemma 8.7(d). (c) Take in (a) $\mathbf{X}(b)=\sum_\rho\mathsf{k}^\rho(x_b)[\mathbf{w}(W_{b,p(b,\rho)})+\mathbf{w}(W_{b,p(b,-\rho)})]$; then $v_{\mathbf{X}}a_p=\sum_{b\subset\partial p}\langle\mathbf{X}(b),\mathbf{w}(W_{b,p})\rangle$, $\operatorname{div}v_{\mathbf{X}}$ is the number c_{k} minus $3\sum_p a_p$ times a weight formed from k, and the in-plane remainder is $-2a_p^2$, of order 4. (d) At a constant field strength, with $G=\nabla\eta$ and $T_{lr}=\operatorname{tr}B_lB_r$, the classical density of $\Delta_K[\eta]$ is $\mathsf{b}[\operatorname{tr}G\operatorname{tr}T-\operatorname{Tr}GT]-\frac{\mathsf{b}}{2}\operatorname{tr}G\operatorname{tr}T-\frac{\mathsf{b}}{2}\operatorname{Tr}(H^{\mathrm{cons}}T)=0$, since $\operatorname{Tr}(H^{\mathrm{cons}}T)=\operatorname{tr}G\operatorname{tr}T-2\operatorname{Tr}GT$; the Taylor remainder of η gives F^1. (e) $\sum_{p\ni b}a^{-1}(x_b-x(p))_\lambda\mathbf{w}(W_{b,p})=\mathbf{u}_{b,\lambda}$ and the form is bilinear; with $w_\pm=\mathbf{w}(W_{b,p_\pm})$, $|w_\pm|^2=a_{p_\pm}(2-a_{p_\pm})$ and $\Psi_\lambda(p_-)=-\frac14|w_++w_-|^2-\frac14(a_{p_-}^2+a_{p_+}^2)$, and the parallelogram law $4|\mathbf{u}_{b,\lambda}|^2=|w_+-w_-|^2=2|w_+|^2+2|w_-|^2-|w_++w_-|^2$ gives the first identity; the formula for $\mathfrak{s}_{\nu\nu}$ is the same computation at the two bonds of p of the direction other than ν, and no vector $x_b-x(p)$ has a component normal to p.

Inserting these in $T_{mm}(\varphi)=\beta\sum_p\varphi(x(p))[\mathfrak{s}_{mm}(p)-a_p]$ and $\mathsf{b}\check{D}_m(\varphi)=\beta\sum_p\varphi(x(p))a_p(1-2\cdot\mathbf{1}\{\lambda(p)=m\})$, the plaquettes normal to m cancel, and moving the shifts $a_{p\pm ae_m}$ onto φ gives $\tilde\varphi_m$. Finally $\sum_m\check{D}_m=3\mathcal{O}-2\mathcal{O}=\mathcal{O}$. (f) $\mathcal{O}(f)=a^{-1}\sum_p f(x(p))a_p$ and $v_{\mathbf{X}}a_p=\sum_{b\subset\partial p}\langle\mathbf{X}(b),\mathbf{w}(W_{b,p})\rangle$; with $f(x(p))=f(x_b)+(f(x(p))-f(x_b))$ and $f(x_b)\mathbf{X}^{\mathsf{k}}(b)=\mathbf{X}^{f\mathsf{k}}(b)$, the first part is $a^{-1}v_{\mathbf{X}^{f\mathsf{k}}}A=\mathsf{b}^{-1}\beta v_{\mathbf{X}^{f\mathsf{k}}}A=\mathsf{b}^{-1}(\mathfrak{N}[f\mathsf{k}]+\operatorname{div}v_{\mathbf{X}^{f\mathsf{k}}})$ and the second is $\mathfrak{C}'[\mathsf{k};f]$: this is (N1). (N2) is the integration by parts of (a) along $\mathbf{X}^{\mathsf{k}}$ against $e^{\mathcal{O}(w)}e^{-\beta A}$.

At the source $w_z=\sum_{l\in\mathsf{A}}z_lf_l$, (N2) says that the mean of $\mathfrak{N}[\mathsf{k}]-\sum_q z_q\,v_{\mathbf{X}^{\mathsf{k}}}\mathcal{O}(f_q)$ under the measure with the source vanishes, and this function is affine in z; the mixed derivative in z at 0 gives $\langle\mathfrak{N}[\mathsf{k}];(\mathcal{O}(f_l))_{l\in\mathsf{A}}\rangle=\sum_{q\in\mathsf{A}}\langle v_{\mathbf{X}^{\mathsf{k}}}\mathcal{O}(f_q);(\mathcal{O}(f_l))_{l\neq q}\rangle$, and inserting (N1), whose first part is a null term of the same kind with $f_q\mathsf{k}$ for k, an induction on $\#\mathsf{A}$ gives (N3). (N4): $\operatorname{div}v_{\mathbf{X}^{\mathsf{k}}}=c_{\mathsf{k}}-3\sum_p a_p\,\mathsf{e}^{\mathsf{k}}(p)$,

by $\partial_b^{\mathsf{a}}\langle\sigma_{\mathsf{a}},\mathbf{w}(W_{b,p})\rangle = 1-a_p$; $|\mathsf{e}^{f\mathsf{k}}| \le 4\sup|f\mathsf{k}|$, $|x(p)-x_b|_\infty = \frac{a}{2}$, and the boxes of the densities lie within the sup distance $\frac{3}{2}a$ of $x(p)$.

The merging: if $Q=\{1,\dots,n\}$, points of $S_0,\dots,S_n$ within r of one point of T are pairwise at most $2r<D$ apart, which the spread forbids; otherwise, for $t\in T$, $y_l\in S_l$ ($l\notin Q$) and points $y_0\in S_0$, $y_q\in S_q$ within r of t, some pair of the family $y_0,(y_q),(y_l)$ is at least D apart, it is no pair among $y_0,(y_q)$, and so two of the y_l, or one y_l and t, are at least $D-r$ apart. □

Lemma 8.11 (The chain with an entry; the cubic insertion)**.** Let $\gamma^{-2}\le \mathsf{b}_-\le \mathsf{b}_+$, $MR(\mathsf{b}_+)\le L^m$, $\ell = 2L^m$, $0<\tau\le\frac14$, $0<\phi<\frac{1}{42}$, $u=\lceil\phi K\rceil$, $t=K-u$ and $c_0' = \min\{\frac{1}{14}-\frac{\tau}{7},\frac{1}{14}-3\phi\}$. Let K_ϕ be the least integer $K\ge 2$ with $(1-\phi)K\ge 2$, $L^{\phi K}\gamma^{-2}\ge \mathsf{t}_\natural$ and $\phi K > 16\mathfrak{p}_0^2 c_{\log}/(\log L)^2$, $\mathsf{t}_\natural$ being the calibration of Section B.13 and $c_{\log}=\log L/\log\gamma^{-2}$; it depends on the constants and on ϕ alone. For $K\ge K_\phi$ and $\mathsf{b}'\in[\mathsf{b}_-,\mathsf{b}_+]$ let $\rho_0 dU$ be the measure of T_ℓ at $\beta = L^K\mathsf{b}'$; the data (K,b',m) with the top level t form the setting (Th) (Section B.13), and the small-field chain is formed along the couplings $x_j = L^{K-j}\mathsf{b}'$ up to the level t. Let $\mathcal{M}^k$ be the block map to the level k, Cut_k the field cut and $\mathrm{In}_k\subset\mathrm{Cut}_k$ the inner ball of the level k (the definitions preceding Lemma YMM1:113.10), $\mathfrak{G}_k[x_k]\ge 0$ the gauge-fixing factor and $\chi^{\mathrm{sf}}_{x_k}\in\{0,1\}$ the fluctuation test of the step from the level k (Section B.2), and

$$\mathsf{p}_k(U) = \mathbf{1}_{\mathrm{Cut}_k}(\mathcal{M}^k U)\prod_{j<k}[\mathbf{1}_{\mathrm{Cut}_j}\,\mathfrak{G}_j[x_j]\,\chi^{\mathrm{sf}}_{x_j}](\mathcal{M}^j U),$$

the weight of the small-field chain up to the level k: a bounded Borel function with values in $[0,\infty)$, with $\mathsf{p}_0=\mathbf{1}_{\mathrm{Cut}_0}$ and $\mathsf{p}_{k+1} = (\mathbf{1}_{\mathrm{Cut}_{k+1}}\circ\mathcal{M}^{k+1})\,((\mathfrak{G}_k[x_k]\chi^{\mathrm{sf}}_{x_k})\circ\mathcal{M}^k)\,\mathsf{p}_k$; and $(\mathbf{1}_{\mathrm{In}_t}\circ\mathcal{M}^t)\,\mathsf{p}_t$ is the weight $\mathfrak{w}_t^{\mathrm{sf}}$ of the small-field chain of the definitions preceding Proposition YMM1:115.2. Let $\nu_k = (\mathcal{M}^k)_*(\mathsf{p}_k\rho_0 dU)$, the measure of the level k of the chain among the construction results at the source 0 (Proposition YMM1:114.2 and the proof of Proposition YMM1:115.2), a finite positive measure with $\nu_{k+1} = \mathbf{1}_{\mathrm{Cut}_{k+1}}\mathbf{T}(\mathfrak{G}_k[x_k]\chi^{\mathrm{sf}}_{x_k}\nu_k)$, $\mathbf{T}$ the image under the block averaging; let $Q_k h$ be the density of $\mathbf{1}_{\mathrm{Cut}_{k+1}}\mathbf{T}(\mathfrak{G}_k[x_k]\chi^{\mathrm{sf}}_{x_k}h\,\nu_k)$ with respect to ν_{k+1}, the mean of h over the range Rg_{x_k} of the chart of the fibre of the step (Lemma B.3), and $Q_{t\leftarrow 0}=Q_{t-1}\cdots Q_0$, so that $(\mathcal{M}^t)_*(\mathsf{p}_t Y\rho_0 dU) = (Q_{t\leftarrow 0}Y)\,\nu_t$ for bounded Borel Y: $(Q_{t\leftarrow 0}Y)\circ\mathcal{M}^t$ is the conditional mean of Y given $\mathcal{M}^t U$ under $\mathsf{p}_t\rho_0 dU$.

An *entry of the type* $(m_J,c,\hat c,N)$ is a finite family $J=(\mathsf{Q}_\iota,j_\iota,\varkappa_\iota)_\iota$ of boxes $\mathsf{Q}_\iota = \{x+a\sum_\mu n_\mu e_\mu : 0\le n_\mu\le r_\mu\}$, $(r_1,r_2,r_3)\in\{0,1,2\}^3$ with at least two $r_\mu\ge 1$, x the lowest site of the box, of densities j_ι on them and of complex weights $\varkappa_\iota$, at most N indices having one lowest site. A density on a box is a polynomial in the entries of the complex configurations $\mathbf{U}(b)\in\mathrm{SL}(2,\mathbb{C})$ at its bonds, $\mathbf{U}(\bar b)=\mathbf{U}(b)^{-1}$, invariant under the gauge transformations of the box; it has the height $\hat c$ if $|j|\le\hat c$ wherever $|\mathbf{U}(b)|\le 2$ at all the bonds, and the order m_J with the constant c if $|j|\le c\,\epsilon^{m_J}$ wherever, besides, $|\partial\mathbf{U}(q)-\mathbf{1}|\le\epsilon$ at all the plaquettes q of the box, $0<\epsilon\le 1$.

Zero insertions and zero scalar sources are omitted before inverse norms and source radii are formed; the multilinear estimates are immediate when an insertion vanishes. We write $J(U)=\sum_\iota \varkappa_\iota j_\iota(U|_{\mathsf{Q}_\iota})$ and $|\varkappa|_\infty = \max_\iota|\varkappa_\iota|$; the carrier of J is the set of the sites of the boxes with $\varkappa_\iota\ne 0$.

(a) For $K\ge K_\phi$, an entry of the type $(m_J,c,\hat c,N)$ with $m_J\ge 2$, $|s|<r_J$ with $r_J^{-1}\le C|\varkappa|_\infty$, and $1\le k\le t$:

$$(\mathcal{M}^k)_*(\mathsf{p}_k e^{sJ}\rho_0 dU) = \exp\Big[\sum_{i\le k}c_i(s)\Big]\mathbf{1}_{\mathrm{Cut}_k}e^{\Phi_k^s}\,dV,$$

the numbers $c_i(s)$ and the action Φ_k^s being holomorphic in s and sums of local families, each of which depends on $\varkappa$ in its domain only. $Q_{t\leftarrow 0}J$ is a number plus $\partial_s\Phi_t^s|_{s=0}$ ν_t-almost everywhere on Cut_t, and its oscillation is at most $CK^{2\mathfrak{p}_0}L^{4u-K}|\varkappa|_\infty$ for $m_J=2$ and $CK^{3\mathfrak{p}_0}L^{4u-\frac32 K}|\varkappa|_\infty$ for $m_J\ge 3$. Here C depends on the constants, ℓ, b_+, ϕ and the type of the entry.

(b) There are $K_2 \geq K_\phi$, C_2, p_2, depending on these data alone, such that for $K \geq K_2$ and every $\mathsf{b}' \in [\mathsf{b}_-, \mathsf{b}_+]$ the following holds. For every field Ξ there is a number a with $|Q_{t\leftarrow 0}(\beta\mathfrak{K}^\sharp[\Xi]) - \mathsf{a}| \leq C_2\mathsf{H}(\Xi)K^{p_2}L^{-c_0'K}$ ν_t-almost everywhere on Cut_t. The same holds at real sources: let $n \geq 1$, $f_1, \dots, f_n$ real Lipschitz functions, $\mathsf{M}_t \leq CK^{2\mathfrak{p}_0}\ell^3 L^{3u}$ the inverse radius of the sources of the chain at the level t, and x real in the polydisc $\mathbb{D}_t$ of the radii $r_i = (8n\mathsf{M}_t\|f_i\|_\sharp)^{-1}$; then $w_x = \sum_i x_i f_i$ lies in the class of sources of the setting (Th), and with the measure $\rho_0 e^{\mathcal{O}(w_x)}dU$ in the place of $\rho_0 dU$, its chain measure $\nu_t^{w_x}$ and its conditional mean $Q_{t\leftarrow 0}^{w_x}$, and the entry with the moved weight $\mathfrak{K}^\sharp[(\beta - a^{-1}w_x)\Xi]$ in the place of $\beta\mathfrak{K}^\sharp[\Xi]$, the same bound holds with a number $\mathsf{a}(x)$, the numbers C_2, p_2, K_2 being free of x and of b'.

The number $\mathsf{a}(x)$ is the sum, over the levels $j \leq t$, of the values at the configuration $\mathbf{1}$ of local families of the level j whose member at a polymer X reads w_x and Ξ on the plaquettes of X alone and vanishes if Ξ vanishes at the barycentres of these plaquettes. For free photons the cubic piece vanishes identically.

■

Proof sketch. (a) The entry is typed anew at each level. At a height $j \geq 1$ the sum of the $\varkappa_\iota j_\iota$ over the boxes whose cubes of the level j form a given polymer is a pointed family of the level j: at most $8N(ML^j)^3$ boxes have one polymer, and on the cores each density is at most $c\,\alpha_0^{m_J}L^{-2m_J j}$ by its order, so that the family has the size $8NM^3 c\,\alpha_0^{m_J}|\varkappa|_\infty L^{-(2m_J-3)j}$; this is the power counting, of order $|\varkappa|_\infty L^{(3-2m_J)j}$ in level-j units. At the height 0 the family in the fourth place $\sum_\iota \varkappa_\iota[j_\iota(e^{iB'}\mathbf{U}) - j_\iota(\mathbf{U})]$, B' the fluctuation field with its values at the pivot bonds, sums to $J(e^{iB'}\mathbf{U}) - J(\mathbf{U})$ and has the size of a number times $N\hat{c}\,\delta(x_0)|\varkappa|_\infty$, by the height and Schwarz's lemma in the fluctuation field.

So for $|s| < r_J$, $r_J^{-1} \leq C|\varkappa|_\infty$ with C reading N, c and $\hat{c}$, the entry enters each step as one more local term, inside the radii of the one-step theorem with sources (Proposition E.7); the members of the families are holomorphic in s and read s only on the polymers that the entry meets. The identity of the measures follows by induction on k from the recursion of p_k: the images $\nu_k^s = (\mathcal{M}^k)_*(\mathsf{p}_k e^{sJ}\rho_0 dU)$ obey $\nu_{k+1}^s = \mathbf{1}_{\mathrm{Cut}_{k+1}}\mathbf{T}(\mathfrak{G}_k[x_k]\chi_{x_k}^{\mathrm{sf}}\nu_k^s)$, the small-field pushforward in Lemma B.3, a chart integral over Rg_{x_k} that the one-step theorem evaluates; one function $e^{\Phi_k^s}$ is both the density reached at the level k and the integrand of the step from the level k.

The derivative of the exponent in s at 0 is the conditional mean up to the number $\dot{c}_t = \sum_i \partial_s c_i(0)$. On Cut_t the plaquette variables of the background are within $\mathsf{e}_t^{\mathrm{c}}L^{-2t}$ of $\mathbf{1}$, $\mathsf{e}_t^{\mathrm{c}}$ the radius of the field cut, so that the entry at the background is at most $N(\ell L^K)^3 c\,(\mathsf{e}_t^{\mathrm{c}})^{m_J}L^{-2m_J t}|\varkappa|_\infty$; with what the families of the earlier levels carry, $|\Phi_t^s - \Phi_t^{s'}| \leq |s - s'|\,\mathsf{o}_t$ with o_t of the order of the stated oscillation, which is at most $2\mathsf{o}_t$. The threshold $K \geq K_\phi$ makes t a top level of the setting (Th): $(1-\phi)K \geq 2$ gives $1 \leq t \leq K-1$, $L^{\phi K}\gamma^{-2} \geq \mathsf{t}_\natural$ gives $x_t = L^u\mathsf{b}' \geq \mathsf{t}_\natural$, and the third condition keeps the size of a source at the coupling x_k, $k \leq t$, below the bound of the step; this size θ_k obeys $L\theta_k \leq \Theta_K L^{-(K-k)/2}$, Θ_K a power of K. (b) Let $S = \beta\mathfrak{K}^\sharp[\Xi] = \sum_p \varkappa(p)\mathfrak{r}_{\lambda(p)}^\sharp(p)$, $\varkappa(p) = L^{2K}\mathsf{b}'\,\Xi^{\lambda(p)}(x(p))$, so that $\max|\varkappa| \leq L^{2K}\mathsf{b}_+\mathsf{H}(\Xi)$; the density vanishes to the third order at $\mathbf{1}$ (Lemma 8.10(b)).

At a real source the weight is moved, $\varkappa(p) = L^{2K}(\mathsf{b}' - w_x(x(p)))\Xi^{\lambda(p)}(x(p))$, and the chain carries the source; we write the source 0, the other case being the same with the index w_x. Let $s_0 = S$ and $s_j = S \circ U_j$ on Cut_j, the entry read at the background of the level j. For a pointed family f of a level $\leq n$ let $\Sigma_n[\mathsf{f}](V)$, $V \in \mathrm{Cut}_n$, be the sum over the polymers of the members of f at the background $U_n(V)$, and $\mathrm{Sum}[\mathsf{f}](\mathbf{1})$ the same sum at the configuration $\mathbf{1}$, a number. Let $S_n\mathsf{f}$ be the first-order response of the step from the level n to a family f of a level $i \leq n$, a family of the level $n+1$ with $\|S_n\mathsf{f}\|_{n+1} \leq \theta_n L^{-(n-i)}\|\mathsf{f}\|_i$, so that $Q_n\Sigma_n[\mathsf{f}] = \Sigma_{n+1}[\mathsf{f} + S_n\mathsf{f}]$ on Cut_{n+1}; and let $D^{(j)} = D^{(j)}[w;\varkappa]$ be the family born at the level j from the entry at the source w and the weight $\varkappa$: $Q_{j-1}s_{j-1} - s_j = \Sigma_j[D^{(j)}]$ on Cut_j.

With $T_t = \mathrm{id}$ and $T_n\mathsf{g} = T_{n+1}(\mathsf{g} + S_n\mathsf{g})$, the carriage of a family from the level n to the level t with all that it feeds, $Q_{t-1}\cdots Q_n\Sigma_n[\mathsf{g}] = \Sigma_t[T_n\mathsf{g}]$; so, with $n_0 = K - \lceil \frac{K}{7} \rceil$ and $Q_{t\leftarrow n_0} = Q_{t-1}\cdots Q_{n_0}$,

$$Q_{t\leftarrow 0}S = Q_{t\leftarrow n_0}s_{n_0} + \sum_{j\le n_0} \Sigma_t[T_j D^{(j)}] \qquad \text{on } \mathrm{Cut}_t.$$

The births are small by the parity in the fluctuation field: the part of the variation of the density that is odd in the fluctuation field has the size $g_{j-1} = x_{j-1}^{-1/2}$ and the Gaussian mean 0, so that it meets only the odd part of the interaction, of the size $g_{j-1}(\log x_{j-1})^{\mathfrak{p}_0}$, while the even part has the size g_{j-1}^2; so $\|D^{(j)}\| \le C(\log x_{j-1})^{\mathfrak{p}_0} g_{j-1}^2 L^{-3(j-1)} \max|\varkappa|$ once $K - j$ exceeds a fixed construction threshold, and $L^j\|D^{(j)}\| \le CK^{\mathfrak{p}_0}L^{K-j}\mathsf{H}(\Xi)$. $T_jD^{(j)}$ is $D^{(j)}$ plus the sum of the chains $S_{k_m}\cdots S_{k_1}D^{(j)}$, $j \le k_1 < \cdots < k_m < t$, of the families that it feeds; each chain is stopped at a level n of its own, chosen with the free fraction τ, at which the variation $\mathrm{Sum}[\mathsf{f}](U_n(V)) - \mathrm{Sum}[\mathsf{f}](\mathbf{1})$ of a family f of the level i is at most $\beta_n L^i\|\mathsf{f}\|_i$, $\beta_n = CK^pL^{3(K-n)-K}$, the square of the radius of regularity of the level n entering. $Q_{t\leftarrow n}$ does not enlarge an oscillation, and each feeding costs $L\theta_k \le \Theta_K L^{-(K-k)/2}$, so that what is fed is forgotten.

The variation of $\mathrm{Sum}[D^{(j)}]$ over Cut_{n_0}, $j < n_0$, is where the parity of the cubic density enters. The step is covariant under the isometries of the lattice of its level, and $\mathfrak{v}^\sharp$ transforms as a vector (Lemma 8.10(b)); so under the inversion $r_z : y \mapsto 2z - y$ through a site z of the lattice of the level j, $\mathrm{Sum}[D^{(j)}[w;\varkappa]](r_zU) = -\mathrm{Sum}[D^{(j)}[r_z^*w; r_z^*\varkappa]](U)$, $(r_z^*v)(p) = v(r_zp)$. With a partition of unity $\psi_z \ge 0$ over these sites, $\psi_z \circ r_z = \psi_z$, $\psi_z(p) = 0$ unless $|x(p) - z|_\infty \le \frac{1}{2}L^{j-K}$, and $\Sigma_z[w;\varkappa] = \mathrm{Sum}[D^{(j)}[w;\psi_z\varkappa]]$, this gives the exact split

$$\Sigma_z[w;\varkappa](U) = \tfrac{1}{2}(\Sigma_z[w;\varkappa](U) - \Sigma_z[w;\varkappa](r_zU)) + \tfrac{1}{2}\Sigma_z[w;\varkappa - r_z^*\varkappa](U) + \tfrac{1}{2}(\Sigma_z[w;r_z^*\varkappa](U) - \Sigma_z[r_z^*w;r_z^*\varkappa](U)).$$

(I) The first part compares the background with its image under r_z. In the Hölder gauge (Theorem BT for real backgrounds) the curvature, a 2-form, is even under the inversion, so that the linear part of the potential is kept and the potential and its image differ by the odd part of the Hölder remainder, at most $R^2\vartheta^{2+b}e_3$ on a cube of the radius R about z, $\vartheta = L^{-(n_0-j)}$, $b = \frac{3}{4}$, e_3 of the order of the radius of regularity of the level n_0: a gain ϑ^b. (II) The second part carries the asymmetry of the weight, $|\varkappa - r_z^*\varkappa| \le L^{2K}\mathrm{Lip}(\Xi)L^{j-K}$ where $\psi_z \ne 0$. (III) The third part is the asymmetry of the source in the step: it vanishes at the source 0, and at a real source it is of the second order at the trivial triple, of the size $\mathrm{Lip}(w_x)\,\delta(x_{j-1})$, $\delta(x_{j-1})$ of the order of $L^{-(K-j)/2}$ being the threshold of the level.

Summed over $j < n_0$, the parts (I), (II) and (III) are $O(L^{-3K/14})$, $O(L^{-4K/7})$ and $O(L^{-K/14})$; the stopped entry contributes $O(L^{-5K/14})$ and the family born at n_0 $O(L^{-3K/7})$; forgetting leaves $O(L^{-(\frac{1}{14}-\frac{\tau}{7})K})$ of what is fed, and against the factor L^{3u} of the levels above t it leaves $O(L^{-(\frac{1}{14}-3\phi)K})$; all this up to powers of K. The least of these exponents is c_0'; at the source 0 the last two meet at $\frac{1}{14}$ as $\tau, \phi \to 0$, and at a real source the part (III) meets them there. The number a, the sum of the values at the configuration $\mathbf{1}$ of the families born and fed up to their levels of stopping, depends on no V, and each of these families reads the source and the weight on its polymer alone and vanishes where the weight vanishes.

The numbers are uniform on $[\mathsf{b}_-, \mathsf{b}_+]$ because the frame of Definition B.14 holds for the chain along $x_j = L^{K-j}\mathsf{b}'$ at every label of the interval and b' enters only through $x_i \in [\gamma^{-2}L^{K-i}, \mathsf{b}_+L^{K-i}]$ and $\max|\varkappa|$, each time in a monotone way; on the polydisc $\mathbb{D}_t$ the source stays in the class of the setting (Th) and the mass of the small-field chain stays away from 0, and at real x the measures of the chain are positive. □

Lemma 8.12 (The cubic remainder)**.** In the setting of Lemma 8.11, let $n \ge 1$, $\mathsf{d} > 0$ and $c < \frac{1}{14}$. There are C, p, free of K and of b', such that for all $K \ge 2$, $\mathsf{b}' \in [\mathsf{b}_-, \mathsf{b}_+]$, $\beta = L^K\mathsf{b}'$, all real Lipschitz

f_i and all fields η, the spread of $\{\eta \neq 0\}, \operatorname{supp} f_1, \dots, \operatorname{supp} f_n$ being $\geq \mathsf{d}$,

$$|\mathfrak{U}^\sharp[\eta](f)| \leq C K^p L^{-cK} \mathsf{H}(\eta) \prod_i \|f_i\|_\sharp .$$

The spread condition holds if two of the sets are at sup distance $\geq \mathsf{d}$, and if $\eta = 0$ within the sup distance d of one support. By $x \mapsto L^z x$ the same holds at every label and on every side. ■

Proof sketch. Moving the weight of the entry with the sources produces the contact terms:

$$\mathfrak{U}^\sharp[\eta](f) = -\partial_s \partial_{z_1} \cdots \partial_{z_n} \log \Big\langle \exp\Big(s\, \mathfrak{K}^\sharp[(\beta - a^{-1} \textstyle\sum_i z_i f_i)\eta] + \sum_i z_i \mathcal{O}(f_i) \Big) \Big\rangle \Big|_{s=z=0} .$$

After discarding the histories with large fields, Lemma 8.11(b), applied to the chain with the real sources x in its polydisc $\mathbb{D}_t$ and to the field η, makes the conditional mean of the entry with the moved weight equal, up to $\varepsilon = K^p L^{-c_0' K}$, to its number $\mathsf{a}(x)$; and $\mathsf{a}(x)$ is a sum $\sum_i c_i(x)$ of functions each of which does not depend on x_i, up to a remainder below every power of L^{-K}. Indeed, let $c_i(x)$ collect the members of the families of $\mathsf{a}(x)$ at the polymers on whose plaquettes f_i is the first of the sources that vanishes at all the barycentres; such a member reads the sources on its polymer alone, so it does not read x_i; the members at the other polymers, which meet $\{\eta \neq 0\}$ and all the $\operatorname{supp} f_i$, are left over; under the spread such a polymer of the level j has the linear size $\geq \mathsf{d} L^{K-j}/M - 3$, so that these members cost $e^{-\mathsf{d} L^{K-j}/M}$ against the sizes.

Such sums have no mixed derivative. At complex sources the mean is crudely at most $B = C\ell^3 L^{3K} \max|\varkappa|$, $\varkappa$ the weight of the entry. Interpolating between the two bounds, the mixed derivative is at most $2^n \varepsilon^{1-\sigma} B^\sigma (\frac{4n}{\pi\sigma})^n \prod_i r_i^{-1}$ with $r_i^{-1} \leq C K^{2\mathfrak{p}_0} \ell^3 L^{3u} \|f_i\|_\sharp$, and σ, ϕ, τ small give every $c < \frac{1}{14}$. The finitely many $K < K_2$ are paid by the crude bound of the cumulant by the suprema of its entries, which goes into C. For $n \geq 2$ the bound holds also where $\{\eta \neq 0\}$ covers the supports, as in the uses below, since the spread of the $n+1$ sets is at least that of the supports among themselves. □

Lemma 8.13 (Chessboard bound in one cell)**.** Let $0 < g \leq \gamma$, $\ell' = 2\mathsf{l} \in \mathfrak{L}(g)$, $0 < \phi \leq \frac{1}{84}$, $u = \lceil \phi K \rceil$, $t = K - u$, $0 < \delta \leq \frac{1}{8}\mathsf{l}$ and $m \geq 1$. There are C, p, K_3, depending on $g, \ell', \phi, m, \delta$, such that for $(K, \beta) \in \mathfrak{D}(g)$ with $K \geq K_3$, every board of side l with offset in $a_{K-t}\mathbb{Z}^3 = L^{-u}\mathbb{Z}^3$, every cell, every d with $\mathsf{d} L^u \geq K^2$, and m slots $X_1, \dots, X_m$ supported in the cell at sup distance $\geq \delta$ from its walls and pairwise $\geq \mathsf{d}$ apart,

$$\Big\| \prod_a (X_a - \langle X_a \rangle_{K,\ell',\beta}) \Big\|_{\mathrm{ch}} \leq C \prod_a \varpi(X_a)\, \mathsf{n}(X_a),$$

where a slot is $\mathcal{T}_K(H)$, with $\varpi = K^p L^{4u}$ and $\mathsf{n} = |H|_\infty$, or one of

$$\mathcal{T}_K(H^{\mathrm{cons}}[\eta]), \mathrm{St}_K[\eta], \Delta_K[\eta], \mathrm{Rm}_K[\eta], \mathfrak{K}^{\mathrm{v}}[\beta\eta],$$

with $\varpi = K^p L^{3u - K/28}$ and $\mathsf{n} = \|\eta\|_{C^2}$. For $m = 1$ and $\phi = \frac{1}{400}$ we have $\|\mathrm{St}_K[\eta] - \langle\cdot\rangle\|_{\mathrm{ch}} \leq C K^p L^{-K/28} \|\eta\|_{C^2}$ and

$$\|\Delta_K[\eta] - \langle\cdot\rangle\|_{\mathrm{ch}} + \|\mathcal{T}_K(H^{\mathrm{cons}}[\eta]) - \langle\cdot\rangle\|_{\mathrm{ch}} \leq C K^p L^{-K/36} \|\eta\|_{C^2};$$

for a plain tensor entry $\|\mathcal{T}_K(H') - \langle\cdot\rangle\|_{\mathrm{ch}} \leq C K^{2\mathfrak{p}_0} L^{K/100} |H'|_\infty$. At $m = 1$ and $\phi = \frac{1}{400}$, moreover, $\|\mathrm{Rm}_K[\eta] - \langle\cdot\rangle\|_{\mathrm{ch}} = \|\mathrm{St}_K[\eta] - \langle\cdot\rangle\|_{\mathrm{ch}}$, and the bound $C K^p L^{-K/28} \|\eta\|_{C^2}$ holds also for $\|F_\eta\|_{\mathrm{ch}}$, where

$$F_\eta = \mathfrak{K}^{\mathrm{v}}[\beta\eta] - \tfrac{1}{4}\mathfrak{N}[\mathsf{k}_\eta] = \beta \mathfrak{K}^\sharp[\eta] - \sum_{v=1}^{5} \mathfrak{J}_v[\mathsf{k}_\eta] + \tfrac{1}{4} c_{\mathsf{k}_\eta}, \qquad \langle F_\eta \rangle_{K,\ell',\beta} = 0,$$

with $\mathsf{k}_\eta^\rho = \nabla_\rho^+ \eta^\rho$ and the objects of Lemma 8.10(c); for every state s of Lemma 8.9, $s(\mathfrak{K}^{\mathrm{v}}[\beta\eta]) = s(F_\eta)$, so that $|s(\mathfrak{K}^{\mathrm{v}}[\beta\eta])| \leq e^{G_g \mathsf{l}^3} \|F_\eta\|_{\mathrm{ch}}$ by Lemma 8.9 at $q = 1$, $c_1 = 0$. ■

Proof sketch. By Lemma 8.10(c), $\mathrm{St}_K[\eta] = N_\beta[\eta] - \frac14\mathfrak{N}[\mathsf{k}_\eta] - \mathrm{Rm}_K[\eta] - \frac14 c_{\mathsf{k}_\eta}$, so that the slots $\mathrm{St}_K[\eta]$ and $-\mathrm{Rm}_K[\eta]$ differ by null terms and a number; inside the mean of the $8m$ mirror copies on $T_{\ell'}$ the null terms drop, since no other copy depends on their bonds. A product of centred slots in one cell expands into joint cumulants over the partitions into blocks of at least two members. Apply Proposition 3.15(a), with its common insertion radius r_1, size $\bar{\mathsf{d}}$ and polymer sum $\mathsf{t}_\times$. It bounds the higher mixed jets of the exponent as well as the separate conditional means and gives

$$|\langle J_0;\dots;J_r\rangle| \le \mathrm{op}_{r+1}\prod_a \omega_t(J_a) + 9\cdot 2^{r+1}(r+2)\bar{\mathsf{d}}\,\mathsf{t}_\times r_1^{-r} + 4\,\mathrm{op}'_{r+1}\mathsf{R}_t\prod_a \sup|J_a|, \qquad \mathrm{op}_n = \sum_\pi (|\pi|-1)!,$$

π over the partitions of n points, with op'_n as in Proposition 3.15; ω_t is the oscillation of the conditional mean (Lemma 8.11) and R_t the weight of the histories with large fields. After allowing the carrier collars, take $\mathsf{d}_\times \ge c\min\{\mathsf{d},\delta\}$. The hypothesis $\mathsf{d}L^u \ge K^2$ gives $\mathsf{d}_\times L^u \ge cK^2$ for all sufficiently large K, uniformly in d. The prefactor estimates in the proof of Proposition 3.24 bound the second term by a polynomial in K times $L^{AK}e^{-cK^2}$; thus the condition of Proposition 3.15(a) holds and this term is below any prescribed L^{-BK}. The large-field term is controlled there separately. Six of the seven pieces of Rm_K are small by power counting, the seventh is the cubic one, of oscillation $K^pL^{-c'_0K}$. The principal part of Δ_K is null (Lemma 8.10(d)): on the backgrounds of the level $K - \lceil\frac{K}{14}\rceil$ its value is at most $CK^{2\mathfrak{p}_0}L^{\frac72\lceil K/14\rceil - \frac{K}{2}}\mathsf{b}\sup|\nabla\eta|$, what is born below that level is born at a small coupling and is forgotten, and a conditional mean is never larger than a supremum.

Each crude tensor entry costs L^{4u}. At $m=1$: by (a)–(c) of Lemma 8.10, $\mathfrak{K}^{\mathrm{v}}[\beta\eta] = \frac14\mathfrak{N}[\mathsf{k}_\eta] + \beta\mathfrak{K}^\sharp[\eta] - \sum_v \mathfrak{J}_v[\mathsf{k}_\eta] + \frac14 c_{\mathsf{k}_\eta}$, so that F_η consists of six of the seven pieces of $\mathrm{Rm}_K[\eta]$ and a number. The cubic piece has the oscillation $K^pL^{-K/28}\|\eta\|_{C^2}$ by Lemma 8.11(b) at $\tau=\frac14$, where $c'_0 = \frac{1}{28}$ for $\phi \le \frac{1}{84}$; the five pieces $\mathfrak{J}_v$, of the orders $2,2,2$ with weights of the order of $\|\eta\|_{C^2}$ and of the orders $3,4$ with weights at most $\beta\|\eta\|_{C^2}$, have oscillations at most $K^{3\mathfrak{p}_0}L^{4u-K/2}\|\eta\|_{C^2}$ by Lemma 8.11(a); so no factor L^{3u} enters the bound of F_η; in the bounds of the slots of the kind of η it enters through Δ_K alone.

The means of $\mathfrak{K}^{\mathrm{v}}[\beta\eta]$ and of $\mathfrak{N}[\mathsf{k}_\eta]$ on $T_{\ell'}$ are 0 (Lemma 8.10(a), (b)), so is that of F_η, and $s(\mathfrak{N}[\mathsf{k}_\eta]) = 0$ in every state s by Lemma 8.10(a). □

Lemma 8.14 (From sup norms to an integrable density)**.** Let $H \ge 0$ be self-adjoint, $T_t = e^{-tH}$, and for every $\eta > 0$ let $\rho \mapsto S_\eta[\rho]$ be linear from $C_c((-\eta,\eta))$ to the bounded operators, with $\|S_\eta[\rho]\| \le A_J \sup|\rho|$ for $\mathrm{supp}\,\rho$ in a compact $J \subset (-\eta,\eta)$, and $S_\eta[\rho(\cdot - c)] = T_{\delta+c}S_{\eta-\delta}[\rho]T_{\delta-c}$ for $|c| \le \delta < \eta$. Then there is a unique family of bounded operators $B(s,s')$, $s,s' > 0$, with $T_tB(s,s')T_{t'} = B(s+t,s'+t')$ and $S_\eta[\rho] = \int \rho(c)B(\eta+c,\eta-c)\,dc$; for $0 < \gamma' < \eta$ and $\mathrm{supp}\,\rho \subset [-(\eta-\gamma'),\eta-\gamma']$, $\|S_\eta[\rho]\| \le \|S_{\gamma'/2}[\mathrm{tent}_{\gamma'/8}]\|\,\|\rho\|_{L^1}$; and $B(s,s')^* = B(s',s)$ if $S_\eta[\rho]^* = S_\eta[\bar\rho(-\cdot)]$. The same holds in the space directions for commuting momenta P with $H \ge |P_k|$ in the direction k. ■

Proof sketch. For G holomorphic and bounded on the strip $\{|\mathrm{Re}\,z| < h'\}$, $h' > 2h$, integrating $\Gamma(z)\sin^{-2}(\pi z/2h)$, $\Gamma' = G$, over the boundary of the strip gives

$$G(0) = \int \mu_2(ds)\int \mathrm{tent}_{2h}(c)\,G(c+is)\,dc, \qquad \mu_2 = \mu_1 * \mu_1, \quad \mu_1(ds) = \tfrac{\pi}{4h}\mathrm{sech}^2(\tfrac{\pi s}{2h})ds.$$

Thus an average in real time inverts a tent smearing in Euclidean time. Apply it to $z \mapsto \langle T_{\delta+\bar z}\psi_2, S[\rho]T_{\delta-z}\psi_1\rangle$ for vectors ψ_1,ψ_2, holomorphic by the covariance, and use $\rho_0 * \rho_1 = \rho_1 * \rho_0$: the μ_2-average of $e^{-isH}S_{\gamma'/2}[\mathrm{tent}]e^{isH}$ is the operator $\mathbb{B}$ of the density, $S_\eta[\rho] = \int \rho(c)T_{\eta-\gamma'/2+c}\mathbb{B}T_{\eta-\gamma'/2-c}\,dc$. In space, $G(0) = \int h_{d'}(x)\frac12[G(x+id') + G(x-id')]\,dx$ with $h_{d'} = (2d')^{-1}\mathrm{sech}(\pi x/2d')$, with the imaginary translations that $H \ge |P|$ allows. □

Lemma 8.15 (Functions of the block field)**.** For a history h let $\mathfrak{w}_h \ge 0$ be its weight in the law of the field and of the history and $\mathsf{t}(h) = \int \mathfrak{w}_h\rho_0\,dU$ its mass, so that $\sum_h \mathsf{t}(h) = Z$ (equations YMM1:(646)–(648) and Proposition YMM1:44.1).

(i) In the setting of Lemma 8.11, let $1 \le t \le K-1$ be a level up to which the chain is formed (a top level of the chain at the label b'), h_t the history without large-field regions of the level t, $\mathrm{In}_t = \{V : \varpi(V) < 2\varepsilon(x_t)\} \subset \mathrm{Cut}_t$ the inner ball of the level t (the definitions preceding Lemma YMM1:113.10; $\varpi(V)$ is the largest $|\partial V(p') - \mathbf{1}|$ over the plaquettes p' of the level t), and $\mathfrak{w}_t^{\mathrm{sf}}$ the weight of the level t of the small-field chain with its number R_t (the definitions preceding Proposition YMM1:115.2, the definition preceding Proposition YMM1:115.2, YMM1:(2187)): $\mathfrak{w}_t^{\mathrm{sf}}(U) = \mathbf{1}_{\mathrm{In}_t}(\mathcal{M}^t U)\prod_{i<t}[\mathbf{1}_{\mathrm{Cut}_i}\mathfrak{G}_i[x_i]\chi_{x_i}^{\mathrm{sf}}](\mathcal{M}^i U)$, with the gauge-fixing factors $\mathfrak{G}_i[x_i]$ and the fluctuation tests $\chi_{x_i}^{\mathrm{sf}}$ among the construction results, so that $\mathfrak{w}_t^{\mathrm{sf}} = (\mathbf{1}_{\mathrm{In}_t}\circ\mathcal{M}^t)\,\mathsf{p}_t$ with $\mathsf{p}_t(U) := \mathbf{1}_{\mathrm{Cut}_t}(\mathcal{M}^t U)\prod_{i<t}[\mathbf{1}_{\mathrm{Cut}_i}\mathfrak{G}_i[x_i]\chi_{x_i}^{\mathrm{sf}}](\mathcal{M}^i U)$.

The measure ν_t of the level t of the chain is $(\mathcal{M}^t)_*(\mathsf{p}_t\rho_0\,dU)$ (Proposition YMM1:114.2, the measure recursion in Proposition YMM1:114.2), and $Q_{t\leftarrow 0}$ is the conditional mean given $\mathcal{M}^t U$ under $\mathsf{p}_t\rho_0\,dU$; the tower of Lemma 8.11 is read with this p_t. By Proposition YMM1:115.2, $\mathfrak{w}_t^{\mathrm{sf}}$ is a bounded Borel function with values in $[0,\infty)$, $(\mathcal{M}^t)_*(\mathfrak{w}_t^{\mathrm{sf}}\rho_0\,dU) = \mathbf{1}_{\mathrm{In}_t}\nu_t$ YMM1:(2188), $0 \le \mathfrak{w}_{h_t} \le \mathfrak{w}_t^{\mathrm{sf}}$ at every point YMM1:(2189), and $0 \le Z - \int \mathfrak{w}_t^{\mathrm{sf}}\rho_0\,dU \le Z - \mathsf{t}(h_t) \le \mathsf{R}_t Z$ YMM1:(2190): R_t bounds the weight of the histories with a large field up to the level t.

For every bounded real Borel gauge invariant Y, real a_0 and $\epsilon \ge 0$ with $|Q_{t\leftarrow 0}Y - a_0| \le \epsilon\ \nu_t$-almost everywhere on In_t, and every bounded Borel function ψ of the block fields of the level t, $|\langle Y;\psi\circ\mathcal{M}^t\rangle| \le 2[\epsilon + 2(\sup|Y| + |a_0|)\mathsf{R}_t]\sup|\psi|$; if besides $\mathsf{R}_t \le \frac{1}{2}$, then $|a_0| \le \sup|Y| + \epsilon$.

(ii) In the setting of Lemma 8.7 at $0 < g \le \gamma$ with $g^{-2} \ge x_{\mathrm{J}}$ (a first-passage datum $(K,\beta) \in \mathfrak{D}(g)$, a side $\ell \in \mathfrak{L}(g)$, a depth s and the working level k), let $2 \le T \le k$ be a level, h_T the history without large-field regions of the level T, $\mathsf{m}_T = \tau_{h_T}[\rho_0]$ (Lemma 8.7(a)), and $W_T < 1$ the weight of a first creation of a large field at a level $\le T$, so that $Z - \mathsf{t}(h_T) = W_T Z$. A dominated local source F_2 acts on a dominated local source F_1 at the sup distance d', with $L^{K-T}\mathsf{d}' \ge 3M$ and $\mathsf{h}_2(K-T) \le 1$ (the conditions of Lemma 8.7(e) at $t = T$), through a bounded function of the block field of the level T: let r_2 be the real part of the bounded density $D_{T,2}$ of $\tau_{h_T}[F_2\rho_0]$ with respect to m_T, c real, E the essential supremum of $|r_2 - c|$ for m_T, and $\psi = (r_2 - c)\mathbf{1}\{|r_2 - c| \le E\}$, a bounded real Borel function with $\sup|\psi| \le E$ and $\psi = r_2 - c$ m_T-almost everywhere; then

$$|\langle F_1;F_2\rangle - \langle F_1;\psi\circ\mathcal{M}^T\rangle| \le C_2 e^{3-\mathsf{D}_T/M} y_1 y_2 + 2\sup|F_1|(\sup|F_2| + \sup|\psi| + |c|)W_T,$$

with $y_a \le 4\ell^3 L^{4(K-T)}$ times the sizes of the sources and $\mathsf{D}_T \ge L^{K-T}\mathsf{d}'$ the least sup distance of the carriers in level-T units; at $c = \mathrm{Re}\,c_2$, c_2 the constant of F_2 at the level T, $E \le C_1 y_2$ and $|c| \le \sup|F_2| + C_1 y_2$. The display is additive in F_1.

■

Proof sketch. The law of the field and of the history, Proposition YMM1:44.1 with the measures in equation YMM1:(647), gives

$$\mathbf{T}^k(\Psi\rho_0\,dU) = \sum_h \tau_h[\Psi\rho_0],$$
$$\int F\,d\tau_h[\Psi\rho_0] = \int F(\mathcal{M}^k U)\,\mathfrak{w}_h(U)\Psi(U)\rho_0(U)\,dU$$

for every bounded gauge invariant Ψ, when $\varepsilon_j \le \varepsilon_\flat = c_2^{\mathrm{SO}}$ for $j < k$; hence $Z\langle\Psi\cdot\psi\circ\mathcal{M}^k\rangle = \sum_h \int \psi\,d\tau_h[\Psi\rho_0]$, and, as $\mathfrak{w}_h \ge 0$ and $\sum_h \mathsf{t}(h) = Z$,

$$\left|Z\langle\Psi\cdot\psi\circ\mathcal{M}^k\rangle - \int\psi\,d\tau_{h_k}[\Psi\rho_0]\right| \le \sup|\Psi|\sup|\psi|\,(Z - \mathsf{t}(h_k)).$$

(i) At the level t replace $\mathfrak{w}_{h_t}$ by $\mathfrak{w}_t^{\mathrm{sf}}$: the difference $\mathfrak{w}_t^{\mathrm{sf}} - \mathfrak{w}_{h_t}$ is ≥ 0 at every point, of the mass $\int \mathfrak{w}_t^{\mathrm{sf}}\rho_0\,dU - \mathsf{t}(h_t) \le Z - \mathsf{t}(h_t) \le \mathsf{R}_t Z$; with the histories other than h_t this gives $|Z\langle\Psi\cdot\psi\circ\mathcal{M}^t\rangle - \int\Psi\,\psi(\mathcal{M}^t U)\,\mathfrak{w}_t^{\mathrm{sf}}\rho_0\,dU| \le 2\sup|\Psi|\sup|\psi|\mathsf{R}_t Z$, the factor 2 counting the two parts.

By the tower property, $\mathfrak{w}_t^{\mathrm{sf}} = (\mathbf{1}_{\mathrm{In}_t} \circ \mathcal{M}^t)\mathfrak{p}_t$ and $\mathrm{In}_t \subset \mathrm{Cut}_t$, $\int \psi(\mathcal{M}^t U)\,(Y - a_0)\,\mathfrak{w}_t^{\mathrm{sf}} \rho_0\, dU = \int_{\mathrm{In}_t} \psi\,(Q_{t\leftarrow 0} Y - a_0)\, d\nu_t$, of a modulus at most $\epsilon \int_{\mathrm{In}_t} |\psi|\, d\nu_t \le \epsilon \sup|\psi|\, Z$, since $\nu_t \ge 0$ and $\nu_t(\mathrm{In}_t) = \int \mathfrak{w}_t^{\mathrm{sf}} \rho_0\, dU \le Z$. Applied at $\Psi = Y - a_0$, for ψ and for 1, with $\langle Y; \psi \circ \mathcal{M}^t\rangle = \langle (Y - a_0)\,\psi \circ \mathcal{M}^t\rangle - \langle Y - a_0\rangle\langle \psi \circ \mathcal{M}^t\rangle$, this is the bound of (i). If $\mathsf{R}_t \le \frac{1}{2}$: $|Q_{t\leftarrow 0} Y| \le \sup|Y|$ ν_t-almost everywhere and $\nu_t(\mathrm{In}_t) \ge (1 - \mathsf{R}_t) Z > 0$, so In_t holds points at which $|a_0| \le |Q_{t\leftarrow 0} Y| + \epsilon \le \sup|Y| + \epsilon$. (ii) By the first display at the level T, where $Z - \mathsf{t}(h_T) = W_T Z$, the means $\langle F_1 F_2\rangle$, $\langle F_1\, \psi \circ \mathcal{M}^T\rangle$, $\langle F_1\rangle$, $\langle F_2\rangle$ and $\langle \psi \circ \mathcal{M}^T\rangle$ are the integrals against $Z^{-1}\mathsf{m}_T$ of the bounded densities of these functions at h_T, up to the weight W_T times their suprema, and $Z^{-1}\mathsf{m}_T(1) = 1 - W_T$.

The densities of F_1, F_2 and $F_1 F_2$ are $D_{T,1}$, $D_{T,2}$ and $D_{T,1} D_{T,2} + D_{T,12}$; the real part r_2 of $D_{T,2}$ is again a density of the real source F_2, two bounded densities of one function agree m_T-almost everywhere, and $r_2 = \psi + c$ there; so the density of $F_1 F_2$ is $D_{T,12} + D_{T,1}(\psi + c)$ almost everywhere, and subtracting, $\langle F_1; F_2\rangle - \langle F_1; \psi \circ \mathcal{M}^T\rangle$ is $Z^{-1} \int D_{T,12}\, d\mathsf{m}_T$, at most $C_2 e^{3 - \mathsf{D}_T/M} y_1 y_2$ by Lemma 8.7(e), plus two brackets of errors that together are at most $2 \sup|F_1| (\sup|F_2| + \sup|\psi| + |c|) W_T$. At $c = \operatorname{Re} c_2$: $|r_2 - c| \le |D_{T,2} - c_2| \le C_1 y_2$ on the small block fields of the level T, which carry m_T (Lemma 8.7(e)), and $|r_2| \le \sup|F_2|$ there.

Every member but $D_{T,12}$ is formed with F_1 linearly, and $D_{T,12}$ is additive in F_1. □

Lemma 8.16 (One entry against separated sources)**.** Let $0 < g \le \gamma$, $\ell \in \mathfrak{L}(g)$, $n \ge 1$, $\mathsf{d} > 0$, $0 < c_* < \frac{1}{2}$, and let $J = \sum_\iota \varkappa_\iota j_\iota$ be an entry of the order $m \ge 2$ (Lemma 8.11) of the type $(m, c, \hat{c}, N)$: at complex configurations with $|\mathbf{U}(b)| \le 2$ at all the bonds of its box, $|j_\iota| \le c\, r^m$ where the plaquette variables of the box are within $r \le 1$ of $\mathbf{1}$, and $|j_\iota| \le \hat{c}$ everywhere; and at most N indices have boxes with one lowest site. There are C, K_1, depending on g, ℓ, n, d, c_* and the type, such that for $K \ge K_1$, every label $\mathsf{b}' \in [\gamma^{-2}, X_g + \bar{B}]$ (so at every first-passage datum $(K, \beta) \in \mathfrak{D}(g)$, and at $\beta = L^K \mathsf{b}'$ for every $\mathsf{b}' \in I(g)$) and all real Lipschitz f_q, if the spread of the $n + 1$ sets formed by the carrier of J and the $\operatorname{supp} f_q$ is $\ge \mathsf{d}$, as it is when two of them are at sup distance $\ge \mathsf{d}$,

$$|\langle J; \mathcal{O}(f_1); \dots; \mathcal{O}(f_n)\rangle_{K,\ell,L^K \mathsf{b}'}| \le C |\varkappa|_\infty L^{-\mathsf{g}_m K} K^{(2n+1)\mathfrak{p}_0} L^{(\frac{1}{2} - c_*)K} \prod_q \|f_q\|_\sharp, \qquad \begin{array}{l} \mathsf{g}_2 = 1,\ \mathsf{g}_m \\ \qquad = \frac{3}{2}\ (m \ge 3). \end{array}$$

On all the sides at once: let besides $R > 0$ and $\ell' \in \mathfrak{L}(g)$ with $\ell' \ge 2R + 2\mathsf{d}$, and let the weights $\varkappa_\iota$ be real and the densities real on the G-valued configurations. There are C', K_1', depending on g, ℓ', n, d, R, c_* and the type, and on no side, such that for all $(K, \beta) \in \mathfrak{D}(g)$ with $K \ge K_1'$, every side $\ell \ge \ell'$ in $\mathfrak{L}(g)$, every entry of the type whose boxes lie in one sup ball of radius R, and all real Lipschitz f_q on $\mathbb{R}^3$ that vanish outside that ball, read on T_ℓ, with the carrier of the entry at sup distance $\ge \mathsf{d}$ from every $\operatorname{supp} f_q$ (the sources lie anywhere among themselves),

$$|\langle J; \mathcal{O}(f_1); \dots; \mathcal{O}(f_n)\rangle_{K,\ell,\beta}| \le C' |\varkappa|_\infty L^{-\mathsf{g}_m K} K^{1+\mathfrak{p}_0} L^{(\frac{1}{2} - c_*)K} \prod_q \|f_q\|_\sharp;$$

the same holds under every periodic Gibbs state at (K, β) and under every weak limit point of the torus laws as $\ell \to \infty$ in $\mathfrak{L}(g)$, and, with the further factor 2^{n+1}, for complex weights and complex Lipschitz f_q. ■

Proof sketch. Put $\phi = (\frac{1}{2} - c_*)/(3n + 4)$, $u = \lceil \phi K \rceil$, $t = K - u$. Since $M\, R(X_g + \bar{B}) \le L^m$ and R increases, the frame of Definition B.14 holds for the chain along $x_j = L^{K-j} \mathsf{b}'$ at every label of $[\gamma^{-2}, X_g + \bar{B}]$, and from a K_1 on t is a top level of it with $\mathsf{R}_t \le \frac{1}{2}$ and $8a \le \mathsf{d}$.

The cut. Let $D \ge \mathsf{d}$ be the spread. For every site y_0 of the carrier there is a source q with $\operatorname{dist}_\infty(y_0, \operatorname{supp} f_q) \ge \frac{1}{2} D$: otherwise there are points $y_q \in \operatorname{supp} f_q$ with $|y_0 - y_q|_\infty < \frac{1}{2} D$, and $y_0, y_1, \dots, y_n$ are pairwise closer than D, against the definition of the spread. Give each index ι of J the least such q for the lowest site of its box; this cuts J into at most n entries J_q of the same type, the carrier of J_q being at sup distance $\ge \frac{1}{2} D - 2a \ge \frac{1}{4}\mathsf{d}$ from $\operatorname{supp} f_q$, while the other sources lie

anywhere. The cumulant is linear in its first entry and symmetric in the others; in the cumulant of J_q the far source is f_q.

The chain with the entry and a complex source. The chain of Lemma 8.11(a) is formed with the entry sJ_q and with the source $w = \sum_q \zeta_q f_q$ at once, for $|s| < r_J$ and

$$\|w\|_\flat = \max\{\sup|w|, \frac{40}{\sqrt{3}} M \mathrm{Lip}_\infty w\} < 2\varrho$$

(the polydisc of the sources of Theorems YMM1:AJ and YMM1:AD): its families $E^{(i)}[w,s]$ are pointed families of the levels i, holomorphic in (w,s) and local, the member at a domain X reading w on the plaquettes of X alone, and s only if a box of the entry lies in X; with them $(\mathcal{M}^t)_*(\mathfrak{w}_t^{\mathrm{sf}} e^{sJ_q}\rho_0^w\, dU) = \exp[\sum_{i\le t} c_i(w,s)]\mathbf{1}_{\mathrm{In}_t} e^{\Phi_t^{w,s}}\, dV$, $\rho_0^w = \rho_0 e^{\mathcal{O}(w)}$, and on Cut_t

$$|\Phi_t^{w,s} - \Phi_t^{w,s'}| \le |s - s'|\, \mathsf{o}_t, \qquad |\Phi_t^{w,0} - \Phi_t^{0,0}| \le N_t \mathsf{C}_t \|w\|_\flat,$$

wherever the sources lie, with $N_t = \ell^3 L^{3u}$ the number of the sites of the level t and $\mathsf{C}_t \le C K^{2\mathfrak{p}_0}$. The entry enters each step as one more local term, as in Lemma 8.11(a); bounding the radius $\mathsf{e}_t^{\mathrm{c}} \le 1$ of the field cut, raised to the order of the entry, by $\mathsf{e}_t^{\mathrm{c}}$ itself, the size of the entry at the level t and what the steps made of it give $\mathsf{o}_t \le C K^{\mathfrak{p}_0} L^{4u - \mathfrak{g}_m K} |\varkappa|_\infty$.

The bound. Let $T(s,\zeta) = \int e^{sJ_q + \sum_{q'} \zeta_{q'} \mathcal{O}(f_{q'})}\, \mathfrak{w}_t^{\mathrm{sf}} \rho_0\, dU$. The cumulant under the positive measure $\mathfrak{w}_t^{\mathrm{sf}} \rho_0\, dU$ is $\partial_s \partial_{\zeta_1} \cdots \partial_{\zeta_n} \log T(0,0)$, and it differs from the cumulant under the measure of the torus by at most $4\, \mathrm{op}_{n+1} \mathsf{R}_t \sup|J_q| \prod_{q'} 6\ell^3 L^{4K} \sup|f_{q'}|$ (Proposition YMM1:115.2, its cumulant bound), which is smaller than every power of L^{-K}. By the identity of measures, $\partial_s \log T(0,\zeta) = \partial_s \mathsf{C}(0,\zeta) + \langle \partial_s \mathsf{D} \rangle_\zeta$, where $\mathsf{C}(s,\zeta) = \sum_{i\le t}(c_i(w,s) - c_i(w,0))$ collects the values of the families at the trivial triple, $\mathsf{D} = \Phi_t^{w,s} - \Phi_t^{w,0}$, and $\langle\cdot\rangle_\zeta$ is the mean under $e^{\Phi_t^{w,0} - \Phi_t^{0,0}}$ times the image of $\mathfrak{w}_t^{\mathrm{sf}} \rho_0\, dU$, normalised.

On the polydisc $|\zeta_{q'}| < (2nN_t \mathsf{C}_t \|f_{q'}\|_\sharp)^{-1}$ the exponent $\Phi_t^{w,0} - \Phi_t^{0,0}$ is at most $\frac12$, so $|\langle G\rangle_\zeta| \le 3.1 \sup|G|$, and the second member is at most $3.1\, \mathsf{o}_t$. In the first, a member at a domain that does not hold both a box of J_q and a plaquette of the far source f_q does not depend on ζ_q (locality), and has no mixed derivative; the members at the domains X of the levels i that hold both have $d_i(X) \ge (\frac14 \mathsf{d} - a) L^{K-i}/M - 2$, and with the count of the domains their sum is at most a power of L^K times $e^{-\mathsf{d} L^u/8M}$. Cauchy's estimates in the n sources on this polydisc cost $\prod_{q'}(nCK^{2\mathfrak{p}_0} L^{3u} \|f_{q'}\|_\sharp)$.

Together, $K^{(2n+1)\mathfrak{p}_0} L^{(3n+4)u - \mathfrak{g}_m K}$, and $(3n+4)u \le (\frac12 - c_*)K + 3n + 4$.

On all the sides. Let $\mathsf{l} = L^{-i}$ be the largest power of L with $\mathsf{l} \le \frac12 \mathsf{d}$; then $\ell' \ge 2R + 4\mathsf{l}$. On $T_{\ell'}$ and on every T_ℓ, $\ell \ge \ell'$, a board of side l puts the boxes of the entry and the supports of the sources, which lie in one sup ball of radius R inside one period box of side ℓ', in different cells. The cumulant on T_ℓ is a mixed derivative at 0 of a quotient whose coefficients are means on T_ℓ of products of functions of different cells of that period box; the chessboard bound (Lemma 8.9) bounds each by a product of chessboard seminorms on $T_{\ell'}$, at the price $e^{\mathsf{l}^3(p_{\ell'} - p_\ell)} \le e^{G_g \mathsf{l}^3}$ for a cell; this ratio $Z_{K,\ell',\beta}^{1/N'} / Z_{K,\ell,\beta}^{1/N_\ell}$ of the plain partition functions per cell, N' and N_ℓ being the numbers of the cells of $T_{\ell'}$ and of T_ℓ, is the one number that depends on ℓ, and its bound is free of ℓ.

After a subtraction of Wick type in the functions of the cells, which removes the cumulants of the families inside one cell, the chessboard seminorm of the function of the cell of the entry, the mean on $T_{\ell'}$ of the product of its mirror copies, is by the moment–cumulant formula a sum over the partitions of the copies all of whose blocks join different cells; each such cumulant is small by the bound on one torus, read at a free depth u with $C_{\mathrm{u}} K^{1/(2\mathfrak{p}_0)} \le u \le \frac12 K$, $C_{\mathrm{u}} \ge 1$ a number formed with the data and the type: a factor $|\varkappa|_\infty K^{1+\mathfrak{p}_0} L^{4u - \mathfrak{g}_m K}$ for each copy of the entry and a factor of Cauchy's estimate for each copy of a source.

The number of the cells that the ball of radius R meets, at most $(2R/\mathsf{l} + 3)^3$, enters C', and at $u = \lceil \frac14 (\frac12 - c_*) K \rceil$ the bound follows. Every periodic Gibbs state is dominated by the torus measures

through its conditional laws (Proposition YMM1:91.9), and the weak limit points of the torus laws inherit the bound; for complex data the real and imaginary parts are taken apart. □

Lemma 8.17 (The cubic remainder uniformly in the side)**.** Let $0 < g \le \gamma$, $\ell' \in \mathfrak{L}(g)$, $n \ge 2$, $\mathsf{d} > 0$, $c < \frac{1}{14}$, and let Q be a cube of side $\frac{1}{4}\ell'$. There are C, p, K_0, depending on $g, \ell', n, \mathsf{d}, c$ and independent of the larger side ℓ, such that for all $\ell \ge \ell'$ in $\mathfrak{L}(g)$, all $(K,\beta) \in \mathfrak{D}(g)$ with $K \ge K_0$, all Lipschitz fields η and real Lipschitz f_q carried by Q with the supports of the f_q pairwise $\ge \mathsf{d}$ apart,

$$|\mathfrak{U}^\sharp[\eta](f)_{T_\ell}| + |\mathfrak{U}^\sharp[\eta](f)_{T_\ell} - \mathfrak{U}^\sharp[\eta](f)_{T_{\ell'}}| \le C K^p L^{-cK} \mathsf{H}(\eta) \prod_q \|f_q\|_\sharp;$$

the finitely many sides of $\mathfrak{L}(g)$ below ℓ' are covered by Lemma 8.12. ■

Proof sketch. Every label of $\mathfrak{D}(g)$ lies in $[\gamma^{-2}, X_g + \bar{B}]$, and $MR(X_g + \bar{B}) \le L^m$ on every side of $\mathfrak{L}(g)$; so the frame of Definition B.14 holds for the chain along $x_j = L^{K-j}\mathsf{b}$ at the label of every first-passage datum, and Lemma 8.11(b) holds with one triple of numbers for all of them, also with real sources $\sum_i x_i f_i$ in its polydisc. The chain is formed with several entries and complex sources as well, as in the proof of Lemma 8.16 (Lemma 8.11(a), polarisation and locality in each entry).

The reduction. With $\mathcal{S}[\Xi] = a^{-2}\sum_p \Xi^{\lambda(p)}(x(p))\,\mathfrak{r}^\sharp_{\lambda(p)}(p)$ for a field Ξ we have $\beta\mathfrak{K}^\sharp[\eta] = \mathcal{S}[\mathsf{b}\eta]$ and $a^{-1}\mathfrak{K}^\sharp[f_i\eta] = \mathcal{S}[f_i\eta]$, so $\mathfrak{U}^\sharp[\eta](f) = -\langle \mathcal{S}[\mathsf{b}\eta]; \mathcal{O}(f_1); \dots; \mathcal{O}(f_n)\rangle + \sum_i \langle \mathcal{S}[f_i\eta]; (\mathcal{O}(f_l))_{l\ne i}\rangle$, with $\mathsf{H}(\mathsf{b}\eta) \le (X_g + \bar{B})\mathsf{H}(\eta)$ and $\mathsf{H}(f_i\eta) \le 2\|f_i\|_\sharp \mathsf{H}(\eta)$. It suffices therefore to compare $G_\ell = \langle \mathcal{S}[\Xi]; \mathcal{O}(h_1); \dots; \mathcal{O}(h_{n'})\rangle_{K,\ell,\beta}$ with $G_{\ell'}$, $n' \in \{n-1, n\}$, $n' \ge 1$, for Lipschitz fields Ξ and real Lipschitz h_q carried by Q whose supports are pairwise $\ge \mathsf{d}$ apart, nothing being asked of Ξ relative to them.

The fold with one factor for each copy. Place Q in the middle of one cell of the board of side $\mathsf{l} = \frac{1}{2}\ell'$; it lies at sup distance $\ge \frac{1}{8}\ell' \ge 1$ from the walls. On every T_ℓ, $\ell \ge \ell'$, $\mathcal{S}[\Xi]$ and the $\mathcal{O}(h_q)$ are the realisations of one model function each, and their mirror copies in the eight cells of $T_{\ell'}$ are again a cubic entry $\mathcal{S}[\Xi^\kappa]$, $\mathsf{H}(\Xi^\kappa) \le \mathsf{H}(\Xi)$, and sources $\mathcal{O}(h_{(q,\kappa)})$ with $\|h_{(q,\kappa)}\|_\sharp = \|h_q\|_\sharp$; copies in different cells are ≥ 1 apart. The chessboard bound (Lemma 8.9) carries the cumulant on T_ℓ to the mean on $T_{\ell'}$ of the product of the eight mirror copies, at the price $e^{G_g \mathsf{l}^3}$ for each function, and by the moment–cumulant formula of the copies (an identity of formal power series, as in the proof of Theorem AD(g)(ii)) the difference $G_\ell - G_{\ell'}$ reads the joint cumulants on $T_{\ell'}$ of the families B of copies that join different cells alone, the families inside one cell entering nowhere. If each of these is at most $\Gamma \prod_{(i,\kappa)\in B} \omega_i$, where $\Gamma \ge 1$, with one factor ω_0 for each copy of the entry and one factor ω_q for each copy of the source h_q, then

$$|G_\ell - G_{\ell'}| \le \mathsf{c}_{n'}\, e^{(n'+1)G_g\mathsf{l}^3}\, \Gamma^{(n'+1)/2} \prod_{i=0}^{n'} \omega_i,$$

To see the exponent, use the within-cell normalization and logarithm identities of Lemma 7.26. In a fold of q entries, every remaining block joins cells and has at least two members; a partition of the $8q$ copies has at most $4q$ such blocks. Its bound is at most $\Gamma^{4q}\prod_i \omega_i^8$, and the eighth root gives $\Gamma^{q/2}\prod_i \omega_i$. The subsequent logarithm partitions preserve this exponent, since their subset sizes sum to $q = n' + 1$. This proves the display, including the stated pressure factor. Here $\mathsf{c}_{n'}$ is a pure number. With $u = \lceil \phi K \rceil$, $t = K - u$, the factors $\omega_0 = K^p L^{-c_1 K}\mathsf{H}(\Xi)$ and $\omega_q = K^{2\mathfrak{p}_0} L^{3u}\|h_q\|_\sharp$ serve, in three cases. (i) No copy of the entry: the family holds two copies of sources in different cells, ≥ 1 apart, and the bound (27) on $T_{\ell'}$ at separated supports applies. (ii) One copy $\mathcal{S}[\Xi^\kappa]$: moving the weight of the entry with the sources writes the cumulant as $-\mathfrak{U}^\sharp[\Xi^\kappa/\mathsf{b}](h)$ plus, when two or more sources are present, the cubic remainders $-\mathfrak{U}^\sharp[h_\alpha \Xi^\kappa/\mathsf{b}^2]((h_{\alpha'})_{\alpha'\ne\alpha})$ (the supports of the h's being disjoint), and with one source the contact member is a mean of $\mathfrak{K}^\sharp$, which vanishes; a source of another cell is ≥ 1 from the entry, and $h_\alpha \Xi^\kappa$ is carried by $\operatorname{supp} h_\alpha$, at sup distance $\ge \min\{\mathsf{d}, 1\}$ from the other supports: the spread condition holds, and Lemma 8.12 on $T_{\ell'}$ at the rate c_1 applies. (iii)

Two to eight copies of the entry, in different cells, the sources anywhere: the cumulant is a mixed derivative of the logarithm of the generating function of the chain with these entries and the complex source $w_\zeta = \sum \zeta_\alpha h_\alpha$, at the level t. For case (iii), retain the higher mixed jets as in the proof of Proposition 3.15(b). Proposition 3.13(v) permits the fixed complex source w and the several insertion parameters $\mathbf{s}$ together. Write their small-field generating function as $T_w(\mathbf{s}) = T_w(0) e^{\mathsf{C}_w(\mathbf{s})} \langle e^{\mathsf{D}_{w,\mathbf{s}}} \rangle_w$, with the normalized block-field functional $\langle \cdot \rangle_w$. For q copies of the entry and I with $|I| \geq 2$, locality and the Cauchy estimate in that proof give $\max\{|\partial_I \mathsf{C}_w(0)|, \sup |\partial_I \mathsf{D}_{w,\mathbf{s}}|_{\mathbf{s}=0}\} \leq 2E_0 \mathsf{t}'_\times \prod_{a\in I} (q/r_a)$, where r_a are the insertion radii and $\mathsf{t}'_\times$ is the polymer sum of that proposition. Copies of the entry lie in distinct cells with a fixed positive margin. Their inverse radii are at most $CL^{2K} \mathsf{H}(\Xi^a)$, whereas $\mathsf{t}'_\times \leq CK^p L^{AK} e^{-cL^u}$. Hence the mixed-jet bound is below $\prod_{a\in I} \epsilon_a$ for large K, uniformly on a fixed fraction of the displayed, K-dependent source polydisc. Zero entries are omitted. At real sources the block-field functional is positive; at complex sources it has norm at most 3.1 on the smaller polydisc, by the exponent bound in the proof of Lemma 8.16. The moment and logarithm partition formulas in Proposition 3.15(b) therefore apply in both cases, with finite constants adjusted in the complex case. At a real source x in the polydisc of the radii $(CK^{2\mathfrak{p}_0} L^{3u} \|h_\alpha\|_\sharp)^{-1}$, Lemma 8.11(b), applied to the field $\Xi^\kappa/(\mathsf{b} - w_x)$, makes the conditional mean of each copy given the block field of the level t a number up to $\epsilon_a = C\mathsf{H}(\Xi) K^{p_2} L^{-c'_0 K}$. Subtracting these constants from the first jets, and using the higher mixed-jet bound above, the same partition formulas bound the cumulant by a constant times $\prod_a \epsilon_a$. At a complex source, the norm bound for the normalized functional and the mixed-jet estimate instead give a constant times the product of the crude bounds $\hat{\mathsf{o}}_a = C\mathsf{H}(\Xi) K^{\mathfrak{p}_0} L^{4u+\frac{1}{2}K}$ of the oscillations of the cubic entries, of the order 3 and of the weight a^{-2}. The estimate with two constants for a function holomorphic on a polydisc of the radii r_α, bounded by B there and by ϵ at its real points, $|\partial_{\zeta_1} \cdots \partial_{\zeta_{n''}}(0)| \leq \epsilon^{1-\sigma} B^\sigma (\frac{4n''}{\pi\sigma})^{n''} \prod_\alpha r_\alpha^{-1}$, gives one factor $\epsilon_a^{1-\sigma} \hat{\mathsf{o}}_a^\sigma \leq C\mathsf{H}(\Xi) K^p L^{-c_1 K}$ for each copy of the entry, $c_1 = (1-\sigma)c'_0 - \sigma(\frac{1}{2} + 4\phi)$.

In all three cases the histories with a large field up to the level t cost on $T_{\ell'}$ less than every power of L^{-K}. With $\delta = \frac{1}{14} - c$, $\tau = \delta$, $\phi = \delta/(12(n+1))$ and $\sigma = \frac{1}{4}\delta$ one has $c_1 - 3n\phi > c$, and the product $\omega_0 \prod_q \omega_q$ gives the bound of the difference with the rate c and with numbers independent of the larger side ℓ; on $T_{\ell'}$ itself the bound is Lemma 8.12. □

Lemma 8.18 (The flow with an insertion)**.** Let $\ell = 2L^m$ be any side, $0 < \mathsf{b}_- \leq \mathsf{b} \leq \mathsf{b}_+$, $\beta = L^K \mathsf{b}$, $n \geq 1$, $\mathsf{d} > 0$ and f_i real Lipschitz; let $S_\varkappa = \sum_l \varkappa(l)\, \mathrm{dn}_l$ be an insertion of brick densities dn_l (gauge invariant polynomials on boxes of at most five sites along each axis, each holding a plaquette, vanishing at $\mathbf{1}$) of the order r, and let two of the $n+1$ sets formed by the carrier of $S_\varkappa$ and the $\operatorname{supp} f_i$ be at sup distance $\geq \mathsf{d}$, the others in any position. For γ small enough in terms of the other constants there are C, p, K_0, depending on $\ell, \mathsf{b}_\pm, n, \mathsf{d}$ and the type, such that for $K \geq K_0$:

(a) if $r \geq 3$ and $|\varkappa|_\infty \leq \beta h$: $|\langle S_\varkappa; \mathcal{O}(f.)\rangle| \leq CK^p L^{-\lambda_L K/4} h \prod_i \|f_i\|_\sharp$; no norm of $\varkappa$ but its supremum enters;

(b) if $r = 2$, $0 \leq \sigma \leq 1$, $|\varkappa|_\infty \leq L^{\sigma K} h$ and $0 < \epsilon \leq 1$: $|\langle S_\varkappa; \mathcal{O}(f.)\rangle| \leq C_\epsilon K^p L^{-(1-\sigma-\epsilon)K} h \prod_i \|f_i\|_\sharp$; in particular $|\langle \mathcal{O}(w); \mathcal{O}(f.)\rangle| \leq C_\epsilon a^{-\epsilon} \max|w| \prod_i \|f_i\|_\sharp$ for every real weight w, in contact with the f_i or not;

(c) if $r = 2$, the insertion is real with $|\varkappa|_\infty \leq \beta h$, and its densities are of derivative kind, that is, $|G_\nu(b)|^2$ or $\Psi_{\lambda(p)}(p)$: $|\langle S_\varkappa; \mathcal{O}(f.)\rangle| \leq CK^p L^{-c_n K} h \prod_i \|f_i\|_\sharp$, $c_n = \lambda_L/(4(6+3n))$; for every $0 < \theta_1 < 1$ and every real insertion of the order 2 with $|\varkappa|_\infty \leq \beta h$, $\langle S_\varkappa - J_{t_1}; \mathcal{O}(f.)\rangle$ obeys the same bound with $L^{-\lambda_L \theta_1 K/4}$, the numbers C, p, K_0 depending besides on θ_1, where $t_1 = K - \lceil \theta_1 K \rceil$ and J_{t_1} is the classical value of the insertion at the background of the level t_1, a function of the block field.

■

Proof sketch. Run the chain with the insertion, as in Lemma 8.11(a), down to a level t at which the large fields are rare. A transfer inequality bounds the cumulant by

$$2\delta_t(\varkappa)\prod_i(8nM_t\|f_i\|_\sharp)+\mathrm{Con}_t+4\,\mathrm{op}_{n+1}\mathsf{R}_t\sup|S_\varkappa|\prod_i(6\ell^3L^{4K}\sup|f_i|),$$

with δ_t the oscillation of the conditional mean of the insertion given the block field of the level t, M_t the inverse radius of the sources at that level, and Con_t the mixed derivative of the constants of the chain, which is small by locality when a pair of sets is separated (when the separated pair is the insertion and one source, the constants of the sources that meet the insertion are handled by a slow cut-off at the scale d, at the price $(2+480M/\mathsf{d})^{n-1}$). By power counting an insertion of the order r has the size $|\varkappa|_\infty L^{(3-2r)i}$ at the level i, and what the steps make of it is forgotten at the rate $L^{-\lambda_L/2}$ per level, $(L/2)^{-x}=L^{-\lambda_L x}$; this gives (a) and (b).

For (c) two levels are used. Let $0<\theta_1<1$, $\tau_1=\lceil\theta_1K\rceil$, $t_1=K-\tau_1$, and $t=K-\tau$, $\tau=\lceil\theta K\rceil$, $\theta=\lambda_L\theta_1/(4(7+3n))<\theta_1$. The insertion is put into the chain only up to the level t_1, as early members; there it equals its classical value J_{t_1} on the background of the level t_1 plus what the steps up to t_1 made of it, which in level-t_1 terms has the size $C|\varkappa|_\infty L^{-(t_1-1)}L^{-\lambda_L\tau_1/2}$ (what a step makes of an insertion of the order 2 is forgotten at the rate $L^{-\lambda_L/2}$ per level). From the level t_1 to the level t this part is forgotten by the factor $L^{-(t-t_1)}$ of the run, on the field cut of the level t; at the level t the histories with a large field are discarded, at a cost below every power of L^{-K}, and the volume $N_t=\ell^3L^{3\tau}$ and Cauchy's estimates in the n sources cost $L^{3(n+1)\tau}$ up to powers of K; the mixed derivatives of the constants of the chain in the sources are small by locality, two of the sets being separated.

The derivative in the insertion is taken as a difference quotient at a small step s, its second derivative being bounded crudely. Together the exponent is $(7+3n)\tau+1-\frac12\lambda_L\tau_1\le-\frac14\lambda_L\theta_1K+8+3n$: this is the second clause of (c), for every θ_1. For the first clause the classical part is bounded besides: J_{t_1} is a function of the block field of the level t_1, its cumulant with the sources is bounded by Cauchy's estimates in the sources at that level, at the price $L^{3n\tau_1}$, times its supremum, and for densities of derivative kind the supremum is at most $\beta\ell^3L^{3K}\,C\varepsilon_{t_1}^2(1+K\log L)^2L^{-6t_1}$ by the estimate below; the exponent is $K+3K-6(K-\tau_1)+3n\tau_1=-2K+(6+3n)\tau_1$, which at $\theta_1=1/(6+3n)$ is at most $-K+6+3n$.

With the second clause at this θ_1 the rate is $\min\{1,\frac14\lambda_L\theta_1\}=c_n$. For a lattice field B on a box of radius R with $|B|\le A_0$ and $|\mathrm{div}^+B|,|\mathrm{curl}^-B|\le\epsilon_1$, the div–curl estimate $|\partial_j^\pm B_i|\le C_*[A_0/R+\epsilon_1(1+\log R)]$ on the quarter box, applied with the Bianchi identity on a cube, gives $|G_\nu(b)|^2,|\Psi_{\lambda(p)}(p)|\le C\varepsilon_i^2\eta_i^6(1+i\log L)^2$ at the regular backgrounds of the level i, $\eta_i=L^{-i}$, which is the order that (c) needs. □

Proposition 8.19 (The mean plaquette)**.** Let $0<g\le\gamma$, $\ell\in\mathfrak{L}(g)$, $n\ge1$, and $E(\beta)=\langle a_p\rangle$ on a periodic lattice of N_s sites along each axis (it does not depend on p).

(a) For every $R\ge3$, $N_s\ge R$ and β with $116R^3(\beta/2)^{-1/2}\le\frac15$ and $\bar\eta(R,\beta)\le\frac14$, $|\beta E(\beta)-1|\le2\bar\eta(R,\beta)^{1/2}$, with $\bar\eta(R,\beta)\le\frac{9\log(2\beta)+55}{R^3}+\frac{18\log(1+256R^3)+15}{R}+1.21\cdot10^9R^9\beta^{-1/2}$: at $R=\lceil\log\beta\rceil$ this tends to 0 uniformly in all volumes $N_s\ge\log\beta$.

(b) On the side ℓ, with $N_s=\ell L^K$: there are C,K_0, depending on g,ℓ,n, such that $\sup_{\mathsf{b}'\in I(g)}|\beta^nE^{(n-1)}(\beta)-(-1)^{n-1}(n-1)!|\le CK^{2n+3}L^{-K/20}$ for $\beta=L^K\mathsf{b}'$ and $K\ge K_0$.

(c) For all real Lipschitz $f_1,\dots,f_n$ on T_ℓ, with nothing asked of the supports, $|a_K^3S^T_{n;K,\ell,L^K\mathsf{b}'}(f)-3(n-1)!\,\mathsf{b}'^{-n}\int_{T_\ell}\prod_i f_i|\le CK^{2n+3}L^{-K/20}\prod_i\max\{\sup|f_i|,\frac{40}{\sqrt3}M\mathrm{Lip}_\infty f_i\}$.

■

Proof sketch. (a) Cut the lattice into blocks of R to $2R$ sites along each axis, and in each block take a comb tree. Bounding the partition function with plaquette weights $\beta_p\in[\beta_-,\beta_+]$ from above (dropping a few plaquettes) and from below (freezing a few bonds), both bounds become the same

Gaussian integral, $\sum_B (2|B|-2)\log \mathsf{g}(\beta_B) - \mathsf{D}$ with $\mathsf{g}(\beta) = (2/\pi)^{1/2}\beta^{-3/2}$ and a number D of the geometry, up to an error $N\eta$ that is small per site; this uses weak coupling on blocks of $R \le \beta^{1/20}$ spacings alone. The convexity of $\log Z$ in β then pins down its first derivative. (b) For the higher derivatives analyticity in β is needed.

On a torus of a fixed physical side, Theorems YMM1:AJ and YMM1:AD write $Z[\zeta f] = \exp(E + \sum_{j,X} e_j(X;\zeta f))\widetilde{Z}(\zeta f)$ for real f with $\max\{\sup|f|, \frac{40}{\sqrt{3}} M \mathrm{Lip}_\infty f\} \le 1$, with $|e_j(X;w)| \le C_{\mathrm{S}} e^{-\kappa d_j(X)}$, $|\widetilde{Z}| \le e^{C_{\mathrm{S}}\ell^3}$ and $\widetilde{Z}(0) \ge e^{-C_g\ell^3}$; the factor $\widetilde{Z}$ may vanish. Put $N = (\ell L^K)^3$, $h_f(\zeta) = \widetilde{Z}(\zeta f)/\widetilde{Z}(0)$ and $D_f(\zeta) = (3N)^{-1}[\sum_{j,X} e_j(X;\zeta f) + \sum_p \log(1 - \zeta f(x(p))/\mathsf{b}')]$, the per-site exponent; by the count of polymers $|D_f| \le M_0$ on a disc $|\zeta| < \rho_1$, with M_0 and ρ_1 free of K. Then $h_f(0) = 1$, $h_f > 0$ on the real axis and $|h_f| \le e^{\Gamma}$ with $\Gamma = (C_{\mathrm{S}} + C_g)\ell^3$, a number free of K.

First, Cauchy's estimate on circles of radius $\frac{1}{2}\rho_1$ gives $|h_f - 1| \le \frac{1}{2}$ on $|\zeta| \le \frac{1}{4}\rho_1 e^{-\Gamma}$, so that $\log h_f$ is defined there and $|(\log h_f)^{(n)}(0)| \le n!\,(4e^{\Gamma}/\rho_1)^n$: this member does not grow with the cutoff, and it is of the order $1/N$ per site. Second, the Poisson–Jensen formula and Harnack's inequality, applied to the non-negative function $\Gamma - \log|h_f|$, give $\int_{-\rho_1/2}^{\rho_1/2} |\log|h_f(x)||\,dx \le 9\rho_1\Gamma$; with this, the two-sided real-axis bound of (a), at the plaquette weights $\beta(1 - xf(x(p))/\mathsf{b}')$, controls the per-site exponent in L^1 on the segment: $\int_{-\rho_1/2}^{\rho_1/2} |D_f(x)|\,dx \le \rho_1\delta$ with $\delta = \frac{1}{3}(2\bar{\eta}(R,\beta) + Ra_K + R^{-3}) + 3(C_{\mathrm{S}} + C_g)L^{-3K}$.

Third, A. Markov's inequality for the derivatives of the Taylor polynomial of D_f of the order $\mathsf{m} = \max\{n, \lceil \log_2(M_0/\delta)\rceil\}$, with Cauchy's estimate for the rest of the series, gives $|D_f^{(n)}(0)| \le 4\,(2/\rho_1)^n \mathsf{m}^{2n}(\mathsf{m}+1)^2\delta$, and at $R = \lfloor \beta^{1/20} \rfloor$ this is the rate. By Jensen's formula h_f has at most $\Gamma/\log 2$ zeros in $|\zeta| < \frac{1}{2}\rho_1$, a number that does not grow with the cutoff; the bound on $(\log h_f)^{(n)}(0)$ above does not need it. At $f \equiv 1$, where $S_n^T(1,\dots,1) = a_K^{-n}(-1)^{n-1}3N\,E^{(n-1)}(\beta)$, the identity of (c) below gives (b). (c) is the same argument at a general f: $S_n^T(f,\dots,f) = (n-1)!\mathsf{b}'^{-n}\sum_p f(x(p))^n + 3N D_f^{(n)}(0) + (\log h_f)^{(n)}(0)$, with the per-site exponent D_f and the factor h_f of Theorems YMM1:AJ and YMM1:AD; polarisation gives distinct entries. □

Use the separated regions and the actual averaging constraints of Proposition Q.10, with its block-number and small-triple hypotheses in addition to the width condition below. Require also the geometric and regularity hypotheses of Theorem YMM1:I and Proposition YMM1:29.1, with their block-number, torus-size and gap floors. The matrix-valued plaquette-divergence bound in that theorem follows from the regular curvature and current bounds by equation YMM1:(579), with a factor 2 absorbed in the regularity ceiling. These are numerical floors and small-radius conditions on the data, not assumptions about the inverse estimate to be proved. Also retain the four local-system radii at most a_H, the block floor $\mathfrak{M} \ge M_H$, and the permitted decay rate of Lemma Q.7. Write $\xi = \eta_k$ and $\ell_n = \xi L^n$ for the physical layer scale. For clarity distinguish D_0, the covariant differential from sites to bonds, from D_1, the covariant differential from bonds to plaquettes. Let U be a real background, critical for the unweighted action on the kernel of the averaging constraint, regular at radius $\alpha \le \alpha_{\mathrm{lin}}(L) \le (16L^2)^{-1}$, with curvature bounded by the envelope $e(x) = \varepsilon_{j(x)}$ in the scaled norm below, and $\sup e \le e_0(L)$. The layer radii satisfy $0 < \varepsilon_j \le \varepsilon_{j+1} \le L\varepsilon_j$. Require $R_1\mathfrak{M} \ge w_{\mathrm{lin}}(L)$.

At each bare site x_* of layer $n \ge 2$, fix a real adjoint gauge g_{x_*} on the cube of physical sup radius $\ell_n/4$ such that

$$|g_{x_*}(b_-)\,\mathrm{Ad}\,U(b)g_{x_*}(b_+)^{-1} - I| \le L^2\alpha/L^n.$$

The gauge hypotheses are part of the setting. All Hölder quotients below compare components of the same orientation in these gauges. The cube for a potential is the concentric cube of radius $\ell_n/8 - 2\xi$; those for a curvature and a source two-form have radius $\ell_n/4$. Quotients are taken over distinct admissible base points in the indicated cube, with the usual physical Euclidean distance.

We use the following scaled spaces. For a field of inverse length degree r, put

$$|f|_{r,h} = \sup_i \frac{\ell(i)^r |f(i)|}{h(x_i)}, \qquad [f]_{r,1/2,h} = \sup_{n\ge 2, x_*} \frac{\ell_n^{r+1/2}}{h(x_*)} [g_{x_*} f]_{1/2;C(x_*)}.$$

For an index i, let $\ell(i)$ be the largest layer scale of the sites in the stencil defining that field value or first difference. For a row use its prescribed scale ξ_c. The envelope is read at the indicated base point x_i. This fixes the norm convention also for indices meeting a layer boundary. The adjacent-layer comparison of Lemma YMM1:21.2 makes it equivalent, with constants depending only on L, to the base-point scale convention. Set $\|f\|_{r,1/2,h} = |f|_{r,h} + [f]_{r,1/2,h}$. For the first two layers only the supremum term is required; their ratios $\ell_n/\xi \le L$ are uniformly bounded. The curvature hypothesis above means $\|F_U\|_{2,1/2,e} \le 1$.

The row units are dimensionless. If Q_{ph} is the physical averaging derivative with row pairing of weight ξ_c^3, put

$$QA(c) = \xi_c Q_{\mathrm{ph}} A(c), \qquad \omega(c) = \xi_c^3 \omega_{\mathrm{ph}}(c).$$

Use the row pairing of weight ξ_c^{-1} for Q^{T}. Then $Q^{\mathsf{T}}\omega = Q_{\mathrm{ph}}^{\mathsf{T}}\omega_{\mathrm{ph}}$, since both pairings with A are $\sum_c \frac{1}{2}\operatorname{tr}(Q_{\mathrm{ph}} A(c)\omega(c))$. This conversion changes units only; it retains the same row set and averaging germ. Row data b and multipliers have degree zero.

Let $h = e\theta$, where $\theta > 0$ and $|\log\theta(x) - \log\theta(x')| \le c_U d(x,x')$. Choose c_U at most one eighth of each decay rate used below and at most $1/(6L)$. Thus, for fixed constants $C_h = C_h(L)$ and $0 < \nu \le \delta_2/2$,

$$h(z)/h(y) \le C_h e^{\nu d(y,z)}. \tag{32}$$

Take the same condition on the local comparison cubes. Define

$$\|(A,\omega)\|_{\mathcal{X}_h} = \|A\|_{1,1/2,h} + \|D_1 A\|_{2,1/2,h} + |D_0^{\mathsf{T}} A|_{2,h} + |\omega|_{0,h},$$
$$\|(Y,f,b)\|_{\mathcal{F}_h} = \|Y\|_{2,1/2,h} + |f|_{3,h} + |b|_{0,h}.$$

The ordinary and divergence sources are read only through $f + D_1^{\mathsf{T}} Y$. For a complex anisotropy an, its size $t(\mathrm{an})$ is its supremum plus the scaled Hölder-1/2 seminorm on the same plaquette cubes.

Lemma 8.20 (Linear response at a variable anisotropy)**.** There are positive numbers $w_{\mathrm{lin}}, \alpha_{\mathrm{lin}}, e_0$, $t_{\mathrm{lin}}, K_{\mathrm{lin}}$, depending only on L, such that the following holds in the setting above. If $t(\mathrm{an}) \le t_{\mathrm{lin}} \le 1/4$, the system

$$QA = b, \qquad T_\tau A = f + D_1^{\mathsf{T}} Y + Q^{\mathsf{T}}\omega, \qquad \tau = 1 + \mathrm{an}, \tag{33}$$

has a unique solution, linear in the data, with

$$\|(A,\omega)\|_{\mathcal{X}_h} \le K_{\mathrm{lin}} \|(Y,f,b)\|_{\mathcal{F}_h}. \tag{34}$$

Here $T_\tau = D_1^{\mathsf{T}} \tau c D_1 + V_0' + D_0 R D_0^{\mathsf{T}}$ is the second variation of the weighted action at the reference field, with the slice term. The coefficient c_p is determined by $\partial U(p) = c_p I + i\xi^2 F_U(p)$, and V_0' contains the curvature commutator terms of that second variation. The nonlinear block-constraint remainder and its multiplier are kept in the forcing when the lemma is applied to the nonlinear equation. The row and slice conventions are those of the setting. All constants are uniform in the volume, the number of layers and the permitted envelopes. For the mean-scheme rows of a label, rotated into the comb frame, the same estimate holds with $2K_{\mathrm{lin}}$. ∎

Proof of the linear estimate. We first treat the unweighted operator. The block constraint must be retained in this argument: the inverse of the gauge-fixed operator without the constraint is not the required Green operator. Put

$$T = T_\tau|_{\mathrm{an}=0}, \qquad G = (T + Q^{\mathsf{T}}Q)^{-1}, \qquad M = QGQ^{\mathsf{T}},$$

and define

$$H = GQ^{\mathsf{T}} M^{-1}, \qquad \widetilde{G} = G - HQG. \tag{35}$$

Thus $QH = 1$, $Q\widetilde{G} = 0$ and $\widetilde{G}T = 1 - HQ$. The rows are the interior and outward determining bonds; inward bonds are discarded, so there are no edge rows. On a row of level j, the derivative of the iterated comb average is

$$QA(c) = \xi\,(\mathbf{Q}(W_{j-1})\cdots\mathbf{Q}(W_0)A)(c).$$

The factors read only the double block beneath that row. Separation keeps these blocks inside the domains on which the averages are defined. The row conversion above therefore identifies this Q with the physical averaging derivative in the regular constrained system, without changing the set of constraints.

The regular current bound supplies the matrix-divergence hypothesis used for that system. Indeed, at a full bond the quaternion decomposition gives

$$D_U^{\mathsf{T}}\partial U = aI + i\xi^2 J(U), \qquad |a| \le \xi^{-1}\max_{p\ni b}|\partial U(p) - I|^2.$$

Since the adjacent plaquette scale is at least the bond scale and the latter is at least ξ, the regularity bounds give $|D_U^{\mathsf{T}}\partial U| \le 2\alpha\xi^2\ell(b)^{-3}$. This is equation YMM1:(579); our choice $2\alpha_{\mathrm{lin}} \le a_Q$ permits the application below.

Here are the unweighted bounds that will be used. Write $|f|_{(r)} = \sup_i \ell(i)^r|f(i)|$ and $\|A\|_X = \max\{|A|_{(1)}, |\nabla A|_{(2)}\}$. For sufficiently small regularity radius, there are $K_1, K_7 \ge 1$, depending only on L, such that

$$\begin{gathered}\|\widetilde{G}f\|_X \le K_7|f|_{(3)}, \qquad \|Hb\|_X \le K_1\sup|b|, \qquad \sup|H^{\mathsf{T}}f| \le K_1|f|_{(3)},\\ \sup|(D_1H)^{\mathsf{T}}Y| \le 3K_1|Y|_{(2)}, \qquad \sup|(D_0^{\mathsf{T}}H)^{\mathsf{T}}\lambda| \le 3K_1|\lambda|_{(2)}, \qquad |R\lambda|_{(2)} \le (1+K_1^3)|\lambda|_{(2)}.\end{gathered} \tag{36}$$

These estimates are unchanged by passing to the units of any layer. The averaging rows are dimensionless, their pairing has weight $\ell(c)^{-1}$, and their transposes are taken for that pairing. They are precisely the bounds of Proposition YMM1:29.1, applied after the row identification just made. Its proof also records their exponential versions. For the transpose estimates, test against a datum supported at one row c. The row pairing contributes a factor $\ell(c)$, while the number of bonds or plaquettes in a cell of scale ℓ_y is at most $3(\ell_y/\xi)^3$. The resulting kernel sum has factor $\ell(c)/\ell_y$, which is absorbed by the exponential decay. The same calculation with the first differences gives the fourth and fifth estimates, including the zero-extension terms at the boundary. These are equations YMM1:(459) and the following divergence estimate. The scalar estimate follows from $R = 1 - G'Q'^{\mathsf{T}}(Q'G'^2Q'^{\mathsf{T}})^{-1}Q'G'$. At a bond meeting the complement of the ambient region, the zero-extension difference has local scale ξ and is bounded by $|A|_{(1)}$. Thus these estimates also include boundary differences. For an empty ambient region all spaces are zero. The operators preserve real fields, so the estimates extend to complex fields by their real and imaginary parts, with constants enlarged by a fixed factor.

The same operators have exponential decay in the weighted distance. Their first-difference Hölder estimates follow from the ordinary kernel estimates in Lemma Q.7. Multiplying the input at z and output at y by the envelope ratio costs $h(z)/h(y)$. The permitted growth of this ratio consumes only part of the exponential decay. The remaining kernel is summable by Lemma YMM1:21.2. This gives the envelope versions of (36), with constants independent of the torus and the number of layers.

For $q = f + D_1^{\mathsf{T}}Y$, elimination of the multiplier in $TA = q + Q^{\mathsf{T}}\omega$, $QA = b$, gives the exact formulas

$$A = \widetilde{G}q + Hb, \qquad \omega = H^{\mathsf{T}}(THb - q). \tag{37}$$

Indeed $(T + Q^{\mathsf{T}}Q)A = q + Q^{\mathsf{T}}(\omega + b)$, and applying QG determines $\omega + b$. The identity $M^{-1} = H^{\mathsf{T}}TH + 1$ gives the displayed formula for ω. The six bounds control the ordinary forcing, the lift, and all multiplier terms. The remaining issue is the first-slot divergence $D_1^{\mathsf{T}}Y$.

Cover each layer of index at least two by cubes of size comparable to its layer scale. In the local gauges, write $U = e^{i\xi a}$, with a and its first differences bounded in the units of that layer. A partition

of unity reduces the divergence source to the flat equation on these cubes. Convolution with the lattice Laplace Green kernel gives a local potential; its first differences involve second differences of that kernel. These preserve the Hölder exponent by Lemma YMM1:19.4. The cancellation in that lemma is essential: a bound on the absolute kernel alone would give a logarithmic loss.

Cut off these local potentials and carry them back to the original gauge. Their sum Φ satisfies

$$T\Phi = D_1^{\mathsf{T}} Y + J, \qquad |J|_{3,h} \le C\|Y\|_{2,1/2,h}.$$

Here J consists of cutoff commutators, the terms containing the local potential and curvature, the lower-order term $V_0'\Phi$, the term $-D_0(1-R)D_0^{\mathsf{T}}\Phi$, and the untreated sources in layers zero and one. The first differences of the local gauge potential bound the coefficient terms; the cutoff derivatives have the inverse powers of the local scale. In the first two layers the scale-to-spacing ratio is bounded by L, so a bare difference is bounded by the corresponding scaled supremum. These are ordinary sources of degree three. The parametrix identity is

$$\widetilde{G} D_1^{\mathsf{T}} Y = \Phi - HQ\Phi - \widetilde{G} J. \tag{38}$$

The row datum $Q\Phi$ is bounded in the dimensionless row norm: each average reads a double block on which the scale and envelope are comparable, and the factor $\ell(c)$ in the physical path average cancels the scale ℓ^{-1} of Φ. The remainder J has the degree-three norm displayed above. Thus both correction terms lie in the ordinary-input classes of Lemma Q.7. Its estimates are read at $s = 1$, with the same rows and their row pairing. This proves the required potential and curvature bounds. The first-difference Hölder bounds for the correction terms are the ordinary kernel bounds; those for Φ are the same-exponent Green-kernel bounds just used. Their supremum estimates also bound the divergence. To pass from the comparison cubes of radius $\ell/56$ to the cubes in the norm, cover the latter by comparison cubes and use the local gauge transition bounds. On an overlap those transitions have differences bounded by $C(L)\alpha/\ell$; the Hölder product inequality and the supremum bound therefore control the change of gauge. The bounded overlap gives a constant depending only on L. No Hölder estimate is obtained here by applying an estimate with a positive loss of exponent at zero loss.

For completeness, the potential Hölder norm can also be read directly from its curvature and divergence. On a cube C_R in bare units, let the adjoint transports differ from the identity by at most v/R. If $6v \le \sigma_H$, then

$$\sup_{C_{R/2-2}} |E| + (R/2-2)^{1/2}[E]_{1/2;C_{R/2-2}} \le 2C_H\big((R-1)^{-3/2}\|E\|_2 + R|DE| + R|D_0^* E|\big).$$

To obtain it, apply Proposition YMM1:18.1 to each component, whose flat Laplacian is the divergence of its flat curvature and divergence. Replacing the covariant quantities by the flat ones adds at most Cv times the supremum on the next larger cube. On radii increasing from $3R/4$ by $R/8, R/16, \dots$, choose v so that this factor is at most $1/12$. Iteration absorbs the supremum; the terminal error is at most $12^{8-\log_2 R}\|E\|_2$. A second application on cubes of radius $R/4$ gives the Hölder bound. For $R < 64$ the supremum is bounded by the finite-volume ℓ^2 norm. At $R = L^n/4$, the condition follows by reducing the regularity radius so that $\alpha \le \sigma_H/(8L^2)$.

We have proved the estimate at zero anisotropy with a constant $K^{(0)}$. At a nonzero anisotropy, the same solution solves the unweighted system with data

$$(Y - \operatorname{an} c D_1 A,\ f - V_0'[\operatorname{an}]A,\ b).$$

The Hölder product inequality bounds the first change by $Ct(\operatorname{an})\|D_1 A\|_{2,1/2,h}$; the second is bounded by $C|\operatorname{an}|_\infty \alpha |A|_{1,h}$. Choose $K^{(0)} C t_{\mathrm{lin}} \le 1/2$ and absorb these terms. The bound holds with $K_{\mathrm{lin}} = 2K^{(0)}$.

The real part of the form of T_τ on $N(Q)$ is coercive at these radii, as proved below. Hence a homogeneous solution has $A = 0$, by pairing its equation with $\bar{A}$, and then $Q^{\mathsf{T}}\omega = 0$ gives $\omega = 0$.

The finite square system is therefore invertible. This proves existence and uniqueness as well as the estimate.

Finally, the mean-scheme rows of a label, rotated into the comb frame, have the form $Q + E$. Their comparison kernel is supported in the double block of the row and obeys

$$|EA|_{0,h} \le c_E \alpha |A|_{1,h}, \qquad |E^{\mathsf{T}}\omega|_{3,h} \le c_E \alpha |\omega|_{0,h}.$$

The system with these rows is the one just solved with data $(Y, f + E^{\mathsf{T}}\omega, b - EA)$. Taking $K_{\mathrm{lin}} c_E \alpha \le 1/2$ proves its bound, with $2K_{\mathrm{lin}}$, by a contraction. This is the row comparison needed when the estimate is applied to a label. □

Lemma 8.21 (The energy of the displacement)**.** In the setting of Lemma 8.20, decrease the regularity radius and the envelope ceiling by constants depending only on L. Put

$$\mathcal{E}(A) = \xi^3 \sum_p |D_1 A(p)|^2 + \xi^3 \sum_b \ell(b)^{-2} |A(b)|^2, \qquad |b|_{\mathrm{row}}^2 = \sum_c \ell(c)^{-1} |b(c)|^2.$$

For the linear solution with data (Y, f, b),

$$\mathcal{E}(A) \le K^{(2)} \left(\xi^3 \sum_p |Y(p)|^2 + \xi^3 \sum_b \ell(b)^2 |f(b)|^2 + |b|_{\mathrm{row}}^2 \right). \tag{39}$$

For the small fixed point with zero block datum,

$$\mathcal{E}(A[\mathrm{an}; 0]) \le C |\mathrm{an}|_\infty^2 \xi^3 \sum_p |F_U(p)|^2. \tag{40}$$

At a permitted complex block datum b_0, the difference $A' = A[\mathrm{an}; b_0] - A[0; b_0]$ instead satisfies

$$\mathcal{E}(A') \le C |\mathrm{an}|_\infty^2 \left(\xi^3 \sum_p |F_U(p)|^2 + |b_0|_{\mathrm{row}}^2 \right). \tag{41}$$

The constants are independent of the number of layers and the volume. The last two statements concern fixed points in the small ball of the linear estimate. ■

Proof. We need an estimate on the field energy, including the forcing from the nonlinear block constraint. A contraction in a stronger energy norm of the field and multiplier is unnecessary.

At zero anisotropy the operator $T + Q^{\mathsf{T}} Q$ is real, symmetric and positive by Theorem YMM1:I. Its restriction to $N(Q)$ is T, so the constrained Green operator is positive on that subspace. Apply the first estimate of (36) to an eigenvector of the largest eigenvalue of $\ell^{-1} \widetilde{G} \ell^{-1}$. If that eigenvalue is λ, it gives

$$\lambda \sup_b \ell(b)^2 |g(b)| \le K_7 \sup_b \ell(b)^2 |g(b)|.$$

Thus the quadratic form of T on $N(Q)$ controls the weighted potential square sum with constant K_7^{-1}. Its expression as a curvature form, a slice term and V_0' gives the second lower bound. The plaquette coefficient satisfies $c_p \ge 1/2$, while the form of V_0' is bounded by $C_V \alpha$ times the weighted potential square sum. Since $|\mathrm{an}|_\infty \le 1/4$, reducing α so that $3 C_V K_7 \alpha \le 1$ gives

$$\mathrm{Re}(\bar{A}, T_\tau A)_\xi \ge c^{(2)} \mathcal{E}(A) + \tfrac{1}{2} \| R D_0^* A \|_\xi^2, \qquad A \in N(Q), \tag{42}$$

where $c^{(2)} = \min\{1/8, (4K_7)^{-1}\}$. Pairing the equation with $\bar{A}$ removes the multiplier. Cauchy–Schwarz bounds the remaining pairing by $\mathcal{E}(A)^{1/2}$ times the square root of the first two data sums in (39).

For nonzero row data use the lift $A^\circ = Hb$. Then $A - A^\circ \in N(Q)$ and its equation has the additional forcing $-T_\tau A^\circ$. The bounds on H, its first differences and their transposes in (36), applied by the weighted Schur test, give

$$\mathcal{E}(A^\circ) + \| D_0^* A^\circ \|_\xi^2 \le C_H |b|_{\mathrm{row}}^2.$$

The row weight is $\ell(c)^{-1}$; using an unweighted row sum would not give a constant uniform in the layers. Apply (42) to $A - A^\circ$ and use this lift estimate. This proves (39).

At the nonlinear fixed point the data are

$$(-\mathrm{an}F_U - Y_3(A),\ -f_3(A) + (dC_2(U,A))^{\mathsf{T}}(\omega_0+\omega),\ -C_2(U,A)).$$

Here Y_3, f_3 are the terms of order at least two in the displacement in the first variation, and C_2 is the nonlinear remainder of the block constraint. The last entry is not zero. The small-ball bound on A and the multiplier implies that the square-sum norm of the nonlinear data is at most $c_{\mathrm{ms}} \sup e\, \mathcal{E}(A)^{1/2}$. To see the row estimate in the same units, write $l(c) = \ell(c)/\xi$. The Taylor kernel of the block average and Cauchy–Schwarz give

$$|C_2(U,A)(c)| \le C l(c)^{-1} \sum_{b \text{ beneath } c} |\xi A(b)|^2.$$

There are at most $Cl(c)^3$ bonds beneath the row, their scales are comparable to $l(c)$, and each bond lies beneath at most a constant number of rows. Hence the row square sum is bounded by $C(\sup_b \ell(b)|A(b)|)^2 \mathcal{E}(A)$. The same bilinear kernel bounds the transposed derivative paired with $\omega_0+\omega$, whose scaled supremum is at most $C \sup e$. The plaquette and bond remainders are treated by their local product bounds, using one small factor and one energy factor.

Choose the envelope ceiling so that $K^{(2)} c_{\mathrm{ms}}^2 (\sup e)^2 \le 1/16$. The nonlinear data can then be absorbed in (39). The remaining forcing is $-\mathrm{an}F_U$, which proves (40).

At $\mathrm{an} = 0$ and datum b_0 the same argument gives $\mathcal{E}(A[0;b_0]) \le 4K^{(2)}|b_0|_{\mathrm{row}}^2$. Subtract the two fixed-point equations at the same b_0. The terms linear in an are bounded by its supremum times the square root of $\xi^3 \sum |F_U|^2 + \mathcal{E}(A[0;b_0])$. The remaining differences have the factor $C \sup e$; the multiplier difference is bounded by testing against the same row lift. One further reduction of the envelope ceiling absorbs these differences. This proves (41). □

Definition 8.22 (Complex scalar gauge transfer)**.** Consider a small complex potential a and the small gauge $e^{i\lambda}$ relative to its real reference configuration. Define N and q by the exact identities

$$D^* a^{e^{i\lambda}} = D^* a - D^* D\lambda + N(a,\lambda),$$
$$T^{-1} i^{-1} \log \mathcal{R}(a; e^{i\lambda}) = Q'\lambda + q(a,\lambda).$$

Here $\mathcal{R}$ is the induced gauge at the retained block tops, and T is the orthogonal transport in its linearization; these are the maps in the proof of Lemma YMM1:30.4. Their linear scalar system is precisely the compression $\mathbb{K}^{[2]}$ of Section YMM1:23.2, in the covariant form of Section YMM1:25:

$$\mathbb{K}^{[2]}(\lambda, w, \sigma) = (\Delta'_a \lambda + w,\ \Delta'_a w - Q'^* \sigma,\ Q'\lambda), \qquad \Delta'_a = \Delta_D + Q'^* \mathsf{a}' Q'.$$

Here Δ_D is the scalar Dirichlet Laplacian; the boundary identity is $RD^*D = R\Delta_D$. Let $\mathcal{S}(f,b)$ be the first component of the solution with data $(f + Q'^* \mathsf{a}' b, 0, b)$. Its first and third rows give $w = f - \Delta_D \lambda$, while its second row says $Rw = 0$. Consequently the two desired gauge conditions are exactly the fixed point $\lambda = \mathcal{S}(D^*a + N(a,\lambda), -q(a,\lambda))$. The mass term $Q'^* \mathsf{a}' b$ is necessary when $b \ne 0$. In the norm $\|\lambda\|_{\mathcal{Z}_h} := |\lambda|_{0,h} + \|(D\lambda, 0)\|_{\mathcal{X}_h}$, assume

$$\begin{aligned} \|\mathcal{S}(N(a,\lambda) - N(a,\tilde\lambda), -q(a,\lambda) + q(a,\tilde\lambda))\|_{\mathcal{Z}_h} &\le \tfrac{1}{2}\|\lambda - \tilde\lambda\|_{\mathcal{Z}_h}, \\ \|(a^{e^{i\lambda}} - a, 0)\|_{\mathcal{X}_h} &\le C\|\lambda\|_{\mathcal{Z}_h}. \end{aligned} \tag{43}$$

These bounds are required on one small complex ball, invariant under the scalar iteration, for each admitted envelope h, including the exponentially decaying envelopes used for a cutoff repair. They include the same bounds after subtracting a given solution and localizing its scalar system. Thus the initial forcing in a cutoff repair is the commutator forcing supported where the cutoff varies. The scalar inverse itself is supplied by Theorem YMM1:G; (43) is the additional uniform complex nonlinear estimate, not a claim about that theorem.

■

Lemma 8.23 (The re-filing of the counterterms)**.** Let $1 \le j \le K$, $m' < m + K - j$, $b_0, b_1, \kappa' > 0$ and let c' be a complex function of the plaquettes. For a site z of the level j let $\square_z$ be the cube of π_j (of side M in level-j units) that holds z, and $X_z = \square_z^{\sim}$ the block of the $3 \times 3 \times 3$ cubes of π_j about it, the box of the site z: $X_z \in \mathcal{D}_j$, $z \in X_z$, $d_j(X_z) \le 7$ for the linear size d_j of YMM1:72 (the definitions of $\mathcal{D}_j$ and d_j at its beginning) (Section YMM1:72 (the definitions of $\mathcal{D}_j$ and d_j at its beginning)), every plaquette p with $h_z^{(j)}(p) \ne 0$ has its four corners in X_z and its four bonds in $\mathrm{Bd}(X_z)$, and at most M^3 sites z' have $X_{z'} = X_z$, namely those of $\square_z$ (the tent domains and support assertions are those preceding equation YMM1:(762) and in Lemma YMM1:49.7).

Here $h_z^{(j)}$ is the tent of the level j at z, the product of the hat functions $\max\{1 - |u_\mu|, 0\}$ of the coordinates in level-j units, read at the barycentres (equation YMM1:(760)): $0 \le h_z^{(j)} \le 1$, $h_z^{(j)}(y) \ne 0$ exactly when $|y - z|_\infty < 1$ in level-j units, $\sum_z h_z^{(j)} = 1$, and $\sum_p h_z^{(j)}(p) = 3\eta_j^{-3}$ (Proposition YMM1:49.6 and the plaquette-count calculation in the proof of Lemma YMM1:49.7). For a complex weight c and a complex bare configuration $\mathbf{U}$ put $A^\eta(c, \mathbf{U}) = \eta^{-1} \sum_p c(p) a_p(\mathbf{U})$ (equations YMM1:(6)–(7)), and for a triple $P = (U, A', J)$ of a level q let $\mathbf{U}_P = e^{i\eta_q A'} U$ be its configuration. The tent family at the weight c',

$$A^t[c'](X, P, z) = A^{\eta_j}(c' h_z^{(j)}, \mathbf{U}_P) = \eta_j^{-1} \sum_p c'(p) h_z^{(j)}(p) a_p(\mathbf{U}_P) \ \text{ if } X = X_z, \qquad A^t[c'](X, P, z) = 0 \ \text{ for the other } X \in \mathcal{D}_j,$$

$z \in X$ a site of the level j, is, on the cores $\mathcal{U}_j^\circ(X; b_0, b_1)$, a pointed family of the level j at (b_0, b_1) (Definitions YMM1:49.4 and YMM1:49.5), complex linear in c' and 0 at the trivial triple; its size YMM1:(759), the supremum of $e^{\kappa' d_j(X)} |A^t[c'](X, P, z)|$ over the $X \in \mathcal{D}_j$, the sites $z \in X$ and the triples P of the core, obeys $\|A^t[c']\|_{j,\kappa'} \le \frac{3}{2} |c'|_\infty b_0^2 e^{7\kappa'}$; at $c' = 1$ it is the tent family of equation YMM1:(762); and $A^{\eta_j}(c', \mathbf{U}) = \sum_z A^{\eta_j}(c' h_z^{(j)}, \mathbf{U})$ for every complex $\mathbf{U}$. Consequently, let $1 \le n \le K$ with $m' < m + K - n$, and let $E^{(i)}$, $1 \le i \le n$, be pointed families of the levels i at (α_0, α_1) with complex counterterms e_i, let an be a complex weight with $|\mathrm{an}|_\infty = s$, and $\hat{E}^{(i)} = E^{(i)} - e_i A_i^t[\mathrm{an}]$, A_i^t the tent family of the level i; let P be a triple of one level $k \ge n$ on the whole torus whose restrictions $\rho_X P = \rho_X^{k \to i} P$ to the domains X of the levels $i \le n$ lie in the cores; since $\eta_i L^{-(k-i)} = \eta_k$, the configuration of $\rho_X P$ is $\mathbf{U}_P$ on X. Then, identically in P,

$$\sum_i \Big[\sum_z \sum_{X \ni z} (E^{(i)}(X, \rho_X P, z) - E^{(i)}(X, \mathbf{1}, z)) - e_i A^{\eta_i}(1 + \mathrm{an}, \mathbf{U}_P) \Big] = \sum_i \Big[\sum_z \sum_{X \ni z} (\hat{E}^{(i)}(X, \rho_X P, z) - \hat{E}^{(i)}(X, \mathbf{1}, z)) - e_i A^{\eta_i}(1, \mathbf{U}_P) \Big],$$

$\hat{E}^{(i)}(X, \mathbf{1}, z) = E^{(i)}(X, \mathbf{1}, z)$, and $\|\hat{E}^{(i)} - E^{(i)}\|_{i,\kappa'} \le \frac{3}{2} s |e_i| \alpha_0^2 e^{7\kappa'}$.

On the label $\mathcal{S}$ of a history $h \in \mathcal{H}_k$ with regular regions Λ_j, assume $m' < m + K - j$ at every level used. The same identity then holds in the following form. Let φ_j be the profile of Λ_j (equation YMM1:(666) and the definition of φ_j following it): $0 \le \varphi_j \le 1$, $\varphi_j h_z^{(j)} = h_z^{(j)}$ at the sites z of $\Lambda_j^{\sim -1}$, which is Λ_j less one layer of its cells, and $\varphi_j(x(p)) \ne 0$ only if all the corners of p lie in Λ_j (the tent identity in Section YMM1:44.4; the corner assertion also follows since a nonzero profile is more than one quarter of a cell width from Z_j, while every plaquette corner is less than one bare spacing from its center). The exponent on the label (equation YMM1:(1476)) holds, besides its Wilson term and its vacuum constant, the regular sums in equation YMM1:(1474), over the set $\mathsf{lx}_j^{\mathrm{rs}}(\mathcal{S})$ of the places (z, X) with $X \subset \Lambda_j$ and $z \in \Lambda_j^{\sim -1}$, with the counterterms $-e_j A^{\eta_j}(\varphi_j, \cdot)$, and the boundary sums in equation YMM1:(1475), which hold the made boundary entries $\mathscr{B}(j, X, \mathrm{mk})$ at the filing places $X \in \mathsf{lx}_j^{\mathrm{mk}}(\mathcal{S})$ and the edge parts of equation YMM1:(1388) of the families, the members with base points outside $\Lambda_j^{\sim -1}$, at the places $X \in \mathsf{lx}_j^{\mathrm{ed}}(\mathcal{S})$ (the index sets and domains preceding Proposition YMM1:62.2); each member is filed at exactly one place (by the separate

level, domain and origin indexing in Proposition YMM1:62.2); the entries are boundary terms of their filing places, additive in the exponent, of the sizes $\le \mathsf{B}\, e^{-\kappa d_j(X)}$ of a well filed system (Proposition YMM1:62.2, on its stated layered output spaces); with the anisotropy the counterterms are $-e_j A^{\eta_j}((1+\mathrm{an})\varphi_j, \mathbf{U}_P)$.

For a site y of the level j outside $\Lambda_j^{\sim -1}$ put $\epsilon_y = 1$ if $X_y \subset \Lambda_j$ and $\epsilon_y = 0$ otherwise, and

$$r_{(j,y)} = -e_j \eta_j^{-1} \sum_p \mathrm{an}(p)\,[\varphi_j(x(p)) - \epsilon_y]\, h_y^{(j)}(p)\, a_p(\mathbf{U}_P).$$

Then the exponent formed with the families $E^{(j)}$, the entries $\mathscr{B}$ and the counterterms $-e_j A^{\eta_j}((1+\mathrm{an})\varphi_j, \mathbf{U}_P)$ equals, identically, the exponent formed with the families $\hat{E}^{(j)}$ at the regular places and in the edge parts, the entries $\mathscr{B}(j, X, \mathrm{mk}) + \sum\{r_{(j,y)} : y \notin \Lambda_j^{\sim -1},\ X_y = X\}$ and the counterterms $-e_j A^{\eta_j}(\varphi_j, \mathbf{U}_P)$. Here $r_{(j,y)} = 0$ unless the tent of y meets the set where $\varphi_j \ne \epsilon_y$, a collar of the boundary of Λ_j, and then $X_y \in \mathsf{lx}_j^{\mathrm{mk}}(\mathcal{S})$; $r_{(j,y)}$ is linear in an, reads $\mathbf{U}_P$ in X_y alone and is 0 at the trivial triple; and on the space of the filing place (j, X_y, mk), namely the layered output space at level j specified before Proposition YMM1:62.2, where the plaquettes concerned have their plaquette variables within $r_0\eta_j^2$ of $\mathbf{1}$, $r_0 = \mathsf{r}_0((j, \mathrm{out}); j)$ being the prescribed output-layer curvature radius at level j (the same radius used for the edge-tent estimate in the proof of Proposition YMM1:58.22), $|r_{(j,y)}| \le \frac{3}{2} s |e_j| r_0^2$; in a frame of Theorems YMM1:AJ and YMM1:AD the radius of the level is at most $\alpha_0/(1+\beta_{\mathrm{s}}) < \alpha_0$. The values at the trivial triple are unchanged. ■

Proof. The room condition gives $2L^{m+K-j-m'} \ge 2L$ cubes of π_j in each coordinate direction. The three consecutive cubes in each projection of X_z therefore determine its middle cube. Thus $X_{z'} = X_z$ exactly for the M^3 level-j sites $z' \in \square_z$.

On the cores $|\partial \mathbf{U}_P(p) - \mathbf{1}| < b_0 \eta_j^2$ at the plaquettes with their bonds in $\mathrm{Bd}(X_z)$, and $a_p = \frac{1}{2}\det(\partial \mathbf{U}_P(p) - \mathbf{1})$ for a matrix of determinant 1, so $|a_p| \le \frac{1}{2} b_0^2 \eta_j^4$; with $h_z^{(j)} \ge 0$ and $\sum_p h_z^{(j)}(p) = 3\eta_j^{-3}$ this gives $|A^t[c'](X_z, P, z)| \le \eta_j^{-1} |c'|_\infty \cdot 3\eta_j^{-3} \cdot \frac{1}{2} b_0^2 \eta_j^4 = \frac{3}{2} |c'|_\infty b_0^2$, and $d_j(X_z) \le 7$ gives the factor $e^{7\kappa'}$. Each member is a polynomial in the entries of the $U(b)^{\pm 1}$ and $e^{\pm i \eta_j A'(b)}$ at the bonds of $\mathrm{Bd}(X_z)$, entire in (A', J), a function of the pair, gauge invariant, and 0 at the trivial triple (Lemma YMM1:49.7).

The tents form a partition of unity, so $A^{\eta_j}(c', \mathbf{U}) = \sum_z A^{\eta_j}(c' h_z^{(j)}, \mathbf{U})$; at $\mathbf{U} = \mathbf{U}_P$ the counterterm $e_i A^{\eta_i}(\mathrm{an}, \mathbf{U}_P)$ is the sum over the sites z of the members $e_i A_i^t[\mathrm{an}](X_z, \rho_{X_z} P, z)$, which vanish at the trivial triple, and moving each from the counterterm into the family of its box is the display, term by term: the two members differ by $\sum_i e_i \eta_i^{-1} \sum_p \mathrm{an}(p)[a_p(\mathbf{U}_P) - a_p(\mathbf{U}_P)] = 0$, the counterterm and the families being read at the one configuration $\mathbf{U}_P$. On a label, by the partition of unity and $\varphi_j h_z^{(j)} = h_z^{(j)}$ on $\Lambda_j^{\sim -1}$, for every rule $\epsilon_y \in \{0, 1\}$,

$$A^{\eta_j}(\mathrm{an}\,\varphi_j, \mathbf{U}) = \sum_{z \in \Lambda_j^{\sim -1}} A^{\eta_j}(\mathrm{an}\, h_z^{(j)}, \mathbf{U}) + \sum_{y \notin \Lambda_j^{\sim -1}} \epsilon_y A^{\eta_j}(\mathrm{an}\, h_y^{(j)}, \mathbf{U}) + \sum_{y \notin \Lambda_j^{\sim -1}} A^{\eta_j}(\mathrm{an}\,(\varphi_j - \epsilon_y) h_y^{(j)}, \mathbf{U}).$$

For $z \in \Lambda_j^{\sim -1}$ the place (z, X_z) is a regular place, and for $y \notin \Lambda_j^{\sim -1}$ the domain X_y is an edge place exactly when $X_y \subset \Lambda_j$; the exponent with $\hat{E}^{(j)}$ holds $-e_j A_j^t[\mathrm{an}]$ at the regular places and in the edge parts, which are the first sum and the members of the second with $\epsilon_y = 1$: this is why $\epsilon_y = 1$ at the edge places and $\epsilon_y = 0$ elsewhere, and $-e_j$ times the third sum is $\sum_y r_{(j,y)}$, the contribution to the made boundary entries. This identity also holds at $e_j = 0$. If $\mathrm{an}(p)[\varphi_j(x(p)) - \epsilon_y] h_y^{(j)}(p) \ne 0$, the corners of p lie in X_y, and in Λ_j (by the profile corner property just stated if $\varphi_j(x(p)) \ne 0$; and if $\varphi_j(x(p)) = 0$, then $\epsilon_y = 1$ and $X_y \subset \Lambda_j$); as $\Lambda_j \subset \Omega_j$, its bonds lie in the bonds of the label in X_y, and its base point, a corner, is a site of X_y and of Ω_j, so that X_y and Ω_j have a bare cube in common; and as $y \in X_y$ lies outside $\Lambda_j^{\sim -1}$, $X_y \in \mathsf{lx}_j^{\mathrm{mk}}(\mathcal{S})$: this index set consists precisely of domains sharing a bare cube with Ω_j and not contained in $\Lambda_j^{\sim -1}$, as defined before Proposition YMM1:62.2.

The size: $|\varphi_j - \epsilon_y| \le 1$, the mass $3\eta_j^{-3}$ of the tent and $|a_p| \le \frac12 r_0^2\eta_j^4$ on the space of the filing place give $\frac32 s|e_j|r_0^2$; in a frame of Theorems YMM1:AJ and YMM1:AD, $r_0 \le \alpha_0/(1+\beta_{\mathrm s})$. The tent families and φ_j, ϵ_y read no history beyond the label, and the values at the trivial triple are unchanged, the tent families vanishing there. □

8.5. **Proofs of the theorems.**

Proof of Theorems AD–AG, AH and AI, and of the remarks. Step 1: Theorem AD(a)–(c). (a) is Lemma 8.8 for the rough entries $F_a = \mathcal O(w_a)$, and its second bound is the second decomposition in the sketch of that lemma, applied to the weights $u_a\mathbf 1\{\lambda(\cdot) = \lambda_a\}$; for a weight that vanishes the cumulant is 0. (b) Let $\ell' = 2\mathsf l$, $\mathsf d = \min\{\mathsf d_0, \frac{\mathsf l}{4n}, \frac12\}$, and let K_1 be the least $K \ge K_0(r,\mathsf d)$, $2 \le r \le 8n$, with $a_K \le \frac{\mathsf l}{4n}$. For $K \ge K_1$ cut each f_i into at most $(\frac R\rho + 2)^3$ pieces in balls of radius $\rho = \frac{\mathsf l}{8n}$; each choice of pieces lies, for a suitable offset (a pigeonhole on the n centres), in cells of a board of side $\mathsf l$ at sup distance $\ge \frac{\mathsf d}{2}$ from the walls, so that the mirror copies stay $\ge \mathsf d$ apart, and Lemma 8.9 with (a) gives

$$\Big\|\prod_{a\le r}(\mathcal O(w_a) - c_a)\Big\|_{\mathrm{ch}} \le e^{G_g\mathsf l^3}\Big[\sum_\pi \prod_{I\in\pi} k(\#I,\mathsf d)\Big]^{1/8}\prod_a \sup|w_a|,$$

π over the partitions of $8r$ points into blocks of at least two; the moment–cumulant formula, $\langle F_1;\dots;F_n\rangle = \sum_\pi(-1)^{|\pi|-1}(|\pi|-1)!\prod_{B\in\pi}\langle\prod_{a\in B}(F_a - c_a)\rangle$, gives a bound $T_n(\mathsf d)$. For $K < K_1$ we use $|\mathcal O(f)| \le m_K(R)\sup|f|$, $m_K(R) = 6a_K^{-1}(\frac{2R}{a_K}+1)^3$, increasing in K; so $C_n = \max\{(\frac R\rho + 2)^{3n}T_n(\mathsf d),\, m_{K_1}(R)^n\sum_\pi(\#\pi-1)!\}$. On T_ℓ the same board is placed with $\ell \ge L\ell'$, and a periodic Gibbs state is dominated through its conditional laws (Lemma 8.9). The bound on $\nu' - \nu$ is the case $n = 1$ with the centring at the mean of the torus. (c) The bounds of (b) give equicontinuity in the sup norm, and a diagonal argument over a countable dense family of tuples gives a convergent subsequence; the lattice symmetries and the reflection positivity of the states pass to the limit, at the three coordinate mirrors in both cases and, for periodic Gibbs states, also at the six diagonal mirrors; the translations by all $v \in \mathbb R^3$ follow through $v_j \in a_{K_j}\mathbb Z^3$, $v_j \to v$, and the Lipschitz continuity of the limits; the growth in n follows by cutting into $\lceil\frac{2\mathsf l}{\mathsf d_0}\rceil^3$ cells and counting, with $B = 2e^{3+p}(\frac{8R}{\mathsf l}+2)^3\mathsf d_*^{-p}\max_{r\le P}[e^{G_g\mathsf l^3}\mathrm{Bl}_{8r}^{1/8}]^{1/r}$, $\mathsf d_* = \min\{\mathsf d_0, \frac14, \frac12\}$, $P = \lceil\frac{2\mathsf l}{\mathsf d_0}\rceil^3$; the sum over the planes is the scalar cumulant by linearity.

Step 2: Theorem AD(d). Put $\sigma = \lfloor K/(1260n)\rfloor$. (i) Let $s = \lfloor\sigma/(8n+3)\rfloor$ be the coarse depth, $T = K - s$, and $\nu = \sigma - s \ge (8n+2)s$ the number of the levels between the fine depth σ and the coarse one. By forgetting, with the never-large term and the sources switched on at the level $K-\sigma$, each $\mathcal O(w_a)$ is exchanged for the weighted energy, plane by plane, of the background over the block field $\mathcal M^{K-\sigma}U$: what a source creates at the levels between $K-\sigma$ and T is forgotten by $L^{-\nu/2}$ over these ν levels. For the n sources, at mutual corner distances $\ge \mathsf d' = \frac12\mathsf d$, the cumulants of the $\mathcal O(w_a)$ and of the energies differ by at most

$$\mathsf K_n\big[2L^{4n}\mathsf V_\ell(b)L^{-(b+1)s} + n\,C_{\mathrm{fg}}(\nu+1)^{2\mathfrak p_0+2}L^{-\nu/2} + 2e^{3-L^s\mathsf d'/M}\big]\prod_a y_a, \qquad y_a \le 4\ell^3L^{4s}\sup|w_a|,$$

for every real $b \ge 4n$, with numbers $\mathsf K_n$, C_{fg} and $\mathsf V_\ell(b)$ that read no K: the sup norms of the sources are paid at the coarse depth, which brings the factor L^{4ns}, and the histories with a first creation of a large field up to the level T bring $\mathsf V_\ell(b)L^{-(b+1)s}$; the member $2e^{3-L^s\mathsf d'/M}$ is the factor of the distance of the mixed parts at the level T (Lemma 8.7(a), (e)), read under the conditions $L^s\mathsf d' \ge 3M$ and $\mathsf h_2(s) \le 1$ of Lemma 8.7(e) at $t = T$, which hold for $K \ge K_1$, since s grows with K and $\mathsf h_2(s) \to 0$ as $s \to \infty$. At $b = 4n+1$, $L^{4ns}L^{-(4n+1)s} = L^{-s}$; and $L^{4ns}L^{-\nu/2} \le L^{-s}$ since $\nu \ge (8n+2)s$; so this error is at most $C\ell^{3n}K^{2\mathfrak p_0+2}L^{-s}\prod_a\sup|w_a|$, the factor ℓ^{3n} of $\ell^{3(n+1)}$ in the statement coming from $\prod_a y_a$ (the further ℓ^3 comes from (iii)), and $s \ge \theta_nK - 2$. (ii) For one block field at the level t and

the cutoffs K, $K+1$ at equal label the plane-wise energies of the two backgrounds, formed with the coefficient function c of the weights, differ per block site by $Ct^{1/2}L^{-t/2}(\sup|\mathsf{c}|+L^{t-K}\mathrm{Lip}_\infty\mathsf{c})$.

For the sum of the three planes this is equation YMM1:(2156). For one plane, retain the parallel-plaquette support in the proof of Proposition YMM1:15.1. More precisely, for a set S of coarse plaquettes and a finer real field W with $\varpi=\varpi_{\mathcal{N}(S)}(W)\le\varpi'_L$,

$$\Big(\sum_{p'\in S}a_{p'}(\mathcal{M}(W))\Big)^{1/2}\le L^{1/2}\Big(\sum_{p\in\mathcal{N}^{\mathsf{W}}(S)}a_p(W)\Big)^{1/2}+\sqrt{12}\,C_0^{\mathrm{SO}}\,\varpi\Big(\sum_{p\in\mathcal{N}(S)}a_p(W)\Big)^{1/2},$$

where $\mathcal{N}(S)$ consists of the fine plaquettes in the cones of S, and $\mathcal{N}^{\mathsf{W}}(S)$ consists of those parallel to a corresponding plaquette of S. To verify the estimate, put $f_W(p)=|\partial W(p)-1|$. Lemma YMM1:14.9 bounds $f_{\mathcal{M}(W)}(p')$ by $(\mathsf{W}f_W)(p')+C_0^{\mathrm{SO}}\varpi_{p'}^2$. The kernel in Lemma YMM1:14.8 uses only parallel plaquettes, so its squared-norm bound is $L\|f_W\|^2_{\mathcal{N}^{\mathsf{W}}(S)}$. Equation YMM1:(146) gives

$$\sum_{p'\in S}\varpi_{p'}^4\le 12\varpi^2\|f_W\|^2_{\mathcal{N}(S)}.$$

The triangle inequality and $f_W(p)^2=2a_p(W)$ give the displayed energy bound. Applied to the plaquettes of one plane at which the coefficient exceeds a level λ, and integrated over λ, this bounds the plane-wise energy of the block average by that of the finer background up to the factor $1+C_{\mathrm{en}}\varpi$ and up to the variation of the coefficient over a block; this is the one place where the Lipschitz constants enter, with the factor $L^{-\sigma}$. (iii) The laws of the block fields of depth at most $\lceil K/1260\rceil$ at the two cutoffs at equal label differ, on every bounded Borel gauge invariant function F, by at most $C_{\mathrm{bf}}\ell^3K^{p'}L^{-K/10}\sup|F|$: this is Corollary B.30(a), (246), with the number C_{bf} of Definition B.29(5) and the exponent $p'=2\mathfrak{p}_0+\frac12$, the exponent defined before Theorem YMM1:AR at $n=0$.

With $\sigma=\lfloor K/(1260n)\rfloor$ and $s=\lfloor\sigma/(8n+3)\rfloor$ the three errors are at most $L^{-s}\le L^2L^{-\theta_nK}$, $L^{4n\sigma}L^{-(K-\sigma)/2}\le L^{-K/3}$ and $L^{4n\sigma}L^{-K/10}\le L^{-K/11}$, which gives θ_n and the exponent $\max\{2\mathfrak{p}_0+2,p',1\}$ of K; it equals $2\mathfrak{p}_0+2$, since $p'=2\mathfrak{p}_0+\frac12$ and $\mathfrak{p}_0\ge1$. The comparison of two lattices at equal label, Theorem YMM1:AR in the setting (E) of Section B.13, applies: it asks $\mathsf{b}\ge\gamma^{-2}$, which holds because $\mathsf{b}>g^{-2}+\bar B>\gamma^{-2}$, and $MR(\mathsf{b})\le L^{m-1}$, which holds because $L^{m_{\mathfrak{L}}(g)}\ge LM\,R(L(g^{-2}+\bar B))$ by the definition of the sides (equation YMM1:(1528)), $\mathsf{b}\le L(g^{-2}+\bar B)$ and R increases.

For $\mathsf{b}\ge2\max\{\gamma^{-2},x_{\mathrm{J}}\}$ and $g=(\mathsf{b}/2)^{-1/2}$ we have $g^{-2}=\frac{\mathsf{b}}{2}\ge x_{\mathrm{J}}$ and $\mathsf{b}\in I(g)$. On a compact interval of labels the numbers are monotone in b; the dilation is the change of units $x\mapsto L^zx$, which carries $\mu_{K,\ell,\beta}$ to $\mu_{K-z,L^z\ell,\beta}$ and multiplies the label by L^z. For continuous ϕ_a with supports at sup distances $\ge2\mathsf{d}$, uniform approximation by Lipschitz functions with supports at distances $\ge\mathsf{d}$ and the bound of (b), uniform in K, make (G_K) a Cauchy sequence. With one plane field among action densities, (ii) is needed for the plane field alone, the action densities being compared at the two cutoffs by the comparison of two lattices at equal label (Theorem YMM1:AR).

The plane field is a connected function at both cutoffs: with the tent $\theta_K(y)=\max\{0,1-(2/a_{K+1})\mathrm{dist}_\infty(y,\mathrm{Bc}_\lambda)\}$ about the barycentres Bc_λ of the plaquettes normal to λ at the cutoff $K+1$, $k_0=k\,\theta_K$ is Lipschitz, $\mathrm{supp}\,k_0\subset\mathrm{supp}\,k$, $\sup|k_0|\le\sup|k|$, and $k_0(x(p))=k(x(p))\mathbf{1}\{\lambda(p)=\lambda\}$ at the plaquettes of both cutoffs, L being odd; so $\langle\mathcal{O}_\lambda(k);\mathcal{O}(f.)\rangle=S^T_{n+1}(f_1,\dots,f_n,k_0)$ at both cutoffs. The comparison statements on two cutoffs at equal label (Theorem YMM1:AR with the lemmas on which it rests, Definition B.29 and Corollary B.30) hold, with the same proofs, at any two depths $u<s$ in the places of the depths there: their proofs read of the depths only conditions on the cutoff, which hold for $K\ge K_0$ when u and s are fixed fractions of K.

Take $u=\lceil K/(80(3n+8))\rceil$, at whose level $t_1=K-u$ the sources are carried by the run, and $s=\lceil K/20\rceil$, at whose level $K-s$ the plane field is compared. Three members are left, each with the factor L^{3nu} of Cauchy's estimates in the n sources at the level t_1. What the plane field makes below the level $K-s$ is forgotten over the $s-u$ levels up to t_1, by $L^{-(s-u)}$, against the volume L^{3u} of the level t_1 and the size $L^{s/2}$ of its first variation at the level $K-s$: the exponent

$(3n+4)u - \frac{1}{2}s \le -\frac{1}{80}K + 3n + 4$. The forgetting of the run between the two depths, against the size of the first variation at the level t_1, gives the exponent $(3n+\frac{15}{2})u - s \le -\frac{3}{80}K + 3n + 8$.

The classical comparison of the plane-wise energies of the two backgrounds at the level $K-s$, as in (ii), with the factor $K^{1/2}L^{-(K-s)/2}(\sup|k| + L^{-s}\mathrm{Lip}_\infty k)$ against the volume L^{3s}, bounds the difference of the two first variations at the real points of the polydisc of the sources; at its complex points the first variations are bounded crudely, and the estimate with two constants for holomorphic functions, with the exponents $\frac{3}{4}$ and $\frac{1}{4}$, gives the exponent $3nu + \frac{23}{4}s - \frac{3}{8}K \le -\frac{6}{80}K + 3n + 6$. The histories with a first creation of a large field up to the level t_1, and the mixed derivatives of the constants of the run in the sources, which are small by locality, cost less than every power of L^{-K}.

The largest of the three exponents gives the rate $L^{-K/80}$, and the powers of K of Cauchy's estimates in the n sources give $K^{2\mathfrak{p}_0(n+2)+2}$. For the sharpness: L being odd, the barycentres of $a_K\mathbb{Z}^3$ are barycentres of $a_{K+1}\mathbb{Z}^3$ in the same plane, of density L^{-3} among them; so the indicator of the points of a ball that are barycentres at an even cutoff and at no smaller cutoff samples to a weight of density close to 1 in the ball at the even cutoffs and close to L^{-3} at the odd ones, and for suitable smooth spectators the cumulants along the even and along the odd cutoffs have different limits.

Step 3: Theorem AD(e)–(g). (e) $\mathcal{O}_\lambda(f) = \mathcal{O}(f\chi_\lambda)$, χ_λ the indicator of the plaquettes normal to λ. Proposition YMM1:126.4, the two-point law on a torus of small side against the lattice kernel, is stated for every test pair of $\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ and every shape parameter $\vartheta \in (0,1)$, with a tolerance $\epsilon_g(s(\mathsf{d}))$ that depends neither on ϑ nor on a_K/d. A pair of non-negative Lipschitz functions, neither identically 0, carried by balls of radius d whose supports are between d and $6\mathsf{d}$ apart, is a test pair for every $\vartheta \in (0,1)$ below four positive numbers formed from their masses, their sup norms and their Lipschitz constants (Lemma I.1).

For non-negative weights w_1, w_2 carried by balls of radius $\mathsf{d} - a_K$ about x_0, y_0 with $3\mathsf{d} \le |x_0 - y_0| \le 4\mathsf{d}$, the functions $\sum_p w_a(p)\,\mathrm{pk}_p$, pk_p the tent of height 1 and sup radius $\frac{1}{2}a_K$ at $x(p)$, are Lipschitz, take the values w_a at the barycentres, so that $\mathcal{O}(\sum_p w_a(p)\mathrm{pk}_p) = \mathcal{O}(w_a)$, and form such a pair; so Proposition YMM1:126.4 applies to them with its tolerance; real weights are differences of two non-negative ones (four terms), complex weights have real and imaginary parts (sixteen terms). This applies to the weights $f\chi_\lambda$, $h\chi_{\lambda'}$, which depend on the plane, and the kernel bounds of equations YMM1:(2245)–(2246), with the bounds that enter the template sums of Proposition YMM1:121.2 and Lemma I.2, compare the lattice kernel with $\mathbb{K}_3$ plane by plane at the Lipschitz pair (f,h).

The lower bound on $\mathcal{K}_{\lambda\lambda'}$ follows from the masses and the Lipschitz constants of test pairs. For $\mathcal{O}_1 - \mathcal{O}_2$: with $\hat{u} = u/|u|$ and $\mathbb{K}_3(u)_{\lambda\mu} = (3\hat{u}_\lambda\hat{u}_\mu - \delta_{\lambda\mu})/(4\pi|u|^3)$,

$$[\mathbb{K}_3(u)_{11}]^2 - 2[\mathbb{K}_3(u)_{12}]^2 + [\mathbb{K}_3(u)_{22}]^2 = \frac{(3\hat{u}_1^2-1)^2 - 18\hat{u}_1^2\hat{u}_2^2 + (3\hat{u}_2^2-1)^2}{16\pi^2|u|^6} = \frac{9(\hat{u}_1^2-\hat{u}_2^2)^2 - 6(\hat{u}_1^2+\hat{u}_2^2) + 2}{16\pi^2|u|^6},$$

which is at least $(32\pi^2|u|^6)^{-1}$ where $\hat{u}_1^2 + \hat{u}_2^2 \le \frac{1}{4}$, the bracket being then at least $2 - \frac{3}{2}$; this holds at all $u \in \operatorname{supp} f - \operatorname{supp} h$ for the test pairs of the statement, for instance for those carried by balls of radius d whose centres are $4\mathsf{d}e_3$ apart. With $|u| \le 10\mathsf{d}$ there (Lemma I.1(a)) and the masses $\ge \vartheta\mathsf{d}^3\|f\|_\infty$, $\vartheta\mathsf{d}^3\|h\|_\infty$ of the non-negative pair (Lemma I.1), the main term of the two-point function of $\mathcal{O}_1 - \mathcal{O}_2$ is at least $\frac{3}{2}\mathsf{b}^{-2}(32\pi^2)^{-1}10^{-6}\vartheta^2\|f\|_\infty\|h\|_\infty$, and its error is at most 4 times the error of the display, one for each of the four two-point functions of the planes $1,2$; so it is positive for small d, whereas a plane field that is a multiple of $\mathcal{O}$ would make $\mathcal{O}_1 - \mathcal{O}_2$ vanish.

The combination $\mathcal{O} - 2\mathcal{O}_m$ has coefficients of modulus 1 in three planes, whence the factor 9 for two entries. Multilinearity gives one further factor b in both the main term and the error for each entry multiplied by b. (f) For free photons, expansion of $\log\det(1 - \mathsf{b}^{-1}M_\lambda)^{-3/2}$, where

$M_\lambda = \sum_a \lambda_a Q^{\mathrm{T}} \mathrm{diag}(w_a) Q$, gives $3\mathsf{b}^{-n}\mathcal{K}_K^{(n)}$ exactly. For the interacting weights the lattice comparison is $(\mathrm{Q_n})$. The kernel comparison and bound YMM1:(2245)–(2246), applied to the factors of each ring and telescoped plane by plane, give the displayed C'_n error; multilinearity gives the factors for plane combinations and rescaled entries. (g)(i) Lemma 8.9 on T_{ℓ_g}, applied to the Wick monomials of the tuple, whose eight mirror copies have as mean a mixture over histories, with jets that are nearly constant at the working level and with large fields that are rare on the small side.

A real multilinear form that is invariant under the lattice translations and bounded by a at every choice of signs of a packing of $N_c \sim \mathsf{d}^{-3(1-\sigma)}$ translates of the tuple in one cube of side $\sim \mathsf{d}^\sigma$ is bounded by a/N_c; this gives the factor $\mathsf{d}^{3(1-\sigma)}$. Each derivative in a source is paid by Cauchy's estimate on the polydisc of the height, which costs $(\frac{4}{3}\bar{\mathsf{b}}/\mathsf{d})^{[\frac{n}{2}-1]_+}$, $\bar{\mathsf{b}} = L(g^{-2} + \bar{B})$; the sizes at the working depth give a factor $\Lambda(\mathsf{d}) \le C(\log \frac{1}{\mathsf{d}})^c$; so $\mathsf{e}'_n = 2^{n-1}(\frac{42L}{M})^3(\frac{4}{3}\bar{\mathsf{b}})^{[\frac{n}{2}-1]_+}[c_n^\circ Q_0 \Lambda(\mathsf{d})]^n \mathsf{d}^{3(1-\sigma)-[\frac{n}{2}-1]_+}$ with $c_n^\circ = n2^{3n}(1 + n4^{n-1})$ and Q_0 a constant of the stability bounds on T_{ℓ_g}.

Every periodic Gibbs state is a state at g. (ii) For real weights, the mean of the product of the eight mirror copies of the Wick polynomials Ξ_B, centred at the cumulants of $T_{\ell'}$, is exactly the sum over the partitions of the copies all of whose blocks link different copies of the products of the cumulants of the blocks (an identity of formal power series). Hypotheses $(\mathrm{Q_m})$, $2 \le m \le 8n$, apply to the real plaquette weights without an upper bound on their mutual distances. Together with the following Gaussian ring bound, they show that a linking cumulant is at most $\mathsf{e}_m + \mathsf{v}_m$, where $\mathsf{v}_m = \frac{3}{2}(m-1)!(81(1+3C_{\mathrm{lat}}))^m(\frac{4\mathsf{d}}{\ell'})^6$ bounds the linking lattice rings, two copies in different cells being $\ge \frac{1}{4}\ell'$ apart; with $\mathrm{Bl}_N(k) = \sum_\pi \prod_{I\in\pi} k_{\#I}$ over the partitions of N points into blocks of at least two, Lemma 8.9 gives the second display with $\eta^\sharp = 2^n e^{G_g|^3} \max_{m\le n} \mathrm{Bl}_{8m}(\mathsf{e}+\mathsf{v})^{1/8}$ and $\mathsf{e}_n^\sharp = \mathsf{e}_n + \eta^\sharp(1+\eta^\sharp)^{n-1}$.

Step 4: Theorem AD(h). (i) On the least torus a pair of narrow bumps, of width ρ at the distance d, is treated at the level $k_1 = \max\{K - s(\mathsf{d}), 2\}$ of the distance d, the working level of Lemma 8.7 at the depth $s(\mathsf{d})$: there the jet of each bump at the background is a constant plus an explicit quadratic form of the curvature, up to errors that the bounds of Theorem YMM1:D make summable over the levels. The induction over the levels with the two sources runs upward from the level k_1 to the last level K, at which the block field is trivial and the quadratic form vanishes, and carries this to the Gaussian value, the explicit part $\frac{3}{2}\mathsf{b}^{-2}\sum f_1 f_2 (C_K^{\mathrm{free}})^2$, with the error $\epsilon_2^{\mathrm{nar}}(g,\mathsf{d})(\rho/\mathsf{d})^6$ in natural sizes, $\epsilon_2^{\mathrm{nar}} \le C(g)(\log\frac{1}{\mathsf{d}})^{19\mathfrak{p}_0}\mathsf{d}^{1/2}$.

The remainder of the two-point function beyond the Gaussian value is bounded by placing a dummy bump at the distance ρ from the first bump, applying the bound on the remainder of three sources of (iii) at the lengths (ρ,ρ,d), and setting the parameter of the dummy bump to 0 in the mixture over the histories; it is $\le C\mathsf{b}^2\mathsf{d}^{3/2}(\rho/\mathsf{d})^6$; the chessboard bound, read at two lengths (the fold at two lengths), carries it to every state with a further error $\le C(g)(\rho/\mathsf{d})^6\mathsf{d}^{3/2}$; the comparison of $\sum_{\lambda(p)=\lambda,\lambda(q)=\mu}\varphi_1\varphi_2(C_K^{\mathrm{free}})^2$ with $\mathcal{K}_{\lambda\mu}$ costs $C[\frac{a_K}{\vartheta\rho} + (\frac{\mathsf{d}}{\ell_g})^3](\rho/\mathsf{d})^6$.

The change of units $x \mapsto L^z x$ multiplies the label, the side and the distances by L^z, and for z large it carries a first-passage datum at $g \le \gamma$ to one at a coupling below γ_σ; this gives the narrow form at every $0 < g \le \gamma$. (ii) For bumps of radius ρ the bounds of (i) are $A\rho^6\prod\|\phi_a\|_\infty$, uniform in j; a bilinear form with such bounds at all small radii has a Borel kernel with $|k| \le (\frac{3}{\pi})^2 A$; the subsequence is taken at all pairs through partitions of unity; every periodic Gibbs state at $\mathfrak{D}(g)$ is invariant under the lattice translations, and the tori too, so the kernels depend on $x-y$; $\sum_\lambda \mathcal{O}_\lambda = \mathcal{O}$ gives $\sum \tau_{\lambda\mu} = \mathsf{s}_2^T$. (iii) With three sources at two scales, an induction over the levels shows: let $k_1 = \max\{K - s(\mathsf{d}), 2\}$ be the level of the distance d, $\mathsf{b}_{k_1} = A_1(\log x_{k_1})^{\mathfrak{p}_0}$ its threshold and $\delta_{k_1} = \delta(x_{k_1}) = A_1 x_{k_1}^{-1/2}(\log x_{k_1})^{\mathfrak{p}_0} \le A_1 Y_{s(\mathsf{d})}^{\mathfrak{p}_0}(\mathsf{d}/\mathsf{b})^{1/2}$ (equation YMM1:(634)), and $Z = Z_0(1+\mathsf{b}_{k_1})^2$ with a number Z_0 formed with the constants among the construction results, so that $Z^m \le C\, Y_{s(\mathsf{d})}^{2m\mathfrak{p}_0}$; if at the level k_1 each jet of the sources is a constant plus an explicit quadratic form of the curvature, up to $\epsilon_\circ \mathsf{v}_\beta$ with weights v_β whose products over partitions do not exceed v_β, then at every later

level, up to the last level K, it is the Gaussian value, up to $\mathsf{a}_m Z^m \varpi \mathsf{v}_\beta$ with $(\mathsf{a}_m) = (1, 14, 285)$ and $\varpi \le \epsilon_\circ + C\delta_{k_1}$, provided $(K - k_1)\varpi \le 1$, which holds for d below a threshold depending on g.

As $Y_{s(\mathsf{d})} \le 2\log\frac{1}{\mathsf{d}} + C(g)$, the factors Z^m and $\mathsf{b}_{k_1}^2\delta_{k_1}$ give the powers of $\log\frac{1}{\mathsf{d}}$ below. The explicit Gaussian part is the ring $3\mathsf{b}^{-3}\mathcal{K}_K^{(3)}$, with the error $C(g)(\log\frac{1}{\mathsf{d}})^{39\mathfrak{p}_0+2}\mathsf{d}^{1/2}$ times the natural size $\rho^9 r^{-3}\mathsf{d}^{-6}\mathsf{b}^{-3}\prod\|f_a\|_\infty$; the remainder $S_3^T - \mathsf{J}_3$ is at most $C\mathsf{b}^3\mathsf{d}^{3/2}$ times the natural size, with no power of r; the passage over the least torus costs $(\mathsf{d}/\ell_g)^3$, and the comparison of the lattice and continuum rings at two scales is explicit. As in (i), the fold at two lengths carries the three-point law at narrow bumps from the least torus to every state, with the further error $C_3^{\mathrm{tr}3}(g)\,\mathsf{d}^{3/2}\rho^9 r^{-3}\mathsf{d}^{-6}\prod_a\|f_a\|_\infty$, $C_3^{\mathrm{tr}3}(g)$ a number formed with g and the constants among the construction results; E_3 contains this term, the labels at g lying in a compact interval and $\mathsf{d}^{3/2} \le \mathsf{d}^{1/2}$, and the law of (h)(iii) along the states s_j rests on it. (iv) follows from (ii), (iii) and the free identity

$$\left|\tfrac{2\pi}{3}\mathsf{b}r^3 \cdot 3\mathsf{b}^{-3}k_3(c + \tfrac{r}{2}n, c - \tfrac{r}{2}n, z) - \mathsf{t}^\circ(n, c - z)\right| \le 2.66\,(r/\mathsf{d})^2\mathsf{b}^{-2}\mathsf{d}^{-6},$$

with $|t_\lambda(c,z) - \mathsf{t}^\circ(e_\lambda, c-z)| \le 6\epsilon_\sigma(g, |c-z|)\mathsf{b}^{-2}|c-z|^{-6}$ almost everywhere by (ii) and the identity for t° of the setting; the null set lies in (c, z) alone because s_3^T is continuous. (v) The limit in K exists at disjoint supports by (d): its clause on one plane field among action densities gives the limit of $\langle\mathcal{O}_\lambda(\phi_1); \mathcal{O}(\phi_2)\rangle$ at the fixed label, and $\langle\mathcal{O}(\phi_1); \mathcal{O}(\phi_2)\rangle$ converges by the convergence of S_2^T at a fixed label. For the identification, the narrow bumps are the $f_\pm^c$ of the statement, the radial tents of radius $\rho = \frac{r}{8}$, of mass 1 and of height $3/(\pi\rho^3) = 1536/(\pi r^3)$ about $c \pm \frac{r}{2}e_\lambda$; the threshold on K is $128a_K \le r$, that is $16a_K \le \rho$, and $s(\rho) \le K$, which gives $s(\frac{r}{2}) \le K$, the depth function being non-increasing.

The number r_* is taken so that for $0 < r \le r_*$ the depth $s = s(\frac{r}{2})$ obeys $s \ge 3$ and $L^2 C_W(s) Y_s^{3\mathfrak{p}_0} \le L^{s-3}$, the condition under which the family near the pair is formed, and $\frac{r}{2} \le \min\{r_0(\mathsf{b}), r_1(\mathsf{b})\}$, the radii up to which the induction of (iii) and the frame of the pair are formed, which read g and b; all three hold for small r, since $s(\frac{r}{2}) \to \infty$ as $r \to 0$ and the second holds at all large s; and $r_* \le \frac{1}{6}\mathsf{d}$. Write $S_3^T = \mathsf{J}_3 + (S_3^T - \mathsf{J}_3)$, J_3 the explicit Gaussian part, cut ϕ_2 into pieces carried by cubes of side $\frac{1}{4}r$, of the natural size $\mathsf{b}^{-2}\mathsf{d}^{-6}r^3\|\phi_2\|_\infty$, and compare, at each $c \in \operatorname{supp}\phi_1$ and for each piece, the pair of narrow bumps at $c \pm \frac{r}{2}e_\lambda$, weighted by $\frac{2\pi}{3}\mathsf{b}r^3$, with the plane field $\mathcal{O}_\lambda - \frac{1}{3}\mathcal{O}$ at c.

For the remainder: for almost every block field, at every level n with $a_{K-n} \ge r^{1/2}$, the difference jet at the background, the jet of the weighted pair minus that of the plane field, is a constant up to $C[r^{\beta_H/72} + (a_K/r)^{1/18}]\varepsilon_n^2 a_{K-n}^{-4}$, ε_n the radius of regularity of the level n and β_H the Hölder exponent; this comes from the Hölder regularity, with the exponent β_H, of the backgrounds at the scale of the pair, carried over the levels by the induction of (iii). Integrating over the mixture of the histories on the least torus, whose moments of the scale of regularity are bounded uniformly in K, gives for the remainder the difference estimate $C(g, \mathsf{b})\mathsf{d}^{-5/2}[r^{\beta_H/72} + (a_K/r)^{1/18}]$ times the natural size.

The explicit Gaussian parts are compared on the lattice of T_{ℓ_g}, with $C(g, \mathsf{b}, \vartheta_0)\mathsf{d}^{-9/2}$ and the same bracket. In the ring of the left member the near leg, between the two tents, whose plaquettes are between $\frac{3}{4}r$ and $\frac{5}{4}r$ apart, is $a_K^3\mathbb{K}_3(re_\lambda)$ up to the cost $(a_K/r)^2 + (r/\ell_g)^3$, by the comparison YMM1:(2245) of the lattice kernel with $\mathbb{K}_3$ in the setting. The two far legs a, a', from the two tents to the support of ϕ_2, enter through $\mathsf{a}\mathsf{a}' = \frac{1}{2}(\mathsf{a}^2 + \mathsf{a}'^2) - \frac{1}{2}(\mathsf{a} - \mathsf{a}')^2$: the term $(\mathsf{a} - \mathsf{a}')^2$ costs $(r/\mathsf{d})^2$ by the bound on the differences of C_K^{free} along one plane of the setting, its two plaquettes being parallel, equally oriented and at most $\frac{5}{4}r \le \frac{1}{4}(\mathsf{d} - \frac{5}{8}r)$ apart; and in each square the far leg reads one tent alone.

There the lattice sums over the tents are Riemann sums, at the cost $a_K/\rho = 8a_K/r$; the entries of $\mathbb{K}_3$ are harmonic off 0, so its mean over the two radial tents, over the one through the sum over its plaquettes and over the other through the integral over c, is its value at re_λ; and the integral over c moves the argument of ϕ_1 by at most r, at the cost $r\operatorname{Lip}\phi_1 \le r\|\phi_1\|_\infty/(\vartheta_0\mathsf{d})$. Finally

$\frac{2\pi}{3}r^3\cdot 3\mathbb{K}_3(re_\lambda)=\frac{3}{2}(E_{\lambda\lambda}-\frac{1}{3}\mathbf{1})$, so the weighted pair becomes the plane field $\mathcal{O}_\lambda-\frac{1}{3}\mathcal{O}$ at c in the explicit part of the two-point function of the right member, whose legs are lattice kernels as well.

Each of these costs is a number formed with $g,\mathsf{b},\vartheta_0,\mathsf{d}$ times the bracket, as $a_K/r\le\frac{1}{128}$ and $r\le 1$. Summing over the at most $9^3(\mathsf{d}/r)^3$ pieces and integrating over c, against the mass $\le\frac{4\pi}{3}\mathsf{d}^3\|\phi_1\|_\infty$, gives the display of (h)(v), uniformly in K. Letting $K\to\infty$ at a fixed r, which is allowed since $128a_K\le r$ and $s(\rho)\le K$ from some K on, and then $r\to 0$ gives the identification at the fixed d.

Step 5: Theorem AE(a), (b). By Lemma 8.8, $-\beta\sum_p h_{\omega,\chi}=\mathsf{b}\,\mathrm{Pf}(k^h)$, with $\|\mathrm{Pf}(k^h)\|\le 156|\omega|\,\mathrm{Lip}(\chi)R_1(\chi)\le 468\ell'|\omega|\,\mathrm{Lip}_\infty(\chi)$, and (i) is Lemma 8.8 at $r=n+1$, with $C_n^\flat(\rho)=468\ell' k_n^\flat(\rho)$, $k_n^\flat(\rho)=\max\{k'(n+1,\frac{\rho}{2}),$ the crude bound below $K_0'\}$. Both clauses follow the one rule of the statement for a rough entry F: its norm $\|F\|$ times a number, and, free of the side and of the state, times the counts N_F and N_i of the cubes of the mesh that meet its carrier and the supports. For (ii) we put the rough entry alone in its cell of a board and the Lipschitz fields in other cells, in any mutual position.

For groups G_j of entries, $R_G=\partial_G[e^{\sum_{e\in G}z_eX_e}/\nu(e^{\sum_{e\in G}z_eX_e})]_{z=0}$ has $\nu(\prod_j R_{G_j})=\sum_\pi\prod_{I\in\pi}\kappa(I)$ over the partitions all of whose blocks meet two groups; and, for integers $n\ge 0$, $p\ge 1$ and numbers $s_1,\dots,s_n>0$, $\rho_*>0$, $Q\ge 1$, $\alpha_1,\dots,\alpha_p\ge 0$: if $A_1,\dots,A_p,B$ are holomorphic on the domain $\mathsf{D}=\{z\in\mathbb{C}^n:\sum_r|z_r|s_r<\rho_*\}$, with $B(0)=1$, $|A_j(z)|\le\alpha_jQ^{\#z}$ and $|B(z)|\le Q^{\#z}$ on D, $\#z$ being the number of the non-zero coordinates of z, then $A_1\cdots A_pB^{-p}$ is holomorphic near 0 and $|\partial_{[n]}(A_1\cdots A_pB^{-p})(0)|\le\binom{n+p-1}{n}n!\prod_j\alpha_j\prod_r(2eQs_r/\rho_*)$.

The chessboard bound of Lemma 8.9 and the bounds of Theorems YMM1:AJ and YMM1:AD on tori for the scalar fields, through their cumulant polynomial, with $e^{nc_V\ell'^3}$, conclude. On the larger sides the chessboard seminorm of a centred rough entry is at most $e^{G_g|^3}k_{N_0}(\mathsf{d})\|F\|$, $k_N(\mathsf{d})=[\sum_\pi\prod_{I\in\pi}k'(\#I,\mathsf{d})]^{1/N}$ over the partitions of N points into blocks of at least two, by its N_0 mirror copies on the reference side; a partition of unity by tents of the mesh $h(n,\rho)$ cuts the shell and the fields, which gives the counts N_χ,N_i; the domination of the periodic Gibbs states (Lemma 8.9) gives the states, and the change of units $x\mapsto L^zx$ gives every label and side.

The whole flux insertion is the rough entry $\mathsf{b}\,\mathrm{Pf}(k^h)+\mathcal{O}(v^{\mathfrak{B}})$, of the norm $13\mathsf{b}|k^h|_1+|v^{\mathfrak{B}}|_\infty\le(158\mathsf{b}+3a)|\omega|\,\mathrm{Lip}(\chi)R'(\chi)$, $R'(\chi)=\max\{R_1(\chi),R_1'(\chi)\}$ (Lemma 8.8), and the same rule bounds it. For $\Theta_\beta[\eta]$ we use $\Theta_\beta[\eta]=\mathsf{b}\,\mathrm{Pf}(k^\eta)$; for $\mathfrak{K}^{\mathrm{v}}[\beta\eta]$, Lemma 8.10(a) gives $\mathfrak{K}^{\mathrm{v}}[\beta\eta]=N_\beta[\eta]-\Theta_\beta[\eta]+\mathsf{b}\,\mathcal{O}(\mathrm{div}^s\eta)-\frac{3}{2}a\,\mathcal{O}(e^\eta)$, and the null term drops beside fields that do not depend on the bonds near $\mathrm{supp}\,\eta$. (b) The spin densities written in petals give $T_{lr}(\varphi)=\mathsf{b}(\mathrm{Pf}(k^{lr})+\mathcal{O}(v^{lr}))$; for two entries the two-source mixed derivatives of Lemma 8.7(a), (e) give the bound first at $0<g\le\gamma$ with $g^{-2}\ge x_{\mathrm{J}}$, the setting of that lemma, with the factor $(2\ell/\mathsf{d}'')^6k_2(g,s(\mathsf{d}''))g^4$.

Every $0<g\le\gamma$ is then reached by the change of units $x\mapsto L^zx$, which carries $\mu_{K,\ell,\beta}$ to $\mu_{K-z,L^z\ell,\beta}$ and multiplies the label by L^z: take z with $L^z\gamma^{-2}\ge 2\max\{\gamma^{-2},x_{\mathrm{J}}\}$. The labels of $\mathfrak{D}(g)$ lie in the compact interval $[\gamma^{-2},X_g+\bar{B}]$, whose image under the multiplication by L^z lies in $[2\max\{\gamma^{-2},x_{\mathrm{J}}\},\infty)$; every b' there lies inside $I(g')$ at $g'=(\mathsf{b}'/2)^{-1/2}\le\gamma$, where $g'^{-2}=\frac{1}{2}\mathsf{b}'\ge x_{\mathrm{J}}$, so finitely many intervals $I(g_i')$ cover the image, and at the cutoffs $K>z$ the bound at the couplings g_i' applies; the cutoffs $K\le z$ are bounded crudely, by the suprema of the entries.

The limits are formed as in Step 1. For the symmetry in (l,r) of the limits: for Lipschitz φ, by Lemma 8.10(e), $(T_{lr}-T_{rl})(\varphi)=\beta\sum_b\sum_{p\ni b}(\varphi(x(p))-\varphi(x_b))a^{-1}[(x_b-x(p))_l\mathfrak{d}_{b,p,r}-(x_b-x(p))_r\mathfrak{d}_{b,p,l}]$, which is b times a rough entry of norm $\le 15a\,\mathrm{Lip}\,\varphi$; so, by the two-entry bounds just proved, at every first-passage datum and every $0<g\le\gamma$, both $\langle(T_{lr}-T_{rl})(\varphi);\mathcal{O}(f)\rangle$ and $\langle(T_{lr}-T_{rl})(\varphi);T_{l'r'}(\varphi')\rangle$ are $O(a)$ at separated supports. The limits are continuous in the sup norms of the entries, by the same bounds, and the Lipschitz functions are dense in the continuous ones in the sup norm; so every limit point is symmetric in (l,r).

Step 6: Theorem AE(c), (d). (c) By Lemma 8.10(a) the null term drops, and $a\,\mathcal{O}(e^\eta)$ contributes $O(a)$ by Theorem AD(a). By Lemma 8.10(b), $\mathfrak{K}^{\mathrm{v}}[\beta\eta]=-\mathsf{b}\sum_\rho P_\rho(\nabla_\rho^+\eta^\rho)+\beta\mathfrak{K}^\sharp[\eta]$, $P_\rho(\mathsf{k})=$

$a^{-1}\sum_p \mathsf{k}(x(p))\Psi_\rho(p)$: a bilinear half and a cubic half. In the bilinear half an exact identity in U, direction by direction and with one integration by parts, is used. For a real weight W of the plaquettes and a direction ρ, let (μ,ν,ρ) be the cyclic permutation of $(1,2,3)$ that ends with ρ; for a bare site y let $p(y;\alpha,\alpha')$ be the plaquette with the corners y, $y+ae_\alpha$, $y+ae_\alpha+ae_{\alpha'}$, $y+ae_{\alpha'}$, and $w_0(y)=W(p(y;\mu,\nu))$, the weight of the plaquette normal to ρ at y; let $g_\mu(y)=G_\rho(\langle y,y+ae_\mu\rangle)$ and $g_\nu(y)=G_\rho(\langle y,y+ae_\nu\rangle)$, the transported differences of the field strengths of the setting, and $E_\mu(y)=\sum_{p\ni b}\mathbf{w}(W_{b,p})$, the sum over the four plaquettes that hold the bond $b=\langle y,y+ae_\mu\rangle$, the lattice equation of motion at b, and $E_\nu(y)$ in the same way. Then

$$-4\sum_p W(p)\Psi_\rho(p)=\sum_y w_0(y)\big[\langle g_\mu,E_\mu\rangle+\langle g_\nu,E_\nu\rangle\big]+\mathrm{Bil}+\mathrm{Cub}+\mathrm{Q4},$$

where Bil comes from the differences of the weight W, Cub from the defect of the linear Bianchi identity and from commutators (factors $\mathrm{Ad}(W_{b,p})-\mathbf{1}$ of plaquette holonomies), and Q4 from $a_p^2+a_{p_+}^2$. For each plaquette $p=p(y;\mu,\alpha')$ through the bond $b=\langle y,y+ae_\mu\rangle$, the one-bond term $\beta\langle\mathbf{w}(W_{b,p}),E_\mu(y)\rangle-3(1-a_p)$ has vanishing cumulants with every entry that does not depend on $U(b)$ (an integration by parts in $U(b)$, as in Lemma 8.10(a)), and $g_\mu(y)$ is the sum of the $\mathbf{w}(W_{b,p})$ over the two plaquettes through b in the directions $\pm\rho$; so β times the first sum is, up to a number, $-3a\,\mathcal{O}(v)$ inside cumulants whose other entries avoid the bonds concerned, with the weight $v=w_0(y)+w_0(y+ae_\rho)$ on the plaquettes $p(y;\rho,\mu)$ and $p(y;\rho,\nu)$ and $v=0$ on the plaquettes normal to ρ; $|v|\le 2\sup|W|$ gives the factor $\frac32$ below; $\beta\,\mathrm{Bil}$ is $a\mathsf{b}\,\mathrm{Lip}_\infty\mathsf{k}$ times a bounded petal form; Cub and Q4 are block forms all of whose monomials have an order ≥ 3, whose sizes fall like L^{-2j} with the level j and give $L^{-(K-s-1)/4}$ at the working depth s (Lemma 8.7(c), (d)).

So, for $r\ge 1$ spectators F_q of the sizes ω_q (block forms with weights, or $\mathcal{O}(v_q)$) whose carriers are at Euclidean distances $\ge\mathsf{d}$ from one another and from $\{\mathsf{k}\ne 0\}$, at all first-passage data with $36a\le\mathsf{d}$, $K\ge s(\mathsf{d}_1'')$ and $K\ge s(\mathsf{d}_1''')$, $\mathsf{d}_1=\frac34\mathsf{d}$,

$$|\mathsf{b}\langle P_\rho(\mathsf{k}\circ x);F_1;\dots;F_r\rangle|\le\Big\{a\big[\tfrac32\sup|\mathsf{k}|+190\,\mathsf{b}\,\mathrm{Lip}_\infty\mathsf{k}\big]e_2+50\,\mathsf{b}\,\Gamma L^{-(K-s-1)/4}e_3\sup|\mathsf{k}|\Big\}\prod_q\omega_q,$$

where $e_2=e_2(r{+}1,\mathsf{d}_1)$ and $e_3=e_3(r{+}1,\mathsf{d}_1)$, the cumulant having $r{+}1$ entries; for a number $r'\ge 2$ of entries and a distance d_1, $e_2(r',\mathsf{d}_1)=(3\ell'/\mathsf{d}_1'')^{3r'}k_{r'}^{\mathrm{loc}}(g,s(\mathsf{d}_1'');\ell')g^{2r'}$, $\mathsf{d}_1''=\min\{\frac45\mathsf{d}_1,L^{-\bar s(r')}\}$, with the depth $\bar s(r')$ of the proof of Lemma 8.8, the least integer $s\ge 3$ with the condition $2\mathsf{T}_{r'}(3)\theta(L^{s-2}g^{-2})\le 1$ of Lemma 8.7(b), read with the series $\mathsf{T}_{r'}$ of the mixed derivatives of the order r' and the size θ stated there, and the number $k_{r'}^{\mathrm{loc}}$ of Lemma 8.7(b); $e_3(r',\mathsf{d}_1)=(3\ell'/\mathsf{d}_1''')^{3r'}\tilde k_{r'}(g,s(\mathsf{d}_1''');\ell')g^{2r'}$ is the like number at the second depth $\mathsf{d}_1'''=\min\{\frac34\mathsf{d}_1,L^{-\tilde s(r')}\}$, $\tilde s(r')$ the least integer $s\ge 3$ with the condition of Lemma 8.7(c) at $p=r'$, and $\tilde k_{r'}$ the number of the bound of Lemma 8.7(c); $\Gamma=\max\{\Gamma^\circ_{\mathrm{Cub}},\Gamma^\circ_{\mathrm{Q4}}\}$, the larger of the comparison weights Γ°_c of Lemma 8.7(d) of the two block forms Cub and Q4; and $s=s(\mathsf{d}_1''')$ at $r'=r+1$.

In (c) this is used with $r=n$ spectators $\mathcal{O}(f_i)$ and $\frac12\mathsf{d}$ in the place of d, so that the numbers are formed at $(n+1,\frac38\mathsf{d})$. These numbers depend on g,ℓ',r,d and on no K or β. The cubic half is Lemma 8.12, the spread being $\ge\mathsf{d}$; the norm $\|\cdot\|_\sharp$ and the rate $c<\frac{1}{14}$ come from it alone. (d) For the cubic half in sup norms we couple on one probability space the chain of the first-passage datum and the chain along $x_j=L^{K-j}\mathsf{b}$ of Lemma 8.11, which share only the block map, the Haar measure and the bare density, and use the law of total covariance given the block field of the level $t=K-\lceil\phi K\rceil$:

$$\langle X;F\rangle=\int(r_{XF}-r_Xr_F)\,d\mathsf{m}_t+\int(r_X-\mathsf{a})(r_F-f_0)\,d\mathsf{m}_t+(\text{large fields}),$$

r_X,r_F,r_{XF} the densities at the never-large history. The first term is a mixed derivative of two separated sources, $\le C_2e^{3-L^u\mathsf{d}'/M}y_Xy_F$, $\mathsf{d}'=\frac12\mathsf{d}$, $y_X=4\ell'^3L^{4u}\cdot 608\,\mathsf{b}L^K\sup|\eta|$, by Lemma 8.7(e) at the level t, whose conditions $L^u\mathsf{d}'\ge 3M$ and $\mathsf{h}_2(u)\le 1$ hold for large K; the second is the oscillation

of Lemma 8.11(b) times $3C_1 y_F$, $y_F = 4\ell'^3 L^{4u} \sup|w|$, and $4\phi < c_0'$; the rest is at most $\mathsf{V}_{\ell'}(\mathsf{b}) L^{-11K}$. In words (Lemma 8.15): a spectator acts on the cubic insertion only through a bounded function of the block field, and the cubic insertion is uncorrelated with every function of the block field up to its oscillation, at the price $L^{4\phi K}$, which a small ϕ pays.

For n spectators the mixed derivatives of every order of the never-large term are bounded by Cauchy's estimates, locality and a count, $e^{-L^u \mathsf{d}/2M}$ paying every power of L^K. In the bilinear half in sup norms, $\mathsf{b}\, a^{-1} \sum_p w(p) \Psi_{\lambda(p)}(p)$, summed over the plaquettes of one normal, is a dominated local source of the weight $76\mathsf{b} \sup|w|$ (Lemma 8.10(b)), and a source cut at a level, with the Hölder bound BT, gives $L^{-K/200}$. For two cubic insertions the same argument is used twice, and the factor L^{4u} does not enter; two orbital insertions and two stress insertions follow with the bilinear half and the null identity.

The numbers of Lemma 8.11(b) are uniform on $[\gamma^{-2}, X_g + \bar{B}]$, which holds every label of $\mathfrak{D}(g)$. The several-source statements used above hold clause by clause in their own ranges: Lemma 8.7(a), (e), which the clauses on the cubic insertion alone read, at $0 < g \le \gamma$ with $g^{-2} \ge x_{\mathrm{J}}$; Lemma 8.7(b), (c), which the bilinear half reads, at $0 < g \le \gamma_W^{\mathrm{ref}}$, and so does Theorem AD(a), which bounds the term $a\,\mathcal{O}(e^{\eta})$. So at every first-passage datum at g on every side of $\mathfrak{L}(g)$, with numbers that depend on g and on no label, the clauses on the cubic insertion alone hold for $0 < g \le \gamma$ with $g^{-2} \ge x_{\mathrm{J}}$, and the other clauses for $0 < g \le \gamma_W^{\mathrm{ref}}$, where $g^{-2} \ge x_{\mathrm{J}}$ holds of itself; and $x \mapsto L^z x$ gives every fixed label and side.

Step 7: Theorem AE(e)–(g). In the mean of the mirror copies $\mathrm{St}_K[\eta]$ may be replaced by $-\mathrm{Rm}_K[\eta]$ (Lemma 8.10(a) and the proof of Lemma 8.13). A partition of unity cuts η, η', H' into at most $C(R/\mathsf{d})^3$ pieces of sup diameter $\le \frac{1}{8}\mathsf{d}$, at the cost $C\mathsf{d}^{-2}$ in the C^2 norms. For two sets of sup diameter $\le \frac{1}{8}\delta_0$ that are δ_0 apart along one direction there is an offset in $h\mathbb{Z}^3$, $h \le \frac{1}{64}\delta_0$, of a board of side $\frac{1}{2}\ell_g$ for which they lie in different cells at sup distance $\ge \frac{1}{16}\delta_0$ from the walls; Lemmas 8.9 and 8.13 give $|\nu(A^\nu[F_1]A^\nu[F_2])| \le 2e^{2G_g|^3} \|F_1 - c_1\|_{\mathrm{ch}} \|F_2 - c_2\|_{\mathrm{ch}}$.

Two stress insertions give $L^{-K/28}$ each, hence $L^{-K/14}$; for two conserved tensors $L^{-K/36}$ each gives $L^{-K/18} \le L^{-K/20}$; against a plain tensor entry, which costs $L^{4u} = L^{K/100}$, the factor $L^{-K/36}$ leaves $L^{-K/60}$; and $\mathsf{b}\,\mathcal{T}_K(H^{\mathrm{cons}}[\eta]) = \mathrm{St}_K[\eta] - \Delta_K[\eta]$. For the mean of the orbital insertion, cut into the pieces of the partition of unity, $\nu(\mathfrak{K}^{\mathrm{v}}[\beta\eta]) = \nu(F_\eta)$ with $F_\eta = \mathfrak{K}^{\mathrm{v}}[\beta\eta] - \frac{1}{4}\mathfrak{N}[\mathsf{k}_\eta]$, $\mathsf{k}_\eta^\rho = \nabla_\rho^+ \eta^\rho$, since $\nu(\mathfrak{N}[\mathsf{k}_\eta]) = 0$ by Lemma 8.10(a); Lemma 8.13 at $m = 1$, $\phi = \frac{1}{400}$ gives $\|F_\eta\|_{\mathrm{ch}} \le CK^p L^{-K/28} \|\eta\|_{C^2}$, F_η having the mean 0 on $T_{\ell'}$, and Lemma 8.9 at $q = 1$, $c_1 = 0$ gives $|\nu(\mathfrak{K}^{\mathrm{v}}[\beta\eta])| \le e^{G_g|^3} CK^p L^{-K/28} \|\eta\|_{C^2}$. (f) n sets of sup diameter $\le \frac{1}{4n}$ lie at sup distance $> \frac{1}{8n}$ from all the walls of some board with offset on a grid of mesh $< \frac{1}{2n}$ (a pigeonhole); several slots may share a cell (Lemma 8.13); Lemma 8.9 holds with any number of cells; recentring from the torus mean to ν costs 2^n terms; and $4\phi(n-1) < \min\{c_0', \frac{1}{28} - 3\phi\}$ pays the factors L^{4u}.

At $n_1 = 1$, $c = \frac{1}{56}$, a fixed $\mathsf{d} > 0$ satisfies $\mathsf{d}L^u \ge K^2$ for $K \ge K_0(\mathsf{d})$. (g) $\sigma(H^{\mathrm{cons}}[\eta], H_2, \dots, H_n)$ is the limit of the left member of (f) at $n_1 = 1$, which tends to 0 at every fixed $\mathsf{d} > 0$, and disjoint compact supports have a positive sup distance. By reflection positivity of σ at the mirror θ, $\sigma(H^{\mathrm{cons}}[\theta\eta], H^{\mathrm{cons}}[\eta])$ is the square of the norm of the vector of $\mathcal{T}(H^{\mathrm{cons}}[\eta])$ in the reconstruction, which therefore vanishes. The equivalence along the sequence is Lemma 8.10(a) with the bound on Δ_K in (e), the labels lying in $[\gamma^{-2}, X_g + \bar{B}]$.

For $0 < g \le \gamma_W^{\mathrm{sd}}$ the cited bound on centred products of tensor entries and a diagonal argument give the convergent subsequences; the covariance and the reflection positivity pass to the limits from the periodic Gibbs states, and $\mathcal{T}_K(f\mathbf{1}) = \mathcal{O}(f)$ gives the trace part.

Step 8: Theorem AF(a), (b). (a) We write $\mathfrak{U}_{\omega,\chi} = (\mathfrak{U}_{\omega,\chi} - \mathfrak{U}^\sharp[\chi\,\omega y]) + \mathfrak{U}^\sharp[\chi\,\omega y]$, where $\chi\,\omega y$ is a field with $\mathsf{H}(\chi\,\omega y) \le (2 + 3\ell)|\omega| \|\chi\|_{C^{1,1}}$; since χ covers the f_i, $f_i\chi = f_i$, and the cubic member of the bulk term is $\mathfrak{U}^\sharp[\chi\,\omega y](f)$. The first part has $2(n+1)$ members, a spin member and a bilinear orbital member for each $\varphi \in \{\chi, f_1, \dots, f_n\}$. The spin members are $-\beta\langle \mathfrak{S}_\omega[\chi]; \mathcal{O}(f.)\rangle$, with

$\beta\,\mathfrak{S}_\omega[\chi] = \mathsf{b}\,a^{-1}\mathfrak{S}_\omega[\chi]$, and $\langle a^{-1}\mathfrak{S}_\omega[f_i];(\mathcal{O}(f_l))_{l\neq i}\rangle$. By Lemma 8.10(e), $\sum_{p\ni b} a^{-1}(x_b - x(p))_\lambda \mathfrak{d}_{b,p,\rho}$ is symmetric in (λ,ρ) and ω is antisymmetric, so that

$$a^{-1}\mathfrak{S}_\omega[\varphi] = \sum_b \sum_{p\ni b} \sum_\rho k^\varphi_{b,p,\rho}\,\mathfrak{d}_{b,p,\rho}, \qquad k^\varphi_{b,p,\rho} = a^{-1}\big(\varphi(x(p)) - \varphi(x_b)\big) \sum_\lambda \omega_{\rho\lambda}\, a^{-1}(x_b - x(p))_\lambda :$$

an entry of the order 2 with real weights $|k^\varphi| \le \frac14 |\omega| \mathrm{Lip}\,\varphi$, which vanish unless $\varphi(x(p)) \neq \varphi(x_b)$; $\beta\,\mathfrak{S}_\omega[\chi]$ is b times such an entry. By Lemma 8.10(b), and since $\nabla^+_\rho(\varphi\,(\omega y)_\rho) = (\omega y)_\rho \nabla^+_\rho \varphi$, $(\omega y)_\rho$ being free of y_ρ, the bilinear members are $\langle \mathfrak{J}^{\mathrm{bl}}[\mathsf{k}^\chi];\mathcal{O}(f.)\rangle$ and $-\mathsf{b}^{-1}\langle \mathfrak{J}^{\mathrm{bl}}[\mathsf{k}^{f_i}];(\mathcal{O}(f_l))_{l\neq i}\rangle$, where $\mathfrak{J}^{\mathrm{bl}}[\mathsf{k}] = \beta \sum_{p,\rho} \mathsf{k}^\rho(x(p))\Psi_\rho(p)$ and $\mathsf{k}^{\varphi,\rho}(y) = (\omega y)_\rho \nabla^+_\rho \varphi(y)$; these vector fields are Lipschitz, with norm $\le 5|\omega|(1+\ell)\|\varphi\|_{C^{1,1}}$, which is where the norms $\|f_i\|_{C^{1,1}}$ enter, and supported in the a-neighbourhood of $\mathrm{supp}\,\varphi$.

By Lemma 8.10(c), $\mathfrak{J}^{\mathrm{bl}}[\mathsf{k}] = -\frac14 \mathfrak{N}[\mathsf{k}] + \sum_{v=1}^5 \mathfrak{J}_v[\mathsf{k}] - \frac14 c_{\mathsf{k}}$: a null term, entries of the orders $2,2,2,3,4$ with weights of the order of the norm of k and, for the orders $3,4$, of β times it, and a number, which drops from the cumulants. In (i) let $D \ge \mathsf{d}$ be the spread of the supports. Two rules on spreads are used. A family of sets has a spread at least that of each of its subfamilies of two or more sets. And if $2r' < D$ and a set T lies within the sup distance r' of one of the sets and of each set of an index set Q, then T is empty when these are all the sets, and otherwise T and the remaining sets have a spread $\ge D - r'$: points of T and of the remaining sets that were closer would give points of all the sets that are pairwise closer than D.

With χ in the first entry, the carrier of the entry and the supports have a spread $\ge D$. With f_i in the first entry, the carrier lies within $\frac32 a$ of $\mathrm{supp}\,f_i$ and the cumulant is taken with the $\mathcal{O}(f_l)$, $l \neq i$: the spread is $\ge D - \frac32 a$. The null terms meet the sources: the covering fixes χ at the barycentres and at the bond midpoints of the plaquettes of the supports, while k^χ reads χ at the points $y + a e_\rho$ as well, so that $\mathrm{supp}\,\mathsf{k}^\chi$ may meet a support; and $\mathrm{supp}\,\mathsf{k}^{f_i}$ may meet $\mathrm{supp}\,f_l$. They are taken apart by the contact formula of Lemma 8.10(f): by (N3) the cumulant of $\mathfrak{N}[\mathsf{k}]$ with the sources of a set A is a sum of cumulants of the entries $\mathfrak{R}[f_{q_1}\cdots f_{q_{j-1}}\mathsf{k}; f_{q_j}]$ with the remaining sources, and by (N4) each such entry is a number, the density a_p and densities of the order 2, with no factor β, carried within the sup distance $2a$ of $\mathrm{supp}\,\mathsf{k}$ and of the supports that it absorbs.

The spread of $\mathrm{supp}\,\mathsf{k}^\chi$ and the supports is $\ge D$, and that of $\mathrm{supp}\,\mathsf{k}^{f_i}$ and the $\mathrm{supp}\,f_l$, $l \neq i$, is $\ge D - a$; once these exceed $4a$, the terms that absorb all the sources vanish, the numbers drop from the others, and by the merging of sets of Lemma 8.10(f) every remaining entry has with the remaining supports a spread $\ge D - 2a$, resp. $\ge D - 3a$. So in every term that is left the spread is $\ge \mathsf{d} - 3a$, which is $\ge \frac12 \mathsf{d}$ once $6a \le \mathsf{d}$, and Lemma 8.16 gives $L^{-K+(\frac12 - c_*)K} \le L^{-c_* K}$ for the orders 2 and $L^K \cdot L^{-\frac32 K + (\frac12 - c_*)K} = L^{-c_* K}$ for the orders $3,4$. The cubic part is Lemma 8.12, whose spread condition holds because the support of the field $\chi\,\omega y$ is added to the supports, whose spread is D.

In (ii), $n = 1$: the members with f_1 in the first entry are means, of the spin insertion and of the bilinear density $\mathfrak{K}^{\mathrm{v}} - \mathfrak{K}^\sharp$, and vanish by the mirror symmetries of the measure (Lemma 8.10(b)); in the members with χ the weights vanish unless χ varies across the plaquette or the bond, so, χ being 1 on the d-neighbourhood of $\mathrm{supp}\,f_1$, their carriers are at sup distance $\ge \mathsf{d} - 2a$ from $\mathrm{supp}\,f_1$, the null term meets no source, and Lemma 8.16 applies to the pair. The cubic member is $\mathfrak{U}^\sharp[\chi\,\omega y](f_1) = -\beta\langle \mathfrak{K}^\sharp[\chi\,\omega y];\mathcal{O}(f_1)\rangle$, the contact member $a^{-1}\langle \mathfrak{K}^\sharp[f_1 \chi\,\omega y]\rangle$ being a mean of $\mathfrak{K}^\sharp$, which vanishes (Lemma 8.10(b)).

Here $\mathrm{supp}\,f_1$ lies in the set where the field does not vanish, and a periodic field is subtracted: let s be the ℓ-periodic continuous function with $\mathsf{s}(\tau) = \tau$ for $|\tau| \le \frac{\ell}{2} - \delta_0$ that is affine on $[\frac{\ell}{2} - \delta_0, \frac{\ell}{2} + \delta_0]$, and $\zeta^\rho(y) = \sum_\lambda \omega_{\rho\lambda} \mathsf{s}(y_\lambda)$. Then $\zeta = \omega y$ on the closure of the cube of the margin, ζ^ρ does not depend on y_ρ, $\sup|\zeta^\rho| \le |\omega|\ell$ and $\mathrm{Lip}_\infty \zeta^\rho \le |\omega|\ell/\delta_0$. As $\zeta^\rho(y + s e_\rho) = \zeta^\rho(y)$ for all y, s and ρ, the clause of Lemma 8.10(b) on such fields gives $\langle \mathfrak{K}^\sharp[\zeta];\mathcal{O}(f_1)\rangle = 0$: for each direction ρ and each plaquette q, the mirror normal to ρ through the barycentre of q keeps the measure, a_q and ζ^ρ, and changes the sign of $\mathfrak{K}^\sharp[\zeta^\rho e_\rho]$.

The field $\eta' = \chi\,\omega y - \zeta$ vanishes on the d-neighbourhood of $\operatorname{supp} f_1$, where $\chi = 1$ and $\zeta = \omega y$; so $f_1\eta' = 0$, $\mathfrak{U}^\sharp[\chi\,\omega y](f_1) = \mathfrak{U}^\sharp[\eta'](f_1)$, and Lemma 8.12 applies, η' vanishing within d of the support, with $\mathsf{H}(\eta') \le |\omega|[(\ell+2)\sup|\chi| + \ell\,\mathrm{Lip}_\infty\chi + \ell + \ell/\delta_0]$: here the margin δ_0 enters C. In (iii), $\chi - \chi'$ vanishes within d of all the supports, so the exact identity gives $\langle \mathfrak{B}_{\omega,\chi} - \mathfrak{B}_{\omega,\chi'}; \mathcal{O}(f.)\rangle = \beta\langle \mathfrak{S}_\omega[\chi-\chi'] + \mathfrak{K}^{\mathrm{v}}[(\chi-\chi')\omega y]; \mathcal{O}(f.)\rangle$, an insertion that vanishes near the sources, and no condition on the supports is needed.

The limit of the flux follows from the exact identity, $\nabla^s_\omega f = (\omega y)\cdot\nabla f + D_f$ with $\|D_f\|_\sharp \le C_0 M|\omega|(1+\ell)a\|f\|_{C^3}$ by Taylor's formula, the bound (27) on connected functions at separated supports, and the convergence of S_n^T at a fixed label with the rate $K^pL^{-K/10}$ (Corollary YMM1:117.1). For the quarter turn: $e^{\frac{\pi}{2}\omega_{13}}$ is a signed permutation of the axes, an exact symmetry of the lattice measure on T_ℓ, so $S_n^T(f^{\pi/2}) = S_n^T(f)$; since $\frac{d}{dt}f^t = -(\omega y)\cdot\nabla f^t$, $\int_0^{\pi/2}\sum_i S_n^T(\dots,(\omega y)\cdot\nabla f_i^t,\dots)dt = 0$ at every K; with the exact identity and $\nabla^s_\omega f^t - (\omega y)\cdot\nabla f^t = O(a)$ this is the first display, and in the limit the second. (b) In $\mathfrak{U} - \mathfrak{U}^\sharp$ the entries sit where χ_R varies, in $\{\frac43 R \le |y| \le \frac53 R\}$ up to $2a$, or near one of the supports, which lie in $\{|y| < \frac{R}{2}\}$ at mutual distances $\ge \mathsf{d}_0$; all the boxes and supports lie in the sup ball of radius $2R$ about 0, and in each cumulant the carrier of the entry is at a sup distance $\ge \min\{\frac{5R}{6\sqrt3}, \frac{\mathsf{d}_0}{\sqrt3}\} - 2a \ge \mathsf{d}_{\mathrm{b}} := \frac12\min\{\frac{5R}{6\sqrt3}, \frac{\mathsf{d}_0}{\sqrt3}\}$ from every source of that cumulant, for K large, the cumulants with f_i in the first entry being taken with the other sources.

So Lemma 8.16 in its form on all the sides, at the radius $2R$, the distance d_{b} and on the sides $\ell \ge \ell'$ with $\ell' \ge 4R + 2\mathsf{d}_{\mathrm{b}}$, gives the bracket with a number free of the side, the finitely many smaller sides being covered by the form on one torus; the spin part comes with $L^{-(\frac12 + c_*)K}$. The cubic member $\mathfrak{U}^\sharp[\chi_R\,\omega y](f)$ has its entry on top of the sources, so no wall parts them; it is Lemma 8.17, with Lemma 8.12 for the finitely many smaller sides. Weak limit points of the torus laws inherit the bounds. Along a sequence with converging connected functions, the exact identity gives $\mathfrak{U}^{(j)} + \langle \mathfrak{B}; \mathcal{O}(f.)\rangle^{(j)} = \sum_q S_n^T(f_1,\dots,\nabla^s_\omega f_q,\dots) \to -\frac{d}{dt}S_n(f(e^{-t\omega}\cdot))|_{t=0}$, and $\mathfrak{U}^{(j)} \to 0$.

For the volume-first limits Theorem YMM1:AP gives invariance under O(3), so the flux tends to 0. With the limits one after the other: at a label $\mathsf{b}' \in I(g)$, on each torus T_ℓ, $\ell \in \mathfrak{L}(g)$, (a) gives the limit in K of the flux, $\sum_i S_n^{(\ell,\mathsf{b}')}(f_1,\dots,(\omega y)\cdot\nabla f_i,\dots,f_n)$, through every enclosing shell. Along the sides $\ell_k \to \infty$ the convergence $S_n^{(\ell_k,\mathsf{b}')} \to S_n^\circ$ is the hypothesis of the clause; the functions $(\omega y)\cdot\nabla f_i$ are Lipschitz, with the supports of the f_i, so the limit in k is $\sum_i S_n^\circ(f_1,\dots,(\omega y)\cdot\nabla f_i,\dots,f_n)$; and this is $-\frac{d}{dt}S_n^\circ(f(e^{-t\omega}\cdot))|_{t=0}$, as S_n° is multilinear and bounded per ball in the norms $\|\cdot\|_\sharp$, the per-ball bound of Proposition YMM1:91.13 passing to the limit once $\ell \ge 16n(R+1)$ and the fixed supports lie in the central cube, and $t \mapsto f_i(e^{-t\omega}\cdot)$ is differentiable in these norms with the derivative $-(\omega y)\cdot\nabla f_i$ at $t = 0$.

The integers $K_k^* \ge k$ are chosen so that for $K \ge K_k^*$ and $n \le k$ the connected functions on T_{ℓ_k} at the label b' lie within $\frac1k$ of $S_n^{(\ell_k,\mathsf{b}')}$ at all tuples of norms $\|\cdot\|_\sharp \le 1$ with supports in the ball of radius $R_k = \min\{k, \frac18\ell_k\}$ about 0 at mutual distances $\ge \frac1k$, by the rate $K^pL^{-K/10}$ of Corollary YMM1:117.1; every tuple of the clause lies, up to a factor, in these classes from some k on, so along every sequence $K_k \ge K_k^*$ the connected functions converge to S_n°. For given f_i and χ_k, raising K_k^* makes the bulk term on T_{ℓ_k} at most $\frac1k$ as well, by (a), and the flux converges along such sequences to the limit of the display.

For slowly growing tori, the threshold in the cutoff comparison must also be uniform in the side. Fix $n \ge 2$ and a positive separation d. Take the label interval

$$J = [\mathsf{b}_-, \mathsf{b}_+], \qquad \mathsf{b}_- = g^{-2} + B_\sharp - L^{-1}\bar B \ge g^{-2}, \qquad \mathsf{b}_+ = L(g^{-2} + \bar B).$$

It contains all first-passage labels by Corollary YMM1:74.2. For large sides $\ell = 2L^m$, $MR(\mathsf{b}_+) \le L^m$, so the interval is admitted by Theorem YMM1:AR. Its cutoff comparison uses

$$\phi_1 = \frac{1}{180(3n+4)}, \qquad u = \lceil \phi_1 K\rceil, \qquad s = \lceil K/9\rceil.$$

All its smallness conditions are products of powers of ℓ and quantities decaying exponentially or faster in K, except for the volume factor in the discarded mass. The proof of that theorem writes the latter majorant as

$$\bar{\mathsf{R}} = 2M^{-3}\ell^3 L^{3u}\exp\!\left[-c'A_0^2(\log(L^u\mathsf{b}_-))^{2\mathfrak{p}_0}+C_3\ell^3\right], \qquad C_3=\mathsf{C}^{\Sigma}_{\mathrm{maj}}+2+C_{\mathrm{low}}(\mathsf{b}_+).$$

Put

$$c_\ell(n,g)=\left[\frac{c'A_0^2(\phi_1\log L)^{2\mathfrak{p}_0}}{2C_3}\right]^{1/3}.$$

If $\ell\le c_\ell(n,g)K^{2\mathfrak{p}_0/3}$, the positive volume exponent uses at most half of the negative exponent, since $\mathsf{b}_-\ge\gamma^{-2}\ge 1$ and $\log(L^u\mathsf{b}_-)\ge\phi_1 K\log L$. As $2\mathfrak{p}_0>1$, the remaining bound decays faster than every exponential in K, uniformly over these sides. The other comparison conditions then hold beyond a threshold independent of the side; they continue to hold at every $K'\ge K$ with the side fixed. Theorem YMM1:AR and Corollary YMM1:117.1 give

$$\sum_{K'\ge K}|S^T_{n;K'+1,\ell}-S^T_{n;K',\ell}|\le C\ell^{3(n+1)}K^{\mathfrak{p}_n}L^{-K/10}\prod_i\|f_i\|_\sharp, \qquad \mathfrak{p}_n=2\mathfrak{p}_0(n+1)+\tfrac12.$$

Under the stated side bound this is at most $C'K^{2\mathfrak{p}_0(n+1)+\mathfrak{p}_n}L^{-K/10}\prod_i\|f_i\|_\sharp$, which tends to zero. Thus the finite-cutoff connected functions and their spacing limits on those tori have the same limit, and increasing the cutoffs changes the values by at most the same tail.

For completeness, the label bounds follow directly from the canonical flow, as in Proposition YMM1:74.1 and Corollary YMM1:74.2. Put $\mathcal{W}_K(g)=\{\beta:(K,\beta)\in\mathfrak{D}(g)\}$ and $X_g=L(g^{-2}+B_\sharp)$. The flow has increments of modulus at most $B_\sharp$ and satisfies

$$|x_j(\beta)-L^{-j}\beta|\le\bar B(1-L^{-j}).$$

At its first passage, $x_K(\beta)\le X_g<x_{K-1}(\beta)$. Thus, for $\mathsf{b}=L^{-K}\beta$,

$$L\mathsf{b}>X_g-\bar B, \qquad \mathsf{b}\le X_g+\bar B-\bar BL^{-K}\le X_g+\bar B.$$

These imply the outer inclusion because $L^{-1}(X_g-\bar B)=g^{-2}+B_\sharp-L^{-1}\bar B$ and $X_g+\bar B=L(g^{-2}+\bar B)$. To prove the inner inclusion, take $\mathsf{b}\in I(g)=(L^{-1}(X_g+\bar B),X_g-\bar B]$ and put $\beta=L^K\mathsf{b}$. The first passage exists at some $K'\ge1$, since $\beta>X_g$. Its label $\mathsf{b}'=L^{K-K'}\mathsf{b}$ obeys the preceding two inequalities. If $K'\ge K+1$, then $L\mathsf{b}'\le\mathsf{b}\le X_g-\bar B$, a contradiction. If $K'\le K-1$, then $\mathsf{b}'\ge L\mathsf{b}>X_g+\bar B$, also a contradiction. Hence $K'=K$. Existence and uniqueness of the first passage also show that the sets $\mathcal{W}_K(g)$ are disjoint and have union (X_g,∞).

Step 9: Theorem AF(c)–(e). (c) By Lemma 8.10(e), $T_{mm}(\varphi)-\mathsf{b}\check D_m(\varphi)$ is β times orbital potentials in the plane, which are $-\frac14|G_m(b)|^2$ up to densities of the order 4, plus β times densities of the order 4 with weights $\le\sup|\varphi|$, plus $\mathsf{b}\,\mathcal{O}(\tilde\varphi_m)$ with $|\tilde\varphi_m|\le\frac12 a\,\mathrm{Lip}\,\varphi$. Lemma 8.18(c) bounds the first by $CK^pL^{-c_nK}\sup|\varphi|\prod_i\|f_i\|_\sharp$, Lemma 8.18(a) the second by $CK^pL^{-\lambda_L K/4}$, and Lemma 8.18(b) the third by $C_\epsilon a^{1-\epsilon}\mathrm{Lip}\,\varphi$. The sum over m gives the trace. By Lemma 8.10(e), $\sum_{p\ni b}a^{-1}(x_b-x(p))_\lambda\mathfrak{d}_{b,p,\rho}$ is symmetric in (λ,ρ), so $(T_{lr}-T_{rl})(\varphi)=\beta\sum_b\sum_{p\ni b}(\varphi(x(p))-\varphi(x_b))a^{-1}[(x_b-x(p))_l\mathfrak{d}_{b,p,r}-(x_b-x(p))_r\mathfrak{d}_{b,p,l}]$, an insertion of the order 2 with weights $\le\beta a\,\mathrm{Lip}\,\varphi$, and Lemma 8.18(b) at $\sigma=0$ gives $O(a^{1-\epsilon})\mathrm{Lip}\,\varphi$; at $\sigma=1$ it gives $C_\epsilon a^{-\epsilon}\sup|\varphi|$ for T_{lr} itself.

By Lemma 8.10(b), $\mathfrak{K}^{\mathrm v}[\beta\eta]-\beta\mathfrak{K}^\sharp[\eta]=-\mathsf{b}\sum_\rho P_\rho(\nabla^+_\rho\eta^\rho)$, whose in-plane potentials are $-\frac14|G|^2$ up to the order 4 and whose normal potentials are $\Psi_{\lambda(p)}(p)$: Lemma 8.18(a), (c). The limit at a fixed label follows from the clause of Theorem AD(d) on one plane field among action densities, with the convergence of the connected functions of $\mathcal{O}$ at a fixed label, since $\check D_m=\mathcal{O}-2\mathcal{O}_m$. (d) One lattice step along e_r is $U(b)\mapsto W(\pm r,\mu_b)U(b)$ up to a gauge, and for every gauge invariant Φ

$$a\,v_{e_r}\Phi=\tfrac12(\mathrm{Sh}^+_r-\mathrm{Sh}^-_r)\Phi+\mathcal{P}_r\Phi-\mathrm{Sh}^-_r\mathcal{P}_r\Phi+\mathcal{R}_r\Phi, \qquad |\mathcal{P}_r\Phi|\le C\bar a,\quad |\mathcal{R}_r\Phi|\le C\bar a^{3/2},$$

$\mathrm{Sh}_r^{\pm}$ the shifts by $\pm a e_r$ and $\bar a$ the largest plaquette term near the support of Φ. With the null identity of Lemma 8.10(a), its contact form and (c), every member of the Ward identity for the field $\chi\xi$ but $\mathfrak{U}^\sharp[\chi\xi](f)$ is its stated limit up to $O(K^p L^{-c_n K})$, and $\mathfrak{U}^\sharp[\chi\xi](f)$ is bounded by Lemma 8.12, the spread being positive (the field $\chi\xi$ vanishes near the supports of the f_i with $i \notin I$, and near the boundary of the chart for $\xi = \omega y, y$). For $\xi = y$, $\partial_l y^r = \delta_{lr}$, so the contraction with T_{lr} contains the trace, which by (c) is $\mathsf{b}\,\mathcal{O}$; this gives the terms $|I|S_n - \mathsf{b}S_{n+1}(\chi, f)$. For $\xi = e_r$ and χ a function of y_3 alone, $\sum_l T_{lr}(\xi^r \partial_l \chi) = T_{3r}(\chi')$. (e) The equality is the exact identity for the constant field e_ρ (Lemma 8.10(a) with the contact terms; the stress functional of a constant field vanishes). Put $(\tau_\pm f)(y) = f(y \pm a e_\rho)$, $g_i = \nabla^s_\rho f_i$, $f_i^e = \frac12(\tau_+ f_i + \tau_- f_i)$ and $h_i = (f_i^e - f_i)/a^2$. The measure is invariant under the lattice translations, so $S_n^T(\tau_+ f) = S_n^T(\tau_- f)$; with $\tau_\pm f_i = f_i^e \pm a g_i$ this gives $0 = 2\sum_{|J|\ \mathrm{odd}} a^{|J|} S_n^T(g_J, f^e_{J^c})$, and with $f^e = f + a^2 h$,

$$\sum_i S_n^T(g_i, (f_l)_{l\neq i}) = -\sum_{|J|\geq 3\ \mathrm{odd}} a^{|J|-1} S_n^T(g_J, f^e_{J^c}) - \sum_i \sum_{J'\neq\emptyset} a^{2|J'|} S_n^T(g_i, h_{J'}, f_{\mathrm{rest}}),$$

at most $2^n + n2^n$ terms, each with a factor a^k, $k \geq 2$. The functions g_i and h_i are averages of translates of $\partial_\rho f_i$ and of $\frac12 \partial_\rho^2 f_i$, so their norms $\|\cdot\|_\sharp$ are bounded by those of these derivatives, and their supports lie in the a-neighbourhoods of the $\operatorname{supp} f_i$; the bound (27) on connected functions at separated supports bounds each term. At $n = 2$, $\langle \mathcal{O}(\tau_\pm f_1); \mathcal{O}(f_2)\rangle = \langle \mathcal{O}(f_1); \mathcal{O}(\tau_\mp f_2)\rangle$ by the invariance, and the two members cancel exactly: the statement has content for $n \geq 3$ and expresses the invariance under lattice translations and the failure of the Leibniz rule for ∇^s_ρ. For the second display, the contact form of Lemma 8.10(a) at the field χe_ρ, where $\Theta_{f_i}[\chi e_\rho] = 0$ because $\chi(x_b) = \chi(x(p))$ at every plaquette p at which f_i does not vanish and at its four bonds b, and the vector weight $f_i \chi e_\rho$ is $f_i e_\rho$ for $i \in I$ and 0 otherwise, gives the left member as $-\sum_{i\in I} S_n^T(\dots, \nabla^s_\rho f_i, \dots)$; and $\nabla^s_\rho f - \partial_\rho f$ is an average of translates of $\partial_\rho^3 f$ with the total weight $\frac{a^2}{6}$.

Step 10: Remark 8.4. For a trilinear form that is invariant under the lattice translations along e_ρ, write the functions through their Fourier coefficients at $k_1 + k_2 + k_3 = 0$ and put $z_i = e^{iak_i}$; then ∇^s_ρ and ∇^+_ρ act by $(z - z^{-1})/2a$ and $(z-1)/a$, and since $z_1 z_2 z_3 = 1$,

$$\prod_{i=1}^3 (z_i - 1) = \sum_i z_i - \sum_{i<j} z_i z_j = \sum_i (z_i - z_i^{-1}),$$

which is the displayed identity. Proposition 8.19(c) gives $a^3 S_3^T(g_1, g_2, g_3) \to 6\mathsf{b}'^{-3} \int g_1 g_2 g_3$ for Lipschitz functions, without a separation assumption. Thus the two sides can have order a^{-1} when the supports meet. In the rotational identity the flux through a shell separated from the supports stays bounded, by Theorem AE(a), whereas the difference between the symmetric and continuous generators contains three derivatives.

We first give the free-photon calculation. Its local part requires a difference estimate for the curvature kernel. For equally oriented parallel plaquettes p, p', put $u = x(p) - x(q)$, using a least lift. If $|x(p) - x(p')| \leq |u|/4$ and $|u| \geq 8a$, then

$$|C_K^{\mathrm{free}}(p, q) - C_K^{\mathrm{free}}(p', q)| \leq C_\nabla a^3 |x(p) - x(p')|\, |u|^{-4}, \qquad C_\nabla = 256\sqrt{3} C_{\mathrm{h}}(1 + 3C_{\mathrm{lat}}). \tag{44}$$

Here C_{h} is an absolute constant in the interior gradient estimate for a scalar discrete harmonic function; Theorem 6.3.8(a) of [5] gives this estimate, with the finitely many small radii absorbed into the constant. Indeed, $dd^* + d^*d$ acts on each plane component as the scalar lattice Laplacian and commutes with the projection onto exact 2-forms. Applied to the column $C_K^{\mathrm{free}}(\cdot, q)$, it gives $dd^*\delta_q$, which vanishes beyond the plaquettes sharing a bond with q. The column is therefore harmonic at distance at least $2a$ from $x(q)$. Join $x(p)$ to $x(p')$ by a lattice path of length at most $\sqrt{3}|x(p) - x(p')|$. This path stays at distance at least $|u|/2$ from $x(q)$. On balls of radius $|u|/4$ about its points, equation YMM1:(2246) bounds the column by $4^3(1 + 3C_{\mathrm{lat}}) a^3 |u|^{-3}$. The gradient estimate bounds each lattice step by $4^4 C_{\mathrm{h}}(1 + 3C_{\mathrm{lat}}) a^4 |u|^{-4}$. Summing along the path proves (44).

Let the real functions f_i have compact supports inside the margin and bounded derivatives through order five, and let $\chi = 1$ on a neighbourhood of these supports. Write θ_p for the three-colour Gaussian curvature of covariance $\beta^{-1}C_K^{\mathrm{free}}$. In this model

$$a_p = \tfrac{1}{2}|\theta_p|^2, \qquad \mathbf{w}(W_{b,p}) = \pm\theta_p, \qquad \Psi_\rho(p) = -\tfrac{1}{4}|\theta_{p_+} - \theta_p|^2.$$

The sign records the plaquette orientation. The spin densities and the other insertions are quadratic. The linear Bianchi identity gives $\mathfrak{r}^\sharp = 0$, hence $\mathfrak{U}^\sharp = 0$, and Wick's formula gives the connected functions as rings. The exact Ward identity remains valid after removing the terms $\frac{3}{2}a\,\mathcal{O}(\cdot)$ coming from the curvature of $SU(2)$; against separated sources these terms are $O(a)$. The expression with the continuous generator is therefore, up to $O(a)$,

$$\mathfrak{U}_{\omega,\chi}(f) - \sum_i S_n^T(\ldots, \nabla_\omega^s f_i - (\omega y)\cdot\nabla f_i, \ldots). \tag{45}$$

The terms with χ in the first slot have their quadratic insertion separated from the supports. The ring formula makes them $O(a)$. The terms with f_i in that slot are local. For the bilinear part their kernel is

$$M_\rho(p,q) = [C_K^{\mathrm{free}}(p_+,q) - C_K^{\mathrm{free}}(p,q)]^2.$$

Equation (44) bounds it by $Ca^8|u|^{-8}$ for $|u| \geq 8a$; at the remaining distances use the kernel bound and the projection bound on the diagonal. The spin part has one additional factor a and kernels $C_K^{\mathrm{free}}(q,q')C_K^{\mathrm{free}}(q',p)$, where the plaquettes q meet a bond of p.

Expand the test functions about the midpoint of $x(p), x(p_+)$ in the first case and about x_b in the second. In lattice units these kernels have uniformly bounded moments through orders four and two, respectively; the third-order tail in the second case is even and has degree -6. Together with

$$\nabla_\omega^s f - (\omega y)\cdot\nabla f = \frac{a^2}{6}\sum_\rho (\omega y)_\rho \partial_\rho^3 f + O(a^4),$$

the expansion writes (45) as local forms with factors $a^{-3}, a^{-2}, a^{-1}, a^0$, plus an $O(a)$ remainder for $n = 2$ and an $O(a\log(1/a))$ remainder for $n = 3$. The infinite-lattice coefficients are independent of a by scaling. The torus correction changes each term by $O(a)$. At order three, configurations with two nearby entries and a third at distance $|u|$ use the fourth moment of a kernel of degree -7. Their contribution is bounded by a times the sum of $a^3|u|^{-3}$ over $a \leq |u| \leq 1$, which gives the logarithm. Five derivatives suffice for these Taylor remainders and for the $O(a^4)$ error in replacing the lattice sum of $(\omega y)\cdot\nabla\prod_i f_i$ by its integral. The constants use the suprema of derivatives through order five.

All four local terms vanish. Inversion through the centre of the chart preserves the Gaussian measure and the expression, and removes the odd orders in this local expansion, namely the coefficients of a^{-2} and a^0. The coefficient of a^{-3} is a multiple of

$$\int (\omega y)\cdot\nabla\prod_i f_i = 0,$$

since $\mathrm{div}(\omega y) = 0$. For the coefficient of a^{-1}, use the other expression for the same quantity: the variation of S_n^T under continuous rotations minus the bounded shell flux. The potentially divergent terms are rotation derivatives of cubic-invariant local forms with at most two derivatives. A cubic-invariant symmetric tensor of rank two is a scalar multiple of the identity, so these forms are rotation invariant. At $n = 2$ the terms can also be written as combinations of

$$\int (\omega y)_\rho \partial_\rho(\partial_\rho f_1 \partial_\rho f_2) = 0, \qquad \int \left[(\omega y\cdot\nabla f_1)\Delta f_2 + (\omega y\cdot\nabla f_2)\Delta f_1\right] = 0.$$

The first identity uses that $(\omega y)_\rho$ is independent of y_ρ. The first cubic-invariant local form that need not be rotation invariant has four derivatives. Thus only the stated remainders remain. Finally,

$a^3 S_3^T \to 6\mathsf{b}^{-3}\int$ in the Gaussian model and

$$\sum_i \int (\omega y)_\rho \partial_\rho^3 f_i \prod_{l\neq i} f_l = 3\int (\omega y)_\rho \prod_i \partial_\rho f_i.$$

Multiplying the difference of the generators by a gives the asserted limit of $a\mathfrak{U}_{\omega,\chi}$.

At order one the neighbourhood condition has a concrete role. Take

$$S=[-1,1]\times[-2,2]\times[-1,1], \qquad \kappa(y)=3-y_1y_2, \qquad f_1=\kappa\ \mathrm{dist}(\cdot,\partial S)\ \text{on } S, \qquad f_1=0\ \text{off } S.$$

The faces of S are lattice planes at every cutoff, and f_1 is Lipschitz with a kink at its boundary. Let $\chi=\varsigma(\mathrm{dist}(\cdot,S))$, where $\varsigma\in C^{1,1}$ equals $1-\mu s^2/2$ for $0\le s\le s_0$, with $\mu>0$, and decreases to zero inside the margin. Then $\chi=1$ on S but on no neighbourhood of it. It covers f_1: the barycentre and bond midpoints of every contributing plaquette lie in S. Choose $\omega_{21}=-\omega_{12}=1$, with the other entries zero. The contact terms are means of the spin and vector insertions and vanish by reflection, as in Lemma 8.10(b). Hence

$$\mathfrak{U}_{\omega,\chi}(f_1)=-\beta\langle \mathfrak{S}_\omega[\chi]+\mathfrak{K}^{\mathrm{v}}[\chi\omega y];\mathcal{O}(f_1)\rangle.$$

Its bilinear part is

$$-\tfrac{3}{4}\mathsf{b}^{-1}\sum_{p,q,\rho}(\omega x(p))_\rho \nabla_\rho^+\chi(x(p))f_1(x(q))M_\rho(p,q), \qquad M_\rho\ge 0.$$

Away from the edges of a face with normal $n_F=\pm e_\nu$, only $\rho=\nu$ contributes. The factor $-(n_F)_\nu\nabla_\nu^+\chi$ is μa times a nonnegative function of the exterior lattice distance; f_1 is κa times the interior lattice distance. Summing the kernel over pairs across the plane and then over the a^{-2} plaquettes per unit area gives

$$\tfrac{3}{4}\mathsf{b}^{-1}\mu c_{\mathrm{lat}}\int_{\partial S}(\omega y)\cdot n_F\,\kappa\,dS.$$

The positive constant c_{lat} is the pair sum per unit lattice face. Cubic symmetry makes it the same for every face; its convergence is bounded by $\int_0^\infty\int_0^\infty st(s+t+1)^{-6}\,ds\,dt$. Pairs a fixed distance apart contribute $O(a^2)$. The contribution near the edges vanishes with the width of the edge neighbourhood; the spin part is $O(a\log(1/a))$ by its $a^6|u|^{-6}$ kernel, and the torus correction is $O(a)$. The divergence theorem gives

$$\int_{\partial S}(\omega y)\cdot n_F\,\kappa\,dS=\int_S(\omega y)\cdot\nabla\kappa=\int_S(y_2^2-y_1^2)=16.$$

Consequently $\mathfrak{U}_{\omega,\chi}(f_1)\to 12\mathsf{b}^{-1}\mu c_{\mathrm{lat}}>0$.

For the $SU(2)$ example, choose an even smooth function $\psi:\mathbb{R}\to[0,1]$, equal to one on $[-1,1]$ and zero off $[-2,2]$, and put $\mathsf{c}=100$ and

$$\mathit{\Pi}_{(r_1,r_2,r_3)}(y)=\psi((y_1-\mathsf{c})/r_1)\psi(y_2/r_2)\psi(y_3/r_3).$$

Set $g_3=\mathit{\Pi}_{(1,1,1)}$, $g_2=\mathit{\Pi}_{(3,3,3)}$, $g_1=\mathit{\Pi}_{(7,7,7)}$, and

$$G_i(y)=\int_{-\infty}^{y_2} g_i(y_1,t,y_3)\,dt, \qquad f_i=G_i(\cdot+30e_2)+G_i-2G_i(\cdot-30e_2)\quad (i\le 3).$$

For $3<j\le n$ take $f_j=\mathit{\Pi}_{(15,45,15)}$ and take $\chi=\mathit{\Pi}_{(31,91,31)}$, with the same ω as above and $\delta_0=\mathsf{d}=1$. These fixed smooth data have compact supports with a common point. The cutoff is one on their closed unit neighbourhood and vanishes outside $\{|y|_\infty\le 182\}$, inside the margin of every admitted side, since its exponent m is at least seven.

Reflection in $y_1=\mathsf{c}$ removes the rotation about the axis through $\mathsf{c}e_1$; the remaining vector field is $\mathsf{c}e_2$. Translation invariance therefore writes the left side of the exact identity as

$$\frac{\mathsf{c}}{2a}\sum_{|J|\ge 3}(|J|-2)a^{|J|}S_n^T((\nabla_2^+f_i)_{i\in J},(f_j)_{j\notin J}).$$

The bulk term is this expression minus the flux. The latter has a quadratic insertion, weights $O(\beta)$ and distance at least $1/2$ from the supports. Lemma 8.16, at $c_* = 1/4$, bounds it by $CK^{(2n+1)\mathfrak{p}_0}L^{K/4}$. If J contains an index above three, its derivative entry vanishes near the support of f_3, so the same bound applies. For $J = \{1,2,3\}$ the three derivatives are translates of $g_i^K = a^{-1}\int_0^a g_i(\cdot + te_2)\,dt$ with coefficients $(1,1,-2)$. Replace the spectators by one, discard triples with different translates, and replace g_1^K, g_2^K by one. Each error has an entry separated by at least $1/2$ and is again covered by that lemma. The equal translates sum to $1+1-8=-6$. With $I_K = (a^3/3)\sum_p g_3^K(x(p))$, translation invariance gives

$$S_n^T(g_3^K, 1, \dots, 1) = 3a^{-n-3} I_K (-1)^{n-1} E^{(n-1)}(\beta).$$

Thus, up to $CK^{(2n+1)\mathfrak{p}_0}L^{-3K/4}$,

$$a_K \mathfrak{U}_{\omega,\chi}(f) = 900 I_K (-1)^n \mathsf{b}'^{-n} \beta^n E^{(n-1)}(\beta).$$

The inner and outer boxes of g_3^K give $1 \le I_K \le 125$, and its Lipschitz approximation gives $I_K \to \int g_3$. Proposition 8.19(b) gives $(-1)^n\beta^n E^{(n-1)}(\beta) = -(n-1)! + O(K^{2n+3}L^{-K/20})$, uniformly in $\mathsf{b}' \in I(g)$. Finally $900/2 = 450$ and $900 \cdot 125 \cdot 2 \le 2.3 \cdot 10^5$ give the asserted two-sided bounds.

Step 11: Theorem AG. Let a board of side $a_i \le \frac{\ell'}{2}$ be placed, $\{x_3 = c\}$ one of its wall planes, θ_c the mirror at it, $\tau_{a_i e_3}$ the translation by $a_i e_3$, and let $\tilde{w}$ be a real weight carried by the cell between $\{x_3 = c\}$ and its translate by a_i that vanishes within $\frac{1}{2}\mathsf{d}$ of the walls. The centred entry $D = \mathcal{O}_K(\tilde{w}) - c_0$, c_0 its mean on $T_{\ell'}$, has the chessboard seminorm $\|D\|_{\mathrm{ch}} \le \mathsf{q}_i(\mathsf{d}) \sup|\tilde{w}|$ for $K \ge K^{\#}(i,\mathsf{d})$, with $\mathsf{q}_i = e^{G_g a_i^3}\mathrm{Bl}_{N_i'}(k(\cdot,\mathsf{d}))^{1/N_i'}$, $N_i' = (\ell' L^i)^3$ and $\mathrm{Bl}_N(k) = \sum_\pi \prod_{I\in\pi} k(\#I,\mathsf{d})$ over the partitions of N points into blocks of at least two: the mean on $T_{\ell'}$ of the product of its N_i' mirror copies is, by the moment–cumulant formula, the sum over these partitions of products of cumulants of copies that are $\ge \mathsf{d}$ apart, each bounded by Lemma 8.8 at the orders $\le N_i'$ (Theorem AD(a)), and the passage between the sides costs $e^{G_g a_i^3}$ (Lemma 8.9). A law ν of the lattice that is invariant under its symmetries, reflection positive at the wall planes of the boards, and dominated by the torus measures through its conditional laws obeys the reflection inequality

$$|\nu(\overline{\theta_c F'}\, D\, \tau_{a_i e_3} F)| \le \|D\|_{\mathrm{ch}}\, \|F'\|\, \|F\|, \qquad \|F\| = \nu(\overline{\theta_c F} F)^{1/2},$$

for bounded local functions F, F' of the bonds in the half space $\{x_3 > c\}$: the form $(F,G) \mapsto \nu(\overline{\theta_c F} G)$ is positive, and the Cauchy–Schwarz inequality for it, repeated at the walls of the board on the dominating tori (the chessboard estimate, Proposition YMM1:86.3, with the Cauchy–Schwarz inequalities of Proposition YMM1:91.4), bounds the left member by the chessboard seminorm of D read along these tori. Every periodic Gibbs state has the three properties: it is invariant under the lattice symmetries, it is reflection positive at all the families of mirrors (Proposition YMM1:103.4), and it is dominated by the torus measures (Proposition YMM1:91.9). Recentring from c_0 to $\nu(\mathcal{O}_K(\tilde{w}))$ costs $\mathsf{q}_i(\mathsf{d}) \sup|\tilde{w}|\, \|F'\|\, \|F\|$ more, by Lemma 8.9 at $q = 1$ and $|\nu(\overline{\theta_c F'}\, \tau_{a_i e_3} F)| \le \|F'\|\, \|F\|$; whence the factor 2:

$$|\nu(\overline{\theta_c F'}\, [\mathcal{O}_K(\tilde{w}) - \nu(\cdot)]\, \tau_{a_i e_3} F)| \le 2\mathsf{q}_i(\mathsf{d}) \sup|\tilde{w}|\, \|F'\|\, \|F\| \qquad (K \ge K^{\#}(i,\mathsf{d}));$$

eight shifted boards cover all positions. Along subsequences the limits exist (Theorem AD(c)), and in the reconstruction the bound is what Lemma 8.14 asks, and that lemma gives $B^{(m)}$, the density and the L^1 bound. The reconstruction of the limits of Gibbs sequences at $0 < g \le \gamma$ has $H \ge 0$ (Theorem YMM1:AP), the hypothesis of Lemma 8.14 in the direction x_3; and it has $H \ge |P_k|$, $k = 1,2$, for the commuting momenta P_k that generate the translations $U(\vec{x})$ in the directions orthogonal to e_3, the hypothesis of the last sentence of that lemma in the directions x_1, x_2: every periodic Gibbs state obeys the five-point inequality (241) of Lemma F.5 at the mirror normal to e_3 and the direction e_k, which passes to the limit and puts the spectral measure of every class on $\{\cosh(tE) + \cos(tq_k) \ge 2\}$ for a dense set of $t > 0$, hence on $\{E \ge |q_k|\}$, as $\cosh(tE) + \cos(tq_k) = 2 + \frac{1}{2}t^2(E^2 - q_k^2) + O(t^4)$.

The same holds for the reconstruction of a tensor limit. So Lemma 8.14 applies in the three directions, which gives the density in all three coordinates and the L^1 bound in them. For the bound on $\|B^{(m)}\|$: for $g \le \gamma_W^{\mathrm{sd}}$ the chessboard seminorm of a centred tensor entry in a cell of side a_i is at most $2\mathsf{C}_T Y_i^{\mathsf{q}_T} a_i^{-11/2}\mathsf{b}^{-1}|H|_\infty$, uniformly in the cutoff, the datum, the board, the side and the state (Section 2, (4) of Theorem B(a)); with Lemma 8.14 every tensor limit has the insertion bound with every $p > \frac{17}{2}$, and $B^{(m)}$ is the compression to the scalar subspace of the point operator at $e = \mathbf{1} - 2E_{mm}$, $|e| = \sqrt{3}$; that every limit with converging labels arises from a tensor limit along a further subsequence is the extraction of Theorem AE(g).

For the behaviour under turns: by Section 5, every tensor limit at $0 < g \le \gamma_W^{\mathrm{sd}}$ obeys $\sigma(RX) = \sigma(X)$, $R \in \mathrm{O}(3)$, at tuples with one non-scalar entry among scalar ones (Theorem U, which gives Theorem R(c) at these tuples); $R(\mathbf{1} - 2E_{33})R^{\mathrm{T}} = \mathbf{1} - 2nn^{\mathrm{T}}$ with $n = Re_3$, and the sum over $\pm\alpha$ cancels the off-diagonal part of nn^{T}, leaving $2\cos^2\alpha(\mathbf{1} - 2E_{33}) + 2\sin^2\alpha(\mathbf{1} - 2E_{ii})$; the entries of nn^{T} are combinations of 1, $\cos 2\alpha$ and $\sin 2\alpha$, which gives the form $c_0 + c_1\cos 2\alpha + c_2 \sin 2\alpha$ and the second derivative.

Step 12: Theorem AH. (a) Put $\lambda = L^{-(k-j)}$, $d = d_j(Z)$ and $S = \sup|E|$; the left member is at most $2S$, and the numbers a_3, C_2^Q, $\bar{C}_2 = \max\{C_2^Q, 1\}$, c_3^Q, $c_s = c_s^Q$ and λ_Q are those of the extended list. The trivial cases come first: if $\lambda > \lambda_Q$, then $2S \le 2\lambda_Q^{-4}\lambda^4 S$; if $(d+4)\lambda > c_s$, then $2S \le 2((d+4)\lambda/c_s)^4 S \le 32 c_s^{-4}(d+2)^4\lambda^4 S$, as $d + 4 \le 2(d+2)$. Let now $\lambda \le \lambda_Q$ and $(d+4)\lambda \le c_s$. Then $\lambda \le 1/(4a_3)$, and on a cube that holds the box of Z, whose sites lie within the ℓ^1-distance $l = 3(d+4)M$ (level-j units) of its least site, the definition of the cores gives a gauge in which the real part of the potential obeys $|A| \le \lambda$ and $|\nabla A| \le \lambda^2$ in level-j units; with the clause on the complex part this gives a complex potential A^0 of the sizes λ and λ^2, up to the complex gauge transformations $g_t = e^{itm}$, $0 \le t \le 1$, with $|m| \le l\lambda a_3 \le 3Ma_3 c_s \le \frac{1}{4}$, as $c_s \le 1/(12Ma_3)$, so of the size $e^{1/4}$.

The constant part, of the first order, is removed by g_1: a term is invariant under real gauge transformations and holomorphic, so it is invariant under every complex gauge transformation that is reached by a path inside its domain, and the path $t \mapsto g_t$ stays there, its triples lying in the cores and below the third radius. What is left, $\tilde{A}$, vanishes at the least site of the cube and has the gradient $|\nabla\tilde{A}| \le C_2^Q\lambda^2 \le \bar{C}_2\lambda^2$, so that $|\tilde{A}| \le l\bar{C}_2\lambda^2 = 3(d+4)M\bar{C}_2\lambda^2$ on the cube; the disc $\zeta \mapsto (\mathbf{1}, \zeta\tilde{A}, \zeta\tilde{J})$ of the radius $R = c_3^Q/(l\bar{C}_2\lambda^2) = c_3^Q/(3(d+4)M\bar{C}_2\lambda^2)$, of the order $((d+2)\lambda^2)^{-1}$, stays in the domain, because the Hölder number depends only on the curl of the potential, up to squares, and scales with the power $\frac{5}{2} > 2$ under $\rho_Z^{k\to j}$; at the trivial field the first derivative of a gauge invariant term vanishes, since the adjoint representation of SU(2) has no invariant vector; and the Schwarz lemma gives $|E((\mathbf{1}, \tilde{A}, \tilde{J})) - E(\mathbf{1})| \le 2SR^{-2} = 2l^2\bar{C}_2^2(c_3^Q)^{-2}\lambda^4 S \le 72M^2\bar{C}_2^2(c_3^Q)^{-2}(d+2)^2\lambda^4 S$, since $l \le 6(d+2)M$ (if $R \le 1$ the bound $2S \le 2SR^{-2}$ holds already).

This is the clause with $(d+2)^2$, and with the trivial cases it gives

$$C_Q = \max\{2\lambda_Q^{-4}, 32c_s^{-4}, 72M^2\bar{C}_2^2(c_3^Q)^{-2}\}$$

and the power $(d+2)^4$. For $\mathrm{U}(1)^3$ the field strength scales like λ^2 and the linear term survives. The power 4 is attained by a term of the second order in the field strength at one plaquette, against a triple with a constant field strength of the largest admitted size. (b) A block of the level k holds $L^{3(k-j)}$ regions of the level j, each constant up to $L^{-4(k-j)}$ by (a); the count of regions among the construction results with the rate $\kappa_{\mathrm{lf}} \ge 4\log 18432$ of (b) gives the bound, uniformly in k. (c) The complex centre of each Gaussian integral is kept as a free argument, one 1-form for every earlier level, in a polydisc.

The first order of a plane weight gives $\sup|w|L^{-5/2}\mathrm{hol}$, hence the third radius, which is small at the true points and stable under the shift system among the construction results; the weight and the trees enter as potentials, so that the action of the step carries no explicit weight; a tree of the level

j weighs L^{k-j+1} seen from the level k, there are $L^{3(k-j)}$ of them and each is smaller by $L^{-5(k-j)}$; the non-classical terms stay at their levels and are lifted afresh at every step by (b), at the rate r_1, which (b) admits since $r_1 > \mathsf{C}_{\mathrm{cs}} > 4\log 18432$. Each step is then the identity of the statement, classical times ideal times the exponential of a tiny term, with $c_k(W)\Xi_0[V_{\mathsf{m}}](Q) = \Phi_{k+1}[\omega](W)$; at $k = 0$ the step is written with bond labels.

On the plain cores the Hölder number is at most α_0 times a factor that grows like $L^{n/2}$ with the level, while $\alpha_2/\alpha_0 \geq 4.99 \cdot 10^6 e^{L/4}$; so the condition of the third radius follows from the plain core at the levels $n \leq (\frac{L}{2} + 29.39)/\log L$. At $k = 0$ the weight enters linearly through the bond labels, and the centre, the solution of the linear system of the step with a source of the size σ, is at most $K_Z\sigma$. The extended list, stated before Theorem AH, places each new constant after the constants on which it depends and before γ; its four new lower bounds are laid on the chosen constants C_{ex}, κ, $\bar{\kappa}$ and M, which are free upward, each by a function of earlier constants, its new conditions on γ are ceilings whose left members tend to 0, and it lays no condition on L itself; so it keeps the admissible shape, its choices exist, and they restrict to choices of the lists of Theorems YMM1:D, YMM1:AJ and YMM1:AD.

At every choice $L > 4 \cdot 10^{19}$: the retained floor $L \geq L_\Pi = 2\mathsf{C}_{\mathrm{ex}}(1 + 4\beta_{\mathrm{s}})/(1 - 2\delta_{\mathrm{w}}) \geq 2\mathsf{C}_{\mathrm{ex}}$ (equation YMM1:(904), with $\beta_{\mathrm{s}} > 0$ and $0 < \delta_{\mathrm{w}} < \frac{1}{2}$), the new lower bound $\mathsf{C}_{\mathrm{ex}} \geq 2\mathsf{C}_{\mathrm{cs}}$, and $\mathsf{C}_{\mathrm{cs}} \geq 24C_{\mathrm{E}}^2 e^{24}$ by the choice preceding equation YMM1:(1332), $C_{\mathrm{E}} = 4096$, give $L \geq 4\mathsf{C}_{\mathrm{cs}} \geq 96C_{\mathrm{E}}^2 e^{24} > 4 \cdot 10^{19}$. The further conditions named in the statement are of three kinds. The tower hypotheses of Section P and the inequality $\alpha_0 + \alpha_1 \leq a^\sharp$, even $2(\alpha_0 + \alpha_1) \leq a^\sharp$, are closed inequalities between constants that hold at every choice of the list of Theorem YMM1:D, and so at every choice of the extended list, which restricts to such a choice.

The standing conditions of the frame of Definition B.14 follow, condition by condition, from members of the lists of Theorems YMM1:D, YMM1:AJ and YMM1:AD, to which the choices of the extended list restrict. The locality for all pairs of regions and the gauge covariance at all decoupling parameters are properties of the Gaussian structure among the construction results as it is formed, at all admitted constants: its structures form a local system, and they are covariant under real gauge transformations at all decoupling parameters s of the closed polydisc (Theorem YMM1:U(2) and the covariance of the operators in YMM1:(765): restrictions commute with the unitary gauge actions, as do inversion and the functional calculus used to form the covariance and coupling).

Step 13: Theorem AI. (a) Proposition 8.6 proves the uniform critical-background and Hessian assertions. We give the remaining comparisons and check the actual step data.

At $U_0 = 1$ with all regions the whole torus, the quadratic form for plane weights is

$$\langle B, Z_\epsilon B\rangle = \min_{Qd=B}\{(\partial d, \mathsf{a}\,\partial d) + \|RD^{\mathsf{T}}d\|^2\}, \qquad 1 - \epsilon \leq \mathsf{a} \leq 1 + \epsilon.$$

Each form before minimization lies between $1 - \epsilon$ and $1 + \epsilon$ times the unweighted form, including its nonnegative slice term. Taking the infimum gives the claimed comparison of block Hessians. For the single mixed tensor term, $2|\langle f_{\mu\nu}, f_{\mu\lambda}\rangle| \leq |f_{\mu\nu}|^2 + |f_{\mu\lambda}|^2$ gives the same form comparison in the stated normalization. Adding the square of the linearized block averages preserves it. Thus the linearization of the constrained system is invertible at zero. On each fixed finite lattice the analytic implicit-function theorem gives the stated family near zero.

The reason a uniform Hölder estimate needs the Hölder norm of the weight can be seen in this same quadratic problem. Fix $B \in Y_0$, $B \neq 0$, and write $h_\epsilon = d_b A \cdot B$ at $b = 0$. Take the torus side $N = 2L^{m+K-k}$ in level units, as in the construction; it has the even number $N/\eta_k = 2L^{m+K}$ of bare sites in each direction. Choose a plane $(\mu\nu)$ in which $F^0 = \partial h_0$ has largest component norm, and put $v_{\mu\nu}(x) = \epsilon(-1)^{x_\mu/\eta_k}$, with all other plane weights zero. Then

$$Qh_\epsilon = B, \quad RD^{\mathsf{T}}h_\epsilon = 0, \quad \partial^{\mathsf{T}}\mathsf{a}\,\partial h_\epsilon = Q^{\mathsf{T}}Z_\epsilon B.$$

The supremum of the source on the right is at most $(1 + \epsilon)C_{\mathrm{tr}}c_Z\|B\|$, with $c_Z \geq \|Z_0\|$ and the row-to-supremum norm C_{tr} of Q^{T} depending only on L. Since $\delta = h_\epsilon - h_0$ has $Q\delta = 0$, subtracting

the two variational equations and testing by δ gives

$$\|\partial\delta\|^2 + \|RD^{\mathsf{T}}\delta\|^2 = -\epsilon((-1)^{x_\mu/\eta_k}(\partial h_\epsilon)_{\mu\nu}, (\partial\delta)_{\mu\nu}).$$

It follows that

$$\|(\partial h_\epsilon)_{\mu\nu}\| \geq (1+\epsilon)^{-1}\|F^0_{\mu\nu}\| \geq (1+\epsilon)^{-1}(\gamma^{\mathrm{pc}}/3)^{1/2}\|B\|.$$

On the torus of side N in level units, its supremum f_ϵ is therefore at least $(1+\epsilon)^{-1}(\gamma^{\mathrm{pc}}/(3N^3))^{1/2}\|B\|$. At two neighbouring sites in direction μ, use the bond equation at the site carrying the factor $1+\epsilon$. It expresses $2\epsilon(\partial h_\epsilon)_{\mu\nu}$ as η_k times the source minus two first differences of curvature components, with coefficients at most $1+\epsilon$ and 1. Consequently

$$2\epsilon f_\epsilon \leq (2+\epsilon)\,\mathrm{osc}(\partial h_\epsilon) + \eta_k(1+\epsilon)C_{\mathrm{tr}}c_Z\|B\|.$$

Here osc is the largest modulus of the change of one curvature component between neighbouring bare sites. For $\eta_k \leq c_\eta\epsilon N^{-3/2}$ this gives

$$[\partial h_\epsilon]_{\beta_H} \geq \frac{1}{6}\Big(\frac{\gamma^{\mathrm{pc}}}{3N^3}\Big)^{1/2}\epsilon\eta_k^{-\beta_H}\|B\|.$$

Here the seminorm includes neighbouring sites. At fixed N this diverges as $k\to\infty$, although the weight has supremum ϵ. Since the background vanishes at zero block datum, the example concerns its derivative there. Cauchy's estimate would bound that derivative if the backgrounds had a uniform Hölder bound on a common block-datum ball.

The constant-weight assertion follows from the exact identity

$$F + T_{(h,v+c)} = (1+c)(F + T_{(h,v)/(1+c)}).$$

Multiplying the critical equation multiplies its multiplier by $1+c$ and leaves its constraint and gauge unchanged. Uniqueness in Proposition 8.6 then gives the asserted identity of critical fields.

For the history application use the collared sequence before the step and its completion by the next large-field region. The background of the run is its real unweighted critical configuration at the prescribed averages. The block field A_k is read about its finer average in the axial gauge, and its row datum is $b = JA_k$, extended by zero to the remaining rows. The regular-background and chart estimates for these actual step fields, Lemma YMM1:37.5, Proposition YMM1:53.12, and the fibre-chart bounds in Section B.2, give

$$\alpha \leq 2C_{\mathfrak{P}}\mathfrak{M}B_3\varepsilon(x_t), \qquad \sup|b| \leq 2C_\chi \mathsf{c}_{\mathrm{fl}}\delta(x_k), \quad C_{\mathfrak{P}} = 504L^2B_1^{\mathrm{p}}.$$

For the natural-class assertion, apply Lemma YMM1:37.5 with the separated witness $m = \mathfrak{M}$, increasing the common block floor if necessary. The layerwise regularity radius of the real background is at most $2B_3\varepsilon(x_t)$, so that lemma gives the displayed natural-class radius on the completed sequence. The chart converts the fluctuation field to the row datum with the displayed factor $2C_\chi$. Choose

$$a_N \leq \min\{a_*, a^{\mathrm{pc}}, \gamma^{\mathrm{pc}}/(4e_0)\}, \quad \rho_N^+ \leq \frac{\gamma^{\mathrm{pc}}\rho_*}{4\kappa_0}, \quad z_N^+ \leq \frac{\gamma^{\mathrm{pc}}z_*}{4\kappa_0},$$

also keeping $\rho_N^+ < \rho_*$ and $z_N^+ < z_*$. Impose the ceilings, for all $x \geq \gamma^{-2}$,

$$2C_{\mathfrak{P}}\mathfrak{M}B_3\varepsilon(x) \leq a_N, \qquad 2C_\chi\mathsf{c}_{\mathrm{fl}}\delta(x) \leq \rho_N^+.$$

Their left sides tend to zero with γ. Thus $e_0\alpha \leq \gamma^{\mathrm{pc}}/4$ and $\kappa_0 s \leq \gamma^{\mathrm{pc}}/4$ at every step $t \geq 2$, which gives the asserted half-floor.

At the first step $k=0$, the lattice spacing is one, the block averages are the identity and the slice projection vanishes. There is no minimization at this step. At the real regular reference the fluctuation floor differs from the action Hessian by the second derivative of the block constraint paired with the current. Its loss is at most $8c_{\mathrm{pc}}\alpha$, where $c_{\mathrm{pc}} = \sqrt{2}C_K n_{\mathrm{pc}}$ and $n_{\mathrm{pc}} = 36L^3$. For a complex block field $A^{(0)}$ with $r_A = \sup|A^{(0)}|$, differentiating the four link factors in each plaquette and summing their incident bonds gives the following three operator-norm bounds: the change in

the plain action Hessian is at most $128 r_A e^{4r_A}$; the tensor term has norm at most $512 e^{8r_A}\|h\|_\infty$; and the plane term has norm at most $32 e^{4r_A}\sup|v|$. Therefore

$$\operatorname{Re}(F+T_{\mathbf{h}})''(JA^{(0)})[J\bar{B},JB] \ge (\gamma^{\mathrm{pc}} - 8c_{\mathrm{pc}}\alpha - 128 r_A e^{4r_A} \\ - 512 e^{8r_A}\|h\|_\infty - 32 e^{4r_A}\sup|v|)\|B\|^2.$$

This uses the real natural pair on the two-region sequence (Ω_0,Ω_1) and $\mathfrak{M} \ge M^{\mathrm{pc}}$, exactly as in the unweighted positivity argument above. Take

$$a_N^1 \le \min\{a^{\mathrm{pc}}, \varpi_\chi, \gamma^{\mathrm{pc}}/(64c_{\mathrm{pc}})\}, \quad r_N^1 = \min\{1/4, \gamma^{\mathrm{pc}}/(1024e)\}, \quad z_N^1 = \gamma^{\mathrm{pc}}/(2048e^2).$$

The ceilings

$$2C_{\mathfrak{P}}\mathfrak{M}B_3\varepsilon(x) \le a_N^1, \qquad 2C_\chi \mathsf{c}_{\mathrm{fl}}\delta(x) \le \min\{r_N^1, r_\chi\}, \qquad x \ge \gamma^{-2},$$

put the first-step data in these ranges. The losses through α, through r_A, and through the weights are at most $\gamma^{\mathrm{pc}}/8$, $\gamma^{\mathrm{pc}}/8$, and $\gamma^{\mathrm{pc}}/4$ respectively. This leaves $\gamma^{\mathrm{pc}}/2$ for the stated complex data.

(b) Lemma Q.9 identifies the perturbation as $D^{(1)\mathsf{T}} v D^{(1)} + Z_{1,v}$. The complete mean-square argument is Proposition Q.10: its proof first controls the divergence-input system with the actual averaging rows, inserts $vD^{(1)}A$ as a source, and then localizes with a divergence-form cutoff. It proves both inverse existence and the termwise walk bounds without taking a difference of v.

The grouping by visited pieces after Proposition Q.10 gives the connected-set factor in (b). (c) The label supplies its background regular at the radius $C_m\varepsilon_k$ with the envelope $e(x) = C_m\varepsilon_{j(x)}$. Two of the three ceilings of the statement are the label's: $\sup_{x\ge\gamma^{-2}} C_m\varepsilon(x) \le \alpha_\star$ bounds the radius of regularity and the envelope at every level by the number $\alpha_\star$ of L, and $\sup_{x\ge\gamma^{-2}} \max\{w_{\mathrm{G}}, w_{\mathrm{lin}}\}(\log x)^{-r} \le 1$ gives $MR(\gamma^{-2}) \ge \max\{w_{\mathrm{G}}, w_{\mathrm{lin}}\}$, $w_{\mathrm{G}} = 4c_U^{-1}(7\log L + \log 2)$; under these, and with $t(\mathrm{an}) < t_0 \le t_{\mathrm{lin}}(L) \le \frac{1}{4}$, Lemma 8.20 and the locality below are applied; the third, the membership ceiling, is read below.

Use Lemma 8.20 and assume the complex scalar transfer bound (43). The pair (A,ω) is the fixed point of the critical-point contraction built on (34) and the local Hölder bounds. To localize it, write $G' = (\Delta_D + Q'^*\mathsf{a}'Q')^{-1}$ in the scalar notation and retain $Q'Q'^* = 1$. Since $\ker R = \operatorname{ran}(G'Q'^*)$, the slice condition is equivalently the local equation $(1 - Q'^*Q')\Delta_D D^*A = 0$. Cut the far field off with a slow cutoff ch of width $w(L)$ and bounded scaled first and second differences. In the augmented scalar system the cutoff error is supported where ch varies. Its inverse is the actual compression $\mathbb{K}^{[2]}$ described in Definition 8.22; the two nonlinear remainders are precisely N and q there. The additional estimate (43) therefore makes the scalar correction a contraction in the exponentially weighted norm. It repairs the slice and the induced block gauge and retains exponential decay away from the cutoff. The repaired field nearly solves the critical-point system about U. Applying its contraction gives the stated locality estimate with c_U and $K_U = 7K_{\mathrm{lin}}^2(1+2L^3)^2 e^{c_U w_*}$, after the permitted enlargement of K_{lin}, where $w_* = w + 21L$.

Continuity: a uniform limit of iterates, with the error $\frac{2}{3}4^{-n}$. Uniqueness is in the normalized class: the gauge functions preserve the block averages and induce the identity at the tops. If $v_j[A']$ denotes the accumulated averaging gauge, this means

$$u(y) = v_j[A'^u](y)\,v_j[A'](y)^{-1} \quad \text{at every top } y \text{ of level } j.$$

The scalar transfer carries a sufficiently small critical point into the slice. Its multiplier is absorbed in the fixed-point equation using the same small-radius condition, so the resulting pair lies in the contraction ball and equals the constructed pair. Two normalized gauges with this property agree at every top. Their quotient preserves W, hence is covariantly constant along its bonds. It is therefore the identity along every pillar from a top, and those pillars cover the bare sites. This proves the stated uniqueness. Energy: apply (40) to the fixed point, with its actual row forcing $-C_2(U,A)$. Since $|\xi^2 F_U(p)|^2 \le 2a_p(U)$, the local plaquette product estimate gives $\sum_p |\partial U(p)^{-1}\partial W(p) - 1|^2 \le C(L)|\mathrm{an}|_\infty^2 \sum_p a_p(U)$. Cauchy–Schwarz with the unperturbed plaquette defects gives the stated

action comparison. Full covariant gradient: let x_* lie in a layer $n \geq 2$, of the scale l_n, and pass to the axial gauge in the cube of radius $\frac{1}{4} l_n$ about x_*, built from the transports of U along coordinate paths; the transports differ from $\mathbf{1}$ there by $O(e(x_*) l_n^{-1})$ in modulus and in Hölder-$\frac{1}{2}$ quotient.

In this gauge the potential A solves a flat system for its curl and its divergence, $dA = \Phi$, $d^* A = \varpi$, where Φ is the curvature and ϖ the divergence of A, each up to products of A with the transports minus $\mathbf{1}$; by the curvature norm of Lemma 8.20 and the slice estimate for the divergence below, Φ and ϖ are bounded and Hölder-$\frac{1}{2}$ in the scale of the layer, with the sizes $K t(\mathrm{an}) e(x_*) l_n^{-2}$ and, for the Hölder quotients, $K t(\mathrm{an}) e(x_*) l_n^{-5/2}$, K a constant of L alone. The divergence is even Lipschitz: on the slice $R D^* A = 0$, so $D^* A = G' Q'^* m$ for some m, and the range of $G' Q'^*$ has first differences bounded in the scale of the layer, $|\eta_k^3 (D D^* A)(b)| \leq K t(\mathrm{an}) e(x_b) l(b)^{-3}$.

After a cut-off at the radius $\frac{1}{8} l_n$ whose first and second differences are $O(l_n^{-1})$ and $O(l_n^{-2})$, the identity $\Delta = d^* d + d d^*$ writes each first difference of A as second differences of the lattice Green function of the Laplacian applied to the cut data; an interior estimate of Schauder type for these kernels against Hölder-$\frac{1}{2}$ data, on a cube of radius $\sim l_n$, bounds all nine covariant first differences, $l(x)^2 |\eta_k^2 (\nabla_\kappa A_\nu)(x)| \leq K_5 \, t(\mathrm{an}) \, e(x)$ with K_5 a function of L alone; in the layers $0, 1$ the bound $|\nabla_\kappa A_\nu(x)| \leq |A_\nu(x + e_\kappa)| + |A_\nu(x)|$ suffices. Membership: the plain triple of U lies in the cores at half the radii (Corollary YMM1:58.4, under its support, radius and smallness hypotheses); the moved triple is the plain triple with the displacement substituted, and in the units of each layer λ the displacement, its first differences, the change of the plaquette variables and the change of the current are at most $K_5' \, t(\mathrm{an}) \, C_m \varepsilon_\lambda$, by Lemma 8.20 and the gradient estimate, where $C_m \varepsilon_{j(x)}$ is the envelope with which the label supplies its background, K_5' is a number formed with L through K_{lin} and K_5, and $t(\mathrm{an}) < t_0 \leq t_{\mathrm{lin}}(L) \leq \frac{1}{4}$, Lemma 8.20 being applied at the anisotropy an.

These are small against the radii, as the substitution asks, under the third ceiling of the statement,

$$\sup_{x \geq \gamma^{-2}} 2 K_5' C_m \, \varepsilon(x) \leq b_2, \qquad \varepsilon(x) = A_0 x^{-1/2} (\log x)^{\mathfrak{p}_0} \text{ (equation YMM1:(634))},$$

b_2 being the radius of Proposition P.2 among the construction results, with which the substitution with three pairs of radii carries the cores at half their radii into the cores at three quarters of them: under this ceiling they are at most $\frac{1}{8} b_2$, and the ceiling is of the admissible shape, its left member tending to 0 as $\gamma \to 0$. Then this substitution puts the moved triple in the cores at three quarters of the radii, all the tower clauses included. Frames retain the following six admissions, supplied by the ordered choice of Proposition YMM1:69.1 and its source continuation in Section YMM1:82: (1) the geometric and background hypotheses used in that choice; (2) consistent data and a coupling sequence with flow bound $B_\sharp$; (3) at every level n, $x_n > \bar{B}$, $y_n > 2\mathfrak{p}_0$, $g_n \leq \gamma$ and $2\varepsilon_n \leq \bar{\varepsilon}$; (4) $\varepsilon_q \leq \varepsilon_\flat$ at every level q; (5) at every level t,

$$C_{\mathrm{reg}} \varepsilon_t \leq \varepsilon_{\mathrm{v}}, \qquad L^2 C_{\mathrm{reg}} \varepsilon_t \leq c_2^{\mathrm{SO}}, \qquad 2 L^2 C_{\mathrm{reg}} \varepsilon_t \leq \bar{\varepsilon};$$

and (6) $x_t \geq 2 B_\sharp$ at every level. The layer and support conclusions used here are those of Corollary YMM1:58.4, with these actual admissions; the pivot evaluation additionally retains the ceilings preceding Lemma YMM1:66.1.

The real and sourced constructions use the same coupling sequence, tests and canonical real domains, by Lemmas YMM1:82.4 and YMM1:82.5. Condition (1) is part of the geometric choice in Proposition YMM1:69.1; condition (2) is the admissible-sequence and room hypothesis of Theorem YMM1:D. The proof of Proposition YMM1:69.1 imposes $x \geq 2 B_\sharp$, $x > \bar{B}$ and $\log x > 2\mathfrak{p}_0$ uniformly for $x \geq \gamma^{-2}$. The additional ceilings in the proof of Lemma YMM1:82.5 give $2\varepsilon_t \leq \bar{\varepsilon}$, $\varepsilon_t \leq \varepsilon_\flat$ and $L^2 C_{\mathrm{reg}} \varepsilon_t \leq c_2^{\mathrm{SO}}$ at every level, as well as the remaining graded-field conditions there. These are (3)–(6). (d) The Hessian of the Lagrangian at a critical background annihilates, against every field, a gauge direction whose gauge transformation preserves the block averages of every configuration. For a gauge direction whose linearized block average vanishes only at the background, it annihilates the fields in $N(Q)$; against other fields the remaining term lies in the range of Q^{T}

and is absorbed by changing the multiplier. Thus Lemma 8.20, applied on the longer sequence in its own gauge, inverts the linearized system in the axial gauge. Its weighted maximum bound is that lemma. Its square-sum bound follows from Lemma 8.21; the multiplier is bounded by testing against a row lift $H\varsigma$ in

$$\langle \omega, \varsigma \rangle = \langle T_\tau A - f - D_1^{\mathsf{T}} Y, H\varsigma \rangle .$$

All constants depend only on L.

With Cauchy's inequalities for the remainder of the system this gives exactly one centre in the polydisc $|\mathsf{n}(b)| < \theta_3 \mathsf{b}_k$ of the statement, $\mathsf{b}_k = A_1 (\log x_k)^{\mathfrak{p}_0}$ the threshold of the level k, and it lies in the half polydisc, $|\mathsf{n}(b)| \le \frac{1}{2} \theta_3 \mathsf{b}_k$, once the following hold. The envelope of the step is that of (c) with C'/L in the place of C_m, where $C' = \max\{L C_m, 2 L C_\chi (1 + 2\theta_3) A_1 / (\rho_{\mathrm{u}} A_0)\}$ is the number of the statement and $\rho_{\mathrm{u}} = \rho_{\mathrm{u}}(L)$ the radius of the ball in which the centre is unique: the first member keeps the envelope at least that of (c), and the second puts every complex block datum of the box of the step, read in the chart of the fibre, inside that ball in the norm of the envelope; this is the one number that is enlarged, and it is read by the two conditions that follow.

The size of the anisotropies is below the number of the statement, $t_\theta = \min\{t_0, t_{\mathrm{u}}(L), c_{\mathrm{ce}} \theta_3 A_1 / A_0\}$, where $t_{\mathrm{u}}(L)$ is the number below which the moved backgrounds with a complex block datum are formed and $c_{\mathrm{ce}} > 0$ is formed with L and C'; so $t_\theta \in (0, t_0]$ is formed with θ_3 and with constants placed before γ. And γ is below ceilings of the shape $\sup_{x \ge \gamma^{-2}} C' \varepsilon(x) \le c(L)$, of the admissible shape, among them the ceiling $C_\chi (1 + 2\theta_3) \delta(x) < \frac{1}{8} r_c$, $x \ge \gamma^{-2}$, of the statement, with the numbers C_χ, r_c of L: it keeps the box $|\mathrm{Re}\, B_1(b)| + |\mathrm{Im}\, B_1(b)| < (1 + 2\theta_3) \mathsf{b}_k$ of the complex block data of the step, of the unscaled radius $(1 + 2\theta_3) \delta(x_k)$, and with it the polydisc $|\mathsf{n}(b)| < \theta_3 \mathsf{b}_k$, of the unscaled radius $\theta_3 \delta(x_k)$, inside the ball of the radius r_c, in the unscaled norm, in which the system of the centre has exactly one solution.

The centre is $\mathsf{n} = g_k^{-1} a''$, $g_k = x_k^{-1/2}$, where a' is the finer block average of $W[\mathrm{an}; b_0]$ read about that of $W[0; b_0]$, the two backgrounds having the same row datum, and a'' is this relative field turned into the block axial gauge; n is holomorphic in an, real at real an and real b_0, and 0 if an is one number. By the bound of (c) on the displacement in the units of the level, read with the envelope $(C'/L)\varepsilon_j$, and the passage to the block axial gauge, $|a''(b)| \le K'' t(\mathrm{an}) (C'/L) \varepsilon_k$ with a number K'' of L; as $x_k^{1/2} \varepsilon_k = (A_0/A_1) \mathsf{b}_k$, this is $|\mathsf{n}(b)| \le C_\theta t(\mathrm{an}) \mathsf{b}_k$ with $C_\theta = K'' C' A_0 / (L A_1)$, a number of L, θ_3, A_1/A_0 and C_m, and $C_\theta t(\mathrm{an}) \le \frac{1}{2} \theta_3$ at $t(\mathrm{an}) < t_\theta$ once $c_{\mathrm{ce}} \le L/(2K''C')$.

The square sum for $1 \le k < K$, over all the bonds of the step, follows in mean square, in three inequalities. The passage to the axial gauge: $|a''(c)|^2$ is at most a number of L times $|a'(c)|^2$ plus the sum of $|a'(c')|^2$ over the bonds c' inside the two blocks that c meets, a bond c' being counted at most $12 L^3$ times. The averages in the mean square: the square sum of the block averages a' over a set of bonds is at most a number of L times the square sum of the displacement A' over the bonds beneath them, each in the units of its level. The displacement is the difference $A' = A[\mathrm{an}; b_0] - A[0; b_0]$ at the same complex row datum. Its energy is bounded by (41). At $b_0 = 0$ this is at most $C |\mathrm{an}|_\infty^2 \xi^3 \sum_p |F_U(p)|^2$; in bare units it is the corresponding bound by $C |\mathrm{an}|_\infty^2 \sum_p |\tilde{F}_U(p)|^2$, where $\tilde{F}_U = \xi^2 F_U$ and $|\tilde{F}_U(p)|^2 \le 2 a_p(U)$.

At $b_0 = 0$, since $|\mathsf{n}|^2 = x_k |a''|^2$ and, in a frame, $x_k L^k \le \frac{37}{11} \beta_t(y)$ at every point y, this gives $\sum_b |\mathsf{n}(b)|^2 \le C^2 |\mathrm{an}|_\infty^2 A(\beta_t, U)$, C a number of L; at $k = 0$ the same holds at the external bonds of the step. The centres $\mathsf{n}^{(i)}$ of the earlier steps $0 \le i < k$ are formed by the same rule about the moved background of the label, so that $g_i \mathsf{n}^{(i)}$, $g_i = x_i^{-1/2}$, is the block average at the level i of its displacement, turned into the block axial gauge; by the bound of (c) on the displacement in the units of each layer, each obeys $|g_i \mathsf{n}^{(i)}(b)| \le C t(\mathrm{an}) \varepsilon_i$, that is $|\mathsf{n}^{(i)}(b)| \le C t(\mathrm{an}) (A_0/A_1) \mathsf{b}_i$, as $x_i^{1/2} \varepsilon_i = A_0 (\log x_i)^{\mathfrak{p}_0} = (A_0/A_1) \mathsf{b}_i$, with one C of L for all the levels; this is at most $\frac{1}{2} \theta_3 \mathsf{b}_i$ at $t(\mathrm{an}) < t_\theta$ once $c_{\mathrm{ce}} \le 1/(2C)$, and $c_{\mathrm{ce}} = \min\{L/(2K''C'), 1/(2C)\}$ is a number formed with L and C'.

The stored bonds, which are the external bonds of these steps, lie for the level i within $2L^i$ (bare units) of the layer i; the square sums of the block averages of all the levels over the bonds near their own layers are bounded together, with one number of L, by the square sum of the displacement weighted by the scales of the layers, because the layers are wide and the bonds near the own layers of different levels overlap boundedly; and the ℓ^2 bound of the linear system, as for the centre of the step, then gives $\sum_{i<k}\sum_b |\mathsf{n}^{(i)}(b)|^2 \le C^2|\mathrm{an}|_\infty^2 A(\beta_k,U)$, b running over the stored bonds, with one C of L, $A(\beta_k,U)$ being the action of the background with the couplings of the level k. (e) The room hypothesis of Lemma 8.23 holds at every level: $L^m \ge MR(x_K) \ge LM$ gives $m > m'$, hence $m' < m + K - j$ for $j \le K$. The identity is that lemma on a label, for any list of families with counterterms, with the explicit boundary terms of its clause on a label; the trivial values do not change because the tent families vanish at the trivial triple, and, at a fixed triple with the original families and counterterms held fixed, the linear changes in the re-filed local and boundary entries are those of the tent families.

The size bounds require the stated margin: by Lemma 8.23 with $\kappa' = \kappa + 1$ and $|e_j| \le B_\sharp$, $\|\hat E^{(j)} - E^{(j)}\|_{j,\kappa+1} \le \frac{3}{2}|\mathrm{an}|_\infty B_\sharp \alpha_0^2 e^{7(\kappa+1)} \le \frac{3}{2}\sigma_3\|\mathrm{an}\|B_\sharp\alpha_0^2 e^{7(\kappa+1)} \le \theta E_0\|\mathrm{an}\|$, and the triangle inequality, with the bound $(1-\theta)E_0$ of the families before the re-filing, gives $\|\hat E^{(j)}\|_{j,\kappa+1} \le E_0$ and the distance from the family at zero source; the boundary terms are at most $\frac{3}{2}M^3|\mathrm{an}|_\infty B_\sharp\alpha_0^2 e^{7\kappa}e^{-\kappa d_j(X)} \le \theta M^3 E_0 e^{-7}\|\mathrm{an}\|e^{-\kappa d_j(X)}$ in a frame of Theorems YMM1:AJ and YMM1:AD, where the radius of the level is at most α_0. □

8.6. **Scope of the conclusions.** Theorems AD(d), AE(c), (d) and AF(a), (c), (d) live on one torus, with constants that depend on its side; so does Theorem AF(e), whose numbers are free of the side when the closed a-neighbourhoods of the supports lie in balls of radius R and $\ell \ge 16n(R+1)$. On $\mathbb{R}^3$ the statements concern limit points and tensor limits, at separated or disjoint supports. Theorem AF(d) concerns cumulants with one stress entry among action densities on one torus, at a fixed label. The kernels of Theorem AD(h) and the operators of Theorem AG are those of each limit, taken along the subsequence that gives it. Theorems AH and AI concern one step, the never-large term, and the backgrounds, centres and counterterms of the construction.

Along growing tori and in the periodic Gibbs states the section asserts the following. The cumulants of the plane fields have limit points along every sequence of first-passage data at g with $K_j \to \infty$, in periodic Gibbs states and on tori T_{ℓ_j} with $\ell_j \to \infty$, whatever the relation between K_j and ℓ_j, with the bounds, the invariance and the reflection positivity of Theorem AD(c). The bulk term of the rotational Ward identity vanishes with a rate and with numbers that read no side, so that a limit along tori is invariant under rotations exactly when the flux through a shell about the supports tends to 0; this flux tends to 0 for the volume-first scalar limits; and, with the limits taken one after the other, at a label $\mathsf{b} \in I(g)$ the limit in K of the flux on each torus T_ℓ is $\sum_i S_n^{(\ell,\mathsf{b})}(f_1,\dots,(\omega y)\cdot\nabla f_i,\dots,f_n)$ through every enclosing shell, and along sides $\ell_k \to \infty$ in $\mathfrak{L}(g)$ on which the limits $S_n^\circ = \lim_k S_n^{(\ell_k,\mathsf{b})}$ exist, the limit in k of these limits, through any shell that covers the supports, a fixed one or a far one, is $-\frac{d}{dt}S_n^\circ(f(e^{-t\omega}\cdot))|_{t=0}$, and there are integers K_k^* such that S_n° is the limit of the connected functions along $(K_k,\ell_k,L^{K_k}\mathsf{b})$ for every sequence $K_k \ge K_k^*$ (Theorem AF(b)).

For sides up to $a^{-\theta}$, $\theta < \frac{1}{30}$, a limit along tori at first-passage labels is the limit taken spacing first, then volume, and raising the cutoffs at fixed sides and labels does not change it (Theorem AF(b)). With numbers that read no side, in every periodic Gibbs state the stress insertion collapses onto its classical tensor and the conserved tensor decorrelates from any number of tensor entries at separated supports (Theorem AE(e), (f)); every tensor limit is conserved at disjoint supports (Theorem AE(g)); and the translation identity of Theorem AF(e), with its null term and its contact terms, holds per ball with numbers free of the side.

9. The two-term short-distance law on the torus

For the action density, the first correction to the free two-point law is of relative order d/b. More precisely, the two-term approximation is

$$c_2 b^{-2}[\mathcal{K}_6 + c_1 b^{-1}\mathcal{K}_5](f,h), \qquad c_2 = \frac{9}{16\pi^2}, \quad c_1 = \frac{8}{3\pi},$$

The error is $[\bar{\varepsilon}(d)b^{-3}d + C_{\mathrm{lat}}b^{-2}a_K/d]\|f\|_\infty\|h\|_\infty$. Theorem AJ states the cutoff and label ranges, the improvement to a remainder of order $d^{3/2}$, and the averaged logarithmic correction. Corollary 9.3 passes the law to every periodic state and to the continuum limits and their components.

The proof first expresses the covariance as an average of source-energy jets over translated pairs. A complex field scale separates the free term, of order four, from the correction, of order six. A composed block-field chart identifies the latter with a constrained lattice Laplace coefficient. Comparison of two bare tori and removal of the flat block constraint then connect it to the infinite-lattice coefficient. The lattice calculation is proved in Section A.

That calculation first takes the weak-coupling limit in a fixed box and then exhausts the lattice. Its box-dependent remainder is not a bound in the simultaneous continuum and large-volume limit. The renormalisation and finite-torus comparisons below provide the separate passage needed here.

9.1. **Parameters and test pairs.** We use the Wilson $G = \mathrm{SU}(2)$ model in three dimensions. Its Lie algebra consists of the hermitian traceless 2×2 matrices with $\langle X, Y\rangle = \frac{1}{2}\operatorname{tr} XY$, extended complex bilinearly. The trace is the ordinary matrix trace, and $|X|$ is the operator norm on $\mathbb{C}^2$. Near the identity we use $\log X = -\sum_{n\geq 1}(I-X)^n/n$, for $|X-I|<1$. For $U \in \mathrm{SU}(2)\setminus\{-I\}$ the intrinsic branch is $\log U = iY$, where Y is Hermitian and traceless and $|Y|<\pi$; these branches agree on their common domain. Fix a mollifier, a source radius $2\varrho > 0$, and one common choice of the constants in Proposition YMM1:69.1 and Section YMM1:82. In particular $L \geq 13$ is odd and $a_j = L^{-j}$. We retain all the real-step conditions when imposing the sourced-step conditions: restricting to the real construction leaves every retained constant unchanged. The two radius conditions are

$$2\varrho \leq \sigma^{\mathrm{S}}(x - \bar{B}), \qquad 2\varrho x^{-1/2}(\log x)^{\mathfrak{p}_0} \leq \sigma^{\mathrm{S}}_{\mathrm{L}} \qquad (x \geq \gamma^{-2}).$$

They are imposed by Proposition YMM1:82.2, after the radius-independent choices of Section YMM1:82. Thus all uses of the real flow, the sourced progression and the sourced chain below refer to the same numerical assignment and the same canonical data.

The running couplings and the data at a reference coupling, the sides, the torus measures and the states, the weighted progression, the sourced chain on the least torus and its histories are therefore formed with this one choice, and every statement of this section is made at it; where Theorems YMM1:AJ and YMM1:AD enter, they are read at the radius ϱ and at the choice of the longer list. Among the constants are $B_\sharp > 0$, with $\bar{B} = B_\sharp L/(L-1)$, the powers M, C_L of L in the geometric setting of Section YMM1:52.7, $A_0, A_1 > 0$ and $p_0 \in \mathbb{N}$. The real and source hypotheses are those imposed jointly in Section YMM1:82. A number is *determined by the constants* if it depends on them alone.

For $\ell \in \mathfrak{L} = \{2L^m : m \in \mathbb{N}\}$ the torus $T_\ell = \mathbb{R}^3/\ell\mathbb{Z}^3$ carries the lattice of spacing a_K. The *lattice* (ℓ, K), a side with a cutoff, carries the lattices $\mathbb{T}^{(j)} = a_{K-j}\mathbb{Z}^3/\ell\mathbb{Z}^3$ of the levels $0 \leq j \leq K$, of spacing $D_j = a_{K-j}$; the level 0 is the bare lattice, which in bare units is $\Lambda_N = \mathbb{Z}^3/N\mathbb{Z}^3$, $N = \ell L^K$. The *height* i is the averaging step from the level i to the level $i+1$. Blocks, the bonds of the coarser lattices and the non-pivot bonds are those of Section YMM1:4 and the pivot definition preceding Lemma YMM1:40.1, contours those of Section YMM1:4 (coordinate-order contours), and $\mathcal{M}$ is the block-averaging map (equations YMM1:(37)–(39)).

For a plaquette p, $a_p(U) = 1 - \frac{1}{2}\operatorname{tr}\partial U(p)$ and $x(p)$ is its barycentre; $A = \sum_p a_p$, $\mu_{K,\ell,\beta}(dU) = Z^{-1}e^{-\beta A(U)}dU$, $\mathcal{O}(f) = a_K^{-1}\sum_p f(x(p))a_p$, for a complex function w on the bare plaquettes, a *source*, $\mathcal{O}(w) = a_K^{-1}\sum_p w(p)a_p$, so that $\mathcal{O}(f) = \mathcal{O}(f\circ x)$, and $S^T_{2;K,\ell,\beta}(f,h)$ is the covariance of $\mathcal{O}(f)$ and

$\mathcal{O}(h)$ under $\mu_{K,\ell,\beta}$. The lattice isometries preserve $\mu_{K,\ell,\beta}$ and carry $\mathcal{O}(f)$ to $\mathcal{O}$ of the carried function (Lemma G.1: plaquette holonomies are conjugated or inverted, and the positive-bond variables are permuted or inverted under product Haar measure); so $S^T_{2;K,\ell,\beta}(\tau_v f,\tau_v h)=S^T_{2;K,\ell,\beta}(f,h)$ for every $v\in a_K\mathbb{Z}^3$ and all real Lipschitz f,h, whatever their supports, τ_v being the translation by v.

For a reference coupling $0<g\le\gamma$ (γ the last constant) put $X_g=L(g^{-2}+B_\sharp)$, $b_+=L(g^{-2}+\bar B)$ and $I(g)=(g^{-2}+\bar B,X_g-\bar B]$. The sides at g form $\mathfrak{L}(g)=\{2L^m : m\ge m_{\mathfrak{L}}(g)\}$ (equation YMM1:(1528)), with least member ℓ_g; so $\ell_gL^s\in\mathfrak{L}(g)$ for every integer $s\ge0$. A *datum* at g is a first-passage datum (K,β) at g (Corollary YMM1:74.2): its running couplings $x_0=\beta>x_1>\cdots>x_K$ obey $x_{j+1}=L^{-1}x_j-e_{j+1}$ with $|e_{j+1}|\le B_\sharp$, and K is the least index with $x_K\le X_g$; its label is $b=a_K\beta$. The running couplings depend on (K,β) alone.

Every label at g lies in $[g^{-2},b_+]$ YMM1:(1531), and for $b\in I(g)$ the pair (K,L^Kb) is a datum at g for every $K\in\mathbb{N}$ (Corollary YMM1:74.2). The *witness depth* is $s(d)=\min\{s\ge0:L^sd\ge C_W(s)\}$, $C_W(s)=C_{W,0}A_0^2(\log[L^{s+1}(g^{-2}+\bar B)])^{2p_0}$, $C_{W,0}=\max\{1,4L^2M/A_0^2\}$, as in equation YMM1:(2321) and Theorem YMM1:AV; it depends on g, d and the constants, and on no cutoff, label or side. As $C_W(s)\ge4L^2M$, for $d\le L^{-1}$ and $K>s(d)$ one has $L^{s(d)}\ge4L^3M$, $s(d)\ge2$, $K\ge3$ and $a_K\le L^{-1-s(d)}<d/13$; moreover $L^{s(d)}\ge1/d$, so $C_W(s(d))\ge(\log\frac1d)^2$ and $d/a_K\ge LC_W(s(d))\ge L(\log\frac1d)^2$.

Finally $\gamma_W^{\mathrm{sd}}\le\gamma_W^{\mathrm{ref}}\le\gamma$ are the coupling thresholds of the choices in equations YMM1:(2326)–(2327); $(\gamma_W^{\mathrm{sd}})^{-2}\ge4\bar B$.

For $\vartheta\in(0,1)$, $d>0$, and $\mathbb{E}=\mathbb{R}^3$ or $\mathbb{E}=T_\ell$ with $20d\le\ell$, $\mathfrak{T}_{\mathbb{E}}(d;\vartheta)$ is the following class of test pairs: Lipschitz functions $f,h\ge0$ on $\mathbb{E}$, neither 0, with supports in closed balls of radius d at a distance in $[d,6d]$, $\int f\ge\vartheta\|f\|_\infty d^3$, $\operatorname{Lip}f\le\|f\|_\infty/(\vartheta d)$, and the same for h. Then both supports lie in one ball of radius $5d$, and $d\le|x-y|\le10d$ for $x\in\operatorname{supp}f$, $y\in\operatorname{supp}h$. The conditions involve distances alone. So the class is invariant under translations; and for $36d<\ell$ the periodisation of a pair of $\mathfrak{T}_{\mathbb{R}^3}(d;\vartheta)$ is a pair of $\mathfrak{T}_{T_\ell}(d;\vartheta)$ with the same sup norms and the same kernels $\mathcal{K}_q$ below, every pair of $\mathfrak{T}_{T_\ell}(d;\vartheta)$ being the periodisation of one such pair, its *lift*, since all the distances that occur are at most $10d<\ell/2$.

For two sides $\ell\le\check\ell$, the *pair with the same lift* as a pair (f,h) on T_ℓ is the periodisation on $T_{\check\ell}$ of the lift of (f,h).

We put $\eta=\|f\|_\infty\|h\|_\infty$, $\mathcal{K}_q(f,h)=\iint f(x)h(y)|x-y|^{-q}\,dx\,dy$, $\varkappa=c_1c_2=\frac{3}{2\pi^3}$ and $L_b^+=c_2b^{-2}[\mathcal{K}_6+c_1b^{-1}\mathcal{K}_5]$. On $\mathbb{Z}^3$, $\mathsf{B}_1^{\mathrm{lat}}(p,q)$ is the coefficient of β^{-3} in the covariance of a_p and a_q (Definition A.10), and $\mathsf{P}_1^{\mathrm{lat}}(f,h;a)=a\sum_{p,q}f(ax(p))h(ax(q))\mathsf{B}_1^{\mathrm{lat}}(p,q)$. There are a pure number C_{T} and a constant κ^{lat} with

$$|\mathsf{P}_1^{\mathrm{lat}}(f,h;a)-\kappa^{\mathrm{lat}}\mathcal{K}_5(f,h)|\le C_{\mathrm{T}}\vartheta^{-1}a\lg(d/a)\,\eta\qquad((f,h)\in\mathfrak{T}_{\mathbb{R}^3}(d;\vartheta),\ 0<a\le d),$$

$\lg t=1+|\log t|$ (Corollary A.37), and $\kappa^{\mathrm{lat}}=\frac{3}{2\pi^3}=c_1c_2$ (Theorems BR, BS). For real Lipschitz f,h on T_ℓ, $\ell\in\mathfrak{L}(g)$, with disjoint supports and $b\in\overline{I(g)}$, $S_2^{(\ell,b)}(f,h)=\lim_{K\to\infty}S^T_{2;K,\ell,L^Kb}(f,h)$ is the limit of Theorem YMM1:A. That theorem gives existence for every $b>0$, continuity in b on $(0,\infty)$, and bilinearity on real Lipschitz functions supported in two fixed disjoint closed sets. A function on $\mathbb{R}^3$ with support in a ball of radius $<\ell/4$ is read on T_ℓ by periodisation, and $f_\rho:=f(\cdot/\rho)$.

Lemma 9.1 (Kernel bounds for test pairs)**.** For $(f,h)\in\mathfrak{T}_{\mathbb{E}}(d;\vartheta)$ and $q>0$,

$$10^{-q}\vartheta^2d^{6-q}\|f\|_\infty\|h\|_\infty\le\mathcal{K}_q(f,h)\le(4\pi/3)^2d^{6-q}\|f\|_\infty\|h\|_\infty.$$

Moreover $d\le\mathcal{K}_5(f,h)/\mathcal{K}_6(f,h)\le10d$. ∎

Proof. All cross-distances of the two supports lie between d and $10d$. Positivity gives

$$(10d)^{-q}\int f\int h\le\mathcal{K}_q(f,h)\le d^{-q}\int f\int h.$$

The defining mass bounds give the lower estimate, and the volumes of the two radius-d balls give the upper estimate. On a torus the balls have the same volumes because $20d \le \ell$. Finally $|x-y|^{-5} = |x-y|\,|x-y|^{-6}$ on the product of the supports; integration gives the ratio bound. Its denominator is positive by the lower estimate. □

Definition 9.2. Let N_3 be the threefold convolution of $\mathbf{1}_{[-1/2,1/2)}$, $\Phi(x) = \prod_{\mu=1}^{3} N_3(x_\mu)$, $\zeta = 1$ on $[0,7]$, $\zeta(t) = 1-3(t-7)^2+2(t-7)^3$ on $[7,8]$, $\zeta = 0$ on $[8,\infty)$, $P(y) = |y|^2 - \frac{3}{4}$ and $\Xi(y) = P(y)\zeta(|y|)$. For odd $q \ge 1$ let $J_q = \{-\frac{q-1}{2}, \dots, \frac{q-1}{2}\}$, $c_j^q = \prod_\mu q^{-2} \#\{\iota \in J_q^3 : \iota_1+\iota_2+\iota_3 = j_\mu\}$ for $j \in \mathbb{Z}^3$, and

$$\Upsilon^{(q)}(y) = q^{-1} \sum_{j \in \mathbb{Z}^3} c_j^q \, \Xi((y+j)/q) - \Xi(y).$$

With $e(u) = \int \Phi(x)\Xi(x+u)\,dx$ let $\mathsf{k}_6 = \int_0^\infty (4\pi - t^{-2}\int_{S^2} e(t\omega)\,d\omega) t^{-2}\,dt$. ■

9.2. **The quantitative two-term law.**

Theorem AJ. There is $\gamma_{\mathrm{e}} \in (0, \frac{1}{2}]$, determined by the constants, with the following property. Let $0 < g \le \gamma_{\mathrm{e}}$, $\vartheta \in (0,1)$, $\ell = \ell_g$, $P \ge P_\sharp := 3601$, and put $C_{\mathrm{lat}} = \frac{3}{2} C_{\mathrm{tm}} \vartheta^{-1}$ and $C_{\mathrm{lat}}^\flat = \frac{9}{2} C_{\mathrm{tm}} \vartheta^{-1} + 1$, where C_{tm}, determined by the constants, is the constant of the template sums of test pairs (Proposition YMM1:121.2 and Lemma I.2). There are $d_{\mathrm{e}} > 0$, $c_{1/2} < \infty$, $c_{\mathrm{r}} < \infty$ and a non-decreasing $\bar\varepsilon : (0, d_{\mathrm{e}}] \to [0,\infty)$ with $\bar\varepsilon(d) \to 0$ as $d \to 0$, depending on g, ϑ, P and the constants, and on no cutoff, label, pair or position, such that for $0 < d \le d_{\mathrm{e}}$ and $(f,h) \in \mathfrak{T}_{T_\ell}(d;\vartheta)$ the following hold.

(a) At every datum (K,β) at g with $s(d) < K$ and $L^K \le d^{-P}$, with $b = a_K\beta$,

$$|S^T_{2;K,\ell,\beta} - L_b^+|(f,h) \le [\bar\varepsilon(d)\, b^{-3} d + C_{\mathrm{lat}}\, b^{-2} a_K/d]\eta. \tag{46}$$

(b) For every $b \in I(g)$, (46) holds at $(K, L^K b)$ for every $K > s(d)$, and $|S_2^{(\ell,b)} - L_b^+|(f,h) \le \min\{\bar\varepsilon(d), c_{1/2} d^{1/2}\}\, b^{-3} d\,\eta$.

(c) If moreover $g \le L^{-1/4} \min\{\gamma_{\mathrm{e}}, \gamma_W^{\mathrm{sd}}\}$, there are $d_{\mathrm{e}}' > 0$ and $\bar\varepsilon'$ with $\bar\varepsilon'(d) \to 0$, depending on g, ϑ, P, the radius ϱ and the choice of the longer list of which the constants are the restriction, and on no cutoff, label, pair or position, such that (46), with $\bar\varepsilon'$ in the place of $\bar\varepsilon$, holds for $0 < d \le d_{\mathrm{e}}'$, $(f,h) \in \mathfrak{T}_{T_\ell}(d;\vartheta)$ and every datum (K,β) at g with $K > s(d)$.

(d) Let $k_0 \in \mathbb{Z}$ with $44 L^{-k_0} < \ell_g$, $r_0 = L^{-k_0}$, and for $n \ge 1$ let $r_1 = L^{-n} r_0$ and

$$\Delta_n(b) = r_1^{-1} S_2^{(\ell,b)}(\Phi_{r_1}, \Upsilon_{r_1}^{(L^n)}) - c_2 b^{-2} \mathsf{k}_6 (r_1^{-1} - r_0^{-1}) - \frac{6}{\pi^2}\, b^{-3} \log \frac{r_0}{r_1}$$

(the pair has disjoint supports, so that the limit is defined at it). Then Δ_n converges uniformly on $I(g)$ to a bounded continuous function Δ_∞, and there are $C_{\mathrm{co}} < \infty$ and $n_{\mathrm{co}} \in \mathbb{N}$, depending on g, k_0 and the constants, with $\sup_{I(g)} |\Delta_n| \le C_{\mathrm{co}}$ for all $n \ge 1$ and $\sup_{I(g)} |\Delta_n - \Delta_\infty| \le C_{\mathrm{co}} L^{-n/2}$ for $n \ge n_{\mathrm{co}}$.

(e) For every $b \in I(g)$ and every $K > s(d)$,

$$|S^T_{2;K,\ell,L^K b} - L_b^+|(f,h) \le [c_{\mathrm{r}}\, b^{-3} d^{3/2} + C_{\mathrm{lat}}^\flat\, b^{-2} a_K/d]\eta; \tag{47}$$

and (47), with β for $L^K b$, holds at every datum (K,β) at g with $s(d) < K \le K_\sharp(d)$ and $b = a_K\beta$, where $K_\sharp(d)$ is the cutoff of Proposition 9.18 at the side ℓ_g.

(f) Under the assumptions of (c) there are $d_{\mathrm{e}}'' > 0$ and $c_{\mathrm{r}}' < \infty$, depending on g, ϑ, the radius ϱ and the choice of the longer list of which the constants are the restriction, and on no P, which enters them as $P_\sharp$, and no cutoff, label, pair or position, such that (47), with c_{r}' for c_{r} and β for $L^K b$, holds for $0 < d \le d_{\mathrm{e}}''$, $(f,h) \in \mathfrak{T}_{T_\ell}(d;\vartheta)$ and every datum (K,β) at g with $K > s(d)$, $b = a_K\beta$.

■□

As $|x-y|\le 10d$ on the supports, $\mathcal{K}_5(f,h)\ge (10d)^{-5}\int f\int h\ge 10^{-5}\vartheta^2 d\,\eta$ by the nonnegativity and integral floors in Lemma I.1. So clause (b) determines the number:

$$\Big|\frac{(S_2^{(\ell,b)}-c_2b^{-2}\mathcal{K}_6)(f,h)}{c_2b^{-3}\mathcal{K}_5(f,h)}-\frac{8}{3\pi}\Big|\le 10^5c_2^{-1}\vartheta^{-2}\min\{\bar\varepsilon(d),c_{1/2}d^{1/2}\}.$$

The continuum limit on T_{ℓ_g} at a label of $I(g)$ determines first the label, since

$$S_2^{(\ell,b)}(f,h)/(c_2\mathcal{K}_6(f,h))\to b^{-2}$$

along pairs of the class with $d\to 0$, and then the number $\frac{8}{3\pi}$. The number enters the proof at one place, the last link of the chain of Step 3 below, through $\kappa^{\mathrm{lat}}=c_1c_2$; it depends on no L, g, side or label.

Corollary 9.3 (Every state; every side; the limits on $\mathbb{R}^3$)**.** Let g, ϑ and P be as in clause (c) of Theorem AJ, with $d'_{\mathrm{e}},\bar\varepsilon'$ of (c) and $d''_{\mathrm{e}},c'_{\mathrm{r}}$ of (f); let $C_2^{\mathrm{T}}(g)$ and $\mathsf{d}_\star(g,\vartheta)$ be the numbers of Proposition 9.19, and put

$$d_\infty=\min\{d'_{\mathrm{e}},d''_{\mathrm{e}},\tfrac{1}{180},\mathsf{d}_\star(g,\vartheta),L^{-1}\},\qquad \bar\varepsilon_\infty(d)=\min\{\bar\varepsilon'(d),c'_{\mathrm{r}}d^{1/2}\}+C_2^{\mathrm{T}}(g)\vartheta^{-1}b_+d.$$

The numbers d_∞ and $\bar\varepsilon_\infty(d)$ depend on g, ϑ, P, the radius ϱ and the choice of the longer list of which the constants are the restriction, and on no cutoff, label, side, state, sequence, component, pair or position. Let $0<d\le d_\infty$ and $(\tilde f,\tilde h)\in\mathfrak{T}_{\mathbb{R}^3}(d;\vartheta)$, with $\eta=\|\tilde f\|_\infty\|\tilde h\|_\infty$.

(i) For every state $\mathfrak{s}$ at g at a datum (K,β) at g with $K>s(d)$ (Proposition 9.19), $b=a_K\beta$:

$$|S_2^T[\mathfrak{s}]-L_b^+|(\tilde f,\tilde h)\le[(\bar\varepsilon'(d)+C_2^{\mathrm{T}}(g)\vartheta^{-1}b_+d)\,b^{-3}d+C_{\mathrm{lat}}b^{-2}a_K/d]\eta,$$

and the same with $c'_{\mathrm{r}}d^{1/2}$ in the place of $\bar\varepsilon'(d)$ and $C^\flat_{\mathrm{lat}}$ in the place of C_{lat}. In particular this holds for the torus measure of every side of $\mathfrak{L}(g)$ at the periodisations of the pair, and for every periodic Gibbs state at (a_K,β).

(ii) For every side $\ell'\in\mathfrak{L}(g)$, every $b\in I(g)$ and every $(f,h)\in\mathfrak{T}_{T_{\ell'}}(d;\vartheta)$: $|S_2^{(\ell',b)}-L_b^+|(f,h)\le\bar\varepsilon_\infty(d)\,b^{-3}d\,\eta$.

(iii) Let $\mathfrak{s}_j$ be states at g at data (K_j,β_j) at g with $K_j\to\infty$ and labels $b_j=a_{K_j}\beta_j\to b$; the torus measures of sides $\ell_j\in\mathfrak{L}(g)$ that grow with j are among them. Then $b\in[g^{-2},b_+]$, and every limit point S of the sequence $S_2^T[\mathfrak{s}_j](\tilde f,\tilde h)$ satisfies $|S-L_b^+(\tilde f,\tilde h)|\le\bar\varepsilon_\infty(d)\,b^{-3}d\,\eta$. The labels are determined by the two-point functions: if $\mathfrak{s}_j$ are states at g at data (K_j,β_j) at g with $K_j\to\infty$, and $S_2^T[\mathfrak{s}_j](F)$ converges at every pair F of a set that holds, for arbitrarily small $d\in(0,d_\infty]$, a pair of $\mathfrak{T}_{\mathbb{R}^3}(d;\vartheta)$, then the labels $a_{K_j}\beta_j$ converge, to a number $b\in[g^{-2},b_+]$.

Consequently the labels of every convergent Gibbs sequence at g (a sequence (K_j,β_j,ν_j) of data at g with $K_j\to\infty$ and periodic Gibbs states ν_j at (a_{K_j},β_j)) converge, to a number b; and the connected two-point function S_2^σ of the action density of its limit σ, and that of every component of a canonical decomposition of σ, satisfy $|S_2^\sigma-L_b^+|(\tilde f,\tilde h)\le\bar\varepsilon_\infty(d)\,b^{-3}d\,\eta$ whenever $\tilde f$ and $\tilde h$ are of class C^1. Such a pair is a separated tuple, at which these functionals are defined, and $\mathfrak{T}_{\mathbb{R}^3}(d;\vartheta)$ holds pairs of class C^1 for every $d>0$ and $\vartheta\in(0,1)$.

Every volume-first limit at g has one label b, the same along all its defining sequences, and the same inequality holds for it and for its ergodic components (Section K.1 and Definition 15.4(2)) at the pairs of $\mathfrak{T}_{\mathbb{R}^3}(d;\vartheta)$ of class C^1. Every $b\in I(g)$ is the label of such limits.

(iv) In the cases (ii) and (iii), with S the two-point function in question at a pair at which (ii) or (iii) states the inequality, $|(S-c_2b^{-2}\mathcal{K}_6)/(c_2b^{-3}\mathcal{K}_5)-\frac{8}{3\pi}|\le 10^5c_2^{-1}\vartheta^{-2}\bar\varepsilon_\infty(d)$: one number $\frac{8}{3\pi}$ holds for all the limits on the tori of the sides at g, the limits of states at g and their components, and each of these limits determines its label and the number. In the case (i), at a state at a finite cutoff, the same quotient differs from $\frac{8}{3\pi}$ by at most

$10^5 c_2^{-1}\vartheta^{-2}[\bar\varepsilon'(d)+C_2^{\mathrm T}(g)\vartheta^{-1}b_+d+C_{\mathrm{lat}}\,b\,a_K/d^2]$, and by at most the same with $c_{\mathrm r}'d^{1/2}$ in the place of $\bar\varepsilon'(d)$ and $C_{\mathrm{lat}}^{\flat}$ in the place of C_{lat}.

■□

9.3. **Renormalisation and coefficient inputs.** Theorem YMM1:D stands behind all the statements on the renormalisation group that we use, and Theorems YMM1:AJ and YMM1:AD behind the existence of the limit on a torus, the rate of the cutoffs and the agreement of states, into which it enters through the bounds on the partition functions of the tori at the source 0. We use the following construction results: the flow of the coupling and its data (Section YMM1:74, YMM1:74, Section E, Proposition E.7, equation YMM1:(1528), YMM1:74.2, Section YMM1:82, Proposition YMM1:74.1, Corollary YMM1:74.2, the ordered real choice in Proposition YMM1:69.1 and the common source choice of Section YMM1:82, the coupling-sequence quantities in equation YMM1:(634) and the function R of equation YMM1:(634)); the averaging chart and gauge factor of Section B.2, with the measure identity of Lemma B.3 and the cube-form sum in equation YMM1:(828), and the free response on tori (the construction and periodization in Section YMM1:52.6, and the curvature bound YMM1:(2234)); the localisation domains of a torus and of the infinite lattice, their near lifts and their linear sizes (Section YMM1:72 (the definitions of $\mathcal D_j$ and d_j at its beginning), Lemma O.1, Lemma O.2); the sizes YMM1:(759) of families (Definition YMM1:49.5) and the two sizes $|v|_\infty$ and $\mathrm{sw}_k(v)$ of a plaquette weight in Section E.1; the bracket localisation of a bare array and the octet property (Propositions YMM1:51.14 and YMM1:51.16, with equation YMM1:(877)); the one-step theorem (Theorem YMM1:V); the naturality of one step under the charts between two lattices with one cutoff (Section YMM1:52.5, in particular equation YMM1:(928)); the regular progression on all the lattices of a level (Theorem YMM1:Y); the weighted progression, its steps at a complex field scale and its chain classes (Definition B.7 and equation (200), B.16, the definitions preceding (228), the definitions preceding equation YMM1:(2276), Section YMM1:124, (232), E.1, the bracket-localization constants in (Wp4), (196), (196), (198), (199), (228), equation YMM1:(2286), Proposition YMM1:122.1, equation YMM1:(2258), Lemma B.10, equations YMM1:(2286)–(2287), YMM1:124.4, YMM1:124.3, equation YMM1:(2291), Propositions YMM1:122.2, YMM1:123.1, B.21, YMM1:124.2, YMM1:124.5, B.25, E.2, Corollary B.9, Lemma YMM1:126.2), with the restricted Gaussian measures of one step (Lemma M.1); the level-wise sourced density and packed-source amplitudes (Proposition F.1 and Lemma F.3), the first-creation decomposition and its coefficient bounds (Proposition F.2, Corollary F.4 and Proposition M.2), and the least-torus comparison proved in Proposition 9.19; the free template and the template sums (Section YMM1:120, Section YMM1:120, YMM1:(2231), Lemma YMM1:120.1, the test-pair bounds (54), Proposition YMM1:120.3, YMM1:120.5 and YMM1:120.6, YMM1:121.2 and Lemma I.2, Proposition YMM1:120.3); Laplace's method and the lattice coefficient (Definitions A.7, A.10, Lemmas A.6, A.9, A.11, A.24, A.26, A.27, A.38, (156), (157), (169), Corollary A.37, Theorems BR, BS); the rate of the cutoffs on a torus (the constants and thresholds in Theorem YMM1:AR, YMM1:(2206), the two threshold inequalities at the end of the proof of Theorem YMM1:AR, Corollary YMM1:117.1); the limit at every label on a torus (Theorem YMM1:AS, Proposition YMM1:118.3); the separated tuples and the test pairs of class C^1 (Section K.1, the convention in equation YMM1:(2343), Lemma I.1 and equation YMM1:(2247)); the sequences of pairs of laws, their convergence and the connected functions of their limit functionals (Proposition YMM1:92.1 and its moment–cumulant identity YMM1:(1856)); the Gibbs sequences, their limits and the components of these (Definition 15.4(2), Theorem YMM1:AP); and the common construction choice of Section YMM1:82, with the torus limits of Theorem YMM1:A and the growing-torus and volume-first limits of Proposition YMM1:92.1.

9.4. **Source-energy jets and the field-scale expansion.** *Notation.* Throughout, $D=(K,\beta)$ is a datum at g with label b, $\ell=2L^m\in\mathfrak L(g)$, and f,h are real bounded functions on T_ℓ; $w_1=f\circ x$ and $w_2=h\circ x$ are the lattice sources on the bare plaquettes. We write $N=\ell L^K$, $\mathsf N=N+\beta$,

$r = d/a_K$, $l = \max\{1, \log(2b/d)\}$, $\mathfrak{b}(x) = A_1(\log x)^{p_0}$, $\delta(x) = \mathfrak{b}(x)x^{-1/2}$ and $\langle z\rangle = \max\{1, |z|\}$. With $E_\mu^{(j)}$ the local terms of the level j of the weighted progression ((200)) at the datum, with the weight $\mu_1 w_1 + \mu_2 w_2$ of the plaquettes, and $\mathcal{D}_j$ its domains of the level j, the second jet of the level j is

$$\mathsf{n}_j = \sum_{X\in\mathcal{D}_j} \sum_{z\in X\cap\mathbb{T}^{(j)}} \partial_{\mu_1}\partial_{\mu_2} E_\mu^{(j)}(X, \mathbf{1}, z)\big|_{\mu=0}, \qquad \mathsf{J}_2 = \sum_{j=1}^{K} \mathsf{n}_j.$$

The same construction at a complex field scale λ (every fluctuation field multiplied by λ, the coefficient of the action at the height j moved to $\xi_j(\lambda) = L^{-j}x_0 + \lambda^2(x_j - L^{-j}x_0)$) gives the local terms $E_\mu^{(j),\lambda}$ of the level j at the field scale λ, with $E_\mu^{(j),1} = E_\mu^{(j)}$, and their second jets $\mathsf{n}_j^\lambda = \sum_{X\in\mathcal{D}_j}\sum_{z\in X\cap\mathbb{T}^{(j)}} \partial_{\mu_1}\partial_{\mu_2} E_\mu^{(j),\lambda}(X, \mathbf{1}, z)|_{\mu=0} = \sum_{m\geq 0} \mathsf{n}_{j,[2m]}\lambda^{2m}$ (Proposition 9.5); $\mathsf{h}_{2m}^{(n)} = \sum_{j\leq n} \mathsf{n}_{j,[2m]}$, $\mathsf{h}_{2m} = \mathsf{h}_{2m}^{(K)}$, and $\mathsf{H}^{(n)}[D] = \beta^3 a_K^2 \mathsf{h}_6^{(n)}$. As $\beta^{-3}a_K^{-2} = b^{-3}a_K$ and $a_K r = d$, a size $r\eta$ of H is a size $b^{-3}d\eta$ of h_6. Where the side matters we write $\mathsf{J}_2[\ell]$, $\mathsf{h}_6[\ell]$, $\mathsf{H}^{(n)}[D, \ell]$.

The free template (Section YMM1:120) is the free abelian model of the curvature: cochains, plaquette averages and nested projections. At the height $0 \leq i < K$, $\mathsf{A}_i^{\mathrm{cv}} = \mathsf{B}_i^{\mathrm{cv}} + \hat{\mathsf{G}}$ is its one-step quadratic form, a sum of two real symmetric matrices ≥ 0 on the non-pivot bonds of $\mathbb{T}^{(i)}$, and $\mathsf{A}_i^{\mathrm{cv}} \geq \gamma^{\mathrm{tr}}$ with a lower bound $\gamma^{\mathrm{tr}} > 0$ (Proposition YMM1:120.3); T_i is its curvature map onto the bare plaquettes (Proposition YMM1:120.3). Π_0^{tp} is the orthogonal projection onto the exact bare curvatures and Π_n^{tp}, $n \geq 1$, the projection onto those that the plaquette averages of the level n determine, so that $\Pi_0^{\mathrm{tp}} - \Pi_n^{\mathrm{tp}}$ is the orthogonal projection onto the curvatures whose plaquette averages of the level n vanish; $\mathcal{C}_{(j)} = \Pi_{j-1}^{\mathrm{tp}} - \Pi_j^{\mathrm{tp}}$ are the curvature slices, and $C_{K,K-n}^{\mathrm{fl}} = \Pi_0^{\mathrm{tp}} - \Pi_n^{\mathrm{tp}} = \sum_{1\leq j\leq n} \mathcal{C}_{(j)}$ is the fluctuation kernel, the conditional covariance of the free lattice curvature given its plaquette averages of the level n; on a lattice with t levels we write $\Pi_t^{\mathrm{fl}} = \Pi_0^{\mathrm{tp}} - \Pi_t^{\mathrm{tp}}$.

The numbers $\delta_{\mathrm{tp}} \in (0, \frac{1}{12}]$ and $C_{\mathrm{tp}} \geq 1$ of the decay of the slices (Propositions YMM1:120.5 and YMM1:120.6), and the number $C_{\mathrm{tp}}^{\mathrm{row}}$ of the row sums of the curvature maps,

$$\sum_b |\mathsf{T}_i(p, b)| \leq C_{\mathrm{tp}}^{\mathrm{row}} L^{-2i} \qquad \text{for every bare plaquette } p,$$

uniformly in the volume, at the height $i = 0$ and at every height at which the side ℓL^{K-i} of the level i, in its units, is at least N_{H}, so at every height if $\ell \geq N_{\mathsf{H}}$ (Proposition YMM1:120.6), depend on L and on the least admissible side N_{H} fixed with C_{H} and δ_{H} in Section YMM1:52.6 and the beginning of Section YMM1:120.3; they, γ^{tr} and N_{H} are determined by the constants.

The Gaussian measures of the heights. Put $\tau_i = L^{-i}x_0/x_i$ and $\mathsf{M}_i = \tau_i \mathsf{B}_i^{\mathrm{cv}} + \hat{\mathsf{G}}$. ν_i° is the centred Gaussian measure with the precision $\mathsf{M}_i \otimes 1$ on the real $\mathfrak{g}$-valued 1-forms B_i on the non-pivot bonds of $\mathbb{T}^{(i)}$, and ν_i^{r} is ν_i° conditioned on the box $\{|B_i(b)| < \mathfrak{b}(x_i)\ \forall b\}$, $|\cdot|$ being the Euclidean norm of $\mathfrak{g} \cong \mathbb{R}^3$: the boxes are products of Euclidean balls. As $\tau_i \in [\frac{3}{4}, \frac{4}{3}]$ (Proposition 9.4) and both matrices are ≥ 0, $\mathsf{M}_i \geq \min\{\tau_i, 1\}\mathsf{A}_i^{\mathrm{cv}} \geq \frac{3}{4}\gamma^{\mathrm{tr}}$, so every variance in ν_i° is at most $\frac{4}{3\gamma^{\mathrm{tr}}}$.

The measures ν_i° are tied to the steps by Lemma 9.12(iii): at $\lambda = 0$, at the trivial configuration, the density of the step of the height i is proportional to $\exp[-\frac{1}{2}(B_i, (\mathsf{M}_i \otimes 1)B_i)]$ on the box of the height, the height 0 included, where $\tau_0 = 1$ and $\mathsf{M}_0 = \mathsf{A}_0^{\mathrm{cv}}$. For polynomials $X_{a,m}$ ($a = 1, 2$, $m = 0, 1, 2$), W_1, W_2 in these fields and a probability measure ν, with the joint cumulants $\langle\cdot; \ldots; \cdot\rangle$ taken in ν,

$$\begin{aligned}\gamma_2[\nu] = {} & \langle X_{1,2}; X_{2,0}\rangle + \langle X_{1,0}; X_{2,2}\rangle + \langle X_{1,1}; X_{2,1}\rangle - \langle X_{1,1}; X_{2,0}; W_1\rangle \\ & - \langle X_{1,0}; X_{2,1}; W_1\rangle - \langle X_{1,0}; X_{2,0}; W_2\rangle + \tfrac{1}{2}\langle X_{1,0}; X_{2,0}; W_1^2\rangle;\end{aligned} \tag{48}$$

$\gamma_2^{\mathrm{r}} = \gamma_2[\bigotimes_{0\leq i<n} \nu_i^{\mathrm{r}}]$ and $\gamma_2^\circ = \gamma_2[\bigotimes_{0\leq i<n} \nu_i^\circ]$, with the polynomials of Proposition 9.11. If ν is invariant under $B \mapsto -B$, the $X_{a,0}$ are even and W_1 is odd, then $\frac{1}{2}\langle X_{1,0}; X_{2,0}; W_1^2\rangle = \frac{1}{2}\langle X_{1,0}; X_{2,0}; W_1; W_1\rangle$:

a cumulant with a product entry is $\langle X;Y;W^2\rangle = \langle X;Y;W;W\rangle + 2\langle X;W\rangle\langle Y;W\rangle + 2\langle W\rangle\langle X;Y;W\rangle$, and the last two terms vanish by parity.

Laplace's method (Lemma A.11). Let ϕ,ψ,X,Y be real and smooth near $0\in\mathbb{R}^m$, $\phi(0)=0$, $\nabla\phi(0)=0$, with a positive definite Hessian H at 0, and let X, Y vanish at 0 with their gradients. Let ϕ_j,ψ_j,X'_j,Y'_j be their homogeneous Taylor polynomials of order j at 0, and $W_j=\phi_{j+2}+\psi_j$, $X_{1,j}=X'_{j+2}$, $X_{2,j}=Y'_{j+2}$. Then the covariance of X and Y under the density proportional to $e^{-\beta\phi-\psi}$ on a small window about 0 is

$$\beta^{-2}\gamma_0^{\mathrm{L}}+\beta^{-3}\gamma_2^{\mathrm{L}}+O(\beta^{-4})\qquad(\beta\to\infty),\tag{49}$$

where $\gamma_0^{\mathrm{L}}=\langle X_{1,0};X_{2,0}\rangle$ and γ_2^{L} is (48), both in the centred Gaussian measure of covariance H^{-1}. In the variable $\beta^{1/2}x$ the density is the Gaussian one times $e^{-\beta^{-1/2}W_1-\beta^{-1}W_2-\cdots}$ and the observables are $\beta^{-1}(X_{a,0}+\beta^{-1/2}X_{a,1}+\beta^{-1}X_{a,2}+\dots)$; the coefficient of β^{-3} of the covariance, expanded in joint cumulants, is (48), written with the parity just noted, and the half-integer orders vanish by parity. We write $\gamma^{\mathrm{L}}_{m'}[\phi,\psi,X,Y]$, $m'=0,2$. The numbers $\mathsf{g}_{m'}[N,t](p,q)$ of a flat top are set in Proposition 9.13; for functions w_1,w_2 on the plaquettes of Λ_N, $\mathsf{T}[N,t](w)=\sum_{p,q}w_1(p)w_2(q)\mathsf{g}_2[N,t](p,q)$, and for functions $\tilde w_1,\tilde w_2$ of finite support on the plaquettes of $\mathbb{Z}^3$, $\mathsf{T}^{\mathrm{lat}}(\tilde w)=\sum\tilde w_1(\tilde p)\tilde w_2(\tilde q)\mathsf{B}_1^{\mathrm{lat}}(\tilde p,\tilde q)$.

If $\tilde w_1(\tilde p)=\tilde f(a_K x(\tilde p))$, $\tilde w_2(\tilde p)=\tilde h(a_K x(\tilde p))$, then $a_K\mathsf{T}^{\mathrm{lat}}(\tilde w)=\mathsf{P}_1^{\mathrm{lat}}(\tilde f,\tilde h;a_K)$.

Proposition 9.4 (The setting of the expansion)**.** There is $\gamma_{\mathrm{s}}\in(0,\min\{\gamma_W^{\mathrm{ref}},\frac12\}]$, determined by the constants, such that for $0<g\le\gamma_{\mathrm{s}}$, every datum (K,β) at g with $K\ge3$, every $\ell=2L^m\in\mathfrak{L}(g)$, and real bounded f,h with supports in balls of radius d at a distance $\ge d$, $8a_K\le d$, at every position of (f,h):

(i) $2L^{m+K-j+1}\ge C_LM$ for $1\le j\le K$, in particular $\ell L\ge C_LM$; and $\ell\ge N_{\mathsf{H}}$;

(ii) $x_0>x_1>\cdots>x_K>g^{-2}$, $x_{K-1}>Lg^{-2}\ge4L$, and for $0\le j<K$: $\frac34 b/D_j\le x_j\le 2b/D_j$ and $\frac34\le\tau_j\le\frac43$;

(iii) at every level $j<K$ the constants, the lattice of the step $j\to j+1$ and x_j are data under (Im) of Definition B.2;

(iv) the data of the weighted progression (Definition B.7) are given with $k=K-1$, the sources w_1,w_2 and the running couplings as thresholds; the setting (J) of Definition B.16 holds at $k=K-1$; $\log x_{K-1}\ge\max\{2p_0,1+\log L\}$; and $\delta(x_{K-1})$ lies below the threshold of the chain classes (equations YMM1:(2285) and (234)) and below the smallness that Proposition 9.5 asks of its discs.

No condition is put on the witness depth, on the signs or on the Lipschitz constants of f and h. ■

Proof sketch. (i) For a side at g the lattice of a datum is large at every level, by the flow of the coupling (Section YMM1:74, YMM1:74) and Lemma YMM1:126.2; at $j=K$ this is $\ell L\ge C_LM$. The condition on N_{H} and its two companion numbers is a member of the collective condition, which holds at the fixed constants and under which the geometric hypotheses of Section YMM1:52.7 hold; it is a condition on these three numbers, and no side occurs in it. The bound $\ell\ge N_{\mathsf{H}}$ is a property of the sides at g: for $\ell=2L^m\in\mathfrak{L}(g)$ the flow of the coupling gives $LM\,R(x_K)\le L^m$ (Proposition YMM1:74.1; R is the function of equation YMM1:(634)), so $M\,R(x_K)\le L^m$, and with this Lemma YMM1:126.2 gives $\ell\ge N_{\mathsf{H}}$, together with the frames of the datum on T_ℓ; the setting (J) at $k=K-1$ follows in (iv).

(ii) The run equation gives $|x_j-L^{-j}x_0|\le B_\sharp\sum_{i\ge0}L^{-i}=\bar B$, and $L^{-j}x_0=b/D_j$. As K is the first passage, $x_j\ge x_{K-1}>X_g\ge Lg^{-2}$ for $j<K$, and $x_K=L^{-1}x_{K-1}-e_K>g^{-2}$; γ_{s} is so small that $X_g\ge12\bar B$. Hence $|\tau_j-1|\le\bar B/x_j\le\frac{1}{12}$, and $\frac{12}{13}b/D_j\le x_j\le b/D_j+\bar B\le 2b/D_j$. (iii), (iv) $\gamma_{\mathrm{s}}\le\gamma_W^{\mathrm{ref}}$ is the least of two thresholds determined by the constants. For $g\le\gamma_{\mathrm{s}}$, Corollary B.9, Proposition B.21 and Lemma YMM1:126.2 give the data of the progression and the setting (J) at $k=K-1$; in that setting, at every level, the constants, the lattice of the step and x_j are data under (Im), so that in particular the ratio A_0/A_1 lies above the number that (Im) asks.

As $x_{K-1} > L\gamma_{\rm s}^{-2}$ and δ decreases for large arguments, $\delta(x_{K-1}) \le \delta(L\gamma_{\rm s}^{-2})$, which lies below both thresholds for $\gamma_{\rm s}$ small, and $\log x_{K-1} \ge \log(L\gamma_{\rm s}^{-2}) \ge \max\{2p_0, 1+\log L\}$. The sources enter through their supports alone. □

Proposition 9.5 (One field scale)**.** Under the assumptions of Proposition 9.4 the progression is formed at one complex field scale for all its steps. There are $R_j > 1$ $(0 \le j < K)$ with $R_j^{-2} \le c_0(\log x_j)^{2p_0} D_j/b$, and $\rho \in (0, \frac12]$ with $(\rho R_j)^2 \ge 2$, such that, with $c_0, \rho, C_{\mathsf n}, C_{\rm E}, C_{{\rm E},m}, C_{\rm R}, C_{\rm J}$ determined by the constants (they depend on no cutoff, side, run, scale, position or pair), the following hold.

(i) $\lambda \mapsto \mathsf n_{j+1}^\lambda$ is holomorphic and even on $|\lambda| < R_j$, $\mathsf n_{j+1}^1 = \mathsf n_{j+1}$, its Taylor coefficients $\mathsf n_{j+1,[0]}$, $\mathsf n_{j+1,[2]}$ of the orders 0 and 2 vanish, and for $|\lambda| \le \rho R_j$

$$|\mathsf n_{j+1}^\lambda| \le C_{\mathsf n}|\lambda|^2 R_j^{-2} D_j^{-2} \min\{1, (d/D_j)^{5/2}\}\, \Pi_{j+1}\, \eta, \qquad \Pi_{j+1} = \max\{1, (d/D_{j+1})^3\} e^{-[d/(4MD_{j+1})-2]_+}.$$

(ii) $|\mathsf J_2 - \mathsf h_4 - \mathsf h_6| \le C_{\rm E} b^{-4} d^2 l^{8p_0}\eta$ and $|\mathsf h_{2m}| \le C_{{\rm E},m} b^{-m} d^{m-2} l^{2mp_0}\eta$ for $m = 2, 3$.

(iii) For $0 \le n \le K-1$ with $D_n \ge d$ and $m = 2, 3$:

$$\sum_{j=n}^{K-1} |\mathsf n_{j+1,[2m]}| \le C_{\rm R} b^{-m} l^{2mp_0} d^{m-2} (d/D_n)^{\frac52 - (m-2)} \eta.$$

In particular, for $n \le n' \le K$ with $L^n \ge r$: $|\mathsf H^{(n')}[D] - \mathsf H^{(n)}[D]| \le C_{\rm R} l^{6p_0} (r/L^n)^{3/2} r\, \eta$.

(iv) Let $\dot E_a^{(i+1),\lambda} = \partial_{\mu_a} E_\mu^{(i+1),\lambda}|_{\mu=0}$ $(a = 1, 2)$ and $\ddot E^{(i+1),\lambda} = \partial_{\mu_1}\partial_{\mu_2} E_\mu^{(i+1),\lambda}|_{\mu=0}$ be the first and the second jets of the level $i+1$ at the field scale λ, pointed families of the level $i+1$, and let $\psi_i = \min\{1, (d/D_i)^3\}$, $\chi_i = \min\{1, (d/D_i)^{5/2}\}$. At every λ at which they are formed, the member of $\dot E_a^{(i+1),\lambda}$ on a domain X vanishes unless X holds a plaquette of the support of w_a, and the member of $\ddot E^{(i+1),\lambda}$ on X vanishes unless X holds a plaquette of each of the two supports. For $0 \le i \le j < K$ and $|\lambda| \le \rho R_j$, their sizes YMM1:(759) at the rate $\kappa^+ = (1 + 4\beta_{\rm s})\kappa$, at which the parts of the local terms that depend on the sources decay in the linear size of the domain (Proposition YMM1:122.1), obey

$$\|\dot E_a^{(i+1),\lambda}\|_{i+1,\kappa^+} \le C_{\rm J}|\lambda|^2 R_i^{-2} D_i^{-1} \psi_i \|w_a\|_\infty, \qquad \|\ddot E^{(i+1),\lambda}\|_{i+1,\kappa^+} \le C_{\rm J}|\lambda|^2 R_i^{-2} D_i^{-2} \chi_i\, \eta.$$

If w_a vanishes identically, all the jets in the direction w_a vanish; so (i)–(iii) hold trivially if w_1 or w_2 vanishes, and so do the bounds of (iv) that involve a vanishing source. ■

Proof sketch. One step at a complex field scale is Proposition E.2, applied with a parameter set (Definition E.1) that holds the field scales of the earlier steps; the scale is put on the diagonal afterwards. A lower calibration $\mathsf t_\flat$, fixed with the constants, gives room for the size of the deformed bare array, the bound of the step being uniform in the parameter. The counterterms e_i are kept, and the coefficient of the action is moved along $\xi_j(\lambda)$, which stays in the admitted disc about x_j for $|\lambda| < R_j := \delta(\mathsf t_\flat)/(2\delta(x_j))$, because $|\xi_j(\lambda) - x_j| = |\lambda^2 - 1|\,|x_j - L^{-j}x_0| < 2R_j^2\bar B$. To make the last bound smaller than $\sigma_* x_j$, decrease $\gamma_{\rm s}$, if necessary, so that

$$\bar B \delta(\mathsf t_\flat)^2 < 2\sigma_* A_1^2 (\log x_j)^{2p_0}$$

for every coupling of the run. This is possible by the lower bound on x_j in Proposition 9.4; substitution of the formula for R_j gives $2R_j^2\bar B < \sigma_* x_j$. Thus the simultaneous substitution in the field scale and the quadratic coefficient stays within the product domain of Proposition E.2.

By Proposition 9.4(ii), $R_j^{-2} = 4\delta(x_j)^2/\delta(\mathsf t_\flat)^2 \le \frac{16}{3} A_1^2 \delta(\mathsf t_\flat)^{-2} (\log x_j)^{2p_0} D_j/b$. Induction over the heights gives the holomorphy, the evenness, $\mathsf n_{j+1}^1 = \mathsf n_{j+1}$ and the locality in the weight of (iv): the member of the level $i+1$ on a domain X is formed from the members of the lower levels on the domains in X and from the weight on the plaquettes of X, at every field scale as at the field scale 1

(Proposition YMM1:122.1(c)). The derivatives in the weights obey two linear recursions over the levels, by the chain rule and Cauchy's estimate in the direction of the bare array: one step at the field scale λ multiplies the size of the derivative in the direction of a bare array by at most $c\,|\lambda|^2 R_i^{-2}$ (clauses (cx3), (cx8) of Proposition E.2, uniformly in the parameter), and the weight member of the level i in the direction w_a has the size at most $36M^3\alpha_0^2 D_i^{-1}\psi_i\|w_a\|_\infty$, its source meeting at most $35(d/a_K)^3$ plaquettes; so the first derivatives follow the profile $\psi_i = \min\{1,(d/D_i)^3\}$, the second the profile $\chi_i = \min\{1,(d/D_i)^{5/2}\}$.

They close on these profiles for $|\lambda| \le \rho R_j$ by the locality in the weight, the bare array of a source with support of diameter $\le 2d$ meeting at most $77\max\{1,(d/D_i)^3\}$ cubes of the level i, the cubes of side MD_i of the partition π_i of the torus whose wall-connected unions are the domains of the level i (the level-i localization partition of Section YMM1:45); ρ is fixed by the two inequalities that close the induction, and the closed recursions are the two bounds of (iv). A domain that meets both supports holds two points at a distance at least $d/4$, so that its linear size in the units of its level is at least $[d/(4MD_{j+1}) - 2]_+$; with the count of such domains this gives the display of (i).

At the order 2 the earlier members are taken at the field scale 0, where they do not depend on the sources, and the coefficient is a covariance of two linear forms ℓ_Y of the field at the trivial configuration. A constant gauge rotation u fixes the trivial configuration, so $\ell_Y(\mathrm{Ad}(u)B) = \ell_Y(B)$, and $\int_G \mathrm{Ad}(u)Y\,du = 0$ for $Y \in \mathfrak{g}$ gives $\ell_Y = 0$.

(ii), (iii): an even holomorphic H with $|H| \le \mathsf{B}$ on $|\lambda| < R$ has $|H_{[2m]}| \le \mathsf{B}R^{-2m}$ and $|H(1) - \sum_{m\le p} H_{[2m]}| \le \mathsf{B}R^{-2p-2}/(1-R^{-2})$. Applied on $|\lambda| < \rho R_j$, where $(\rho R_j)^2 \ge 2$, with the bound of (i), each level gives at most $c\,b^{-m}(\log x_j)^{2mp_0} D_j^{m-2}\chi_j \Pi_{j+1}\eta$ at the order $2m$, and $m = 4$ for the remainder. The levels with $D_j \ge d$ have $\Pi_{j+1} = 1$, $\log x_j \le l$ and $D_j^{m-2}\chi_j = d^{m-2}(d/D_j)^{\frac{5}{2}-(m-2)}$: a geometric series over the levels. The other levels are summed against Π_{j+1}, which is summable against every power of the logarithm. For (iii) at $m = 3$: $\mathsf{h}_6^{(n')} - \mathsf{h}_6^{(n)} = \sum_{n\le j<n'} \mathsf{n}_{j+1,[6]}$, $D_n \ge d$ if and only if $L^n \ge r$, $d/D_n = r/L^n$ and $\beta^3 a_K^2 b^{-3} d = r$. □

Proposition 9.6 (The front on the least torus)**.** There are $\gamma_{\mathrm{C}} > 0$, determined by the constants, and for $0 < g \le \gamma_{\mathrm{C}}$ numbers $d_{\mathrm{A}}(g) > 0$ and $C_{\mathrm{A}}(g) < \infty$, depending on g and the constants and on no K, β, b, ϑ, d, pair or position, such that for every datum (K,β) at g, $\ell = \ell_g$, $0 < d \le d_{\mathrm{A}}(g)$ with $s(d) \le K$, $\vartheta \in (0,1)$ and $(f,h) \in \mathfrak{T}_{T_\ell}(d;\vartheta)$: $K \ge 3$ and $a_K \le d$; the set

$$\mathsf{Pk} = \{v \in \delta\mathbb{Z}^3 :\ |v_\mu| \le 0.575 - 9d\ (\mu = 1,2,3)\}, \qquad \delta = a_K\lceil 18d/a_K\rceil,$$

which lies in $a_K\mathbb{Z}^3$ and depends on a_K and d alone, consists of vectors of length < 1, has $\#\mathsf{Pk} \ge (30d)^{-3}$, and $(\tau_v f, \tau_v h) \in \mathfrak{T}_{T_\ell}(d;\vartheta)$ for $v \in \mathsf{Pk}$; and

$$\Big|S^T_{2;K,\ell,\beta}(f,h) - \frac{1}{\#\mathsf{Pk}}\sum_{v\in\mathsf{Pk}} \mathsf{J}_2(\tau_v f, \tau_v h)\Big| \le C_{\mathrm{A}}(g)\vartheta^{-1}d^2b^{-2}\eta.$$

■

Proof. Decrease $\gamma_{\mathrm{C}} \le \gamma_{\mathrm{s}}$ to satisfy the source and radius conditions of Section F. These are conditions on the fixed constants and on the lower coupling threshold. Choose $d_{\mathrm{A}}(g)$ small enough for the packing and amplitude bounds below.

If $f \circ x = 0$, every lattice translate of this bare weight is zero. Both the covariance and its source-energy mixed derivative therefore vanish; the assertion follows. The same applies to $h \circ x$. Henceforth neither is zero. Choose x_1 with $\operatorname{supp} f \subset \mathbb{B}(x_1, d)$. Both supports lie in $\mathbb{B}(x_1, 9d)$. The balls $\mathbb{B}(x_1 + v, 9d)$, $v \in \mathsf{Pk}$, have disjoint interiors, since $\delta \ge 18d$, and lie in $\mathbb{B}(x_1, 1)$. Indeed, $|v| \le \sqrt{3}(0.575 - 9d)$ and $\sqrt{3}(0.575 - 9d) + 9d < 1$. The condition $s(d) \le K$ gives $L^K d \ge C_W(s(d)) \ge 4L^2M$, so $a_K \le d$; for d small it also gives $K \ge 3$. Now $\delta \le 18d + a_K \le 19d$.

Thus, for d small,

$$\#\mathsf{Pk} = \left(2\left\lfloor\frac{0.575-9d}{\delta}\right\rfloor+1\right)^3 \geq (30d)^{-3}.$$

The translates preserve the support separation, amplitude and Lipschitz conditions defining the test class.

Use the norm (276) and the holomorphic total source energy $\mathcal{E}$ of Proposition F.1. Lemma F.3 bounds a disjoint sum $w=(\sum_\iota \zeta_\iota u_\iota)\circ x$ by

$$\|w\|_{\mathrm{lw}} \leq \max_\iota |\zeta_\iota|\mathsf{A}_\iota/\mathsf{A}_\star(d), \qquad \mathsf{A}_\star(d)=\min\left\{\sigma_{\mathrm{src}}b^\vee, \frac{\mu_\star}{K_{\mathrm{L}}^\vee}\frac{b^\vee}{(b^\wedge)^{1/2}}\left(\frac{\vartheta d}{4\sqrt{3}M}\right)^{1/2}\right\},$$

where $\|u_\iota\|_\infty \leq \mathsf{A}_\iota$, $\operatorname{Lip} u_\iota \leq \mathsf{A}_\iota/(\vartheta d)$, $b^\vee = g^{-2}-\bar{B}$ and $b^\wedge = b_+$. The total-energy identity in Proposition F.1 shows that J_2 is the mixed derivative of $\mathcal{E}$ at zero. Therefore $S_2^T-\mathsf{J}_2$ is the mixed derivative of $\log(Z[\cdot]/Z[0])-\mathcal{E}$.

For signs $\epsilon\in\{\pm1\}^{\mathsf{Pk}}$ put

$$F^\epsilon=\sum_v \epsilon_v\tau_v f, \qquad H^\epsilon=\sum_v \epsilon_v\tau_v h, \qquad w_z=(z_1F^\epsilon+z_2H^\epsilon)\circ x, \qquad \Omega_\epsilon(z)=Z[w_z]e^{-\mathcal{E}(w_z)}/Z[0].$$

The nonzero sets of the individual bumps are pairwise disjoint. With $u_1=\|f\|_\infty/\mathsf{A}_\star(d)$ and $u_2=\|h\|_\infty/\mathsf{A}_\star(d)$, the amplitude bound gives $\|w_z\|_{\mathrm{lw}}\leq \max_a|z_a|u_a$. Thus Ω_ϵ is holomorphic on $\mathbb{P}=\{|z_1|u_1<1,\ |z_2|u_2<1\}$ and $\Omega_\epsilon(0)=1$.

Split the sourced partition by its first large-field creation, using (284):

$$\Omega_\epsilon=\Omega_\epsilon^{\emptyset}+\sum_{t=1}^{K}\Omega_\epsilon^t, \qquad \Omega_\epsilon^{\emptyset}=e^{-\mathcal{E}(w_z)}m_K^{w_z}(\mathcal{V}_K)/Z[0], \qquad \Omega_\epsilon^t=e^{-\mathcal{E}(w_z)}\mathsf{Cr}_t(w_z)/Z[0].$$

Every source here is supported in the one ball $\mathbb{B}(x_1,1)$. Proposition F.2 therefore gives

$$|\Omega_\epsilon^{\emptyset}|\leq e^{\mathsf{G}_K} \quad \text{on } \mathbb{P}, \qquad |\Omega_\epsilon^t|\leq e^{\|w_z\|_{\mathrm{lw}}(\mathsf{G}_{t-1}+\mathsf{H}_{t-1})}\mathsf{w}_t.$$

Choose $\mathsf{C}_{\mathrm{cnt}}=C_{\mathrm{cnt}}(g)\geq 1$ in (283), and set $\mathsf{Cnt}_t=\mathsf{C}_{\mathrm{cnt}}L^{4(K-t+1)}$. On $\mathbb{P}_t=\{|z_a|u_a\mathsf{Cnt}_t<1, a=1,2\}$ the second bound is at most $e\mathsf{w}_t$. For $\emptyset\neq B\subset\{1,2\}$ write $[z^B]\Omega=(\prod_{a\in B}\partial_{z_a})\Omega(0)$ and $u^B=\prod_{a\in B}u_a$. Cauchy's formula on these polydiscs gives

$$|[z^B]\Omega_\epsilon^{\emptyset}|\leq e^{\mathsf{G}_K}u^B, \qquad |[z^B]\Omega_\epsilon^t|\leq e\mathsf{w}_t\mathsf{Cnt}_t^{|B|}u^B\leq e(\mathsf{C}_{\mathrm{cnt}}L^4)^2L^{8(K-t)}\mathsf{w}_tu^B.$$

By (286), the latter coefficients sum to at most $e(\mathsf{C}_{\mathrm{cnt}}L^4)^2C_8(g)u^B$. Choose $\mathsf{Q}(g)\geq 1$ above this coefficient bound plus $e^{\sup\mathsf{G}_K}$. It is finite and independent of the datum, the positions and the signs. Thus

$$|[z^B]\Omega_\epsilon|\leq \mathsf{Q}(g)u^B, \qquad |\partial_{12}\log\Omega_\epsilon(0)|\leq(\mathsf{Q}+\mathsf{Q}^2)u_1u_2\leq 2\mathsf{Q}^2\mathsf{A}_\star(d)^{-2}\eta.$$

The logarithm is needed only near zero, where $\Omega_\epsilon(0)=1$ ensures its existence.

By bilinearity the last mixed derivative is

$$\sum_{v,v'}\epsilon_v\epsilon_{v'}(S_2^T-\mathsf{J}_2)(\tau_vf,\tau_{v'}h).$$

Average over the independent signs. The terms $v\neq v'$ vanish and the diagonal terms remain. Translation invariance of S_2^T and the packing count then give

$$\left|S_2^T(f,h)-\frac{1}{\#\mathsf{Pk}}\sum_v\mathsf{J}_2(\tau_vf,\tau_vh)\right|\leq(30d)^3\,2\mathsf{Q}^2\mathsf{A}_\star(d)^{-2}\eta.$$

For $d\leq 4\sqrt{3}Mg^{-2}(K_{\mathrm{L}}^\vee/K_{\mathrm{Q}}^\vee)^2$ the second entry in the minimum defining $\mathsf{A}_\star$ is the smaller one. Substitution bounds the last expression by $C(g)\vartheta^{-1}d^2\eta$. Since the label satisfies $b\leq b_+$, enlarging this fixed-g constant by b_+^2 gives the asserted $C_{\mathrm{A}}(g)\vartheta^{-1}d^2b^{-2}\eta$. The finitely many ceilings on d determine $d_{\mathrm{A}}(g)$. □

Proposition 9.7 (The order four)**.** Let $0 < g \le \gamma_{\mathrm{s}}$, (K,β) a datum at g, $\ell \in \mathfrak{L}(g)$, $0 < d \le L^{-1}$, $s(d) < K$, $20d \le \ell$, $\vartheta \in (0,1)$ and $(f,h) \in \mathfrak{T}_{T_\ell}(d;\vartheta)$, at any position. Then $K \ge 3$, $8a_K \le d$, $d/a_K \ge L(\log \frac{1}{d})^2$, and

$$|\mathsf{h}_4 - c_2 b^{-2}\mathcal{K}_6|(f,h) \le \big[\bar\varepsilon_4(g,d)\, b^{-3} d + C_{\mathrm{lat}}\, b^{-2} a_K/d\big]\eta,$$

where, with $l' = \max\{1, \log \frac{2b'}{d}\}$,

$$\bar\varepsilon_4(g,d) = \sup_{g^{-2} < b' \le b_+} \frac{b'}{d}\Big\{3C_{\mathrm{tm}} d^3 + C_{\mathrm{Bx}}\big[d^{3/2} + e^{-\mathsf{c}_\chi(\log \frac{3b'}{4d^{1/2}})^2}\big] + C_{\mathrm{Bt}}\, l'^{\,4p_0} e^{-\mathsf{c}_\flat L(\log\frac{1}{d})^2}\Big\},$$

$C_{\mathrm{Bx}}, C_{\mathrm{Bt}}, \mathsf{c}_\chi > 0$ being determined by the constants and $\mathsf{c}_\flat = \min\{\frac{1}{8ML}, \frac{\delta_{\mathrm{tp}}}{2\sqrt{3}}\}$. The function $\bar\varepsilon_4(g,\cdot)$ depends on g and the constants alone and is the same for all sides and data at g; and $\bar\varepsilon_4(g,d) \le C_4(g) d^{1/2}$, with $C_4(g)$ depending on g and the constants. ■

Proof sketch. The first three assertions are those of the setting on the witness depth. Let $2 \le n \le K$ with $D_n \ge d$.

(1)

The tower at a real field scale. Let $0 < \lambda \le 1$, $g_i = x_i^{-1/2}$, and let $c_{\mathfrak{h}}$ be the constant of the shift systems of the steps. The chain of the levels at the field scale λ is formed downwards from the flat top of the level n: $A_n^\lambda := 0$ and, for $i = n-1, \dots, 1$,

$$A_i^\lambda := A^{\mathrm{lw}}(v^{[i+1]}_{A_{i+1}^\lambda}, \lambda g_i B_i), \qquad \tilde U_i^\lambda := e^{iL^{-i}A_i^\lambda},$$

with the lowered 1-form A^{lw} of equation YMM1:(2286) and the chart point $v_A^{[i+1]}$ of a chain class (equation (232)). A *chart point* of a level k is a pair $v = (A, \mathbf{J})$ of 1-forms on the bare bonds; $P[v] = (\mathbf{1}, A, \mathbf{J})$ is its triple in the chart at the trivial pair (Section YMM1:124), and $P[0]$ is the trivial triple; its norm $\|v\|$ is the largest of the numbers $|A(b)|$, $|\mathbf{J}(b)|$ over the bare bonds b and of the moduli of the difference quotients of A at the spacing L^{-k}; and $\mathsf{Cc}_k(r)$ is the chain class of the level k and the radius r. The A_i^λ are real 1-forms on the bare bonds, and $\tilde U_i^\lambda$, a configuration on the bare bonds, is the *background of the level* i, as in the proof of Proposition 9.11(i): up to a gauge transformation it is a background of the level i in the sense of the actual-background condition in (232); $\mathcal{O}(w_a)$ and the a_p are taken at it.

By Proposition YMM1:124.2, equation YMM1:(2288), read at the field λB_i, which lies in the box, as the box is a product of Euclidean balls, and by the bounds of equation YMM1:(2287) and its domain verification at $\sup|\lambda g_i B_i| \le \lambda\delta(x_i)$, $A_i^\lambda \in \mathsf{Cc}_i(\lambda r_i)$, with $r_n := 0$ and $r_i := L^{-1}r_{i+1} + \frac{11}{10}c_{\mathfrak{h}}\delta(x_i) \le \frac{8}{5}c_{\mathfrak{h}}\delta(x_i)$; the conditions of that Proposition hold at every height, and $r_1 \le \frac{1}{2}r_\alpha$, r_α being the usable radius of the fixed radii (equations YMM1:(933) and YMM1:(2285)), as $\delta(x_{K-1})$ lies below the threshold of the chain classes (Proposition 9.4(iv)).

The same Proposition gives $v^{[i]}_{A_i^\lambda} = v^{\mathrm{lw}}(v^{[i+1]}_{A_{i+1}^\lambda}, \lambda g_i B_i)$, the lowered point of equation YMM1:(2286); the lowered points are holomorphic (the holomorphy following equation YMM1:(2286)) and obey the bounds of equation YMM1:(2287) and its domain verification at complex points as well, so the same recursion, with the lowered points, continues the chain to the complex field scales $|\lambda| \le 1$, where the A_i^λ take complex values and the $\tilde U_i^\lambda$ lie in $\mathrm{SL}(2,\mathbb{C})$; one name, $\tilde U_i^\lambda$, serves for both. For $\mu \in \mathbb{C}^2$ near 0 put $w_\mu = \mu_1 w_1 + \mu_2 w_2$ and

$$D_i^{\lambda,\mu} = \mathcal{O}(w_\mu) + \sum_{i' \le i} \mathsf{Sum}\big[E_\mu^{(i'),\lambda} - E_0^{(i'),\lambda}\big],$$

$\mathsf{Sum}[\cdot]$ being the sum of a pointed family at a configuration or at a triple (the definitions preceding equation YMM1:(2276)). Each step at a height $1 \le i < n$ obeys an identity of its own at the

field scale λ, whose case $\lambda = 1$ uses the quotient argument of Proposition B.25: for $r \le r_{i+1}$, $A \in \mathsf{Cc}_{i+1}(r)$, $v = v_A^{[i+1]}$, $\tilde U = e^{iL^{-i-1}A}$ and $\tilde U^{\mathrm{lw}}(B) = e^{iL^{-i}A^{\mathrm{lw}}(v,\lambda g_i B)}$,

$$\exp D_{i+1}^{\lambda,\mu}(\tilde U) = \int \exp D_i^{\lambda,\mu}(\tilde U^{\mathrm{lw}}(B))\, d\nu_i^\lambda[v](B).$$

Here $\nu_i^\lambda[v]$ is the complex measure of mass 1 on the box of the height i whose density is the integrand of the integral form of the step at the field scale λ, at the source 0 and at the triple $P[v]$ (clause (cx10) of Proposition E.2), divided by its integral, which is not 0: the Gaussian density of the covariance $\tau_i(\lambda)^{-1}\mathbf{C}_*(P[v])$, with $\tau_i(\lambda) = \xi_i(\lambda)/x_i$, positive for real $|\lambda| \le 1$, and the whole covariance $\mathbf{C}_*$ of the step, times $\exp[-\frac{1-\tau_i(\lambda)}{2}\sum_\square (B, \hat{\mathsf{G}}_\square(P[v]|_\square)B)]$, with the gauge-fixing operators $\hat{\mathsf{G}}_\square$ of the fine cubes (equation YMM1:(823)), times the exponential of the potentials of the step at the field scale λ. At complex λ this is the holomorphic continuation supplied by the same one-step theorem, with its nonvanishing normalizer; no positivity is asserted there.

The identity is proved as follows. The integral form of the step at the triple $P[v]$, at the source μ and at the source 0 (Proposition E.2(cx10), at the data of Proposition 9.5), and the quotient of the two give

$$\exp \mathsf{Sum}\,[E_\mu^{(i+1),\lambda} - E_0^{(i+1),\lambda}](P[v]) = \int \exp[\mathbb{V}'[\mathfrak{g}]^{\mathrm{tot}}(P[v]; \lambda B)]\, d\nu_i^\lambda[v](B),$$

because μ stands in the rule of the step alone and the rule is linear in the bare array, $\mathfrak{g}$ being the difference of the bare arrays of the height i at μ and at 0, whose members are the $E_\mu^{(i'),\lambda} - E_0^{(i'),\lambda}$, $i' \le i$, and the weight member of w_μ. Proposition YMM1:124.2, equation YMM1:(2289), which holds for every bare array and every field of the box, read at λB, in the plaquette form of equation YMM1:(2290) and by linearity, gives $\mathbb{V}'[\mathfrak{g}]^{\mathrm{tot}}(P[v]; \lambda B) = D_i^{\lambda,\mu}(\tilde U^{\mathrm{lw}}(B)) - D_i^{\lambda,\mu}(\tilde U)$; and the proof of Proposition YMM1:124.2 gives $\mathsf{Sum}[\cdot](P[v]) = \mathsf{Sum}[\cdot](\tilde U)$ for the family of the level $i+1$. Multiplying by $\exp D_i^{\lambda,\mu}(\tilde U)$ gives the identity. Iterating it from the height $n-1$, where $A = 0$ and $\tilde U = \mathbf{1}$, down to the height 1 along the chain, and taking the mixed derivative in μ at 0 of the logarithms, gives

$$\sum_{j=2}^n \mathsf{n}_j^\lambda = \langle \mathcal{F}_1^\lambda(\tilde U_1^\lambda); \mathcal{F}_2^\lambda(\tilde U_1^\lambda)\rangle_{\mathbb{Q}_n^\lambda} + \int [\mathsf{F}_1^\lambda(\tilde U_1^\lambda) - \mathsf{F}_1^\lambda(\mathbf{1})]\, d\mathbb{Q}_n^\lambda,$$

where $\mathbb{Q}_n^\lambda(dB) = \prod_{1\le i<n} \nu_i^\lambda[v_{A_{i+1}^\lambda}^{[i+1]}](dB_i)$ is a complex measure of mass 1 on the product of the boxes, with a bounded continuous density, each factor being formed at the chart point that the chain gives above its height; $\mathcal{F}_a^\lambda = \mathcal{O}(w_a) + \mathsf{Sum}[\dot E_a^{(1),\lambda}]$ is $\mathcal{O}(w_a)$ plus the first jet of the level 1 in the direction w_a, and $\mathsf{F}_1^\lambda = \mathsf{Sum}[\ddot E^{(1),\lambda}]$ is the second jet of the level 1, with $\mathsf{F}_1^\lambda(\mathbf{1}) = \mathsf{n}_1^\lambda$ (the jets of Proposition 9.5(iv)).

(2)

The limit $\lambda \to 0$. The lattice being fixed, let $\lambda \downarrow 0$ in the identity of (1) divided by λ^4. Its left side tends to $\sum_{j=2}^n \mathsf{n}_{j,[4]}$, by Proposition 9.5(i).

The measures. The chart points of the chain have $\sup_B \|v_{A_{i+1}^\lambda}^{[i+1]}\| \le \lambda r_{i+1} \to 0$, and $\tau_i(\lambda) \to \tau_i(0) = \tau_i$. Two facts tie the step at the trivial configuration to the free template: the whole covariance of the step at the trivial triple is $(\mathsf{A}_i^{\mathrm{cv}})^{-1} \otimes 1$ (equation YMM1:(2297); Proposition YMM1:120.3); and the gauge-fixing operators of the fine cubes at the trivial triple add up to the gauge-fixing operator at the block field $\mathbf{1}$, which is $\hat{\mathsf{G}} \otimes 1$, as the fine cubes partition the sites of the level $i+1$ and the operator of a cube is the gauge-fixing form restricted to the blocks of that cube (equation YMM1:(823); Proposition YMM1:120.3).

The covariance and the gauge-fixing operators at the triple $P[v]$ tend to these, entry by entry, as $v \to 0$ (equation YMM1:(2296); the kernels of the $\hat{\mathsf{G}}_\square$ are holomorphic in the chart point), and

the potentials at the field scale λ are at most $c\lambda$ times a function bounded on the box ((268) of Definition E.1). So the density of $\mathbb{Q}_n^\lambda$ tends, uniformly on the product of the boxes, to the product over the heights of the densities proportional to

$$e^{-\frac{1}{2}(B_i,(\tau_i \mathsf{A}_i^{\mathrm{cv}}+(1-\tau_i)\hat{\mathsf{G}})B_i)} = e^{-\frac{1}{2}(B_i,\mathsf{M}_i B_i)};$$

as the boxes have finite volume and the limits of the normalisations are positive, $\mathbb{Q}_n^\lambda \to \mathbb{Q}_n^0 := \bigotimes_{1\le i<n} \nu_i^{\mathrm{r}}$ in total variation.

The plaquette terms. At every height the linear part of one step of the chain in the field B_i, read in the plaquette angle, is $\mathsf{sg}_i(\mathsf{T}_i \otimes 1)$ with a sign $\mathsf{sg}_i \in \{1,-1\}$ (Lemma YMM1:124.3, which reads $\ell \ge N_{\mathsf{H}}$ of Proposition 9.4(i); its map $\mathsf{T}_i^{\mathrm{cv}}$ is T_i, the definitions preceding Lemma YMM1:124.3). With the expansion of the plaquette terms and of the plaquette angles to the second order at one step (Lemma YMM1:124.4), summed along the chain, this gives, uniformly on the boxes and for every bare plaquette p,

$$|a_p(\tilde{U}_1^\lambda) - \tfrac{1}{2}\lambda^2|\Theta_p(B)|^2| \le c_\Theta \lambda^3, \qquad \Theta_p(B) := \sum_{1\le i<n} \mathsf{sg}_i\, x_i^{-1/2} (\mathsf{T}_i B_i)(p),$$

with c_Θ determined by the constants. Hence $\lambda^{-2}\mathcal{O}(w_a)(\tilde{U}_1^\lambda) \to q_a(B) := \frac{1}{2}a_K^{-1}\sum_p w_a(p)|\Theta_p(B)|^2$ uniformly on the boxes.

The level 1. The local terms of the level 1 at $\tilde{U}_1^\lambda$ take the values of their members at the restrictions of the triple $P[v]$, $v = v^{[1]}_{A_1^\lambda}$, as in the proof of Proposition YMM1:124.2. For a pointed family f of the level 1, a domain X of the level 1, a site z of X and $\kappa' > 0$, $d_1(X)$ being the linear size of X in the units of the level 1,

$$\big|\mathsf{f}(X, P[v]|_X, z) - \mathsf{f}(X, \mathbf{1}, z)\big| \le 2\|\mathsf{f}\|_{1,\kappa'} e^{-\kappa' d_1(X)} \lambda^2 (r_1/r_\alpha)^2 :$$

the function $\zeta \mapsto \mathsf{f}(X, P[\zeta v]|_X, z)$ is holomorphic on $|\zeta| < r_\alpha/\|v\|$, where $r_\alpha/\|v\| \ge r_\alpha/(\lambda r_1) \ge 2$, and bounded there by $\|\mathsf{f}\|_{1,\kappa'} e^{-\kappa' d_1(X)}$; its derivative at 0 vanishes, because a constant gauge rotation u fixes the trivial configuration and acts on the chart point by $\mathrm{Ad}(u)$, the local terms are invariant, and $\int_G \mathrm{Ad}(u) Y\, du = 0$ for $Y \in \mathfrak{g}$; Cauchy's estimate bounds the rest of the series. At $\mathsf{f} = \dot{E}_a^{(1),\lambda}$, whose size at the rate κ^+ is at most $C_{\mathrm{J}} \lambda^2 R_0^{-2} a_K^{-1} \|w_a\|_\infty$ (Proposition 9.5(iv) at $i = 0$, where $\psi_0 = 1$), this shows that the first jet of the level 1 changes along the chain by $O(\lambda^4)$, uniformly on the boxes; as a covariance does not change when constants are added, $\lambda^{-4}\langle \mathcal{F}_1^\lambda(\tilde{U}_1^\lambda); \mathcal{F}_2^\lambda(\tilde{U}_1^\lambda)\rangle_{\mathbb{Q}_n^\lambda} \to \langle q_1; q_2\rangle_{\mathbb{Q}_n^0}$.

At $\mathsf{f} = \ddot{E}^{(1),\lambda}$, whose size is at most $C_{\mathrm{J}} \lambda^2 R_0^{-2} a_K^{-2} \eta$ and whose members vanish on the domains that do not meet both supports (Proposition 9.5(iv) at $i = 0$), the count of the domains of the level 1 that meet both supports, weighted with $e^{-\kappa^+ d_1(X)}$ (Lemma B.10), brings the factor Π_1, as in the proof of Proposition 9.5(i), and gives

$$|\mathsf{F}_1^\lambda(\tilde{U}_1^\lambda) - \mathsf{F}_1^\lambda(\mathbf{1})| \le \lambda^4 \,\mathrm{Er}_\flat, \qquad \mathrm{Er}_\flat = c\, R_0^{-2} a_K^{-2} (r_1/r_\alpha)^2\, \Pi_1\, \eta.$$

So the limit $\mathsf{e}_\flat$ of $\lambda^{-4}\int [\mathsf{F}_1^\lambda(\tilde{U}_1^\lambda) - \mathsf{F}_1^\lambda(\mathbf{1})]\, d\mathbb{Q}_n^\lambda$ exists, $|\mathsf{e}_\flat| \le \mathrm{Er}_\flat$, the total variation of $\mathbb{Q}_n^\lambda$ tending to 1, and

$$\sum_{j=2}^{n} \mathsf{n}_{j,[4]} = \langle q_1; q_2\rangle_{\mathbb{Q}_n^0} + \mathsf{e}_\flat.$$

The covariance $\langle q_1; q_2\rangle_{\mathbb{Q}_n^0}$ does not depend on the signs sg_i: every ν_i^{r} is invariant under $B_i \mapsto -B_i$, its box being symmetric, so that the law of $(\mathsf{sg}_i B_i)_i$ under $\mathbb{Q}_n^0$ is $\mathbb{Q}_n^0$. By Proposition 9.5(i) at $j = 0$ and Cauchy's estimate on $|\lambda| = \rho R_0$, $|\mathsf{n}_{1,[4]}| \le C_{\mathsf{n}} \rho^{-2} R_0^{-4} a_K^{-2} \Pi_1 \eta$. As $x_0 = \beta = b/a_K$, $R_0^{-2} \le c_0 (\log x_0)^{2p_0} a_K/b$, $r_1 \le \frac{8}{5} c_\flat \delta(x_1)$ and $\delta(x_1)^2 \le \frac{4}{3} A_1^2 (\log x_0)^{2p_0} L a_K/b$ (Proposition 9.4(ii)), both $|\mathsf{e}_\flat|$ and $|\mathsf{n}_{1,[4]}|$ are at most $c\, b^{-2} (\log \frac{b}{a_K})^{4p_0} \Pi_1 \eta$.

With $u_0 = d/a_K \ge 8$, $\log \frac{b}{a_K} \le l\,(1 + \log u_0)$ and $\Pi_1 \le \max\{1, u_0^3\} e^{2-u_0/(4ML)}$; as $(1 + \log u)^{4p_0} \max\{1, u^3\} e^{2-u/(8ML)}$ is bounded on $u \ge 8$ and $\mathsf{c}_\flat \le \frac{1}{8ML}$, this is below $C\, b^{-2} l^{4p_0} e^{-\mathsf{c}_\flat d/a_K} \eta$.

(3)

The boxes out at the order four. The cumulants of the orders 2 and 4 of the components $B_i^\alpha(b)$ in ν_i^{r} and in ν_i° differ by at most $C_\chi e^{-\mathsf{c}_\chi(\log x_i)^{2p_0}}$, uniformly in the volume, with C_χ, c_χ determined by the constants (Lemma M.1, read with the one quadratic system of the height and the threshold $\mathfrak{b}(x_i)$); the odd cumulants vanish in both measures by the symmetry $B \mapsto -B$, and the Gaussian ones are $\delta_{\alpha\beta}\mathsf{M}_i^{-1}(b,b')$ at the order 2 and 0 at the order 4.

(4)

Wick's rule and the slices. The B_i are independent in $\mathbb{Q}_n^0$ and each ν_i^{r} is even. With $F_i^\alpha(p) = \mathsf{sg}_i\, x_i^{-1/2}\sum_b \mathsf{T}_i(p,b)B_i^\alpha(b)$, so that $|\Theta_p|^2 = \sum_\alpha\big(\sum_i F_i^\alpha(p)\big)^2$ in an orthonormal basis (t_α) of $\mathfrak{g}$, $c_i^{\alpha\beta}(p,q) = \langle F_i^\alpha(p)F_i^\beta(q)\rangle_{\nu_i^{\mathrm{r}}}$ and $\kappa_i^{\alpha\beta}(p,q)$ the joint fourth cumulant of $F_i^\alpha(p), F_i^\alpha(p), F_i^\beta(q), F_i^\beta(q)$,

$$\langle q_1;q_2\rangle_{\mathbb{Q}_n^0} = \tfrac14 a_K^{-2}\sum_{p,q} w_1(p)w_2(q)\sum_{\alpha,\beta}\Big[2\Big(\sum_i c_i^{\alpha\beta}(p,q)\Big)^2 + \sum_i \kappa_i^{\alpha\beta}(p,q)\Big].$$

By the slice identity $\mathsf{T}_i\mathsf{M}_i^{-1}\mathsf{T}_i^{\mathsf{T}} = L^{-i}\tau_i^{-1}\mathcal{C}_{(i+1)}$ (Proposition YMM1:120.3, valid at every $\tau_i \neq 0$) and

$$x_i^{-1}L^{-i}\tau_i^{-1} = x_0^{-1},$$

the running couplings drop out: in the Gaussian measures $c_i^{\alpha\beta} = \delta_{\alpha\beta}x_0^{-1}\mathcal{C}_{(i+1)}$. As $a_K x_0 = b$, the Gaussian value of $\langle q_1;q_2\rangle$ is $\frac32 b^{-2}\sum_{p,q} w_1(p)w_2(q)\Sigma(p,q)^2$ with

$$\Sigma = \sum_{1\le i<n}\mathcal{C}_{(i+1)} = C^{\mathrm{fl}}_{K,K-n} - \mathcal{C}_{(1)}.$$

The differences of (3) are carried to the F_i^α through the row sums of T_i, which are at most $C_{\mathrm{tp}}^{\mathrm{row}}L^{-2i}$ at every height, uniformly in the volume, as $\ell \ge N_{\mathsf{H}}$ (Proposition YMM1:120.6; Proposition 9.4(i)). By multilinearity, with $\epsilon_i = C_\chi e^{-\mathsf{c}_\chi(\log x_i)^{2p_0}}$, $\mathsf{sg}_i^2 = 1$ and $x_i^{-1}L^{-4i} = \tau_i x_0^{-1}L^{-3i} \le \frac43 x_0^{-1}L^{-3i}$,

$$|c_i^{\alpha\beta}(p,q) - \delta_{\alpha\beta}x_0^{-1}\mathcal{C}_{(i+1)}(p,q)| \le \bar e_i := \tfrac43 (C_{\mathrm{tp}}^{\mathrm{row}})^2 x_0^{-1}L^{-3i}\epsilon_i, \qquad |\kappa_i^{\alpha\beta}(p,q)| \le \tfrac{16}{9}(C_{\mathrm{tp}}^{\mathrm{row}})^4 x_0^{-2}L^{-6i}\epsilon_i.$$

There are at most $35^2(d/a_K)^6$ pairs (p,q) with $w_1(p)w_2(q)\neq 0$, and for them $|x(p)-x(q)|_\infty \ge d/\sqrt3$; with $u_i = d/D_i$ one has $L^{-3i}(d/a_K)^3 = u_i^3$, and Proposition YMM1:120.6 gives $(d/a_K)^3(|\Sigma| + |\mathcal{C}_{(1)}|)(p,q) \le C_{\mathrm{tp}}S_\Sigma$, $S_\Sigma = \sup_{u>0}\sum_{s\in\mathbb{Z}}(uL^s)^3 e^{-\delta_{\mathrm{tp}}uL^s/\sqrt3}$. Expanding the square, with $\mathsf{E}_k = \sum_{1\le i<n} u_i^k\epsilon_i$ for $k = 3, 6$,

$$\Big|\langle q_1;q_2\rangle_{\mathbb{Q}_n^0} - \tfrac32 b^{-2}\sum_{p,q} w_1(p)w_2(q)\Sigma(p,q)^2\Big| \le \tfrac{35^2}{4}\, b^{-2}\big[16C_{\mathrm{tp}}S_\Sigma(C_{\mathrm{tp}}^{\mathrm{row}})^2\mathsf{E}_3 + 32(C_{\mathrm{tp}}^{\mathrm{row}})^4\mathsf{E}_3^2 + 16(C_{\mathrm{tp}}^{\mathrm{row}})^4\mathsf{E}_6\big]\eta.$$

The numbers E_k are bounded in three ranges of levels. As $\log x_i \ge \log\frac{3b}{4D_i} \ge 0$ (Proposition 9.4(ii), and $\frac34 b \ge 1 \ge D_i$), $\log x_i \ge 1$ and $2p_0 \ge 2$, one has $\epsilon_i \le C_\chi e^{-\mathsf{c}_\chi(\log\frac{3b}{4D_i})^2}$. At the levels with $D_i < d$, $\log\frac{3b}{4D_i} = \Lambda_b + t_i$ with $\Lambda_b = \log\frac{3b}{4d} \ge \log\frac{3b}{4d^{1/2}}$ and $t_i = \log u_i > 0$, the t_i being spaced by $\log L$, and $(\Lambda_b + t)^2 \ge \Lambda_b^2 + t^2$, so that $u_i^k\epsilon_i \le C_\chi e^{-\mathsf{c}_\chi\Lambda_b^2}e^{6t_i - \mathsf{c}_\chi t_i^2}$ for $k \le 6$; so these levels give at most $C_\chi S_\chi e^{-\mathsf{c}_\chi\Lambda_b^2}$, with $S_\chi = \sup_{t_0\ge0}\sum_{s\ge0} e^{6(t_0+s\log L)-\mathsf{c}_\chi(t_0+s\log L)^2}$. At the levels with $d \le D_i \le d^{1/2}$, $\sum u_i^3 \le 2$ and $\epsilon_i \le C_\chi e^{-\mathsf{c}_\chi(\log\frac{3b}{4d^{1/2}})^2}$. At the levels with $D_i > d^{1/2}$, $\sum u_i^3 \le 2d^{3/2}$ and $\epsilon_i \le C_\chi$. So

$$\mathsf{E}_3,\ \mathsf{E}_6 \le C_\chi(S_\chi+2)\big[d^{3/2} + e^{-\mathsf{c}_\chi(\log\frac{3b}{4d^{1/2}})^2}\big] \le 2C_\chi(S_\chi+2),$$

and the bracket above gives the member $C_{\mathrm{Bx}}b^{-2}[d^{3/2} + e^{-\mathsf{c}_\chi(\log(3b/(4d^{1/2})))^2}]\eta$, with C_{Bx} formed with C_{tp}, S_Σ, $C_{\mathrm{tp}}^{\mathrm{row}}$, C_χ and S_χ, and so determined by the constants. The missing first slice is small: by Proposition YMM1:120.6, $(d/a_K)^3|\mathcal{C}_{(1)}(p,q)| \le C_{\mathrm{tp}}u_0^3 e^{-\delta_{\mathrm{tp}}u_0/\sqrt3}$, $u_0 = d/a_K$, at $|x(p)-x(q)| \ge d/\sqrt3$; with the terms of the level 1 of (2) it gives the member $C_{\mathrm{Bt}}l^{4p_0}e^{-\mathsf{c}_\flat d/a_K}b^{-2}\eta$.

(5)

The free value. Lemma I.2 (the template sums) gives $|\sum_{p,q} w_1 w_2 (C^{\mathrm{fl}}_{K,K-n})^2 - \frac{3}{8\pi^2}\mathcal{K}_6| \le C_{\mathrm{tm}}[\frac{a_K}{\vartheta d} + (\frac{d}{\ell})^3 + (\frac{d}{D_n})^3]\eta$, and $\frac{3}{2}\cdot\frac{3}{8\pi^2} = c_2$. Take $n = K$, $D_K = 1$: $(d/\ell)^3 + d^3 \le 2d^3$, the member $\frac{3}{2}C_{\mathrm{tm}}\vartheta^{-1}b^{-2}a_K/d$ is $C_{\mathrm{lat}}b^{-2}a_K/d$, and $b^{-2} = \frac{b}{d}\,b^{-3}d$; the supremum over the labels at g and $d/a_K \ge L(\log\frac{1}{d})^2$ give $\bar\varepsilon_4$. Finally $\log\frac{3b'}{4d^{1/2}} \ge \frac{1}{2}\log\frac{1}{d}$, as $\frac{3}{4}b' \ge 1$; so $\frac{b'}{d}e^{-\mathsf{c}_\chi(\cdot)^2} \le b_+ e^{\log\frac{1}{d} - \frac{1}{4}\mathsf{c}_\chi(\log\frac{1}{d})^2}$, $\frac{b'}{d}C_{\mathrm{Bx}}d^{3/2} \le C_{\mathrm{Bx}}b_+ d^{1/2}$, and the other members are smaller: $\bar\varepsilon_4(g,d) \le C_4(g)d^{1/2}$. □

Remark 9.8. With Proposition 9.5(ii) at $m = 3$, Proposition 9.7 gives, on every side $\ell \in \mathfrak{L}(g)$ and at every position,

$$|\mathsf{J}_2 - c_2 b^{-2}\mathcal{K}_6|(f,h) \le [(C_{\mathrm{E},3}l^{6p_0} + C_{\mathrm{E}}b^{-1}d\,l^{8p_0} + \bar\varepsilon_4(g,d))\,b^{-3}d + C_{\mathrm{lat}}b^{-2}a_K/d]\eta,$$

and on T_{ℓ_g}, under the assumptions of Proposition 9.6 besides ($g \le \gamma_{\mathrm{C}}$, $d \le d_{\mathrm{A}}(g)$), by that Proposition, the same for $S^T_{2;K,\ell_g,\beta}(f,h)$ with $C_{\mathrm{A}}(g)\vartheta^{-1}bd$ added to the coefficient of $b^{-3}d$. The member $\bar\varepsilon_4(g,d)\,b^{-3}d\,\eta$ holds the two finite-size terms of the free value, $\frac{3}{2}C_{\mathrm{tm}}b^{-2}[(d/\ell)^3 + (d/D_K)^3]\eta$, of the torus and of the constraint at the top level $D_K = 1$, which the proof of Proposition 9.7 bounds by $3C_{\mathrm{tm}}b^{-2}d^3\eta = 3C_{\mathrm{tm}}bd^2\cdot b^{-3}d\,\eta$: they are at most $3C_{\mathrm{tm}}\,b^{-3}d\,\eta$ for $d^2 \le 1/b$, and of the order bd^2 relative to the first correction beyond.

The other members of $\bar\varepsilon_4(g,d)\,b^{-3}d\,\eta$ are at most $C_4(g)\,d^{1/2}\,b^{-3}d\,\eta$ (Proposition 9.7), and $C_{\mathrm{E}}b^{-1}d\,l^{8p_0} \le C_{\mathrm{E}}c_{\mathfrak{p}}\,l^{6p_0}$ with $c_{\mathfrak{p}} = \sup_{0<t\le 1} t\max\{1,\log\frac{2}{t}\}^{2p_0}$. So, beside the lattice term $C_{\mathrm{lat}}b^{-2}a_K/d$ and the two finite-size terms, the deviation from the free law is at most $C\,l^{6p_0}\,b^{-3}d\,\eta$, with a C formed with g and the constants (and with ϑ on T_{ℓ_g}): of the order of the first correction, up to the factor l^{6p_0}; for $d^2 \le 1/b$ the two finite-size terms are of that order too. The coefficient of the first correction is fixed by the order six.

Lemma 9.9 (Gaussian measures conditioned on a convex set)**.** Let ν be a centred Gaussian measure on $\mathbb{R}^I$, I finite, with variances $\le \sigma_i^2$, and $Q \supset \prod_i(-c_i,c_i)$ open, bounded, convex and symmetric; put $t_i = c_i/\sigma_i$ and $\epsilon = \sum_i e^{-t_i^2/2}$. Let $F_1,\dots,F_r$ ($r = 2,3$) be complex polynomials of orders $\le k_j$ with $|F_j| \le S_j$ on Q, and $k = \sum_j k_j$. If $t_i^2 \ge \max\{4,2k\}$ for all i and $2^k\epsilon \le 1$, the joint cumulants of $F_1,\dots,F_r$ in $\nu(\cdot\,|\,Q)$ and in ν differ by at most $q_r(1+2^k)\epsilon\prod_j S_j$, with $q_2 = 5$, $q_3 = 37$. ■

Proof sketch. For $z \notin Q$ let $s = \max_i |z_i|/c_i \ge 1$. The segment from $-z/s$ to z/s lies in $\bar Q$, so $\tau \mapsto F_j(\tau z/s)$ is a polynomial of order $\le k_j$ bounded by S_j on $[-1,1]$, and the extremal property of Chebyshev's polynomials gives $|F_j(z)| \le S_j(2s)^{k_j}$. On Q^{c}, $s^k \le \sum_i(|z_i|/c_i)^k\mathbf{1}\{|z_i| \ge c_i\}$, and for a centred Gaussian variable of variance $\le \sigma_i^2$, $\mathbb{E}[(|z_i|/c_i)^k; |z_i| \ge c_i] \le e^{-t_i^2/2}$ once $t_i^2 \ge \max\{4,2k\}$; so

$$\nu(Q^{\mathrm{c}}) \le \epsilon, \qquad \int_{Q^{\mathrm{c}}} \prod_j |F_j|\,d\nu \le 2^k\epsilon\prod_j S_j.$$

Let F be a product of some of the F_j, S the product of their S_j, and m, m^{r} its moments in ν and in $\nu(\cdot\,|\,Q)$. Then $m^{\mathrm{r}} - m = m^{\mathrm{r}}\nu(Q^{\mathrm{c}}) - \int_{Q^{\mathrm{c}}} F\,d\nu$ and $|m^{\mathrm{r}}| \le S$, so $|m^{\mathrm{r}} - m| \le (1+2^k)\epsilon S$; and $|m| \le S + 2^k\epsilon S \le 2S$. A joint cumulant of order r is a sum, over the partitions into p blocks, of $(-1)^{p-1}(p-1)!$ times products of p moments; telescoping each product, with the factors bounded by S and by $2S$, bounds its change by $p\,2^{p-1}(1+2^k)\epsilon\prod_j S_j$. So $q_r = \sum_p \mathrm{S}(r,p)\,p!\,2^{p-1}$, S the Stirling numbers of the second kind: $q_2 = 1+4$, $q_3 = 1+12+24$. □

Lemma 9.10 (The coefficients of a logarithm)**.** Let G be holomorphic on $|\lambda| < 1$ with $G(0) = 0$ and $\mathrm{Re}\,G \le \mathsf{E}$. Then every Taylor coefficient $G_{[m]}$, $m \ge 1$, has $|G_{[m]}| \le 2\mathsf{E}$. Consequently, if F is holomorphic on $|\lambda| < 1$, $F(0) = 1$, $F \ne 0$, $|F| \le e^{\mathsf{E}}$, and $F = 1 + \lambda\mathsf{R}_1 + \lambda^2\mathsf{R}_2 + O(\lambda^3)$, then $W_1 = -\mathsf{R}_1$ and $W_2 = \frac{1}{2}\mathsf{R}_1^2 - \mathsf{R}_2$ have $|W_1|, |W_2| \le 2\mathsf{E}$. The condition $F \ne 0$ cannot be dropped. ■

Proof sketch. For $0 < \rho < 1$ and $m \ge 1$, $G_{[m]}\rho^m = -\pi^{-1}\int_0^{2\pi}(\mathsf{E} - \mathrm{Re}\,G(\rho e^{i\phi}))e^{-im\phi}\,d\phi$; the factor $\mathsf{E} - \mathrm{Re}\,G$ is ≥ 0 and has the mean E over the circle, as $\mathrm{Re}\,G(0) = 0$; let $\rho \to 1$. For

F, the function $G = \log F$ is defined on the disc, as F has no zero there; $\operatorname{Re} G = \log|F| \le \mathsf{E}$ and $G = -\lambda W_1 - \lambda^2 W_2 + O(\lambda^3)$. For $F = 1 + \mathsf{c}\lambda$ with $\mathsf{c} \ge 3$, which has a zero in the disc, $|\mathsf{R}_1| = \mathsf{c} > 2\log(1+\mathsf{c}) = 2\mathsf{E}$. □

Proposition 9.11 (The order six at one level)**.** Under the assumptions of Proposition 9.4, let $2 \le n \le K$ and $\mathsf{Bx} = \prod_{0\le i<n}\{B_i : |B_i(b)| < \mathfrak{b}(x_i)\ \forall b\}$, a product of Euclidean balls in $\mathfrak{g}$, one for each non-pivot bond of the heights $0 \le i < n$.

(i) There are functions O_1^λ, O_2^λ, D^λ on Bx, continuous and bounded on $\{|\lambda| \le 1\} \times \mathsf{Bx}$ and holomorphic in $|\lambda| < 1$, with $\mathsf{O}_a^\lambda(B) = \mathsf{o}_a(\lambda B)$ for a function o_a holomorphic near 0, $\mathsf{O}_a^{-\lambda}(-B) = \mathsf{O}_a^\lambda(B)$, $\mathsf{D}^{-\lambda}(-B) = \mathsf{D}^\lambda(B)$, $\int_{\mathsf{Bx}} \mathsf{D}^\lambda dB = 1$, $\mathsf{D}^0 dB = \bigotimes_{0\le i<n} \nu_i^{\mathrm{r}}$, and

$$\sum_{j\le n} \mathsf{n}_j^\lambda = \langle \mathsf{O}_1^\lambda; \mathsf{O}_2^\lambda \rangle_{\mathsf{D}^\lambda dB} \qquad (|\lambda| < 1).$$

Here D^λ is the product over the heights $0 \le i < n$ of the normalised densities of the steps along the chain of the backgrounds, which reads (λ, B) through λB; for $0 \le i < n$, the height 0 included, the density of the step of the height i at $\lambda = 0$, at the trivial configuration, is proportional to $\exp[-\frac12(B_i, (\mathsf{M}_i \otimes 1)B_i)]$ on the box of the height, with the real symmetric $\mathsf{M}_i \ge \frac34 \gamma^{\mathrm{tr}}$ of the measures ν_i° (Lemma 9.12(iii)); and for real $0 < \lambda \le 1$, $\log(\mathsf{D}^\lambda/\mathsf{D}^0)$ is the sum of a term that does not depend on B, of terms $\lambda^{-2}F(\lambda, \lambda B)$ and of terms $F(\lambda, \lambda B)$, with functions $F(\lambda, \zeta)$ holomorphic near $(0,0)$, those of the first kind with $F = O(|\zeta|^2)$.

Uniformly on Bx, $\mathsf{O}_a^\lambda = \lambda^2(X_{a,0} + \lambda X_{a,1} + \lambda^2 X_{a,2}) + O(\lambda^5)$ and $\mathsf{D}^\lambda = \mathsf{D}^0 \exp[-\lambda W_1 - \lambda^2 W_2 + O(\lambda^3)]$, where $X_{a,m}$ is homogeneous of order $m+2$, $X_{a,0} = q_a + q_a^{(0)}$ with the q_a of the proof of Proposition 9.7, formed with the signs sg_i of Lemma YMM1:124.3 there, and a quadratic form $q_a^{(0)}$ that vanishes where $B_0 = 0$, W_1 is odd of order ≤ 3, and W_2 is, up to the constant that the term without B gives, even of order ≤ 4. These are polynomials on the whole space, with Taylor coefficients at the trivial configuration formed with L and the running couplings, so that the cumulants of (48) are formed in $\bigotimes_{0\le i<n} \nu_i^\circ$ as well.

Hence $\mathsf{h}_4^{(n)} = \langle X_{1,0}; X_{2,0}\rangle$ and $\mathsf{h}_6^{(n)} = \gamma_2^{\mathrm{r}}$, the cumulants being taken in $\bigotimes_{0\le i<n} \nu_i^{\mathrm{r}}$.

(ii) If $\gamma^{\mathrm{tr}}\mathfrak{b}(x_{n-1})^2 \ge 80$ and $10240 N^3 e^{-\gamma^{\mathrm{tr}}\mathfrak{b}(x_{n-1})^2/8} \le 1$, then

$$\beta^3 a_K^2 |\gamma_2^{\mathrm{r}} - \gamma_2^\circ| \le \mathcal{U}(x_{n-1}, \mathsf{N}) \|w_1\|_\infty \|w_2\|_\infty, \qquad \mathcal{U}(x, \mathsf{N}) = C_{\mathrm{X}} \mathsf{N}^{36} \exp\big[-\tfrac18 \gamma^{\mathrm{tr}} A_1^2 (\log x)^{2p_0}\big],$$

with C_{X} determined by the constants.

■

Proof sketch. (i)

The chain of the backgrounds. For $|\lambda| \le 1$ and $B \in \mathsf{Bx}$ put $v_n^\lambda := 0$ and, downwards for $i = n-1, \dots, 1$, let v_i^λ be the lowered point (equation YMM1:(2286)) that the step $i+1$ forms of the point v_{i+1}^λ of the level $i+1$ and of the fluctuation $\lambda x_i^{-1/2} B_i$. Its first member A_i^λ is a 1-form on the bare bonds, and $\tilde U_i^\lambda := \exp(iL^{-i} A_i^\lambda)$, a configuration on the bare bonds, is the *background of the level i*. The maps of the step are holomorphic on their domain, at real and at complex points (the holomorphy following equation YMM1:(2286)); by their bounds (equation YMM1:(2287) and its domain verification), as $\sup|\lambda x_i^{-1/2} B_i| \le |\lambda|\delta(x_i)$ on the box, $\|v_i^\lambda\| \le |\lambda| r_i$ at every height, with the radii $r_n = 0$, $r_i = L^{-1} r_{i+1} + \frac{11}{10} c_{\mathfrak{h}} \delta(x_i) \le \frac85 c_{\mathfrak{h}} \delta(x_i)$ of equation YMM1:(2291), which keep the chain in the domain of the maps, as $\delta(x_{K-1})$ lies below the threshold of the chain classes (Proposition 9.4(iv)).

So the chain is formed for $|\lambda| \le 1$, it reads (λ, B) through λB, and for real $\lambda \in [0,1]$ it stays in the chain classes (Proposition YMM1:124.2, equation YMM1:(2288)). At complex λ the background has values in $\mathrm{SL}(2,\mathbb{C})$, and a_p is read there as $1 - \frac12 \operatorname{tr}$ of the product of the variables around p; on $\mathrm{SU}(2)$ this is a_p. The observable is $\mathsf{O}_a^\lambda(B) := a_K^{-1} \sum_p w_a(p)\, a_p(\tilde U_1^\lambda) + \mathsf{w}_a^\lambda(B_0)$: its first member is

$\mathcal{O}(w_a)$ at the background of the level 1, which carries the fields of the heights $1 \le i < n$, and its second, the source term of the height 0, is the sum over the domains of the level 0 of the action term of the source w_a at the point v_1^λ and the field $\lambda x_0^{-1/2} B_0$; the field of the height 0 enters O_a^λ through this term alone.

The density is $\mathsf{D}^\lambda(B) := \prod_{0\le i<n} \rho_i^\lambda / Z_i^\lambda$, with ρ_i^λ the density of the step of the height i at the field scale λ at the point v_{i+1}^λ, the exponential of the quadratic forms of the step in B_i and of its potentials, and Z_i^λ its integral over the box of the height.

The identity. At real $0 < \lambda \le 1$ each step at a height $1 \le i < n$ obeys the identity of one step at the field scale λ of step (1) of the proof of Proposition 9.7, whose case $\lambda = 1$ uses the quotient argument of Proposition B.25, and at the height 0 the source enters linearly, through the action term of the sources. Iterating from the height $n-1$ down,

$$\exp D_n^{\lambda,\mu} = \int_{\mathsf{Bx}} \exp[\mu_1 \mathsf{O}_1^\lambda + \mu_2 \mathsf{O}_2^\lambda] \mathsf{D}^\lambda \, dB,$$

$D_n^{\lambda,\mu}$ the exponent of the progression at the trivial configuration with the sources $\mu_1 w_1 + \mu_2 w_2$. Both sides are holomorphic in μ near 0, and holomorphic in $|\lambda| < 1$, as the maps of the chain are holomorphic at complex points and the normalisations Z_i^λ have no zero (Lemma 9.12(ii)); they agree on $(0, 1]$. The mixed derivative in μ at 0 of the logarithms is the covariance.

At $\lambda = 0$. The chain is trivial and the potentials vanish. At the heights $1 \le i < n$ the density of the step is $\exp[-\frac12 (B_i, ((\tau_i \mathsf{A}_i^{\mathrm{cv}} + (1-\tau_i)\hat{\mathsf{G}}) \otimes 1) B_i)] = \exp[-\frac12 (B_i, (\mathsf{M}_i \otimes 1) B_i)]$, and at the height 0, where $\tau_0 = 1$, it is $\exp[-\frac12 (B_0, (\mathsf{A}_0^{\mathrm{cv}} \otimes 1) B_0)]$, $\mathsf{M}_0 = \mathsf{A}_0^{\mathrm{cv}}$; the sources of these two identities are given with Lemma 9.12(iii). So $\mathsf{D}^0 dB = \bigotimes_{0\le i<n} \nu_i^{\mathrm{r}}$.

The orders. The orders 0 and 1 of O_a^λ vanish, the order 1 by the constant gauge rotations, as in Proposition 9.5. As $\mathsf{O}_a^\lambda = \mathsf{o}_a(\lambda B)$ with o_a holomorphic near 0, the coefficient of λ^{m+2} is a homogeneous polynomial of order $m+2$. For real $0 < \lambda \le 1$ the integral identity of the step at a complex field scale (Proposition E.2), read at the points of the chain, writes each Z_i^λ as $\det^{1/2}$ of the covariance of the step times the exponential of a sum of local terms of the step; in the product of the quotients the families of the progression drop out, by the sum rule of the chain classes (Proposition YMM1:124.2, equation YMM1:(2289)), which telescopes over the heights, and $\mathsf{D}^\lambda(B)$ is a number $c_n(\lambda)$, which does not depend on B, times the exponential of a sum of terms $\lambda^{-2} F(\lambda, \lambda B)$ with $F = O(|\zeta|^2)$, namely the quadratic forms of the steps, λ^{-2} times forms in λB_i whose coefficients read λB through the chain, and the potentials of the marks of the gauge fixing and of the action, $x_i \lambda^{-2}$ times functions of $\lambda x_i^{-1/2} B_i$, and of terms $F(\lambda, \lambda B)$, namely the other potentials, the logarithms of the determinants of the covariances along the chain, the localised Gaussian families of the steps and the counterterms at the backgrounds; in all of them $F(\lambda, \zeta)$ is holomorphic near $(0, 0)$.

This is the form of $\log(\mathsf{D}^\lambda / \mathsf{D}^0)$ stated in (i), the term without B being $\log(c_n(\lambda)/c_n(0))$. With $F = \sum_{k,\alpha} f_{k\alpha} \lambda^k \zeta^\alpha$ the coefficient of λ^m of $\lambda^{-2} F(\lambda, \lambda B)$ is $\sum_{k+|\alpha|=m+2} f_{k\alpha} B^\alpha$, a polynomial of order $\le m+2$, and that of $F(\lambda, \lambda B)$ one of order $\le m$; this gives the orders of W_1 and W_2, and the identity between holomorphic functions of λ passes from $(0, 1]$ to a disc about 0. Odd functions have the mean 0 in $\mathsf{D}^0 dB$, the mass 1 removes the mean of the order 2 of $\mathsf{D}^\lambda / \mathsf{D}^0$, and the coefficient of λ^2 in $\lambda^{-4} \langle \mathsf{O}_1^\lambda; \mathsf{O}_2^\lambda \rangle$ is (48); at λ^0 it is $\langle X_{1,0}; X_{2,0} \rangle$.

By Proposition 9.5(i), $\lambda^{-4} \sum_{j\le n} \mathsf{n}_j^\lambda = \mathsf{h}_4^{(n)} + \lambda^2 \mathsf{h}_6^{(n)} + O(\lambda^4)$.

(ii) By Lemma 9.12, on Bx the $X_{a,m}$ are at most $C_{\mathrm{S}} \mathsf{N}^8 \|w_a\|_\infty$ and W_1, W_2 at most $2 C_{\mathrm{S}} \mathsf{N}^7$; a cumulant of order ≥ 2 does not see the constant in W_2. By (iii) of that Lemma the variances of ν_i° are at most $\frac{4}{3\gamma^{\mathrm{tr}}}$; Bx holds the cube of the half-sides $\mathfrak{b}(x_{n-1})/\sqrt{3}$ in the components, as $x_i \ge x_{n-1}$ for $i < n$; so $t_i^2 \ge \frac14 \gamma^{\mathrm{tr}} \mathfrak{b}(x_{n-1})^2 \ge 20$ and $\epsilon \le 10 N^3 e^{-\gamma^{\mathrm{tr}} \mathfrak{b}(x_{n-1})^2/8}$. Lemma 9.9 at the seven cumulants, whose entries have the total order $k \le 10$, and $\beta^3 a_K^2 \le \mathsf{N}^3$ give (ii). □

Lemma 9.12 (The suprema on the boxes)**.** In the setting of Proposition 9.11(i) there is $C_{\mathrm{S}} \geq 1$, determined by the constants, such that for $|\lambda| < 1$ and $B \in \mathsf{Bx}$:

(i) $|\mathsf{O}_a^\lambda(B)| \leq C_{\mathrm{S}}\mathsf{N}^8\|w_a\|_\infty$ for $a = 1, 2$;
(ii) $\mathsf{D}^\lambda(B) \neq 0$ and $|\mathsf{D}^\lambda(B)| \leq e^{C_{\mathrm{S}}\mathsf{N}^7}|\mathsf{D}^0(B)|$;
(iii) for $0 \leq i < n$, the height 0 included, the density of the step of the height i at $\lambda = 0$, at the trivial configuration, is proportional to $\exp[-\frac{1}{2}(B_i, (\mathsf{M}_i \otimes 1)B_i)]$ on the box of the height: its Gaussian part is ν_i°, the centred Gaussian measure with the real symmetric precision $\mathsf{M}_i \otimes 1 \geq \frac{3}{4}\gamma^{\mathrm{tr}}$, and its normalised restriction to the box is ν_i^{r}, a probability measure; at the height 0, $\tau_0 = 1$ and $\mathsf{M}_0 = \mathsf{A}_0^{\mathrm{cv}}$.

Consequently, on Bx, $|X_{a,m}| \leq C_{\mathrm{S}}\mathsf{N}^8\|w_a\|_\infty$ for $m = 0, 1, 2$, and $|W_1|, |W_2| \leq 2C_{\mathrm{S}}\mathsf{N}^7$. ■

Proof sketch. (i) The first member of O_a^λ is $a_K^{-1}\sum_p w_a(p)a_p(\tilde{U}_1^\lambda)$, at the background $\tilde{U}_1^\lambda$ of the level 1 of the chain of the proof of Proposition 9.11(i), a configuration on the bare bonds whose values stay near $\mathbf{1}$ in $\mathrm{SL}(2, \mathbb{C})$ by the radii of the chain, with at most $3N^3$ plaquettes and $a_K^{-1} \leq N$; the second, the source term of the height 0, is a sum over at most $8N^3$ domains of members of the family of the source, each bounded on the box by the size bounds of the step at a complex field scale (Proposition E.2) and by $\mathfrak{b}(\beta)^2 \leq C\beta$.

(ii) $\mathsf{D}^\lambda = \prod_{0\leq i<n}\rho_i^\lambda/Z_i^\lambda$ along the chain at the complex field scale λ, a product over the at most $K \leq N$ heights. Each ρ_i^λ is the exponential of a finite sum, so $\rho_i^\lambda \neq 0$; its exponent is a sum over at most $8N^3$ places of quadratic forms in the field, whose coefficients are holomorphic along the chain, and of potentials, and on the box each of them is bounded by the size bounds of the step at a complex field scale (Proposition E.2) and by $\mathfrak{b}(x_i)^2 \leq C\beta$, the radii of the chain keeping the points of all the heights in the discs where these bounds hold.

By the integral identity of the step at a complex field scale, Z_i^λ is $\det^{1/2}$ of the covariance of the step times the exponential of a sum of local terms of the step, each bounded by the size bounds of the step; so $Z_i^\lambda \neq 0$, and $|Z_i^\lambda|$ is bounded below by a determinant bound for its Gaussian part. Hence $\mathsf{D}^\lambda \neq 0$, and, with at most CN^3 terms a height, each at most a number determined by the constants times $\mathfrak{b}(\beta)^2 \leq C\beta \leq C\mathsf{N}$, this gives the bound with N^7. (iii) For a height $1 \leq i < n$, at $\lambda = 0$ the chain is trivial and the potentials vanish, and the density of the step at the trivial triple is $\exp[-\frac{\tau_i}{2}(B, \mathbf{C}_*^{-1}B) - \frac{1-\tau_i}{2}\sum_\square(B, \hat{\mathsf{G}}_\square B)]$.

Here the whole covariance of the step at the trivial triple is $\mathbf{C}_* = (\mathsf{A}_i^{\mathrm{cv}})^{-1} \otimes 1$ (equation YMM1:(2297), from Proposition YMM1:120.3 at the place of the height i), and the sum over the cubes of the local gauge-fixing forms is $\hat{\mathsf{G}} \otimes 1$ (equation YMM1:(828) at the trivial block field, with Proposition YMM1:120.3); so the density is $\exp[-\frac{1}{2}(B, ((\tau_i\mathsf{A}_i^{\mathrm{cv}} + (1-\tau_i)\hat{\mathsf{G}}) \otimes 1)B)] = \exp[-\frac{1}{2}(B, (\mathsf{M}_i \otimes 1)B)]$, as $\mathsf{A}_i^{\mathrm{cv}} = \mathsf{B}_i^{\mathrm{cv}} + \hat{\mathsf{G}}$. At the height 0, $\tau_0 = 1$, because $\xi_0 \equiv x_0$, and the gauge-fixing term drops out.

The provision of the step 1 is the canonical provision of the step at $(x_0; \mathfrak{a}_0^{\mathrm{abs}})$, the quadruple $(0, x_0, \mathfrak{a}_0^{\mathrm{abs}}, \mathfrak{w})$ being a place by the setting (J) of Definition B.16 at $k = K - 1$ (Proposition 9.4(iv)); by Proposition YMM1:120.3 and Proposition YMM1:120.6 at $k = 0$, its whole covariance at the trivial triple is the scalar operator with the real matrix $(\mathsf{A}_0^{\mathrm{cv}})^{-1}$. So the density of the height 0 is $\exp[-\frac{1}{2}(B_0, (\mathsf{A}_0^{\mathrm{cv}} \otimes 1)B_0)]$, and $\mathsf{M}_0 = \mathsf{A}_0^{\mathrm{cv}}$. At every height $\mathsf{B}_i^{\mathrm{cv}}$ and $\hat{\mathsf{G}}$ are real symmetric matrices ≥ 0 (equation YMM1:(2231)), $\mathsf{A}_i^{\mathrm{cv}} \geq \gamma^{\mathrm{tr}}$ (Proposition YMM1:120.3) and $\frac{3}{4} \leq \tau_i \leq \frac{4}{3}$ (Proposition 9.4(ii)); so M_i is real and symmetric, $\mathsf{M}_i \geq \min\{\tau_i, 1\}\mathsf{A}_i^{\mathrm{cv}} \geq \frac{3}{4}\gamma^{\mathrm{tr}}$, the Gaussian part of the density is ν_i°, and ν_i^{r} is a probability measure.

The consequences: Cauchy's estimate on $|\lambda| < 1$ for $\lambda \mapsto \mathsf{o}_a(\lambda B)$, whose coefficient of λ^{m+2} is $X_{a,m}(B)$, and Lemma 9.10 for $\lambda \mapsto \mathsf{D}^\lambda(B)/\mathsf{D}^0(B)$. □

Proposition 9.13 (The composed chart; the lattice number of a flat top)**.** Let $N = \ell L^K$, $\ell = 2L^m$, and $1 \leq t \leq K$ with $2L^{m+K-t+1} \geq C_L M$; the levels are those of the lattice (ℓ, K), $\mathcal{V}_j$ is the

space of the configurations of the level j, and Y the space of the $y = (\mathcal{A}_j)_{j<t}$, $\mathcal{A}_j$ a real $\mathfrak{g}$-valued 1-form on the non-pivot bonds of the level j (Section YMM1:4 and the pivot definition preceding Lemma YMM1:40.1).

(i) There are an open neighbourhood O_t of $\mathbf{1}$ in $\mathcal{V}_t$, $\rho_2 \in (0,1]$ and $C_{\mathrm{H}} > 0$ such that, with $\mathsf{Y}_{\rho_2} = \{y \in \mathsf{Y} : |\mathcal{A}_j| < \rho_2,\ j < t\}$: the chain $W_t = W$, $W_j = V_{W_{j+1}}[\mathcal{A}_j]$ of the charts of Section B.2 is defined on $\mathsf{O}_t \times \mathsf{Y}_{\rho_2}$, with $\mathcal{M}(W_j) = W_{j+1}$; $\Psi(W, y) = W_0$ is a real analytic diffeomorphism of $\mathsf{O}_t \times \mathsf{Y}_{\rho_2}$ onto an open set $\mathsf{U} \ni \mathbf{1}$; and there is a real continuous θ, real analytic near $(\mathbf{1}, 0)$, with $\int H\, dU = C_{\mathrm{H}} \int_{\mathsf{O}_t} dW \int_{\mathsf{Y}_{\rho_2}} dy\, e^{-\theta} H \circ \Psi$ for every bounded Borel H that vanishes off U.

(ii) For $\kappa \in (0,\infty)^t$ let $F_\kappa = A + \sum_{j<t} \kappa_j G_j(\mathcal{M}^j \cdot)$, G_j the gauge-fixing function YMM1:(54) at the level j, and $\phi_\kappa = F_\kappa \circ \Psi(\mathbf{1}, \cdot)$. Then $\phi_\kappa \geq 0$, $\phi_\kappa(0) = 0$, $\nabla\phi_\kappa(0) = 0$, and the Hessian of ϕ_κ at 0 is block diagonal for the decomposition of Y by the levels and positive definite.

(iii) The numbers $\mathfrak{g}_{m'}[N,t](p,q) = \gamma^{\mathrm{L}}_{m'}[\phi_\kappa, \theta(\mathbf{1},\cdot), a_p \circ \Psi(\mathbf{1},\cdot), a_q \circ \Psi(\mathbf{1},\cdot)]$, $m' = 0, 2$, do not depend on κ, and they are the same in every adapted chart. An *adapted chart* of $(\mathcal{V}_0, dU, \mathrm{Lg}\, \mathcal{M}^t)$, Lg being the Lie algebra logarithm on the intrinsic logarithm on $G \setminus \{-1\}$, is $(\mathsf{E}', \Psi', \theta', C', \varrho')$ with: E' an open neighbourhood of $(0,0)$ in $\mathsf{W}_t \times \mathbb{R}^{\dim \mathsf{Y}}$, W_t the space of the $\mathfrak{g}$-valued 1-forms w on the bonds of the level t; Ψ' a C^∞ diffeomorphism of E' onto an open subset of the domain of $\mathrm{Lg}\, \mathcal{M}^t$, with $\Psi'(0,0) = \mathbf{1}$ and $\mathrm{Lg}\, \mathcal{M}^t \Psi'(w,y) = w$; θ' a real continuous function on E', with $\theta'(0,\cdot)$ of class C^∞; $C' > 0$; $\varrho' > 0$ a continuous function of w alone; and $\int H\, dU = C' \int_{\mathsf{E}'} \varrho'(w)\, e^{-\theta'(w,y)} H(\Psi'(w,y))\, dw\, dy$ for every bounded Borel H that vanishes off $\Psi'(\mathsf{E}')$.

In it the numbers are $\gamma^{\mathrm{L}}_{m'}[F_\kappa \circ \Psi'(0,\cdot), \theta'(0,\cdot), a_p \circ \Psi'(0,\cdot), a_q \circ \Psi'(0,\cdot)]$. They depend on N, t, L, p, q alone.

(iv) One may take $\mathsf{O}_t = \{e^{iw} : |w| < \rho_2\}$ for every $\rho_2 \in (0, \rho_\star]$, with a $\rho_\star \in (0,1]$. Then W_j, $V_j^{\mathrm{bf}}(W_{j+1})$, $G_j(W_j)$, θ and $a_p \circ \Psi$ are real analytic in (w,y) on $\mathsf{O}_t \times \mathsf{Y}_{\rho_2}$, $W_j(\mathbf{1}, 0) = \mathbf{1}$, $0 < e^{-\theta} \leq \prod_{j<t} (27 L^9)^{\#\Gamma_j}$, and $C_{\mathrm{H}} = \prod_{j<t} (2\pi^2)^{-\#\mathfrak{x}_j^+} L^{-3\#\Gamma_j}$, where $\mathfrak{x}_j^+$ are the positively oriented non-pivot bonds of the level j and Γ_j the positively oriented bonds of the level $j+1$. One may also take $\mathsf{O}_t = \{W \in \mathcal{V}_t : \max_p |\partial W(p) - \mathbf{1}| < \varepsilon_*\}$, p running over the plaquettes of the level t, and $\rho_2 = \rho_*$, with numbers $\varepsilon_*, \rho_* \in (0,1]$ determined by L and the constants and independent of t, K and m; (i)–(iii) hold for this choice as well.

■

Proof sketch. (i), (iv) One real number $\mathfrak{t}_* > 1$ serves at all levels: with it the constants, the lattice of each step and $\mathfrak{t}_*$ are data under (Im) of Definition B.2. For such data Lemma B.3 gives, on an open set of block fields W and for $|\mathcal{A}|$ below the bound that belongs to $\mathfrak{t}_*$: the averaged configuration $V_j^{\mathrm{bf}}(W)$ is defined and $\mathcal{M}(V_j^{\mathrm{bf}}(W)) = W$; $\mathcal{M}(V_W[\mathcal{A}]) = W$; and $\mathrm{Lg}(V_W[\mathcal{A}](b) V_j^{\mathrm{bf}}(W)(b)^{-1}) = \mathcal{A}(b)$ on the non-pivot bonds. Lemma B.3 gives the one-step integral formula, with the constant $(2\pi^2)^{-\#\mathfrak{x}_j^+} L^{-3\#\Gamma_j}$, a Jacobian factor in $(0, (27/8)^{\#\Gamma_j}]$ and a normalisation in $(0, (8L^9)^{\#\Gamma_j}]$.

Neighbourhoods of $\mathbf{1}$ chosen downwards, by continuity in $(W, \mathcal{A})$, keep the chain where these statements apply; by induction over the levels the integral formula holds for every Borel subset of the natural domain of the chain, with C_{H} the product of the constants. The map

$$U \mapsto \Big(\mathcal{M}^t U,\ \big(\mathrm{Lg}(\mathcal{M}^j U(b)\, V_j^{\mathrm{bf}}(\mathcal{M}^{j+1} U)(b)^{-1}) \big)_{j<t} \Big)$$

is a real analytic left inverse of Ψ with injective differential, and $\dim \mathcal{V}_t + \dim \mathsf{Y} = \dim \mathcal{V}_0$; the inverse function theorem gives (i) after shrinking, and (iv) with $W = e^{iw}$, $dW = \varrho_{\mathrm{H}}(w)\, dw$, $\varrho_{\mathrm{H}} > 0$ the continuous density of the Haar measure of $\mathcal{V}_t$ in the variable w, on one set that carries (i)–(iii). For the second choice in (iv) one follows, level by level, a regularity number $\mathfrak{r}_j(W_j)$, which measures the plaquette variables of the averaged configuration of the level j and is comparable with

$\max_p |\partial W_j(p) - \mathbf{1}|$: one step gives $\mathfrak{r}_j(W_j) \le L^{-2}\mathfrak{r}_{j+1}(W_{j+1}) + C_{\mathfrak{r}}|\mathcal{A}_j|$, with $C_{\mathfrak{r}}$ determined by L and the constants.

So a threshold $\mathfrak{r}_\flat$ for $\mathfrak{r}$, with ε_* a fixed fraction of it and $\rho_* \le (1-L^{-2})\mathfrak{r}_\flat/C_{\mathfrak{r}}$, keeps every level in the sets where the statements of one step apply; nothing in this sees t, K or m. (ii) $a_p \ge 0$ and $G_j \ge 0$; at $\mathbf{1}$, $a_p(e^{iA}) = \frac{1}{2}|\mathrm{d}A(p)|^2 + O(|A|^3)$, G_j is half the sum of the squares of the linearised contour variables up to $O(|A|^3)$, and a fibre variable whose linearised curvature and contour variables vanish is 0. At the linear order the composed chart is the chart of the free template: the bare curvature of the field of the level j is T_j applied to it, with values in the slice $\mathcal{C}_{(j+1)}$ (Proposition YMM1:120.3), the slices are mutually orthogonal, and the linearised contour variables of the level j are those of $\mathcal{A}_j$ alone; this makes the Hessian block diagonal.

(iii) By (i) and (iv), near $(0,0)$ the composed chart $(w,y) \mapsto \Psi(e^{iw},y)$, with C_{H}, ϱ_{H} and $\theta(e^{iw},y)$, is an adapted chart: it is a real analytic diffeomorphism onto an open set, $\Psi(\mathbf{1},0) = \mathbf{1}$ ($W_j(\mathbf{1},0) = \mathbf{1}$), $\mathrm{Lg}\,\mathcal{M}^t\Psi(e^{iw},y) = w$, and θ is real analytic. Let $(\mathsf{E}',\Psi',\theta',C',\varrho')$ be an adapted chart, and E_1 an open neighbourhood of $(0,0)$ that the composed chart maps into $\Psi'(\mathsf{E}')$. Then $\sigma := \Psi'^{-1}\circ\Psi$ is a C^∞ diffeomorphism of E_1 onto an open set of the form $\sigma(w,y) = (w, s(w,y))$, both charts carrying $\mathrm{Lg}\,\mathcal{M}^t$ to the first variable, and $\sigma(0,0) = (0,0)$, as $\Psi(\mathbf{1},0) = \mathbf{1} = \Psi'(0,0)$.

The two formulas for dU give

$$C_{\mathrm{H}}\,\varrho_{\mathrm{H}}(w)\,e^{-\theta(e^{iw},y)} = C'\varrho'(w)\,e^{-\theta'(\sigma(w,y))}\,|\det D_y s(w,y)|$$

almost everywhere on E_1, and, both sides being continuous, at every point of E_1; in particular on the fibre $w = 0$, a null set, where the numbers are read. So $y \mapsto s(0,y)$, a diffeomorphism near 0 that fixes 0, carries the phase $F_\kappa\circ\Psi(\mathbf{1},\cdot)$, the observables and the density $e^{-\theta(\mathbf{1},y)}dy$ into $F_\kappa\circ\Psi'(0,\cdot)$, the observables and $e^{-\theta'(0,y')}dy'$, up to the constant factor $C'\varrho'(0)/(C_{\mathrm{H}}\varrho_{\mathrm{H}}(0))$; the Taylor polynomials are taken at the minimum 0 in both charts. The two coefficients of Laplace's method in either chart are those of the expansion of one quantity, the covariance of a_p and a_q under $e^{-\beta F_\kappa}$ on the fibre $\mathcal{M}^tU = \mathbf{1}$ near $\mathbf{1}$, and so they are the same in both.

The gauge transformations equal to $\mathbf{1}$ on the top lattice preserve the fibre, A and the a_p, and the normalised gauge-fixing factor (Definition YMM1:6.1 and equations YMM1:(51)–(52)) integrates to one over their orbits at every strength (Lemma YMM1:5.3 and equation YMM1:(55)); integrating over the orbits, the finest sites first, the covariance does not depend on κ up to errors $e^{-c\beta}$, and neither do its coefficients. Near $(0,0)$ the composed chart is itself an adapted chart. □

Proposition 9.14 (The identification of the order six)**.** Under the assumptions of Proposition 9.11, $\beta^3 a_K^2\gamma_2^\circ = \mathsf{T}[N,n](w)$, the plaquettes being read in bare units on Λ_N; $\mathsf{T}[N,n](w)$ depends on N, n, L and the lattice sources alone. The identity has no error term and holds at every size of the boxes. ■

Proof sketch. By Proposition 9.4(i), Proposition 9.13 applies at $t = n$ on the lattice of the datum. For real $0 < \lambda \le 1$ the exact formula of the steps (Proposition YMM1:123.1), read at the fields λB, and the sum rules of the chain classes (Proposition YMM1:124.2, equation YMM1:(2289)) add the exponents of the steps of Proposition 9.11(i) up to

$$\mathsf{D}^\lambda(B) = c_n(\lambda)\exp\Big[-\lambda^{-2}\Big(x_0 A(W_0) + \sum_{j<n} x_j G_j(W_j)\Big) - \theta\Big],$$

where $c_n(\lambda)$ does not depend on B and (W_j) is the composed chart over the flat top $\mathbf{1}$ of the level n at the fields $\mathcal{A}_i = \lambda x_i^{-1/2}\check{B}_i$, $\check{B}_i = \mathrm{Ad}(u_{i+1})B_i$, with $u_{i+1} \in G$ a function of the fields of the heights $> i$ alone: the chain of Proposition 9.11 runs through configurations in another gauge than the composed chart. The observables become $a_K^{-1}\sum_p w_a(p)a_p(W_0)$ at the same fields. No τ_i and no counterterm e_i is left, because

$$\lambda^{-2}\xi_j(\lambda)L^j + \sum_{i\le j} L^i e_i = \lambda^{-2}x_0$$

by the run equation; this is what ξ_j is chosen for. So the density is the Wilson weight at $\beta\lambda^{-2}$ with the gauge-fixing strengths $\kappa_j = x_j/\beta$ on the fibre $\mathcal{M}^n U = \mathbf{1}$. The triangular change $B \mapsto \check{B}$ preserves the volume and the boxes, which are Euclidean balls $|B_i(b)| < \mathfrak{b}(x_i)$ and are preserved by the rotations $\mathrm{Ad}(u)$; its linear part at 0 is a constant rotation of the colours, so it preserves the Gaussian part $\bigotimes_{i<n} \nu_i^\circ$; and the two numbers of Laplace's method are kept by a diffeomorphism that carries phase, observables and density into each other.

So γ_2° is the second coefficient of Laplace's method (49) at the parameter $\beta\lambda^{-2}$, and $\beta^3 a_K^2 \gamma_2^\circ = \sum_{p,q} w_1(p) w_2(q) \gamma_2^{\mathrm{L}}$ in the chart of Proposition 9.13, which does not depend on κ. The dilation $x \mapsto L^{K-n} x$ carries the lattice (ℓ, K) with its flat top at the level n to the lattice $(\ell L^{K-n}, n)$, with the same bare torus, plaquettes to plaquettes with their barycentres; so the number is $\mathfrak{g}_2[N, n](p, q)$. The argument uses that the boxes are Euclidean balls; it would not apply to boxes that are cubes in the components. □

Lemma 9.15 (An implicit function, Stokes's formula in a box, Wick's rule)**.** (i) Let V be a finite-dimensional complex normed space, $0 < \varsigma \le \frac{1}{120}$, and F holomorphic from $\{\|y\| < \varsigma\} \times \{\lambda \in \mathfrak{g}^{\mathbb{C}} : |\lambda| < \varsigma\}$ to $\mathfrak{g}^{\mathbb{C}}$ with $|F| \le \frac{1}{40}$, $F(0,0) = 0$ and $D_\lambda F(0,0) = 1$. Then for $\|y\| < \varsigma^3$ there is exactly one $h(y)$ with $|h(y)| \le \varsigma^2$ and $F(y, h(y)) = 0$; h is holomorphic, $|h(y)| \le \|y\|/(15\varsigma)$, and h is $\mathfrak{g}$-valued at the real points if F is.

(ii) Let B be the injective image in a bare torus of a box of $\mathbb{Z}^3$. For every closed bare path γ in B there is an integer function k_γ on the plaquettes with all corners in B, $|\mathsf{k}_\gamma| \le |\gamma|$ (the number of bonds of γ), with $a(\gamma) = \sum_p \mathsf{k}_\gamma(p)\, (\mathrm{d}a)(p)$ for every 1-cochain a.

(iii) Let (ζ_ι) be a centred Gaussian family with covariance C, and $P_1, \dots, P_r$ homogeneous polynomials in it of orders $n_1, \dots, n_r$, $n = \sum n_a$, $\|P\|_1$ the sum of the moduli of the coefficients. For monomials the joint cumulant $\langle P_1; \dots; P_r \rangle$ is the sum, over the pairings of the factors that are connected (the graph on $\{1, \dots, r\}$ with an edge for every pair that joins two of the P_a is connected), of the products of the covariances, and by multilinearity this extends to polynomials; the cumulant vanishes if n is odd. With $\mathsf{c} \ge \sup|C|$ on the supports, $|\langle P_1; \dots; P_r \rangle| \le (n-1)!! \prod_a \|P_a\|_1 \mathsf{c}^{n/2}$; if every connected pairing has a pair with $|C| \le \varepsilon$, the bound holds with $\mathsf{c}^{n/2-1}\varepsilon$ for $\mathsf{c}^{n/2}$; and for two covariances C, C' bounded by c the two cumulants differ by at most $(n-1)!! \frac{n}{2} \prod_a \|P_a\|_1 \mathsf{c}^{n/2-1} \sup|C - C'|$.

■

Proof sketch. (i) Put $g(y, \lambda) = \lambda - F(y, \lambda)$, so $|g| \le \frac{1}{40} + \varsigma \le \frac{1}{30}$, $g(0,0) = 0$, $D_\lambda g(0,0) = 0$. Cauchy's estimate and Schwarz's lemma give $|D_\lambda g(y,\lambda)| \le \frac{2}{15}\varsigma^{-2} \max\{\|y\|, |\lambda|\}$ for $\max\{\|y\|, |\lambda|\} \le \frac{1}{2}\varsigma$, and $|g(y,0)| \le \|y\|/(30\varsigma)$. So for $\|y\| < \varsigma^3$ the map $\lambda \mapsto g(y,\lambda)$ sends $\{|\lambda| \le \varsigma^2\}$ into itself and contracts by $\frac{2}{15}$; its fixed point is $h(y)$, the uniform limit of holomorphic iterates, and $|h| \le |g(y,0)| + \frac{2}{15}|h|$. (ii) With the paths P_z from a corner o of the box to z that run first in the direction 1, then 2, then 3, the quantity $a(P_z) + a(e) - a(P_{z+e_\mu})$ of a bond $e = \langle z, z + e_\mu \rangle$ is the sum of $\pm(\mathrm{d}a)$ over a strip of plaquettes of the box; along a closed path the terms $a(P_\cdot)$ telescope.

(iii) By Wick's theorem the moments are sums over all pairings; a pairing determines the partition of the factors into the components of its graph and is connected on each block, which identifies the sums over connected pairings with the joint cumulants. The bounds count the $(n-1)!!$ pairings and use $|\prod_{i \le m} c_i - \prod_{i \le m} c_i'| \le m\, \mathsf{c}^{m-1} \max|c_i - c_i'|$. □

Proposition 9.16 (Two bare tori under one flat top)**.** Let $N = 2L^{\mathsf{m}}$, $N' = L^s N$ ($s \ge 1$), $1 \le t < \mathsf{m}$, $\pi : \Lambda_{N'} \to \Lambda_N$ the reduction, and

$$\nu = N/L^t \ge \nu_{\mathrm{W}} = \max\Big\{192,\ \frac{48(3\log L + \log 2)}{\delta_{\mathrm{tp}} L(L-1)},\ \frac{C_L M}{L}\Big\}.$$

For plaquettes p', q' of $\Lambda_{N'}$ whose base points lie within $N/8$ of each other (the base point of the plaquette $p_{\mu\nu}(x)$ being x, the distance being the sup distance of the bare torus, in bare units) and

$m' = 0, 2$,

$$|\mathsf{g}_{m'}[N,t](\pi p', \pi q') - \mathsf{g}_{m'}[N',t](p',q')| \le C'_{\mathrm{W}} N'^{237} e^{-\delta_{\mathrm{tp}} L\nu/48},$$

with C'_{W} determined by L and C_{tp}. Hence, for real w_1, w_2 on the plaquettes of Λ_N with supports in balls of radius $r \ge 8$, all base points within $N/8$ of each other, and $\breve{w}_a$ equal to $w_a \circ \pi$ on one lift of a ball of radius $N/4$ that holds the supports and 0 elsewhere,

$$|\mathsf{T}[N,t](w) - \mathsf{T}[N',t](\breve{w})| \le 900 r^6 C'_{\mathrm{W}} N'^{237} e^{-\delta_{\mathrm{tp}} L\nu/48} \|w_1\|_\infty \|w_2\|_\infty.$$

■

Proof sketch. Signs. Let $S \in \{N, N'\}$, and read the objects of the lattice $(S/L^t, t)$ in bare units on Λ_S; distances are those of the bare torus, $|\cdot|_\infty$ its sup distance, and $x(p)$ is the barycentre of a plaquette p, its base point being x if $p = p_{\mu\nu}(x)$. For a bond c of the top lattice $\mathbb{T}^{(t)}$, $B^t(c_\pm)$ are the blocks of order t of its end points, its double block is their union, and its corridor $\mathrm{cor}(c)$ is the set of the bare bonds b with $b_- \in B^t(c_-)$, $b_+ \in B^t(c_+)$; $\mathsf{1}_c$ is the bare 1-cochain that is 1 on $\mathrm{cor}(c)$, -1 on the reversed bonds and 0 elsewhere. As $\nu \ge 8$, every bare bond lies in one top block or in exactly one corridor, and no bond of the corridor of c' has both end points in the double block of c unless $c' \in \{c, \bar{c}\}$; the bonds of the double block of c are those with both end points in it.

For a bare site $x \notin \mathbb{T}^{(t)}$, $j(x) = \max\{j : x \in \mathbb{T}^{(j)}\} < t$, its parent $\hat{x} \in \mathbb{T}^{(j(x)+1)}$ is the centre of the block of order 1 that holds x, and $\mathrm{anc}(z) = \{z, \hat{z}, \hat{\hat{z}}, \dots\} \setminus \mathbb{T}^{(t)}$; the sums over x below run over the bare sites off $\mathbb{T}^{(t)}$. Q_k is the linear part of the k-fold block average, and $\xi_A(x) = (\mathsf{Q}_{j(x)}A)(\hat{x}, x)$ is the linearised contour variable of the site x. A $\mathfrak{g}$-valued 1-form y has the coordinates $y(\iota)$, $\iota = (b, \alpha)$, $b > 0$ a bare bond and α a colour; $\iota + \gamma$ is the translate of ι by γ, and $\mathrm{dist}(\iota, \iota') = |b_- - b'_-|_\infty$.

By Proposition 9.13(iii) the numbers do not depend on κ; we take $\kappa \equiv 1$.

A chart made for locality. Q_k is a mean over bare paths: for every bond c of $\mathbb{T}^{(k)}$ there is a probability measure on the bare paths from c_- to c_+ in the double block of c, with at most $(4L)^k$ bonds, whose mean of $A(\gamma)$ is $(\mathsf{Q}_k A)(c)$; and $\mathsf{Q}_t \mathsf{1}_c$ is 1 at c and 0 at the other top bonds. $\mathcal{M}^t(U)(c)$ depends on U on the double block of the top bond c alone. So, for y in $Y_S := \ker \mathsf{Q}_t$ near 0, the constraint $\mathcal{M}^t(e^{i\hat{y}}) = \mathbf{1}$ for $\hat{y} := y + \sum_{c>0} h_c(y) \mathsf{1}_c$ is solved one top bond at a time, with one element $h_c(y) \in \mathfrak{g}$ (three unknowns) for each: Lemma 9.15(i) at $\varsigma = \varsigma_t := (75L)^{-t}/(60L)$, applied to $(y, \lambda) \mapsto \mathrm{Lg}\, \mathcal{M}^t(e^{i(y+\lambda \mathsf{1}_c)})(c)$, which is holomorphic and bounded by $\frac{1}{40}$ on the polydisc of the Lemma, vanishes at $(0,0)$ and has the derivative 1 in λ there, gives exactly one holomorphic h_c with $|h_c(y)| \le \|y\|_\infty/(15\varsigma_t)$ for $\|y\|_\infty < \varsigma_t^3$, $\mathfrak{g}$-valued at real y; it reads y on the double block of c alone, $\hat{y} = y$ on the top blocks, and $\hat{y} = y + O(y^2)$ on Y_S.
