This is the role of the cutoffs: they keep every block field that enters F_K where $\mathcal{M}$ is given by its real-analytic formula. By the product rule and the averaging bound at $\epsilon'_j = 4\theta_{K-j}$, with $\prod_j(1+C_D\epsilon'_j)\le \mathsf{c}_* = \exp(4C_D\sum_{e\ge n_1}\theta_e)$,

$$\Gamma_K(F_K)^{1/2} \le \mathsf{c}_*\Big[\sup\Gamma_n(\Phi)^{1/2} + \sup|\Phi|\sum_{n\le d\le K}\mathsf{k}_d\,\mathbf{1}\{\varpi(\pi_{K,d}U)\ge\theta_d\}\Big],$$

and the event in the sum has μ^K-mass $\le\max\{\mathsf{R}_d,\mathsf{R}_{d-1}\}$, by the first statement of (c) at the depth d, or at the depth $d-1$ if $d=K$. Minkowski's inequality and the decay of R_d faster than every exponential, against $\mathsf{k}_d = O(L^{4d})$, bound every L^p norm uniformly in K, and $\|\Gamma_K(\chi_n^K)^{1/2}\|_{L^{2p}(\mu^K)}\le \mathsf{c}_*\sum_{d\ge n}\mathsf{k}_d\max\{\mathsf{R}_d,\mathsf{R}_{d-1}\}^{1/2p}\to 0$ as $n\to\infty$. Density: a bounded Borel invariant function of a small depth is μ-almost surely a Borel function of a large depth, it is approximated in $L^2(\mu_d)$ by invariant polynomials, and the cutoffs change it by $\le\mathsf{R}_d^{1/2}$.

Then $\mathcal{E}_\star(F)\le\liminf_K\mathcal{E}_K(F_K)$, $\|Q_tF-F\|^2\le 2(F,(1-Q_t)F)\le 2t\sup_K\mathcal{E}_K(F_K)$, and $\nu_F(\{\infty\}) = \|F\|^2-\lim_{t\to0}(F,Q_tF)$. Each property of (Y_t) and of $\mathcal{E}_\star$ stated in (b) and (c) is shared by the frozen process, which keeps Y_0 up to gauge transformations of the threads drawn from the Haar measure independently at different times, so that $Q_t=\Pi$ for $t>0$ and $\mathcal{E}_\star=0$ on L^2_{inv}: motion is the content of (A1). □

Proposition 15.2 (The limiting process on the common core)**.** Assume (E); let $\mathcal{C}$ and F_K be as in Lem. 15.1(c), and $T>0$.

(a) (Paths.) For $F\in\mathcal{C}$ and $1\le p<\infty$, $\mathbb{E}|F_K(U_t)-F_K(U_s)|^{2p}\le C_p(F)|t-s|^p$ uniformly in K; the processes $(F_K(U_t))_{t\le T}$ are tight in $C[0,T]$, and along every limit $F(Y_t)$ has a continuous modification, locally Hölder continuous of every exponent $<\frac12$. For $d\ge n_1$ there is $\mathsf{p}_d(T)$, which does not depend on K and tends to 0 faster than every exponential in d, such that for all $K>d$, with probability at least $1-\mathsf{p}_d(T)$, $\varpi(\pi_{K,e}U_t)<2\theta_e$ for all $d\le e\le K$ and all $t\in[0,T]$.

(b) (Energies.) For $F\in\mathcal{C}$ the limit $\mathcal{E}_\infty(F)=\lim_K\mathcal{E}_K(F_K)$ exists along the full sequence of cutoffs, and $\mathcal{E}_\infty(F)=\int\Gamma_\infty(F)\,\mathrm{d}\mu$ with

$$\Gamma_\infty(F)(Y) = \lim_{d\to\infty}a_d^{-1}\,\mathsf{t}[\tfrac23,\tfrac16;Y_d](\partial F^{[d]}(Y_d)) \quad \mu\text{-almost surely and in } L^1(\mu),$$

where $F^{[d]}$ is the lattice form of F at depth d and

$$\mathsf{t}[\alpha,\beta;V](B)=\alpha\|B\|^2+2\beta\sum_{c}\langle B(c),\mathrm{Ad}(V(c))B(c^+)\rangle,$$

c^+ the bond that follows c in its direction. $\mathcal{E}_\infty(F)$ depends only on the class of F in $L^2(\mu)$, $\mathcal{E}_\star\le\mathcal{E}_\infty$ on $\mathcal{C}$ for every limit, and for $F=\Phi(Y_d)\prod_{e\ge d}\chi_e(Y_e)$ with $\mathsf{R}_d<1$

$$\mathcal{E}_\infty(F)\ge(\tfrac13-\tfrac12\bar\eta_d)(1-\mathsf{R}_d)\,e^{-\mathsf{o}_d}\,a_d^{-1}|\mathsf{I}_d|^{-1}\int_{\mathsf{I}_d}|\partial\Phi|^2dV,\qquad\bar\eta_d\to0.$$

(c) (The laws of the block fields.) For an integer $d\ge1$ with $L^d\mathsf{b}\ge\mathsf{t}_\natural$ and every bounded Borel invariant $f\ge0$ on Ω_d,

$$(1-\mathsf{R}_d)\,e^{-\mathsf{o}_d}|\mathsf{I}_d|^{-1}\int_{\mathsf{I}_d}f\,\mathrm{d}V\le\int f(Y_d)\,\mathbf{1}\{\varpi(Y_e)<\theta_e\text{ for all }e\ge d\}\,\mathrm{d}\mu\le\int f\,\mathrm{d}\mu_d$$
$$\le e^{\mathsf{o}_d}|\mathsf{I}_d|^{-1}\int_{\mathsf{I}_d}f\,\mathrm{d}V+\mathsf{R}_d\sup f,$$

and the same at every cutoff $K>d$, with μ_d^K in the place of μ_d and with the middle member $\int f(\pi_{K,d}U)\,\mathbf{1}\{\varpi(\pi_{K,e}U)<\theta_e\text{ for }d\le e\le K\}\,\mathrm{d}\mu^K$. So an invariant Haar-null set has μ_d- and μ_d^K-mass $\le\mathsf{R}_d$; and if $\mathsf{R}_d<1$, every non-empty open subset of I_d has positive μ_d-mass and μ_d^K-mass bounded below uniformly in K.

(d) (Square field and martingales.) Let (K_j) be a limit and $F\in\mathcal{C}$. There is $\Gamma_\star(F)\in L^2_{\mathrm{inv}}$ with $(2t)^{-1}\mathbb{E}[\phi(Y_0)(F(Y_t)-F(Y_0))^2]\to\int\phi\,\Gamma_\star(F)\,\mathrm{d}\mu$ as $t\to0$ for bounded invariant ϕ; $0\le\Gamma_\star(F)\le\Gamma_\infty(F)$, $\int\Gamma_\star(F)\,\mathrm{d}\mu=\mathcal{E}_\star(F)$, and $\mathcal{E}_\star(\psi(F))=\int\psi'(F)^2\Gamma_\star(F)\,\mathrm{d}\mu$ for $\psi\in C^2(\mathbb{R})$. Along a further subsequence the lattice martingales converge, and $F(Y_t)=F(Y_0)+M_t^F+D_t^F$, with a continuous martingale M^F with $\langle M^F\rangle_t=2\int_0^t\Gamma_\infty(F)(Y_s)\,\mathrm{d}s$, and a continuous process D^F with stationary increments, $\mathbb{E}|D_t^F|^2=2[t\,\mathcal{E}_\infty(F)-(F,(1-Q_t)F)]$, $\mathbb{E}[D_t^F(F(Y_t)-F(Y_0))]=0$, and $\lim_{t\to0}t^{-1}\mathbb{E}|D_t^F|^2=2[\mathcal{E}_\infty(F)-\mathcal{E}_\star(F)]$; in reversed time, $F(Y_t)-F(Y_0)=\frac12M_t^F-\frac12(\hat M_T^F-\hat M_{T-t}^F)$ with a martingale $\hat M^F$ of the law of M^F.

The following are equivalent: $\mathcal{E}_\star(F)=\mathcal{E}_\infty(F)$; $\Gamma_\star(F)=\Gamma_\infty(F)$ μ-almost everywhere; D^F has zero energy; $\lim_{\Lambda\to\infty}\limsup_j\int_{(\Lambda,\infty)}\lambda\,\mathrm{d}\nu_F^{K_j}=0$, ν_F^K the spectral measure of F_K. And F is frozen ($Q_tF=F$ for all t) if and only if $D^F=-M^F$.

(e) (Motion from fields with a divergence.) A vector field with a divergence at the cutoff K is a $\zeta\in L^2(\mu^K;\mathfrak{g}^{\mathrm{bonds}})$ with $\delta_K\zeta\in L^2(\mu^K)$ such that $a_K^{-1}\int\langle\zeta,\partial H\rangle\,\mathrm{d}\mu^K=-\int H\,\delta_K\zeta\,\mathrm{d}\mu^K$ for $H\in C^\infty(\Omega_K)$. If $a_{K_j}^{-1}\int|\zeta_j|^2\,\mathrm{d}\mu^{K_j}\le\mathsf{A}^2$, $\|\delta_{K_j}\zeta_j\|\le\mathsf{D}$ and $\delta_{K_j}\zeta_j\to g$ weakly, then for $F\in L^2(\mu)$ and $t>0$

$$\mathcal{E}_\star(F)\ge\frac{(F,g)^2}{\mathsf{A}^2},\qquad(F,(1-Q_t)F)\ge\frac{t\,(F,g)^2}{\mathsf{A}^2+t\,\mathsf{D}^2};$$

conversely, if $\mathcal{E}_\star(F)>0$, such fields with $(F,g)\ne0$ exist. A field that does not depend on the configuration pairs to zero with every invariant gradient: $\int\langle\partial F,z\rangle\,\mathrm{d}\mu^K=0$ for constant z and invariant F.

(f) (An example.) In a limit of reversible diffusions observed through a block variable whose law converges in total variation, the inequality $\mathcal{E}_\star\le\mathcal{E}_\infty$ can be strict: for the reversible diffusion on $\mathbb{R}^2$ with the weight $e^{-\frac{\kappa}{2}(x-w)^2-\frac12w^2}$, the form $\int(|\partial_xF|^2+s^2|\partial_wF|^2)$ with fixed $s>0$ and the block variable x, as $\kappa\to\infty$ the law of x converges in total variation, the square field of x is 1, the limit is an Ornstein–Uhlenbeck process, Markov and moving, and $\mathcal{E}_\star(x)=s^2/(1+s^2)<1=\mathcal{E}_\infty(x)$.

■

Proof sketch. (a) At every cutoff, for $H \in C^\infty(\Omega_K)$ and $0 \le t \le T$, $H(U_t) - H(U_0) = \frac{1}{2}M_t - \frac{1}{2}(\hat{M}_T - \hat{M}_{T-t})$ with forward and backward martingales of brackets $2\int \Gamma_K(H)$ (the drift drops out, and the square field alone enters); the martingale moment inequalities and stationarity give $\mathbb{E}|H(U_t) - H(U_s)|^{2p} \le c_p 2^p |t-s|^p \int \Gamma_K(H)^p d\mu^K$, and $\mathbb{P}(\sup_{t\le T}|H(U_t) - H(U_0)| \ge \lambda) \le 10T\lambda^{-2}\mathcal{E}_K(H)$. With the bounds of Lem. 15.1(c) this is uniform in K, and the criterion of Kolmogorov and Chentsov gives tightness and Hölder continuity. For the small fields apply the maximal bound to $H = \prod_{d\le e\le K} \chi'_e \circ \pi_{K,e}$, built from a second family of cutoffs, $\chi'_e = \prod_p \varphi_{\mathrm{cut}}(\varpi_p^2/\theta_e^2)$ on Ω_e with the function φ_{cut} of Lem. 15.1(c): χ'_e is 1 where $\varpi \le \theta_e$ and 0 where $\varpi \ge 2\theta_e$, and, as there, each factor has a gradient of norm at most $4\varpi_p/\theta_e^2 \le 8/\theta_e$, so that $\Gamma_e(\chi'_e)^{1/2} \le \mathsf{k}_e \mathbf{1}\{\varpi \ge \theta_e\}$ with the same numbers $\mathsf{k}_e = 24L^{e/2}\theta_e^{-1}(\ell L^e)^3$, which thus bound $\Gamma_e^{1/2}$ of both families.

As in the proof of Lem. 15.1(c), the energy of H is at most $\mathsf{c}_*^2\Sigma_d^2$, $\Sigma_d = \sum_{e\ge d} \mathsf{k}_e \max\{\mathsf{R}_e, \mathsf{R}_{e-1}\}^{1/2}$, with $\mathsf{c}_* = \exp(4C_D \sum_{e\ge n_1} \theta_e)$; $H(U_0) = 1$ off a mass $\le \mathsf{R}_d$, and $H(U_t) > 0$ forces $\varpi(\pi_{K,e}U_t) < 2\theta_e$ for $d \le e \le K$; so $\mathsf{p}_d(T) = \mathsf{R}_d + 10T\mathsf{c}_*^2\Sigma_d^2$.

(b) On the small fields $F_K = F^{[d]} \circ \pi_{K,d}$, $\partial F_K = \mathcal{D}^{(k)}(U)^* \partial F^{[d]}$ with $\mathcal{D}^{(k)}$ the differential of $\mathcal{M}^k$, and the transpose of the differential carries the quadratic forms along: $L^k \mathsf{t}[\alpha,\beta;U](\mathcal{D}^{(k)*}B) = \mathsf{t}[\mathsf{A}_L^k(\alpha,\beta);V](B) + O(\sum_j \epsilon'_j)\|B\|^2$ for horizontal B at $V = \mathcal{M}^k U$, where A_L is the linear map of the flat average, with the eigenvector $(\frac{2}{3}, \frac{1}{6})$ of eigenvalue 1 (the Gram matrix of the kernels that are a tent along the bond and a box across it) and $(\frac{1}{3}, -\frac{1}{6})$ of eigenvalue L^{-2}.

So $\Gamma_K(F_K)$ is close in $L^1(\mu^K)$, uniformly in K, to $a_d^{-1}\mathsf{t}[\frac{2}{3}, \frac{1}{6}; \cdot](\partial F^{[d]}) \circ \pi_{K,d}$, and total variation gives the limit along the full sequence; the same estimate between two depths along a thread gives Γ_∞. A function of $\mathcal{C}$ that vanishes μ-almost everywhere has a gradient that vanishes off an invariant Haar-null set, whose mass is controlled by (c); this gives the dependence on the class. $\mathcal{E}_\star \le \mathcal{E}_\infty$ is the lower semicontinuity of Lem. 15.1(b). The lower bound: on the threads with $\varpi(Y_e) < 2\theta_e$ for all $e \ge d$, where all cutoffs χ_e equal 1 near Y_e and $F^{[e]} = \Phi \circ \mathcal{M}^{e-d}$, the same estimate between the depths d and $e \to \infty$ gives $|\Gamma_\infty(F)(Y) - a_d^{-1}\mathsf{t}[\frac{2}{3}, \frac{1}{6}; Y_d](\partial\Phi(Y_d))| \le \frac{1}{2}\bar{\eta}_d a_d^{-1}|\partial\Phi(Y_d)|^2$, with $\bar{\eta}_d = 4C_{\mathrm{T}}\mathsf{c}_*^2 \sum_{e>d}\theta_e$, $C_{\mathrm{T}} = C_{\mathrm{T}}(L)$ the constant of the term $O(\sum_j \epsilon'_j)$ above and c_* that of the proof of Lem. 15.1(c), so $\Gamma_\infty(F)(Y) \ge (\frac{1}{3} - \frac{1}{2}\bar{\eta}_d)a_d^{-1}|\partial\Phi(Y_d)|^2$ as $\mathsf{t}[\frac{2}{3}, \frac{1}{6}; V] \ge \frac{1}{3}\|\cdot\|^2$; elsewhere $\Gamma_\infty(F) \ge 0$.

The event of the middle member of (c) lies in that set of threads, and (c) at the invariant function $f = |\partial\Phi|^2$ gives the bound.

(c) At the top depth d the chain from level 0 has the density $e^{\Sigma + \Phi_t}$ with respect to Haar measure on I_d, Σ a constant (Prop. YM3_I:115.2, image identity, Prop. YM3_I:114.2), its non-classical part bounded by $C_{\mathrm{nl}}\frac{L}{L-1}E_0(\ell L^d)^3$ (equation YM3_I:(2180)) and the classical part between 0 and $\frac{3}{2}c_\rho^2 A_0^2(\log L^d \mathsf{b})^{2\mathfrak{p}_0}(\ell L^d)^3$ (by YM3_I:(2161) at the weight x_t); its mass lies in $[1 - \mathsf{R}_d, 1]$; the comparison of the chain with the bare density (Prop. YM3_I:115.2, domination and lost-mass bounds) gives the sandwich for μ_d^K, and total variation (Cor. 2.8) for μ_d.

The middle member: the weight of the chain with top depth d vanishes unless $\pi_{K,e}U$ lies in its cut, so in $\{\varpi < \theta_e\}$, for $d \le e \le K$; the function $f(\pi_{K,d}U)\mathbf{1}\{\varpi(\pi_{K,e}U) < \theta_e \text{ for } d \le e \le K\}$ is invariant, by the gauge covariance of $\mathcal{M}$; so, σ^K being at most μ^K on invariant functions (Lem. 15.3(i)), $\int f\,\mathrm{d}\sigma_d^K = \int f(\pi_{K,d}U)\mathbf{1}\{\cdots\}\,\mathrm{d}\sigma^K \le \int f(\pi_{K,d}U)\mathbf{1}\{\cdots\}\,\mathrm{d}\mu^K$, and $\int f\,\mathrm{d}\sigma_d^K \ge (1 - \mathsf{R}_d)e^{-\mathsf{o}_d}|\mathsf{I}_d|^{-1}\int_{\mathsf{I}_d} f\,\mathrm{d}V$ by the lower bound of the density of σ_d^K (Lem. 15.3(iii)).

For μ: at a depth $D > d$ the event $\{\varpi(Y_e) < \theta_e \text{ for } d \le e \le D\}$ is an event of the block field of depth D, it contains the event at the cutoff $K > D$, and total variation at the depth D carries the bound to μ; then $D \to \infty$, a monotone limit. Positivity: for a non-empty open $O \subset \mathsf{I}_d$ and a smaller non-empty open O' with closure in O, the gauge orbit of O' is open, invariant and of positive Haar measure, and it is covered by finitely many gauge translates of O, which all have the mass of O.

(d) For bounded invariant ϕ, the forward–backward decomposition gives $(2t)^{-1}\mathbb{E}[\phi(U_0)(F_K(U_t) - F_K(U_0))^2] \le \int \phi\,\Gamma_K(F_K) + c\,\langle\phi, (1 - P_t)\phi\rangle^{1/2}$ for $\phi \ge 0$; the limit in K and then in t gives

$\Gamma_\star \le \Gamma_\infty$, and, with $\mathsf{e}_t(\phi;F) = (2t)^{-1}\mathbb{E}[\phi(Y_0)(F(Y_t)-F(Y_0))^2]$, the identity $2t\,\mathsf{e}_t(\phi;F) = 2\langle \phi F, (1-Q_t)F\rangle - \langle \phi, (1-Q_t)F^2\rangle$ gives the existence. The chain rule follows from fourth moments of the increments, which are $O(t^2)$. The lattice processes $F_K(U_t)$, their martingales $M^{K,F}$ and brackets are tight in $C[0,T]$, limits of L^4-bounded martingales are martingales, and the brackets converge to $2\int \Gamma_\infty(F)(Y_s)\,\mathrm{d}s$ by (b).

At the cutoff, with the spectral measure ν of F_K, $\mathbb{E}|\int_0^t \mathcal{L}_K F_K(U_s)\,\mathrm{d}s|^2 = 2\int (t\lambda - 1 + e^{-t\lambda})\,\mathrm{d}\nu = 2[t\,\mathcal{E}_K(F_K) - (F_K,(1-P_t^K)F_K)]$ and the drift is orthogonal to the increment; these pass to the limit. The equivalences: $\mathcal{E}_\infty(F) - \mathcal{E}_\star(F) = \lim_\Lambda \lim_j \int(\lambda-\Lambda)_+\,\mathrm{d}\nu_F^{K_j}$, the energy that escapes to infinite frequency, is the energy of the drift and the integral of $\Gamma_\infty - \Gamma_\star$.

(e) Let $H_j \to F$ strongly with $\mathcal{E}_{K_j}(H_j) \to \mathcal{E}_\star(F)$; then $|\langle H_j, \delta_{K_j}\zeta_j\rangle| \le \mathsf{A}\,\mathcal{E}_{K_j}(H_j)^{1/2}$, and the left side tends to $|(F,g)|$. At a positive time, $1-e^{-x} \ge \frac{x}{1+x}$ for $x \ge 0$ (as $e^x \ge 1+x$) and $\int \frac{t\lambda}{1+t\lambda}\,\mathrm{d}\nu = \min_G\{\|H-G\|^2 + t\,\mathcal{E}_K(G)\}$, which is bounded below, for every real s, by $2s\langle H, \delta_K\zeta\rangle - s^2(\|\delta_K\zeta\|^2 + t^{-1}a_K^{-1}\int|\zeta|^2)$. Conversely, $\zeta_j = \partial(1-\mathcal{L}_{K_j})^{-1}H_j$ has $\delta_{K_j}\zeta_j = (1-\mathcal{L}_{K_j})^{-1}H_j - H_j \to (1+A_\star)^{-1}F - F$ by (A3), and $(F,(1+A_\star)^{-1}F - F) = -\int \frac{\lambda}{1+\lambda} d\nu_F \ne 0$. For constant z, $\int \partial_b F\,\mathrm{d}\mu^K$ is invariant under $\mathrm{Ad}(g)$ for all g, hence 0.

(f) The operator of the diffusion on linear functions has the trace $\kappa(1+s^2)+s^2$ and the determinant κs^2; its eigenvalues are $\lambda_+ \sim \kappa(1+s^2)$ and $\lambda_- \to s^2/(1+s^2)$, and the spectral measure of x puts a mass asymptotic to $\frac{1}{1+s^2}\lambda_+^{-1}$ at λ_+, so $\int \lambda\,\mathrm{d}\nu_x^\kappa = 1$ for all κ while $\mathcal{E}_\star(x) = s^2/(1+s^2)$. □

15.1.6. *Conditional fluctuation laws and transport estimates.*

Lemma 15.3 (Conditional laws along the renormalisation chain)**.** Assume (E), let $n \ge 1$ be an integer with $L^n\mathsf{b} \ge \mathsf{t}_\natural$, and let $K > n$. (i) $1 - \mathsf{R}_n \le \sigma^K(\Omega_K) \le 1$, and $\int f\,\mathrm{d}\sigma^K \le \int f\,\mathrm{d}\mu^K \le \int f\,\mathrm{d}\sigma^K + \mathsf{R}_n \sup f$ for bounded Borel invariant $f \ge 0$. (ii) For $0 \le k < t$, $d = K-k$, and every $W \in \mathsf{Cut}_{k+1}$, p_W is a probability measure with a positive continuous density on the box; σ_{d-1}^K is carried by Cut_{k+1}, and

$$\int \Big[\int f(V_W(B))\,p_W(\,\mathrm{d}B)\Big]\sigma_{d-1}^K(\,\mathrm{d}W) = \int f\,\mathrm{d}\sigma_d^K \qquad \text{for every Borel } f \ge 0 \text{ on } \Omega_d;$$

so the images of the p_W under the V_W form a regular conditional law of V_k given $V_{k+1} = W$ under σ^K, and under σ^K the sequence $V_t, \dots, V_0$ is a Markov chain from coarse to fine whose kernel at every $W \in \mathsf{Cut}_{k+1}$ is the image under V_W of p_W; the kernels carry bounded continuous functions on Cut_k to continuous functions on Cut_{k+1}, that is, $W \mapsto \int h(V_W(B))\,p_W(\,\mathrm{d}B)$ is continuous on Cut_{k+1} for every bounded continuous h on Cut_k; kernels and towers do not depend on the top level; $h_k(V_k)$ is the conditional mean of H given V_k; the tower of an invariant H is invariant at every point of Cut_k, with $\inf H \le h_k \le \sup H$; and a density that is a function of the first member V_t changes no kernel and no tower.

(iii) $\sigma_n^K = \mathsf{g}\,\mathrm{d}V$ on I_n, $\sup \mathsf{g} \le e^{\mathsf{o}_n} \inf \mathsf{g}$, and $(1-\mathsf{R}_n)e^{-\mathsf{o}_n} \le \mathsf{g}\,|\mathsf{I}_n| \le e^{\mathsf{o}_n}$ at every point. (iv) For $n \ge n_2$, $0 \le k < t$, $W \in \mathsf{Cut}_{k+1}$: $p_W = e^{-\Psi_W}dB$ with Ψ_W real-analytic and $\frac14\gamma_{\mathrm{r}} \le D^2\Psi_W \le \Lambda_+$; every tangent vector X of the fibre $\{\mathcal{M}V = W\}$ at $V_W(B)$ has $\|X\|^2 \le C_{\mathrm{ch}}\sum|X(b)|^2$, the sum over the bonds that are not pivot bonds; and for bounded $g \in C^1(\mathsf{Cut}_k)$

$$\mathrm{Var}_{p_W}(g\circ V_W),\quad \tfrac12\mathrm{Ent}_{p_W}\big((g\circ V_W)^2\big) \;\le\; C_{\mathrm{P}}\frac{a_d^2}{\mathsf{b}}\int \Gamma_d(g)(V_W(B))\,p_W(\,\mathrm{d}B),$$

with $C_{\mathrm{P}} = 4C_{\mathrm{ch}}/\gamma_{\mathrm{r}}$, which depends only on the constants of the construction, and not on K, k, W, ℓ or b. ■

Proof sketch. (i) is Prop. YM3_I:115.2, domination and lost-mass bounds, the comparison of the small-field chain with the bare density, with the weight $\mathfrak{w}_t^{\mathrm{sf}}$ and the bound R_n of the definitions preceding Prop. YM3_I:115.2; (ii): the weight defined before Prop. YM3_I:115.2 vanishes unless every V_j lies in its cut, so σ_{d-1}^K is carried by Cut_{k+1}. Positivity at every point, by induction over

the scales: with Σ_k the sum of the constants of the steps $1,\dots,k$ at the source 0, $e^{\Sigma_0}F_0 = F_0$ is the bare density on Cut_0 (the definition preceding Prop. YM3_I:114.2), and if $e^{\Sigma_k}F_k > 0$ on Cut_k, then $e^{\Sigma_{k+1}}F_{k+1} = \mathsf{I}[e^{\Sigma_k}F_k] > 0$ on Cut_{k+1} YM3_I:(2174), because the prefactors of the chart integral are positive, G_W and J_W are real ([7, Lem. B.3]) and the chart carries the box into Cut_k (Lem. YM3_I:113.10); so the density of p_W, a positive multiple of $e^{-x_k G_W + \mathsf{J}_W}(e^{\Sigma_k}F_k)\circ V_W$, is positive at every point of the box, and it is continuous, as $(W,B)\mapsto V_W(B), G_W(B), \mathsf{J}_W(B)$ are continuous and the chart integral of a continuous function is continuous ([7, Lem. B.3]), which makes every F_k continuous on Cut_k by the same induction.

The kernels carry bounded continuous functions to continuous functions, in the whole range $L^n\mathsf{b} \geq \mathsf{t}_\natural$: at a bounded continuous h on Cut_k the kernel at W is $\mathsf{I}[hF_k](W)/\mathsf{I}[F_k](W)$, the normalised chart integral [7, eq. 191] of the integrand of the chain; Cut_{k+1} lies in the set O^{im} (Lem. YM3_I:113.10), where the chart, its gauge-fixing form and the exponent of its Jacobians are continuous in (W,B) ([7, Lem. B.3]), and F_k is continuous on Cut_k, into which the chart carries the box; so the chart integrals of the non-negative functions $(\sup|h| \pm h)F_k$ integrate over the fixed box functions that are continuous in (W,B), Fatou's lemma on the box makes them lower semicontinuous in W, and as their sum $2\sup|h|\,\mathsf{I}[F_k] = 2\sup|h|\,e^{\mathsf{c}_{k+1}(0)}F_{k+1}$ is continuous by the induction above, both are continuous; the denominator $\mathsf{I}[F_k]$ is continuous and positive.

The identity: the factors of the weight of the levels $> k$ are functions of V_{k+1}; the measure of the chain of the level k is $\nu_k = e^{\Sigma_k}\mathbf{1}_{\mathsf{Cut}_k}F_k\,\mathrm{d}V$ the measure recursion in Prop. YM3_I:114.2, YM3_I:(2175); and by the identity of measures of the step ([7, Lem. B.3]) the image under $\mathcal{M}$ of $\mathfrak{G}_k[x_k]\chi^{\mathrm{sf}}_{x_k}\,h\,\nu_k$ has the density $e^{\Sigma_k}\mathsf{I}[h\mathbf{1}_{\mathsf{Cut}_k}F_k]$ on the open set O^{im}, which contains $\mathcal{W}_{k+1}(x_k;\alpha_0,\alpha_1)\supset \mathsf{Cut}_{k+1}$ (Lem. YM3_I:113.10), for every bounded Borel h on Ω_d, and on Cut_{k+1} this density is $e^{\Sigma_k}\mathsf{I}[hF_k]$, the chart carrying the box into Cut_k; dividing by $e^{\Sigma_k}\mathsf{I}[F_k]$ gives the identity for bounded Borel $f\geq 0$, and monotone convergence for every Borel $f\geq 0$.

As $V_{k+2},\dots,V_t$ are functions of V_{k+1}, the identity at $f = h\cdot(g\circ\mathcal{M})$ is the Markov property with the kernel p_W. The tower of an invariant H is invariant at every point by the covariance of the chain under the gauge transformations that are constant on blocks; (iii) follows from the statements on the iteration from a level: by Prop. YM3_I:115.2, image identity and Prop. YM3_I:114.2, at the top the density is $e^{\Sigma+\Phi_t}$ on I_n, Σ a constant, with a non-classical part bounded by $C_{\mathrm{nl}}\frac{L}{L-1}E_0(\ell L^n)^3$ (equation YM3_I:(2180)) and a classical part between 0 and $\frac{3}{2}c_\rho^2 A_0^2(\log L^n\mathsf{b})^{2\mathfrak{p}_0}(\ell L^n)^3$ (by YM3_I:(2161) at the weight x_t), so it oscillates by at most o_n, and its mass is that of (i).

(iv): at every $W\in\mathsf{Cut}_{k+1}$, which lies in the class $\mathcal{W}_{k+1}(x_k;\alpha_0,\alpha_1)$ of the sum rule (Lemma YM3_I:113.10), the sum identities in equations YM3_I:(828)–YM3_I:(830) and their preceding Jacobian calculation and the step (Prop. 6.32) give the density of p_W the form $e^{\mathcal{E}(P_W;B)}$, normalised, of Prop. 15.4(b). This form holds at every depth, at every W of the class of the sum rule, where the restrictions of P_W to the polymers lie in the analyticity cores and the sum rules hold, so that every term of $\mathcal{E}(P_W;\cdot)$ is formed and holomorphic in B on $\{|B(b)|<C_A\mathfrak{b}(x_k)\}$ (Thm. YM3_I:W, Prop. YM3_I:51.4 and its proof, the potential definitions in Section YM3_I:51, and §15.3.1); the conditions of n_3 enter Prop. 15.4 only through the ball of complex triples of (a) and through the response.

So the form holds for every integer $n\geq 1$ with $L^n\mathsf{b}\geq\mathsf{t}_\natural$, from n_2 on in particular, as Prop. 15.4(b) states. The density being positive by (ii), $e^{\mathcal{E}(P_W;\cdot)}$ is a constant multiple of a positive function, so the imaginary part of $\mathcal{E}(P_W;\cdot)$ is constant on the connected box, and $\Psi_W = -\mathcal{E}(P_W;\cdot) + \log\int e^{\mathcal{E}(P_W;B')}\,\mathrm{d}B'$, with the branch of the logarithm that makes it real, is real-analytic near the closed box. Its Hessian is $D^2\Psi_W = \mathsf{A}_W - D^2\sum_Y v_Y$, with the form $\mathsf{A}_W = \sum_Y \mathsf{b}_Y(P_W) + \sum_\square \hat{\mathsf{G}}_\square(P_W)$ of the Gaussian integral of one step at P_W, whose inverse is the whole covariance of the step at P_W.

It lies within $\frac{1}{2}\mathsf{u}_{\mathrm{G}}(LM)^{-3}\leq\frac{1}{2}\gamma_{\mathrm{r}}$, in the ℓ^2 operator norm, of a real reference form whose floor and ceiling are γ_{r} and c_{r} (the completeness (St4) of Def. YM3_I:47.2, Thm. YM3_I:W, the proof of Prop. YM3_I:113.4), so $\frac{1}{2}\gamma_{\mathrm{r}}\leq\mathsf{A}_W\leq c_{\mathrm{r}}+\frac{1}{2}\gamma_{\mathrm{r}}$. The potentials are bounded by a constant times

$\delta(x_k)\mathfrak{b}(x_k)^2 e^{-\lambda d(Y)}$ on the whole product of the cores and the polydisc of radius $C_A\mathfrak{b}(x_k)$, so at P_W for every W of the class of the sum rule (Thm. YM3_I:W, Prop. YM3_I:51.4 and its proof, as in the proof of Prop. 15.4(d)), and by Cauchy's estimate their Hessians are at most $C_{\mathrm{Hs}}\delta(x_k) \le \frac{1}{4}\gamma_{\mathrm{r}}$ for $n \ge n_2$; hence $\frac{1}{4}\gamma_{\mathrm{r}} \le D^2\Psi_W \le c_{\mathrm{r}} + \frac{3}{4}\gamma_{\mathrm{r}} \le \Lambda_+$.

The log-Sobolev inequality $\mathrm{Ent}_p(f^2) \le \frac{2}{\kappa}\int |\nabla f|^2 \,\mathrm{d}p$ of a probability measure $p = e^{-\Psi}dx$ on an open convex set with $D^2\Psi \ge \kappa$, at $\kappa = \frac{1}{4}\gamma_{\mathrm{r}}$ on the convex box, gives $\mathrm{Ent}_{p_W}(F^2) \le \frac{8}{\gamma_{\mathrm{r}}}\int |\nabla_B F|^2 \,\mathrm{d}p_W$, and its linearisation the Poincaré inequality with $\frac{4}{\gamma_{\mathrm{r}}}$; since $x_k^{-1} = a_d/\mathfrak{b}$, the chart gives $|\nabla_B(g\circ V_W)|^2 \le C_{\mathrm{ch}}x_k^{-1}|\partial g|^2 = C_{\mathrm{ch}}\frac{a_d^2}{\mathfrak{b}}\Gamma_d(g)\circ V_W$. □

Proposition 15.4 (Log-concavity of the fluctuation law)**.** Assume (E). For $0 \le k < K$, lengths at the level $k+1$ are measured in its units, in which the bare spacing is $\eta_{k+1} = L^{-(k+1)}$; $J^{(k+1)}(U) = \eta_{k+1}^{-3}\partial A_K(U) = L^{-3(K-k-1)}J(U)$ is the current (YM3_I:9.2) formed with this spacing; for a 1-form A and a configuration U, $(\nabla_\mu^U A_\nu)(x) = \eta_{k+1}^{-1}[\mathrm{Ad}(U(\langle x, x+\eta_{k+1}e_\mu\rangle))A_\nu(x+\eta_{k+1}e_\mu) - A_\nu(x)]$, and $|\nabla_U A|(b) = \max_\mu |(\nabla_\mu^U A_\nu)(x)|$ at the bond $b = \langle x, x+\eta_{k+1}e_\nu\rangle$. π_k^M is the partition of the torus into the cubes of side M in the units of level k (the partition π_k of Section YM3_I:72 (the definitions of $\mathcal{D}_j$ and d_j at its beginning)); $\mathcal{D}_k$ is the set of its localisation domains, the unions of cubes of π_k^M that are connected through their faces, which we call polymers; $d(Y) = d_k(Y)$ is the linear size YM3_I:72 (the definitions of $\mathcal{D}_j$ and d_j at its beginning) of a polymer Y, the least number of edges of a tree of edges of its cubes that meets all of them; $\mathrm{Bd}(Y)$ is the set of the bare bonds with an end point in Y; and for a function f of triples and a pair $(a, \mathbf{j})$ of complex 1-forms, $D_{(a,\mathbf{j})}f(P_W) = \frac{d}{dz}f(U_+, za, \mathbf{J}_+ + z\mathbf{j})|_{z=0}$.

There are $r_{\mathrm{c}} \in (0, \alpha_0/256]$, determined by the fixed radii $\alpha_0 < \alpha_1$ of the notation and the constants of Prop. YM3_I:51.10, and $C_{\mathrm{mx}} < \infty$, depending only on the constants of the construction, such that for $K > n \ge n_3$, $0 \le k < K - n$ ($k = 0$ included), $W \in \mathsf{Cut}_{k+1}$, any background U_+ over W, $\mathbf{J}_+ = J^{(k+1)}(U_+)$ and $P_W = (U_+, 0, \mathbf{J}_+)$:

(a) for every polymer $Y \in \mathcal{D}_k$ and complex 1-forms $A', \mathbf{j}$ on $\mathrm{Bd}(Y)$ with $|A'|, |\nabla_{U_+}A'|, |\mathbf{j}| < r_{\mathrm{c}}$ there, the triple $(U_+, A', \mathbf{J}_+ + \mathbf{j})$ on $\mathrm{Bd}(Y)$ lies in the analyticity core $\mathcal{U}_{k+1}^\circ(Y; \alpha_0, \alpha_1)$ (Def. YM3_I:49.1, Prop. YM3_I:51.10, first assertion);

(b) $p_W \propto e^{\mathcal{E}(P_W;B)}dB$, where

$$\mathcal{E}(P;B) = \sum_{Y\in\mathcal{D}_k}\left[-\tfrac{1}{2}(B, \mathsf{b}_Y(P)B) + v_Y(P;B)\right] - \tfrac{1}{2}\sum_{\square\in\pi_k^M}(B, \hat{\mathsf{G}}_\square(P)B),$$

$\mathsf{b}_Y = x_k D_B^2\Psi^{\mathrm{A}}(Y; P, 0)$ with Ψ^{A} of equations YM3_I:(815) and YM3_I:(816), v_Y the potentials of Thm. YM3_I:W and of the fourth family at zero source (Prop. 6.32), $\hat{\mathsf{G}}_\square$ of §15.3.1; the quadratic form, too, is a sum of local terms; and $(A', \mathbf{j}, B) \mapsto \mathcal{E}$ is holomorphic on the product of the ball of (a) with $\{|B(b)| < C_A\mathfrak{b}(x_k)\}$, $C_A \ge 3$, which contains the closed box. The formula for p_W, the locality of its quadratic form and the holomorphy of $B \mapsto \mathcal{E}(P_W; B)$ on $\{|B(b)| < C_A\mathfrak{b}(x_k)\}$ hold as well for every integer $n \ge 1$ with $L^n\mathfrak{b} \ge \mathfrak{t}_\natural$, so from n_2 on, with $K > n$, $0 \le k < K - n$, at every $W \in \mathsf{Cut}_{k+1}$ and any background U_+ over W: they need of W only that it lies in the class $\mathcal{W}_{k+1}(x_k; \alpha_0, \alpha_1)$ of the sum rule (Lem. YM3_I:113.10), at which the restrictions of P_W to the polymers lie in the analyticity cores;

(c) for W at a depth $\ge n_{\mathrm{a}}$, with $\mathcal{H}^+$ the response of U_+ at level $k+1$ (§5.3), $\mathbf{U}_\xi = e^{iL^{-k-1}\mathcal{H}^+(\xi)}U_+$, $W'_\xi = \mathcal{M}^{k+1}\mathbf{U}_\xi$ and $P_\xi = (U_+, \mathcal{H}^+(\xi), J^{(k+1)}(\mathbf{U}_\xi))$, there is $r_0 > 0$, which may depend on W and K, such that for real ξ with $\sup|\xi| < r_0$: $W'_\xi \in \mathsf{Cut}_{k+1}$ is a gauge transform of $e^{i\xi}W$, and $\mathbf{U}_\xi$ lies in the minimal orbits over W'_ξ and over $\mathcal{M}^k\mathbf{U}_\xi$; there is a chart $\check{V}_\xi(B)$ of the fibre over W'_ξ, real-analytic in (ξ, B) near the closed box, $\check{V}_0 = V_W$, with values in a compact invariant

subset of Cut_k; for every bounded Borel invariant H, $h_{k+1}(e^{i\xi}W) = \int h_k(\check V_\xi(B))\,\check p_\xi(\mathrm dB)$, where $\check p_\xi$ has the density $e^{\mathcal E(P_\xi;B)}/\int e^{\mathcal E(P_\xi;B')}\,\mathrm dB'$, real-analytic in ξ uniformly on the closed box, and $\check p_0 = p_W$; the frame, $\check p_\xi$ and $\psi_\xi = \frac{d}{ds}\mathcal E(P_{s\xi};\cdot)|_{s=0}$ do not depend on the choice of the axial element;

(d) for real ζ on the box and every pair $(a,\mathbf j)$ of complex bare 1-forms, with $\mu_y(a,\mathbf j)$ the largest of $|a|$, $|\nabla_{U_+}a|$, $|\mathbf j|$ at the bare bonds with an end point in the block of $y \in \Lambda_{K-k-1,\ell}$,

$$|\partial_\zeta D_{(a,\mathbf j)}\mathcal E(P_W;B)| \le C^\sharp_{\mathrm{mx}}(x_k)\,\mathfrak b(x_k)\,\|\zeta\|\Big(\sum_y \mu_y(a,\mathbf j)^2\Big)^{1/2},$$

with $C^\sharp_{\mathrm{mx}}$ depending on x_k only through $\delta(x_k) \le 1$; and for every real ξ on $\Lambda_{K-k-1,\ell}$, $\sup_B |\partial_\zeta\partial_s\mathcal E(P_{s\xi};B)|_{s=0}| \le C_{\mathrm{mx}}\mathfrak b(x_k)\|\zeta\|\|\xi\|$, $C_{\mathrm{mx}} = \mathsf B\sup_{\mathfrak t\ge\mathfrak t_\natural} C^\sharp_{\mathrm{mx}}(\mathfrak t)$.

■

Proof sketch. (a) Prop. YM3_I:52.3 holds for free radii $b_0, b_1 \in (0,1]$, with the threshold $\varepsilon_{\mathcal W}b_0$ for $\varpi(W)$; the threshold that enters n_3 is the one at the radii $b_0 = \frac12\alpha_0$, $b_1 = \frac12\alpha_1$, that is, $2\theta_d \le \varepsilon_{\mathcal W}\alpha_0$ for $d \ge n_3$. So every $W \in \mathsf{Cut}_{k+1}$ with $K-k-1 \ge n \ge n_3$ has $\varpi(W) < \theta_{K-k-1} \le \frac12\varepsilon_{\mathcal W}\alpha_0$, and by the plain-core verification in its proof P_W lies in the core $\mathcal U^\circ_{k+1}(Y;\frac12\alpha_0,\frac12\alpha_1)$ with half the radii. The outer substitution from half the radii (Prop. YM3_I:51.10 (first assertion) at the radii α_0,α_1) carries this triple, moved by $(A',\mathbf j)$ with $|A'|, |\nabla_{U_+}A'|, |\mathbf j| < r_{\mathrm c}$, into the core with the radii α_0,α_1: the halved radii leave the room $r_{\mathrm c}$.

(b) The density in the chart comes from the sum identities in equations YM3_I:(828)–YM3_I:(830) and their preceding Jacobian calculation and the step (Prop. 6.32); the quadratic form is a sum of local terms, obtained by subtracting polynomials that agree on an open set. The formula for p_W, the locality of its quadratic form and the holomorphy of $B \mapsto \mathcal E(P_W;B)$ on $\{|B(b)| < C_A\mathfrak b(x_k)\}$ need of W only that it lies in the class $\mathcal W_{k+1}(x_k;\alpha_0,\alpha_1)$ of the sum rule (Lem. YM3_I:113.10), where the restrictions of P_W to the polymers lie in the analyticity cores and the sum rules hold, so that every term of $\mathcal E(P_W;\cdot)$ is formed and holomorphic in B there (Thm. YM3_I:W, Prop. YM3_I:51.4 and its proof); so they hold for every integer $n \ge 1$ with $L^n\mathfrak b \ge \mathfrak t_\natural$, from n_2 on in particular.

Only the joint holomorphy in $(A',\mathbf j)$ on the ball of (a) uses (a), and with it the condition $2\theta_d \le \varepsilon_{\mathcal W}\alpha_0$ of n_3. (c) Moving W along the response keeps the background in the minimal orbit, so no control of the axial gauge is needed. With the residual gauge h_ξ such that the background over W'_ξ is $\mathbf U_\xi^{h_\xi}$, $\check V_\xi(B)$ is $V_{W'_\xi}(\mathrm{Ad}(h_\xi)B)$ carried back by h_ξ; its values at the pivots follow from the contraction there (the contraction leading to YM3_I:(800), with the inverse of the one-step pivot derivative bounded by $2L^2$ in YM3_I:(798)) and the implicit function theorem. Every term of $\mathcal E$ is invariant under $(P,B) \mapsto (P^u, \mathrm{Ad}(u)B)$ and depends on $P = (U,A',\mathbf J)$ only through $(e^{iL^{-k-1}A'}U,\mathbf J)$ (Thm. YM3_I:W, Def. YM3_I:52.1, Prop. YM3_I:51.4 and its proof, §15.3.1, and the pair and gauge covariance of Prop. 6.32), and $\mathrm{Ad}(h_\xi)$ keeps dB and the box: so the density depends on P_ξ alone, and no derivative of h_ξ enters.

The values lie in a compact subset because the regularity number of the backgrounds stays strictly below the cut. (d) Each local term is bounded on the whole product of the core and the polydisc (Prop. YM3_I:51.4 and its proof, Thm. YM3_I:W), for instance $|v_Y| \le 32C_V\delta(x_k)(d(Y)+1)C_A^2\mathfrak b(x_k)^2e^{-\lambda d(Y)}$ with constants C_V, λ of the step; Cauchy's estimate on a bidisc, the Cauchy–Schwarz inequality and the sum over polymers [7, eq. 320] give the first bound. At $s=0$, the derivative of $P_{s\xi}$ near y is at most $\mathsf B\,m_y(\xi)$ by Lem. 15.9, which also gives $\sum_y m_y(\xi)^2 \le \mathsf S^2\|\xi\|^2$. □

Proposition 15.5 (One-step transport of the Dirichlet energy)**.** For a level j and a $\mathfrak g$-valued function w of the bare bonds let $[w]_j^2 = \sum_y (L^j \max\{|w(b)| : b_- \in B^j(y)\})^2$, $B^j(y)$ the cube of L^{3j} bare sites centred at $y \in \Lambda_{K-j,\ell}$; then $L^{j/2}[w]_j \le L^{(j+1)/2}[w]_{j+1}$, $\|w\|^2 \le 3L^j[w]_j^2$, $[w]_0 \le \|w\|$, and $[\mathrm{Ad}(g)w]_j = [w]_j$. For $V \in \mathsf{Cut}_j$ at a depth $\ge n_{\mathrm a}$, U in the minimal orbit over V and a real 1-form

X on $\Lambda_{K-j,\ell}$, let $N_V^\flat(X) = L^{j/2}\min_\lambda[L^{-j}D\mathcal{H}_U(0)X - \mathrm{d}_U\lambda]_j$ for $j \geq 1$, $N_V^\flat(X) = \min_\lambda[X - \mathrm{d}_V\lambda]_0$ for $j = 0$, and $\Gamma_{K-j}^\flat(g)(V) = L^K \sup_{X:\, N_V^\flat(X)>0}\langle X, \partial g(V)\rangle^2/N_V^\flat(X)^2$.

$N_V^\flat$ is a seminorm that does not depend on the choice of U and vanishes exactly on the gauge directions; $N_V^\flat(X) \leq L^{j/2}\mathsf{M}\|X\|$, so $\Gamma_d \leq \mathsf{M}^2\Gamma_d^\flat$; $\Gamma_K^\flat(H) \leq 3\Gamma_K(H)$ for invariant H; and $\Gamma_d^\flat(g)$ is Borel for invariant $g \in C^1$. There are n_{a} as in the notation and $C_\flat$, depending only on L, C_Q, M and the constants of §5.3, such that, with $C_{\mathrm{cov}} = \frac{4}{\gamma_{\mathrm{r}}}C_{\mathrm{ch}}^{1/2}\mathsf{M}\sqrt{6}C_Q L^{-1/2}C_{\mathrm{mx}}$, for $K > n \geq n_{\mathrm{a}}$, $0 \leq k < K - n$, $W \in \mathsf{Cut}_{k+1}$:

(a) every real ξ' on $\Lambda_{K-k-1,\ell}$ has a representative ξ modulo gauge at W, depending on W, U_+, ξ' and not on B, with $\|\xi\| \leq \sqrt{6}C_Q L^{-(k+1)/2}N_W^\flat(\xi')$ and $N_{V_W(B)}^\flat(\check{\mathsf{d}}_k(W,B)\xi) \leq (1 + C_\flat\delta(x_k))N_W^\flat(\xi')$ for all B in the box, $\check{\mathsf{d}}_k(W,B)\xi = \frac{d}{ds}\check{V}_{s\xi}(B)|_{s=0}$; more precisely, for every bare velocity w of backgrounds at U_+ of level $k+1$ and $\xi = D\mathcal{M}^{k+1}(U_+)w$, $N_{V_W(B)}^\flat(\check{\mathsf{d}}_k(W,B)\xi) \leq (1 + C_\flat\delta(x_k))L^{(k+1)/2}[w]_{k+1}$;

(b) for real invariant $H \in C^1(\Omega_K)$ the tower has $h_k \in C^1(\mathsf{Cut}_k)$, and for $W \in \mathsf{Cut}_{k+1}$ and real ξ, with ψ_ξ of Prop. 15.4(c),

$$\langle \xi, \partial h_{k+1}(W)\rangle = \int \langle \check{\mathsf{d}}_k(W,B)\xi, \partial h_k(V_W(B))\rangle\, p_W(\,\mathrm{d}B) + \mathrm{Cov}_{p_W}(h_k \circ V_W, \psi_\xi),$$

$$\Gamma_{d-1}^\flat(h_{k+1})(W)^{1/2} \leq (1 + C_\flat\delta(x_k))\int \Gamma_d^\flat(h_k)^{1/2} \circ V_W\,\mathrm{d}p_W + C_{\mathrm{cov}}\,\delta(x_k)\Big(\int \Gamma_d^\flat(h_k) \circ V_W\,\mathrm{d}p_W\Big)^{1/2},$$

so $\Gamma_{d-1}^\flat(h_{k+1})(W) \leq (1 + \epsilon_d^\flat)\int \Gamma_d^\flat(h_k) \circ V_W\,\mathrm{d}p_W$ at every W; the same holds for $\phi_k = f_k^{1/2}$, (f_k) the tower of $G^2 + \epsilon$, G real invariant, $\epsilon > 0$;

(c) for $0 \leq k \leq K - n$,

$$\int \Gamma_{K-k}(h_k)\,\mathrm{d}\sigma_{K-k}^K \leq 3\mathsf{M}^2\Pi_n^\flat \int \Gamma_K(H)\,\mathrm{d}\sigma^K, \tag{15.ii}$$

and, pointwise, $\Gamma_e(g_{t'})(W) \leq 3\mathsf{M}^2\Pi_e^\flat\int \Gamma_K(G)\,\mathrm{d}\mathsf{P}_W$ for the law P_W of (B3) and every $W \in \mathsf{Cut}_{t'}$.

■

Proof sketch. (a) Three facts: the monotonicity of $L^{j/2}[w]_j$ in j, with constant one; $\|D\mathcal{M}^j(U)w\| \leq \sqrt{6}C_Q[w]_j$ when the plaquettes of U lie within $a_Q L^{-2j}$ of $\mathbf{1}$ (equation eq. 5.xxx); and

$$[L^{-j}D\mathcal{H}_V(\zeta)X]_j \leq \mathsf{BS}\|X\|$$

(§5.3). The key is that the gauge compensator is bounded pointwise: every bare velocity $w = L^{-j}D\mathcal{H}_U(0)X - \mathrm{d}_U\lambda$ is also $L^{-j}D\mathcal{H}_U(0)X^w + \mathrm{d}_U\nu$, $X^w = D\mathcal{M}^j(U)w$, with

$$|\nu(x)| \leq (k_6 + \tfrac{3}{2})\,\mathsf{B}\,m_y^j(X^w) + \tfrac{3}{2}L^j \max_{b_- \in B^j(y)}|w(b)| \qquad (x \in B^j(y)),$$

at the block centres by equation YM3_I:(996), with $k_6 = 4\kappa_{\mathrm{av}}$ as fixed in §5.3, and inside a block along a path, by $|\lambda(x)| \leq |\lambda(y)| + \frac{3}{2}L^j\max_{B^j(y)}|\mathrm{d}_U\lambda|$. Lift the velocity of level $k+1$ to a bare velocity w; the fluctuation B moves the background of level k by $O(\delta(x_k))$, so there is a curve of backgrounds of level k over $\check{V}_{s\xi}(B)$, up to a gauge, whose bare velocity differs from w by at most $C_\flat\delta(x_k)L^{1/2}[w]_{k+1}$ in $[\cdot]_k$; the monotonicity then costs nothing. The minimum in $N_W^\flat(\xi')$ is attained at some w; $\xi = X^w$ is the representative, and $\|\xi\| \leq \sqrt{6}C_Q[w]_{k+1}$.

The argument of (a) is deterministic. The properties of $N_V^\flat$: a curve of backgrounds whose block field moves with velocity X has a bare velocity w with $L^{j/2}[w]_j \geq N_V^\flat(X)$; $\Gamma_K^\flat \leq 3\Gamma_K$ because $\langle X, \partial H\rangle^2 = \langle X - \mathrm{d}_V\lambda, \partial H\rangle^2 \leq \|X - \mathrm{d}_V\lambda\|^2|\partial H|^2 \leq 3[X - \mathrm{d}_V\lambda]_0^2|\partial H|^2$ for invariant H and every λ; upper semicontinuity of $(V, X) \mapsto N_V^\flat(X)$ gives the Borel property.

(b) Differentiate Prop. 15.4(c) at $\xi = 0$; domination holds on the closed box, as the moving chart takes its values in a compact subset of Cut_k. The left side depends on ξ only modulo gauge: take the representative of (a); the first term is then at most $L^{-K/2}(1 + C_\flat\delta(x_k))N_W^\flat(\xi')\int\Gamma_d^\flat(h_k)^{1/2}\,\mathrm{d}p_W$. For the plain tower, the Poincaré inequality of p_W used twice gives $|\mathrm{Cov}_p(f,\psi)| \le \frac{4}{\gamma_\mathrm{r}}\|\nabla_B f\|_{L^2(p)}\sup|\nabla_B\psi|$. For the square roots, the log-Sobolev inequality of p_W with $\kappa = \frac14\gamma_\mathrm{r}$ gives $\log\int e^{s(\psi-\int\psi)}\,\mathrm{d}p \le s^2l^2/2\kappa$ when $|\nabla_B\psi| \le l$, and the variational formula of the entropy at ϕ^2 and $s(\psi - \int\psi)$, optimised in s, gives

$$|\mathrm{Cov}_p(\phi^2,\psi)| \le \frac{2l}{\kappa}\,\|\phi\|_{L^2(p)}\|\nabla_B\phi\|_{L^2(p)},$$

with equality for a Gaussian p, $\phi = e^{ax/2}$, $\psi = x$. By Prop. 15.4(d), $\sup|\nabla_B\psi_\xi| \le C_\mathrm{mx}\mathfrak{b}(x_k)\|\xi\|$; the chart factor $x_k^{-1/2}$ turns $\mathfrak{b}(x_k)$ into $\delta(x_k)$, and $L^{K/2}L^{-d/2}L^{-(k+1)/2} = L^{-1/2}$. Directions with $N_W^\flat(\xi') = 0$ contribute zero by gauge invariance; for the other directions divide by $L^{-K/2}N_W^\flat(\xi')$ (for the square roots by $2\phi_{k+1}(W) = 2\|\phi_k\circ V_W\|_{L^2(p_W)}$) and use Jensen's inequality for the probability p_W.

(c) Integrate the one-step bound against σ_{d-1}^K (Lem. 15.3(ii)) and iterate, using $\Gamma_d \le \mathsf{M}^2\Gamma_d^\flat$ at the top and $\Gamma_K^\flat \le 3\Gamma_K$ at the bottom; for the pointwise form iterate at the fixed block field along the kernels. The constant does not depend on K because $\sum_d\delta(L^d\mathfrak{b}) < \infty$. □

Proposition 15.6 (Transport in the ℓ^2 metric)**.** Assume (E). For $V \in \mathsf{Cut}_j$ with $\varpi(V)$ below the radius of §5.3, U in the minimal orbit over V and $\mathsf{Z} = L^{-j}D\mathcal{H}_U(0)$, let $N_V(\xi) = \min_\lambda\|\mathsf{Z}\xi - \mathrm{d}_U\lambda\|$ ($N_V(\xi) = \min_\lambda\|\xi - \mathrm{d}_V\lambda\|$ at $j = 0$). N_V is a seminorm that does not depend on the choice of U and vanishes exactly on the gauge directions; $N_V(\xi)^2 \le \|\mathsf{Z}\xi\|^2 \le C_\mathrm{rs}L^j\|\xi\|^2$, with C_rs depending only on L and the constants of §5.3. Every real ξ is $\xi_* + \mathrm{d}_V\phi$ with exactly one horizontal datum ξ_*, that is, with $\mathrm{d}_U^\mathsf{T}\mathsf{Z}\xi_* = 0$; on horizontal data $N_V(\xi_*) = \|\mathsf{Z}\xi_*\|$; every real ξ has $\|\xi\| \le C_\mathcal{Q}L^{-j/2}\|\mathsf{Z}\xi\|$, so $\|\xi_*\| \le C_\mathcal{Q}L^{-j/2}N_V(\xi_*)$, with $C_\mathcal{Q} = 34(L^3+2)$ as in Lem. 5.32 (a number other than the C_Q and C_Q' of Lem. 5.30); and the two metrics are equivalent: $3^{-1/2}N_V \le N_V^\flat \le \mathsf{M}C_\mathcal{Q}N_V$.

There are $C_\sharp$ and a depth $n_4 \ge n_3$, depending only on b and the constants of the construction, such that for $K - k > n_4$, $W \in \mathsf{Cut}_{k+1}$ and U_+ a background over W the following hold. All clauses of Prop. 15.4(c) hold at W, with the frame $\check V_\xi(B)$ real-analytic in (ξ, B) on $\{\sup|\xi| < r_0\}$ times the open box and with first derivatives in ξ that are bounded there. For every horizontal datum ξ at W, that is, every real ξ on $\Lambda_{K-k-1,\ell}$ with $\mathrm{d}_{U_+}^\mathsf{T}\mathsf{Z}_{k+1,U_+}\xi = 0$, $\mathsf{Z}_{k+1,U_+} = L^{-k-1}D\mathcal{H}^+(0)$, and all B in the box, $s \mapsto \check V_{s\xi}(B)$ is defined and real-analytic near 0 and

$$N_{V_W(B)}(\check{\mathsf{d}}_k(W,B)\xi) \le (1 + C_\sharp\,\delta(L^{K-k}\mathsf{b}))N_W(\xi).$$

Consequently Prop. 15.5(b), (c) hold as well in the metric N for $K > n \ge n_4$, (B3) for $K > e \ge n \ge n_4$, and (B2) in (a)–(c) for $n \ge \max\{n_4, n_\mathrm{c}\}$, in the proposed variant (d), still requiring the multiscale gauge estimate, for $n \ge \max\{n_4, n_\mathrm{e}\}$ with $\mathsf{R}_n < 1$, and in (e) for $n \ge n_4$, with $C_\mathrm{rs}\Pi_n$, $\Pi_n = \prod_{d>n}(1+\epsilon_d)$, $1 + \epsilon_d = [1 + (C_\sharp + \frac{4}{\gamma_\mathrm{r}}(C_\mathrm{ch}C_\mathrm{rs})^{1/2}C_\mathcal{Q}L^{-1/2}C_\mathrm{mx})\delta(L^d\mathfrak{b})]^2$, in the place of $3\mathsf{M}^2\Pi_n^\flat$ (in (B3): $C_\mathrm{rs}\Pi_e$ in the place of $3\mathsf{M}^2\Pi_e^\flat$). ■

Proof sketch. The range of Z. The response is in the Landau gauge on the kernel of the site averages: by equation YM3_I:(837), $\mathsf{R}^\mathrm{La}D^\mathsf{T}\mathcal{H} = 0$, $D = \mathrm{d}_U$, R^La the orthogonal projection onto $D^\mathsf{T}D\mathcal{N}$ and $\mathcal{N}$ the site functions whose site averages Q_q' vanish at the tops (§15.3); so $\mathsf{R}^\mathrm{La}\mathrm{d}_U^\mathsf{T}\mathsf{Z}\xi = 0$ for every ξ. The response is covariant, as the averaging map is, so Z carries the gauge directions $\mathrm{d}_V\psi$ of the block field to gauge directions at U; these meet $\mathrm{d}_U\mathcal{N}$ only in 0 (a $\mathrm{d}_U\mu$, $\mu \in \mathcal{N}$, in the range of Z has $\mathsf{R}^\mathrm{La}\mathrm{d}_U^\mathsf{T}\mathrm{d}_U\mu = 0$ while $\mathrm{d}_U^\mathsf{T}\mathrm{d}_U\mu$ lies in the range of R^La, so $\mathrm{d}_U\mu = 0$), and by the count of dimensions the two together span all the gauge directions at U.

A horizontal velocity of backgrounds at U, $h = \mathsf{Z}X - \mathrm{d}_U\lambda$ with $\mathrm{d}_U^\mathsf{T} h = 0$, is then $\mathsf{Z}X' - \mathrm{d}_U\nu$ with $\nu \in \mathcal{N}$, and $\mathsf{R}^{\mathrm{La}}\mathrm{d}_U^\mathsf{T}\mathrm{d}_U\nu = \mathsf{R}^{\mathrm{La}}\mathrm{d}_U^\mathsf{T}\mathsf{Z}X' = 0$: so $\mathrm{d}_U\nu = 0$ and $h = \mathsf{Z}X'$. The range of Z holds every horizontal velocity of backgrounds, with no compensator.

The decomposition. The part h of $\mathsf{Z}\xi$ orthogonal to the range of d_U is a horizontal velocity of backgrounds, $h = \mathsf{Z}\xi_*$; $\mathsf{Z}(\xi - \xi_*)$ is a gauge direction at U, so $\xi - \xi_*$ is a gauge direction at V; ξ_* is unique, as Z is injective (below) and a horizontal vector that is a gauge direction vanishes.

The bound. Lem. 5.32 applies in the constant frame, with bare spacing L^{-j} and terminal spacing one. It gives $\mathcal{Q}(\mathcal{H}_U(\zeta)) = \zeta$, and hence $L^j K_0 \mathsf{Z}\xi = \xi$, together with $\|K_0\| \le 2L^{-3j/2} \le C_\mathcal{Q} L^{-3j/2}$ on counting-measure ℓ^2. Thus $\|\xi\| \le C_\mathcal{Q} L^{-j/2}\|\mathsf{Z}\xi\|$; on horizontal data $\|\mathsf{Z}\xi_*\| = N_V(\xi_*)$. The equivalence follows from $\|w\|^2 \le 3L^j[w]_j^2$ and $N_V^\flat(\xi) = N_V^\flat(\xi_*) \le L^{j/2}\mathsf{M}\|\xi_*\|$.

The estimate. U_+ is a background of the level k as well, and the same argument at the level k shows that the velocity of a horizontal datum ξ at W is a response one level finer, with no compensator: $\mathsf{Z}_{k+1,U_+}\xi = \mathsf{Z}_{k,U_+}\zeta$, $\zeta = D\mathcal{M}^k(U_+)\mathsf{Z}_{k+1,U_+}\xi$; the fluctuation moves the background of level k by $O(\delta(x_k))$, which costs the factor $1 + C_\sharp\delta$.

The frame from the depth n_4 on. As $n_4 \ge n_3$, θ_d lies below the radius of §5.3; U_+ is a reference of the levels $k+1$ and k; for small real ξ, W'_ξ is a gauge transform of $e^{i\xi}W$ in Cut_{k+1}, $\mathbf{U}_\xi$ lies in the minimal orbits over W'_ξ and over $\mathcal{M}^k\mathbf{U}_\xi$, and $\xi \mapsto \mathcal{M}^k\mathbf{U}_\xi$, $\xi \mapsto W'_\xi$ are real-analytic. The value of $\mathcal{M}(V)$ at a bond c of $\Lambda_{K-k-1,\ell}$ reads V on the bonds of the double block of c alone, of the pivot bonds the pivot bond of c alone, and its derivative in the value at that pivot bond is invertible, with an inverse bounded by $2L^2$, on the compact closure of the set of the restrictions of the $V_W(B)$, B in the box.

The implicit function theorem, with radii that are uniform over this compact set, gives about every base point $V_W(B)$ exactly one solution at each pivot near the value of the base point, real-analytic in the data, with bounded first derivatives. The frame $\check{V}_\xi(B)$ is $e^{ix_k^{-1/2}B(b)}(\mathcal{M}^k\mathbf{U}_\xi)(b)$ at the bonds that are not pivot bonds and this solution at the pivots; by the uniqueness at the pivots and continuation in B along τB, $\tau \in [0,1]$, from $B = 0$, it is $V_{W'_\xi}(\mathrm{Ad}(h_\xi)B)$ carried back by h_ξ. Hence, as in Prop. 15.4(c): the tower identity; the density $e^{\mathcal{E}(P_\xi;B)}/\int e^{\mathcal{E}(P_\xi;B')}\,\mathrm{d}B'$ of $\check{p}_\xi$, which reads the depth only through n_3; the values in a compact invariant subset of Cut_k; analyticity on small ξ times the open box, with ξ-derivatives bounded there, which carries the domination in the differentiation of Prop. 15.5(b); and at the depths $\ge n_\mathrm{a}$ the frame is that of Prop. 15.4(c).

In the differentiated step the representative is used only through $\|\xi\| \le c\,L^{-(k+1)/2}N_W(\xi)$, which the horizontal datum of the class satisfies with $c = C_\mathcal{Q}$; the rest of the proof of Prop. 15.5 is unchanged, with the square field Γ^N built from N as $\Gamma^\flat$ is built from $N^\flat$, $N_V(X) \le C_\mathrm{rs}^{1/2}L^{j/2}\|X\|$ at the top and $\Gamma_K^N \le \Gamma_K$ at the bottom. □

Lemma 15.7 (Connected regions at the coarse scale)**.**

(a) Let $\mathsf{n} \ge \lambda_{\mathrm{BG},3}$, $0 < \kappa' \le \kappa_0$, $\mathsf{n} \ge \kappa'^{-1/2}$, and V a configuration on $(\mathbb{Z}/\mathsf{n})^3$ with $\varpi(V) \le \kappa'$. Some gauge has $|V^u(b) - \mathbf{1}| \le C_\mathrm{BG}\sqrt{\kappa'}$ at every bond; $\{\varpi < \kappa'\}$ lies in the path component of $\mathbf{1}$ in $\{\varpi < C''\kappa'\}$; so, at $\kappa' = r/C''$, for $0 < r \le C''\kappa_0$ and $\mathsf{n} \ge \max\{\lambda_{\mathrm{BG},3}, (C''/r)^{1/2}\}$, every other component of $\{\varpi < r\}$ lies in the shell $\{r/C'' \le \varpi < r\}$.

The estimate involving J block levels remains to be proved, as described under (Multiscale gauge). The proposed estimate requires finite constants; no numerical values for them are asserted here.

(b) For a finite set E of bonds, $0 < \alpha < \pi$, $\mathsf{K} \subset \{A \in \mathfrak{g}^E : |A(b)| < \alpha\}$ open and convex and $V_0 \in G^E$, $A \mapsto e^{iA}V_0$ maps K diffeomorphically onto its image B; there Haar measure is $\prod_b (2\pi^2)^{-1}\mathsf{j}(A(b))\,\mathrm{d}A(b)$, $\mathsf{j}(X) = (\sin|X|/|X|)^2$; $-\log\prod_b \mathsf{j}$ has Hessian $\ge \frac{2}{3}$; and $\mathrm{Ent}_{dV|\mathsf{B}}(\psi^2) \le 3\int_\mathsf{B} |\partial\psi|^2 dV$ for bounded locally Lipschitz ψ, whatever the number of bonds.

(c) If $\nu|_{S_i}$ have log-Sobolev constants c_i on open S_1, S_2 with $\nu(S_1 \cap S_2) > 0$, then $\nu|_{S_1\cup S_2}$ has $2\max_i c_i(1 + 16\nu(S_1 \cup S_2)/\nu(S_1 \cap S_2))$. If Haar measure on an open S' has the constant c,

$\rho(V) = \int \mathbf{1}_{S'}(V^g)\,\mathrm{d}g$, $\rho_0 > 0$ and $w = \min\{1, \rho/\rho_0\}$, then $\mathrm{Ent}_{w\mathsf{g}\,\mathrm{d}V}(\phi^2) \le \frac{c\,\mathsf{g}_+}{\rho_0 \mathsf{g}_-} \int |\partial\phi|^2 w\,\mathsf{g}\,\mathrm{d}V$ for invariant ϕ and Borel $0 < \mathsf{g}_- \le \mathsf{g} \le \mathsf{g}_+$, whatever the boundary of S'. For an open invariant $\mathcal{O}$, a component C of it and a compact invariant $\mathcal{K} \subset \mathsf{C}$ there is a connected finite union S' of sets $\{e^{iA}V_i : |A(b)| < \delta_i\}$ with $\mathcal{K} \subset S' \subset \mathsf{C}$.

(d) The set $\mathcal{N} \subset (0,2)$ of the $r = \varpi(V)$ at which $\sum_p c_p \partial a_p(V) = 0$ for some $c \ge 0$, $c \ne 0$, carried by the plaquettes with $\varpi_p(V) = r$, is Lebesgue-null; for $r \notin \mathcal{N}$, $\{\varpi < r\}$ has finitely many components, each a connected open set with a Lipschitz boundary. The abelian fields whose $(1,2)$ plaquettes all equal $e^{if\sigma_3}$, $f = 2\pi m/\mathsf{n}^2$, and whose other plaquettes are $\mathbf{1}$, are such critical points: $2\sin(\pi m/\mathsf{n}^2) \in \mathcal{N}$ for integers $0 < m < \mathsf{n}^2/2$.

(e) For $0 < r < 2$, every connected component of $\{\varpi < r\}$ is open, invariant, and contains a local minimiser of ϖ. For $\phi_1 \in C^2[0,c)$, $c = \frac{1}{2}r^2$, with $\phi_1' > 0$ and $\phi_1 \to \infty$ at c, the function $\Phi = \sum_p \phi_1(a_p)$ has compact sublevel sets in $\{\varpi < r\}$, every component contains a point where Φ restricted to it is least, and there $\sum_p \phi_1'(a_p)\,\partial a_p = 0$ with weights $\phi_1'(a_p) > 0$ at all plaquettes and $\nabla^2\Phi \ge 0$; $\{\varpi < r\}$ is connected if and only if every local minimiser of Φ lies in the component of $\mathbf{1}$; and $\{\varpi < r\}$ is the increasing union of the sets $\{\sum_p a_p^q < c^q\}$, $q \to \infty$.

(f) Let $0 < \alpha \le \frac{1}{32}$, $r' = 64\alpha^2$, N the number of sites along an axis, and $\mathscr{D} = \{A : |A(b)| < \alpha\ \forall b,\ |Y_p(A)| < r'\ \forall p\}$, $e^{iY_p(A)} = \partial(e^{iA})(p)$, $|Y_p| \le \pi$. Then $\mathscr{D}$ is star-shaped, $\mathscr{D} = \{s\omega : |\omega| = 1,\ 0 \le s < \varrho(\omega)\}$ with $\frac{1}{2}r' \le \varrho \le \rho_{\max} = \alpha\sqrt{3N^3}$ and $|\varrho(\omega) - \varrho(\omega')| \le \frac{4\pi\rho_{\max}^2}{r'}|\omega - \omega'|$; $A \mapsto e^{iA}$ maps $\mathscr{D}$ diffeomorphically onto $\exp\mathscr{D} = \{V : \mathsf{d}(V(b), \mathbf{1}) < \alpha,\ \mathsf{d}(\partial V(p), \mathbf{1}) < r'\}$, and $\mathrm{Ent}_{\mathbf{1}_{\exp\mathscr{D}}dV}(\phi^2) \le C_{\mathscr{D}} \int_{\exp\mathscr{D}} |\partial\phi|^2 dV$ for bounded locally Lipschitz ϕ, with $C_{\mathscr{D}}$ of (B1)(e) at $\alpha_n = \alpha$.

With $w(V) = \int \mathbf{1}\{\mathsf{d}(V^u(b), \mathbf{1}) < \alpha\ \forall b\}\,\mathrm{d}u$ and $\mathsf{In} = \{V : \mathsf{d}(\partial V(p), \mathbf{1}) < r'\ \forall p\}$: $\int_{\mathsf{In}} f\,w\,\mathrm{d}V = \int_{\exp\mathscr{D}} f\,\mathrm{d}V$ for invariant Borel $f \ge 0$; $w(V) \ge [(\frac{1}{2}\alpha - \sin\frac{1}{2}\alpha)/2\pi]^{N^3}$ if some gauge brings all bonds of V within $\frac{1}{4}\alpha$ of $\mathbf{1}$; and $\mathsf{In} \cap \{w > 0\}$ is path connected.

■

Proof sketch. (a) The gauge is built cell by cell on a periodic grid of mesh $\kappa'^{-1/2}$, along the proof of Prop. 15.8; along the ray to 0 in exponential coordinates, $||\partial e^{itA}(p) - \mathbf{1}| - |t\,\mathrm{d}A(p)|| \le 10\alpha^2$, with $dA(p) = A(b_1) + A(b_2) - A(b_3) - A(b_4)$ the plain sum of the bond function A around p, its bonds $b_1, \dots, b_4$ taken with the signs $(+,+,-,-)$ of Lem. 16.2, when $|A| \le \alpha \le \frac{1}{8}$, which keeps the ray in $\{\varpi < C''\kappa'\}$. The multilevel estimate (Multiscale gauge) is a separate task; this construction concerns one scale.

For U(1) the flux sectors are distinct components. (b) The radial function $h(\rho) = -2\log(\sin\rho/\rho)$ on $\mathbb{R}^3$ has

$$h''(\rho) = 2\sum_{m\ge1}\left[(m\pi-\rho)^{-2} + (m\pi+\rho)^{-2}\right] \ge 4\sum_{m\ge1}(m\pi)^{-2} = \tfrac{2}{3}, \qquad \frac{h'(\rho)}{\rho} = 4\sum_{m\ge1}(m^2\pi^2-\rho^2)^{-1} \ge \tfrac{2}{3};$$

$|\nabla(\psi\circ\exp)| \le |\partial\psi|$ since $\frac{d}{ds}e^{i(X+sY)} = iZe^{iX}$ with $Z = \int_0^1 \mathrm{Ad}(e^{iuX})Y\,\mathrm{d}u$, $|Z| \le |Y|$; then the log-Sobolev inequality on a convex set, and locally Lipschitz ψ by the dilations $A_0 + \vartheta(A - A_0)$, $\vartheta \to 1$. (c) The first bound by comparing means on the overlap $S_1 \cap S_2$; the second by applying the inequality on S' in each orbit through the orbit average ρ, capped at ρ_0, and the bounded change of density g; the cover of $\mathcal{K}$ by chart balls inside C is joined along paths in C. (d) Sard's theorem on the strata indexed by the set of the maximal plaquettes; off $\mathcal{N}$ Gordan's alternative gives a common descent direction of all maximal plaquettes, which makes the boundary locally a Lipschitz graph.

At the abelian flux fields $\sum_p \partial a_p$ over the $(1,2)$ plaquettes vanishes. (e) Compactness of sublevel sets in the open set; a component is closed in $\{\varpi < r\}$, so a minimising sequence in it has its limit points in it. (f) Along rays the plaquette angle grows: $\frac{d}{dt}|Y(t)| \ge |Y| - 32\alpha^2$, which gives the star shape and the Lipschitz radial function; the log-Sobolev inequality on a star-shaped domain with

Lipschitz radial function follows by mapping it to a ball, at the cost of the Jacobian and of the Lipschitz constant, which is $C_{\mathscr{D}}$. The identity is Fubini over the gauge group; the lower bound counts, at each site, the gauge transformations within $\frac14\alpha$ of the given one, a ball of normalised volume $(\frac12\alpha-\sin\frac12\alpha)/2\pi$. □

15.1.7. *Completion of the limit and flow arguments. Step 1: compactness, motion and the Markov property, (A1)–(A3).* Let $K>n\ge n''$ and let $H\in C^1(\Omega_K)$ be real and invariant, with tower (h_k). Under σ^K, $h_k(V_k)$ is a martingale from the top to the bare level (Lem. 15.3(ii)), so $\int|H-h_t(V_t)|^2\,\mathrm{d}\sigma^K=\sum_{k<t}\int\mathrm{Var}_{p_W}(h_k\circ V_W)\,\sigma^K_{d-1}(\,\mathrm{d}W)$; Lem. 15.3(iv) at $g=h_k$, eq. 15.ii, $\sigma^K\le\mu^K$ on invariant functions, $\sum_{d>n}a_d^2=\frac{a_n^2}{L^2-1}$, and Lem. 15.3(i) for the passage to μ^K give

$$\|H-(\mathbf{1}_{\mathsf{l}_n}h_t)\circ\pi_{K,n}\|^2_{L^2(\mu^K)}\le\frac{C^\sigma C_{\mathrm P}}{L^2-1}\frac{a_n^2}{\mathsf b}\,\mathcal{E}_K(H)+4\mathsf R_n\sup|H|^2,\qquad\int\Gamma_n(h_t)\,\mathrm{d}\sigma_n^K\le C^\sigma\mathcal{E}_K(H).$$

(A2): after replacing H_j by smooth invariant functions with the same bounds (closure, a smooth contraction, the gauge average), let $c=\sup_j\sup|H_j|$, $e=\sup_j\mathcal{E}_{K_j}(H_j)$, and for $n\ge n''$ and $K_j>n$ let h_n^j be the top of the tower of H_j at $t=K_j-n$ and $g_n^j=\mathbf{1}_{\mathsf{l}_n}h_n^j$. The tops are bounded by c and, by the display and Lem. 15.3(iii), have Dirichlet integrals on l_n for Haar measure bounded uniformly in j. Rellich's theorem on compact subsets of the open set l_n, which needs no regularity of its boundary, the bound c, and diagonal sequences over an exhaustion of l_n by compact sets and over n, give one subsequence along which $h_n^j\to\phi_n$ in $L^2(\mathsf{l}_n,dV)$ for every $n\ge n''$.

The limit ϕ_n is a Haar class; as a function under μ_n we take a representative: let Ψ_n be $\mathbf{1}_{\mathsf{l}_n}$ times the gauge average of a Borel function in the class of ϕ_n with values in $[-c,c]$; it is Borel, invariant at every point, $|\Psi_n|\le c$, and $\Psi_n=\phi_n$ Haar-almost everywhere on l_n, as ϕ_n is invariant almost everywhere. Prop. 15.2(c) for $\mu_n^{K_j}$ at $f=|\Psi_n-g_n^j|^2\le4c^2$, which vanishes off l_n, gives $\int f\,\mathrm{d}\mu_n^{K_j}\le e^{\mathsf o_n}|\mathsf{l}_n|^{-1}\int_{\mathsf{l}_n}|\phi_n-h_n^j|^2\,\mathrm{d}V+4c^2\mathsf R_n$, so with the display

$$\limsup_j\|H_j-\Psi_n\circ\pi_{K_j,n}\|_{L^2(\mu^{K_j})}\;\le\;2c\,\mathsf R_n^{1/2}+\Big(\frac{C^\sigma C_{\mathrm P}}{L^2-1}\frac{a_n^2}{\mathsf b}\,e+4\mathsf R_nc^2\Big)^{1/2}=:\epsilon_n,\qquad\epsilon_n\to0.$$

Total variation enters only here: $\|\Psi_n(Y_n)-\Psi_{n'}(Y_{n'})\|_{L^2(\mu)}=\lim_j\|\Psi_n\circ\pi_{K_j,n}-\Psi_{n'}\circ\pi_{K_j,n'}\|_{L^2(\mu^{K_j})}\le\epsilon_n+\epsilon_{n'}$, so the invariant cylinder functions $\Psi_n(Y_n)$ converge in $L^2(\mu)$ to some G, $|G|\le c$, and $\lim_n\limsup_j\|H_j-\Psi_n\circ\pi_{K_j,n}\|_{L^2(\mu^{K_j})}=0$: $H_j\to G$ strongly. This holds along every sequence of cutoffs. (A1): let $H_j\to\Phi(Y_n)$ be a recovery sequence of Lem. 15.1(b), smooth, invariant, $\sup|H_j|\le\sup|\Phi|$ (truncation and the gauge average do not raise the energy). The conditional mean under σ^K given V_t is an $L^2(\sigma^K)$-contraction that fixes $\Phi(V_t)$, so the tops converge to Φ in $L^2(\sigma_n^K)$, hence in $L^2(\mathsf{l}_n,dV)$ by the lower bound of the density; the bound on $\int\Gamma_n(h_t)\,\mathrm{d}\sigma_n^K$, $\inf\mathsf g\ge(1-\mathsf R_n)e^{-\mathsf o_n}/|\mathsf{l}_n|\ge e^{-\mathsf o_n}/2|\mathsf{l}_n|$ and the lower semicontinuity of the Dirichlet integral give eq. 15.i.

As $\Gamma_n(a_p)=4a_n^{-1}|\mathsf s_p|^2$, by the computation of Lem. 16.2(a) on Ω_n, is positive at the fields of l_n with $\varpi_p>0$, $\mathcal{E}_\star(a_p(Y_n))>0$; since $\nu_\Psi(\{\infty\})=0$ for invariant Ψ, $(\Psi,(1-Q_t)\Psi)=\int(1-e^{-t\lambda})d\nu_\Psi>0$. (A3): for an invariant cylinder function Ψ and $t>0$, $H_j=P_t^{K_j}\Psi_{K_j}$ is invariant, $|H_j|\le\sup|\Psi|$, $\mathcal{E}_{K_j}(H_j)\le\sup|\Psi|^2/2et$ (Lem. 15.1(a)), and $H_j\to Q_t\Psi$ weakly; by (A2) every subsequence has a strongly convergent subsequence, whose limit is the weak limit; so $H_j\to Q_t\Psi$ strongly, which is one of the equivalent properties of Lem. 15.1(b), and with it all of them, (M1), and the convergence of $P_t^{K_j}H_j$ for all $H_j\to F$.

With (M2) of Lem. 15.1(b) the forms converge in the strong and weak sense, which gives the strong convergence of the resolvents by the theorem on the convergence of resolvents under convergence of forms in the strong and weak sense; Lem. 15.1(c) gives a dense domain and strong continuity. Compactness: fix a countable dense set (Φ_i) of invariant cylinder functions; for G_m in the set choose a cylinder function Ψ_m with $\|\Psi_m-G_m\|\le\frac1m$ and, by (M2), truncation at ±1 and the gauge average,

smooth invariant H_m on $\Omega_{K_{j(m)}}$ with $|H_m| \le 1$, $\mathcal{E}_{K_{j(m)}}(H_m) \le 1 + \frac{1}{m}$ and $\|H_m - \Psi_{m,K_{j(m)}}\| \le \frac{1}{m}$, where $j(m)$ increases so fast that $\|\Psi_{m,K} - \Phi_{i,K}\|$ is within $\frac{1}{m}$ of $\|\Psi_m - \Phi_i\|$ for $i \le m$ and $K \ge K_{j(m)}$; by (A2) a subsequence of (H_m) converges strongly to some G, then $G_m \to G$ in $L^2(\mu)$ along it, and $|G| \le 1$, $\mathcal{E}_\star(G) \le 1$ by (M1).

The criterion without a cutoff: $W_j = (1 - \mathcal{L}_{K_j})H_j$ is bounded in L^2, so a subsequence converges weakly to some W (a diagonal sequence over a countable dense set of cylinder functions); for invariant cylinder Ψ, $\int H_j \Psi_{K_j} \, \mathrm{d}\mu^{K_j} = \int W_j (1 - \mathcal{L}_{K_j})^{-1} \Psi_{K_j} \, \mathrm{d}\mu^{K_j} \to (W, (1 + A_\star)^{-1}\Psi)$, the resolvents being symmetric and strongly convergent, so $F = (1 + A_\star)^{-1} W \in D(A_\star)$; the weak limit $F - W = -A_\star F$ of $\mathcal{L}_{K_j} H_j$ does not depend on the subsequence, and $\mathcal{E}_{K_j}(H_j) = \langle H_j, W_j \rangle - \|H_j\|^2 \to (F, W) - \|F\|^2 = \mathcal{E}_\star(F)$. The bilinear forms: with $T_j^\alpha = \alpha(\alpha - \mathcal{L}_{K_j})^{-1}$ and $T^\alpha = \alpha(\alpha + A_\star)^{-1}$, $\mathcal{E}_{K_j}(T_j^\alpha u_j, v_j) = \alpha \langle u_j - T_j^\alpha u_j, v_j \rangle \to \alpha(u - T^\alpha u, v) = \mathcal{E}_\star(T^\alpha u, v)$, as $u_j - T_j^\alpha u_j \to u - T^\alpha u$ strongly; by the spectral theorem $\mathcal{E}_{K_j}(u_j - T_j^\alpha u_j) \le \mathcal{E}_{K_j}(u_j) - \alpha \langle u_j, u_j - T_j^\alpha u_j \rangle$, whose limit $\mathcal{E}_\star(u) - \int \frac{\alpha\lambda}{\alpha + \lambda} d\nu_u$ tends to 0 as $\alpha \to \infty$; with $|\mathcal{E}_{K_j}(u_j - T_j^\alpha u_j, v_j)| \le \mathcal{E}_{K_j}(u_j - T_j^\alpha u_j)^{1/2} \mathcal{E}_{K_j}(v_j)^{1/2}$, $\mathcal{E}_\star(v) \le \liminf_j \mathcal{E}_{K_j}(v_j)$ by (M1) and $\mathcal{E}_\star(T^\alpha u, v) \to \mathcal{E}_\star(u, v)$ this gives the convergence.

Step 2: the connected coarse-scale law, (B1). The regularity number of a background U of level k is $L^{2k} \max_p |\partial U(p) - \mathbf{1}|$, the maximum over the bare plaquettes ([7, Def. B.2]), and Cut_k is the set of the block fields over which it is $< c_\rho \varepsilon(x_k)$ (the definitions preceding Lem. YM3_I:113.10). By the curvature comparison in the proof of Lem. YM3_I:113.10, these numbers contract from level to level, by the factor L^{-2} up to $C_H \delta(x_k)$: for $W \in \mathsf{Cut}_{k+1}$ and B in the box, the regularity number of every background over $V_W(B)$ is at most L^{-2} times that of a background over W plus $C_H \delta(x_k)$; starting the chain j_1 levels higher, at every U in the support of its small-field weight,

$$\varpi(V_t) \le 2\vartheta\varepsilon_n, \qquad \vartheta = \vartheta_\infty + L^{-3j_1/2} c_\rho < 1.$$

The set $\mathcal{K}_0 = \{\varpi \le 2\vartheta\varepsilon_n\}$ is compact and lies in I_n; as D_n and $\mathsf{I}_n \setminus \mathsf{D}_n$ are open, it is the disjoint union of the compact invariant sets $\mathcal{K}_1 = \mathcal{K}_0 \cap \mathsf{D}_n$ and $\mathcal{K}_2 = \mathcal{K}_0 \setminus \mathsf{D}_n$, which are free of K. The convexity of one box joins $V_W(B)$ to $V_W(0)$ at a fixed W only; the j_1 levels are passed with the tower of a continuous function. Let $\mu_{t+j_1} = c_\rho \varepsilon(x_{t+j_1})$ and $\mu_k = L^{-2}\mu_{k+1} + C_H \delta(x_k)$ for $t \le k < t + j_1$, so that $\mu_t \le \vartheta\varepsilon_n$, and let D'_k be the set of the $W \in \mathsf{Cut}_k$ over which the regularity number is $< \mu_k$: $\mathsf{D}'_{t+j_1} = \mathsf{Cut}_{t+j_1}$, $V_W(B) \in \mathsf{D}'_k$ for $W \in \mathsf{D}'_{k+1}$ and every B in the box (Lem. YM3_I:113.10, the curvature comparison in the proof of Lem. YM3_I:113.10), and $\mathsf{D}'_t \subset \mathcal{K}_0$ (the small-curvature averaging bound of Prop. YM3_I:14.1).

Let h be continuous on Ω_n with values in $[0,1]$, $h = 1$ on $\mathcal{K}_1$ and $h = 0$ on $\mathcal{K}_2$ (Urysohn), and let $h_t = h$, $h_{k+1}(W) = \int h_k(V_W(B)) \, p_W(\mathrm{d}B)$, be its tower upward from the level t in the chain from the depth $n - j_1$. The kernels carry bounded continuous functions on Cut_k to continuous functions on Cut_{k+1} (as in the proof of Lem. 15.3(ii), where the integrands F_k are shown continuous on the cuts): the kernel at W is the normalised chart integral [7, eq. 191] of the integrand F_k of the chain at the level k; on Cut_{k+1}, which lies in the set O^{im} of the chart (Lem. YM3_I:113.10), the chart, its gauge-fixing form and the exponent of its Jacobian are continuous in (W, B), and the chart integral of a continuous function is continuous ([7, Lem. B.3]); F_k is continuous on Cut_k, into which the chart carries the box (Lem. YM3_I:113.10), and dominated convergence on the box applies.

By induction on k, h_k is continuous on Cut_k and takes on D'_k the values 0 and 1 alone: for $W \in \mathsf{D}'_{k+1}$ the function $B \mapsto h_k(V_W(B))$ is continuous on the convex box with values in $\{0,1\}$, hence constant, and as p_W is a probability, $h_{k+1}(W) = h_k(V_W(B))$ for every B in the box. Take all the fluctuations 0: for $W \in \mathsf{Cut}_{t+j_1}$ let $W^{(t+j_1)} = W$ and $W^{(k)} = V_{W^{(k+1)}}(0) = \mathcal{M}^k U_+^{(k)}$, $U_+^{(k)}$ a background over $W^{(k+1)}$. The backgrounds are nested: $U_+^{(k)}$ is a background over $W^{(k)}$ as well ([7, Lem. B.4](2)), so the regularity number over $W^{(k)}$ is exactly L^{-2} times that over $W^{(k+1)}$ (the identity $\mathsf{m}_k = L^{-2}\mathsf{m}_{k+1}$), with no $C_H \delta(x_k)$; hence $\varpi(W^{(t)}) < 2L^{-2j_1} c_\rho \varepsilon(x_{t+j_1}) \le 2L^{-3j_1/2} c_\rho \varepsilon_n \le 2\varepsilon_n / C''$, $W^{(t)} \in \mathsf{D}_n$ by Lem. 15.7(a), so $W^{(t)} \in \mathcal{K}_1$ and $h_{t+j_1}(W) = h(W^{(t)}) = 1$.

On the support of the small-field weight of the chain from the depth $n-j_1$, $V_{t+j_1}\in \mathsf{Cut}_{t+j_1}$ and $V_k=V_{V_{k+1}}(B_k)\in \mathsf{D}'_k$, so $h(V_t)=h_{t+1}(V_{t+1})=\cdots=h_{t+j_1}(V_{t+j_1})=1$; as $V_t\in\mathcal{K}_0$ and $h=0$ on $\mathcal{K}_2$, $V_t\in\mathcal{K}_1$. Of the dependence on W this argument uses the continuity of the kernels alone. So $\sigma_n^K(\Omega_n\setminus\mathcal{K}_1)\le \mathsf{R}_{n-j_1}$ by Lem. 15.3(i) for the chain from depth $n-j_1$. Glue finitely many chart balls in D_n to a connected $S'\supset\mathcal{K}_1$ (Lem. 15.7(b), (c)), put $w_n=\min\{1,\rho/\rho_0\}$, $\rho_0=\min_{\mathcal{K}_1}\rho>0$, so that $w_n=1$ on $\mathcal{K}_1$ and $w_n=0$ off D_n: this is (a).

Lem. 15.7(c) with the density of σ_n^K, $\sup \mathsf{g}\le e^{\mathsf{o}_n}\inf\mathsf{g}$ (Lem. 15.3(iii)), and $\Gamma_n=a_n^{-1}|\partial\cdot|^2$ give (b) with $C_n^{\mathrm{t}}=a_nc(S')e^{\mathsf{o}_n}/\rho_0$. (c): the linearisation of (b) gives $\int(\phi-c)^2w_n\,\mathrm{d}\sigma_n^K\le\frac12 C_n^{\mathrm{t}}\int\Gamma_n(\phi)w_n\,\mathrm{d}\sigma_n^K$, and the part where $w_n<1$ costs at most $\mathrm{osc}(\phi)^2\mathsf{R}_{n-j_1}$. (d): $\mathrm{Ent}_{\sigma_n^K}(\phi^2)\le\int\Xi(\phi^2,c')\,\mathrm{d}\sigma_n^K=\mathrm{Ent}_{w_n\sigma_n^K}(\phi^2)+\int\Xi(\phi^2,c')(1-w_n)\,\mathrm{d}\sigma_n^K$. (e): the explicit-top sketch still requires the multiscale gauge estimate. The conditions of n_{e} are those of (Multiscale gauge) at $J=J_n$; a field of I_n whose block fields $\mathcal{M}^jV$, $j\le J_n$, lie in the cuts has a gauge with all bonds within $44\pi L^2\sum_{j<J_n}\theta_{n-j}+C_{\mathrm{S}}L^{-J_n}\le\frac14\alpha_n$ of $\mathbf{1}$, so $w_n^{\mathrm{e}}\ge c_n$ there by Lem. 15.7(f), $\chi_n=1$, and $\sigma_n^K(\chi_n<1)\le\mathsf{R}_{n-J_n}$ by Lem. 15.3(i) for the chain from depth $n-J_n$.

Since $r'_n=2\arcsin\varepsilon_n=64\alpha_n^2$ is the angle of the radius $2\varepsilon_n$, $\mathsf{I}_n=\{\mathsf{d}(\partial V(p),\mathbf{1})<r'_n\ \forall p\}$, and the identity of Lem. 15.7(f) carries the log-Sobolev inequality of Haar measure on $\exp\mathscr{D}$ to invariant functions under $w_n^{\mathrm{e}}dV$, then to χ_ndV at the cost c_n^{-1}, and to $\chi_n\sigma_n^K$ at the cost $e^{2\mathsf{o}_n}/(1-\mathsf{R}_n)$ of the density: this is $C_n^{\flat}$. The set $\{\chi_n>0\}\cap\mathsf{I}_n$ is the path connected set of Lem. 15.7(f); it contains $\mathbf{1}$, so it lies in D_n. For the block-field laws, $\mathrm{Var}_{\mu_n^K}(\Phi)\le\int(\Phi-c)^2\,\mathrm{d}\mu_n^K\le\int(\Phi-c)^2\,\mathrm{d}\sigma_n^K+\mathsf{R}_n\mathrm{osc}(\Phi)^2$ by Lem. 15.3(i), then (c) with χ_n and $\int\Gamma_n(\Phi)\,\mathrm{d}\sigma_n^K\le\int_{\mathsf{I}_n}\Gamma_n(\Phi)\,\mathrm{d}\mu_n^K$; for μ_n by total variation.

Step 3: weak Poincaré bounds and mixing, (A4). Let c be the mean of H under ς^K. The density $w_n(V_t)$ is a function of the first member of the chain, so it changes no kernel and no tower, and

$$\int(H-c)^2\,\mathrm{d}\varsigma^K=\int(H-h_t(V_t))^2\,\mathrm{d}\varsigma^K+\int(h_t-c)^2w_n\,\mathrm{d}\sigma_n^K\le\mathsf{C}_n\mathcal{E}_K(H),$$

the first term by the martingale sum of Step 1, the second by (B1)(b) linearised and eq. 15.ii at $k=t$; passing to μ^K costs $\mathsf{r}_n\mathrm{osc}(H)^2$ by (B2)(a). This is (a), first for smooth H and then by closure. (b): $\frac{d}{dt}\mathrm{Var}(P_t^KH)=-2\mathcal{E}_K(P_t^KH)\le-\frac{2}{\mathsf{C}_n}[\mathrm{Var}(P_t^KH)-\mathsf{r}_n\mathrm{osc}(H)^2]$, as $\mathrm{osc}(P_t^KH)\le\mathrm{osc}(H)$, and $\mathrm{Var}(H)\le\frac14\mathrm{osc}(H)^2$. (c): truncated and gauge-averaged recovery sequences and (a); if $\mathcal{E}_\star(F)=0$, then $\mathrm{Var}_\mu(F)\le\mathsf{r}_n\mathrm{osc}(F)^2$ for all admitted n. For non-constant bounded $F\in L^2_{\mathrm{inv}}$ the spectral measure ν_F is not carried by $\{0\}$, as else $\mathcal{E}_\star(F)=0$, and $\nu_F(\{\infty\})=0$ (Lem. 15.1(c)); so $(F,(1-Q_t)F)=\int(1-e^{-t\lambda})\,\mathrm{d}\nu_F>0$.

(d): $\varphi(t)=\|Q_{t/2}(F-\int F)\|^2$ has $\varphi'(t)=-\mathcal{E}_\star(Q_{t/2}(F-\int F))\le-\mathsf{C}_n^{-1}[\varphi(t)-\mathsf{r}_n\mathrm{osc}(F)^2]$ by (c) and spectral calculus, and $\varphi(0)\le\frac14\mathrm{osc}(F)^2$. If $Q_t\rho=\rho$, then $(\rho,(1-Q_t)\rho)=0$, ν_ρ sits at 0, $\mathcal{E}_\star(\rho)=0$, so $\mathcal{E}_\star(\rho\wedge M)=0$ for every M, and $\rho\wedge M$ is constant by (c): $\rho=1$. (e): apply (a) to H_K truncated at $\pm M_F$, which does not raise the energy and keeps $\|H_K-F_K\|\to0$, so that Var_{μ^K} of the truncation tends to $\mathrm{Var}_\mu F$; the second form is (a) itself.

(f): the same lines with the explicit top of (B1)(e).

Step 4: entropy along the chain and the conditional law, (B2), (B3). (a): Lem. 15.3(i) and $\int f(1-w_n(V_t))\,\mathrm{d}\sigma^K\le\sup f\,\sigma_n^K(w_n<1)$. (b): with f_k the tower of $G^2+\epsilon$ and $\phi_k=f_k^{1/2}$, since the p_W are probabilities the entropy splits along the chain,

$$\mathrm{Ent}_{\varsigma^K}(G^2+\epsilon)=\sum_{k<t}\int\mathrm{Ent}_{p_W}(f_k\circ V_W)\,\varsigma_{d-1}^K(\,\mathrm{d}W)+\mathrm{Ent}_{w_n\sigma_n^K}(f_t);$$

the fibres by Lem. 15.3(iv), $\mathrm{Ent}_{p_W}(\phi_k^2\circ V_W)\le2C_{\mathrm{P}}\frac{a_d^2}{\mathsf{b}}\int\Gamma_d(\phi_k)\circ V_W\,\mathrm{d}p_W$; the top by (B1)(b); and $\int\Gamma_d(\phi_k)\,\mathrm{d}\varsigma_d^K\le3\mathsf{M}^2\Pi_n^{\flat}\int\Gamma_K(G)\,\mathrm{d}\varsigma^K$ (Prop. 15.5(b), (c), as $\Gamma_K((G^2+\epsilon)^{1/2})\le\Gamma_K(G)$); sum over $d>n$ and let $\epsilon\to0$. (c): $\mathrm{Ent}_\nu(G^2)\le\int\Xi(G^2,c')\,\mathrm{d}\nu$ and (a). (d): for the proposed multiscale variant, the function $\mathsf{b}\mapsto2\varepsilon(L^n\mathsf{b})$ is smooth with a non-vanishing derivative where $\log L^n\mathsf{b}>2\mathfrak{p}_0$, so $2\varepsilon_n\notin\mathcal{N}$

for almost every b, for all m and n at once; by Lem. 15.7(d) D_n is then a connected Lipschitz domain, which carries a log-Sobolev inequality for the volume (the extension theorem, with the inequalities of Sobolev and Rellich), and the density bounds give $C_n^\sharp$; $\sigma_n^K(\mathsf{I}_n \setminus \mathsf{D}_n) \le \sigma_n^K(\chi_n < 1) \le \mathsf{R}_{n-J_n}$ by Step 2(e).

For every b, a radius $\tilde r \notin \mathcal{N}$ close to $2\varepsilon_n$ does the same at the cost η: the fields with $\chi_n = 1$ and $\varpi < \tilde r$ lie in the component of $\mathbf{1}$ in $\{\varpi < \tilde r\}$, since along the rays of Lem. 15.7(f) the plaquette angles stay below the larger of $32\alpha_n^2$ and their final values, and the shells $\{\tilde r \le \varpi < 2\varepsilon_n\}$ have σ_n^K-masses at most e^{o_n} times their relative Haar measure, uniformly in K. With χ_n the same lines as in (b). (e) is the splitting of (b) with the top law of σ^K itself. (B3): the splitting of (b), stopped at depth e and taken at a fixed block field W, needs no top: with $\Pi_{(e)} = \prod_{e<d\le K}(1+\epsilon_d^\flat) \le \Pi_e^\flat$,

$$\mathrm{Ent}_{\mathsf{P}_W}(G^2) \le \sum_{e<d\le K} 2C_{\mathrm{P}}\frac{a_d^2}{\mathsf{b}}\,3\mathsf{M}^2\Pi_{(e)}\int \Gamma_K(G)\,\mathrm{d}\mathsf{P}_W \le C_e^{\mathrm{fib}}\int \Gamma_K(G)\,\mathrm{d}\mathsf{P}_W,$$

and the one-step bound of Prop. 15.5(b), iterated pointwise, gives the bound on $\Gamma_e(g_{t'})(W)$; no factor depends on ℓ. P_W is a regular conditional law by Lem. 15.3(ii), also under ς^K, whose weight is a function of the top. Concentration: for real invariant ψ the log-Sobolev inequality, applied to $e^{s\psi/2}$, gives $\int e^{s(\psi-\psi_{t'}(W))}d\mathsf{P}_W \le e^{s^2C_e^{\mathrm{fib}}l^2/4}$, as $\int \psi\,\mathrm{d}\mathsf{P}_W = \psi_{t'}(W)$, then Chebyshev's inequality; for μ^K, the weight $\mathfrak{w}_t^{\mathrm{sf}}$ of σ^K vanishes unless $\mathcal{M}^{t'}U \in \mathsf{Cut}_{t'}$, and Lem. 15.3(i) bounds what μ^K adds to σ^K by R_n; both tails.

Step 5: entropy relaxation, (A5). (a) is (B2)(c) at $\nu = \mu^K$, with $\Xi(x,c) \le \bar M[1+\log(\bar M/c)]$ for $0 \le x \le \bar M$, $0 < c \le \bar M$, and $c' \ge m_2 - \mathsf{r}_n M_G^2$, as $\int G^2\,\mathrm{d}\varsigma^K \ge \int G^2\,\mathrm{d}\mu^K - \mathsf{r}_n M_G^2$ and $\varsigma^K(\Omega_K) \le 1$. (b): (B2)(b) for the normalised measure $\varsigma^K/\varsigma^K(\Omega_K)$ gives Gaussian concentration about $\bar\psi$, and (B2)(a) adds r_n. (c): $P_\tau^K f_0$ is smooth and strictly positive for $\tau > 0$, the kernel of the elliptic diffusion being positive, and

$$\tfrac{d}{d\tau}\mathrm{Ent}_{\mu^K}(P_\tau^K f_0) = -\mathcal{E}_K(P_\tau^K f_0, \log P_\tau^K f_0) \le -4\mathcal{E}_K((P_\tau^K f_0)^{1/2}) \le -\tfrac{4}{\mathsf{C}_n'}\big[\mathrm{Ent}_{\mu^K}(P_\tau^K f_0) - \mathsf{r}_n\bar M(1+\log\tfrac{2\bar M}{m_1})\big]$$

by (a) at $G = (P_\tau^K f_0)^{1/2}$, with $M_G^2 \le \bar M$, $m_2 = m_1$ and $m_1 - \mathsf{r}_n\bar M \ge \frac12 m_1$; Gronwall. For limits: (a) by recovery sequences, as integrals of continuous functions of bounded strongly convergent sequences converge; the decay first for invariant cylinder f_0 with values in $[0,\bar M]$, by (A3), and then by approximation in L^2_{inv} under the strict condition $\mathsf{r}_n\bar M < \frac12 m_1$; $\tau\to\infty$ and then $n\to\infty$ give $\mathrm{Ent}_\mu(Q_\tau F) \to 0$, and Pinsker's inequality gives the convergence in total variation.

The moments of the gauge-fixed field. Steps 6–10 use Prop. 16.1(a) through the following facts. Use the consequence (Adm) of (E) proved in Prop. 16.1, and let d_1 be a depth, free of K, such that every top depth $\ge d_1$ is admissible (the depth d_{adm} of the proof of Prop. 16.1(a)). With $\mathbb{E}^{[d]}$ the normalised chain measure from the top depth d and $\mathbf{B}_K$ its gauge-fixed field: (i) for every admissible d, $K > d$, $q < \infty$ and every index $\kappa' \in (0, \frac16)$,

$$\mathbb{E}^{[d]}\big[\|\mathbf{B}_K\|_{\kappa';a}^q\big]^{1/q} \;\le\; C(q,\kappa')\,L^{20d}, \tag{15.iii}$$

with C free of K and d: given the coarser layers, the layer of depth d' is a function of one fluctuation integral with conditional covariance at most $Ca_{d'}^2/\mathsf{b}$ and Gaussian tails (Lem. 15.3(iv)), the products of layers of two depths in the bilinear part of the rough norm are martingale differences, those of one depth are controlled by the bound (Q) of centred quadratic forms and by the cancellation in colour (Col), the conditional means by (M), all three set in the proof of Prop. 16.1(a), and the top field, of size at most a constant times L^{10d} in its regular gauge, enters to the second power; (ii) the short-time theory of the gauge-fixed flow, which uses no measure: the numbers c_1, c_2, c_3, $s_0(R)$, $a_0(R)$ at every index κ', the four bounds of A_s, ∇A_s, $A_s - P_s\mathbf{B}$, $\nabla(A_s - P_s\mathbf{B})$, monotone in R, the bound of the flowed action and the Lipschitz bound in the rough distance; (iii) for invariant Borel

$F \geq 0$ and $r > 1$,

$$\langle F\rangle_{\mu^K} \;\leq\; \mathbb{E}^{[d_1]}[F] + \sum_{d_1 \leq d \leq K-2} \mathsf{R}_d^{1-1/r}\, \mathbb{E}^{[d+1]}\big[F^r\big]^{1/r} + \mathsf{R}_{K-1} \sup F, \tag{15.iv}$$

from the chains of all the top depths $d \geq d_1$, each compared with the bare density by Lem. 15.3(i), and Hölder's inequality; and $\sum_d \mathsf{R}_d^{1/2} L^{pd}$ and $\sup_K \mathsf{R}_{K-1} L^{pK}$ are finite for every p, as R_d decays faster than every exponential in d; (iv) hence, with $\mathsf{N}' = \mathsf{N}'(U)$ of the head of Prop. 16.1 formed at the index κ', the least $\|\mathbf{B}\|_{\kappa';a}$ over the 1-forms $\mathbf{B}$ with $e^{ia_K\mathbf{B}}$ in the orbit of U, which is at most a fixed power of L^K at every field, $\mathsf{M}_q(\kappa') = \sup_K \langle \mathsf{N}'^q\rangle_{\mu^K} < \infty$, and the moments under μ^K, bounded uniformly in K, of $\sup_{0<s\leq 1} s^{\frac{3}{2}+\kappa'} A^a(U_s)$, of $(J,J)_a(U_\sigma)$ and of $a_K^{-4} \max_p a_p(U_\sigma)$ in Prop. 16.1(a), at every index $\kappa' \in (0, \frac{1}{6})$.

Step 6: flow identities and uniform estimates, (C1), (C2). (C1) is Lem. 15.1(a) with the integration by parts, and $\int \mathcal{L}_K H \,\mathrm{d}\mu^K = 0$. The formula for $P_t^K H^\sigma$: $\frac{d}{ds} P_s^K H^{\sigma+\mathsf{b}(t-s)} = P_s^K(\mathcal{L}_K - \mathsf{b}\,\partial_\sigma) H^{\sigma+\mathsf{b}(t-s)} = P_s^K \Delta_K H^{\sigma+\mathsf{b}(t-s)}$, integrated over $[0,t]$; the martingale is Itô's formula for the time-dependent function $(r,U) \mapsto H^{\sigma+\mathsf{b}(t-r)}(U)$, whose drift is $(\partial_r + \mathcal{L}_K) H^{\sigma+\mathsf{b}(t-r)} = \Delta_K H^{\sigma+\mathsf{b}(t-r)}$. (C2): on $\mathsf{O}_K(\bar C, \bar s)$, for all K and $\sigma \leq \bar s$, $\Lambda_\sigma \leq (8\bar C \sigma^{\frac{1}{4}-\frac{\kappa}{2}} + 4\bar C^2 \sigma^{\frac{1}{2}-\kappa})/(1-2\kappa)$ (Lem. 16.2(e)) and $A^a(U_{\bar s/2}) \leq E_\sharp = 6\ell^3(\bar C^2(\bar s/2)^{-\frac{1}{2}-\kappa} + \bar C(\bar s/2)^{-\frac{3}{4}-\frac{\kappa}{2}})^2$.

For $K \geq K_0$, the least K with $a_K E_\sharp \leq e_0$, Lem. 16.2(f) at $s_1 = \bar s/2$ gives $a_K^{-4} \max_p a_p(U_s) \leq Z_\sharp = \frac{5}{2} E_\sharp \min\{\bar s/2, x_0^4 E_\sharp^{-2}\}^{-3/2}$ for $s \geq \bar s$, so $\Lambda_\sigma \leq \Lambda_{\bar s} + (2Z_\sharp)^{1/2}$ for $\bar s < \sigma \leq 1$. With $G = \varphi(\mathcal{O}(f_1), \dots, \mathcal{O}(f_r))$,

$$\Gamma_K(H_K^\sigma) \leq e^{24\Lambda_\sigma} \|\nabla\varphi\|_\infty^2 \sum_i \Gamma_K(\mathcal{O}(f_i))(U_\sigma), \qquad |\partial_\sigma H_K^\sigma| \leq (\Gamma_K(G)(J,J)_a)^{1/2}(U_\sigma),$$

with $\frac{\sigma}{2}(J,J)_a(U_\sigma) \leq e^{24\Lambda_\sigma} A^a(U_{\sigma/2})$, $A^a(U_{\sigma/2}) \leq 24\ell^3\Lambda_\sigma^2\sigma^{-2}$ for $\sigma \leq \bar s$ and $\leq E_\sharp$ beyond, and Lem. 16.2(d). (b): the same pointwise inequalities without a set, with the moments (iv) of Prop. 16.1(a) above, by (Adm); the Lipschitz bound in σ is the integral of ∂_σ. (c): the second flow-time derivative involves $v^2\mathcal{O}(f)$ along the flow, which is bounded by $\mathsf{h}_s \Gamma_K(\mathcal{O}(f))^{1/2}$ plus $\|f\|_\infty$ times the square of the L^2 norm of the covariant gradient of the current and a term of the first level, $\mathsf{h}_s = a_K^{-7/2} \|\nabla^2 A_K(U_s)\, \partial A_K(U_s)\|$; a second level of the energy estimates rests on a floor of the Hessian on horizontal vectors by the action alone: Prop. 16.6(a) at $k = N-1$, where $\mathsf{e}_N^* = 2A^a$ and $a_K(N-1) \geq \frac{1}{2}\ell$, gives $a_K^{-2}\nabla^2 A_K(V)[X,X] \geq -c(A^a(V)^2 + \ell^{-2})\|X\|^2$ for horizontal X when $\max_p a_p(V) \leq \frac{1}{2}$, with an absolute c.

With it, for every field, $0 \leq \sigma_0 < \sigma$ and $E = A^a(U_{\sigma_0})$,

$$(J,J)_a(U_\sigma) \leq e\, E\, [(\sigma - \sigma_0)^{-1} + 2c(E^2 + \ell^{-2})] + 3072\, \ell^3 E^6.$$

Where $a_K E \leq \frac{1}{2}$, $\max_p a_p(U_s) \leq a_K A^a(U_s) \leq \frac{1}{2}$ for $s \geq \sigma_0$, as the action does not increase along the flow, so the floor applies to the current, which is horizontal and is carried by the linearised flow: $\partial_s (J,J)_a(U_s) \leq 2c(E^2+\ell^{-2})(J,J)_a(U_s)$, and the mean of $(J,J)_a(U_s)$ over the last interval before σ of length $\min\{\sigma - \sigma_0, (2c(E^2+\ell^{-2}))^{-1}\}$ is at most E divided by that length, as $\partial_s A^a(U_s) = -(J,J)_a(U_s)$, while $(J,J)_a(U_\sigma)$ is at most e times that mean; where $a_K E > \frac{1}{2}$, $a_K^{-1} < 2E$, and the crude bound $(J,J)_a \leq 48\ell^3 a_K^{-6}$ gives the last member. The second level needs more than this floor: with $g = \partial A_K(U_s)$, which is horizontal, and $\mathsf{Q}_s = a_K^{-5}\nabla^2 A_K(U_s)[g,g]$, $\partial_s (J,J)_a(U_s) = -2\mathsf{Q}_s$ and

$$\partial_s \mathsf{Q}_s = -2\mathsf{h}_s^2 - a_K^{-7}\nabla^3 A_K(U_s)[g,g,g],$$

and the cubic member has no sign. Plaquette by plaquette, with $|X|_p^2 = \sum_{b\in p} |X(b)|^2$ and the covariant forward differences ∇ of the field, $|\frac{d^3}{dt^3} a_p(e^{itX}V)|_{t=0}| \leq 6|X|_p^2(|\nabla_\nu X_\mu(x)| + |\nabla_\mu X_\nu(x)|) + 25\varpi_p |X|_p^3$ for $p = p_{\mu\nu}(x)$, since the cubic term of the plaquette is a sum of triple products of the four values of X at p, carried to its base point with their signs, each of which holds the sum of

the values at two parallel bonds, a covariant difference up to $2\varpi_p|X|_p$; so $|\nabla^3 A_K(V)[X,X,X]| \le 24\sqrt{2}\,\|X\|_{\ell^4}^2 \mathsf{D}(X) + 200(2A_K(V))^{1/2}\|X\|_{\ell^6}^3$, $\mathsf{D}(X)$ the ℓ^2 norm of ∇X.

Kato's inequality, $||X_\mu(x+a_K e_\nu)| - |X_\mu(x)|| \le |\nabla_\nu X_\mu(x)|$, and the Sobolev inequality of the periodic lattice with constants free of N, $\|u\|_{\ell^6} \le N^{-1}\|u\|_{\ell^2} + \frac{4}{\sqrt{3}}\|\nabla u\|_{\ell^2}$ and $\|u\|_{\ell^4}^4 \le \|u\|_{\ell^2}\|u\|_{\ell^6}^3$, bound these norms through $\|X\|$ and $\mathsf{D}(X) + N^{-1}\|X\|$. The same tools bound the remainder of the Weitzenböck identity of Lem. 16.2(h), at most a constant times $\sum_p \varpi_p |X|_p^2$, by $\frac{1}{8}\mathsf{D}(X)^2 + c(A_K(V)^2 + N^{-2})\|X\|^2$, c taken large enough: this is the floor in the form that keeps the covariant gradient, $\nabla^2 A_K(V)[X,X] \ge \frac{1}{8}\mathsf{D}(X)^2 - c(A_K(V)^2 + N^{-2})\|X\|^2$ for horizontal X when $\max_p a_p(V) \le \frac{1}{2}$, whence at $X = g$, $\mathsf{D}(g)^2 + N^{-2}\|g\|^2 \le 8\|g\|\,\|\nabla^2 A_K(U_s)g\| + 9c(A_K(U_s)^2 + N^{-2})\|g\|^2$.

Let $\sigma_1 = \min I$, $\sigma_0 = \frac{1}{4}\sigma_1$, $\Delta = \sigma_1 - \sigma_0$ and $E = A^a(U_{\sigma_0})$. Where $a_K E \le \frac{1}{2}$, the display bounds $(J,J)_a(U_s)$ by $\bar{\mathsf{y}} = \mathrm{e}\,E[2\Delta^{-1} + 2c(E^2 + \ell^{-2})]$ for $s \ge \sigma_0 + \frac{1}{2}\Delta$, and Young's inequality absorbs the cubic member into h_s^2 ($N^{-1} = a_K/\ell$, $A_K = a_K A^a$):

$$\partial_s \mathsf{Q}_s \le -\mathsf{h}_s^2 + \mathsf{B}, \qquad \mathsf{B} \le C\Big[\bar{\mathsf{y}}^{7/3} + E^2\bar{\mathsf{y}}^3 + ((E^2+\ell^{-2})^{5/4} + (E^2+\ell^{-2})^{3/2}E^{1/2})\bar{\mathsf{y}}^{3/2}\Big],$$

C absolute. Above, Q_s is at most its mean over the interval of length $\frac{1}{2}\Delta$ before s, that is half the fall of $(J,J)_a$ over that interval divided by its length, plus $\frac{1}{2}\mathsf{B}\Delta$; below, the floor gives $\mathsf{Q}_s \ge -c(E^2+\ell^{-2})(J,J)_a(U_s)$. So for $\sigma_1 \le r_1 < r_2$, $\int_{r_1}^{r_2} \mathsf{h}_s^2 ds \le \mathsf{Q}_{r_1} - \mathsf{Q}_{r_2} + \mathsf{B}(r_2 - r_1)$, and $a_K^{-5}\mathsf{D}(g)^2 \le 8\mathsf{Q}_s + 8c(E^2+\ell^{-2})(J,J)_a(U_s)$ bounds the square of the L^2 norm of the covariant gradient of the current. With $A_f = \sum_p f(x(p))a_p$, $v^2\mathcal{O}(f) = a_K^{-5}[\langle \nabla^2 A_K\, g, \partial A_f\rangle + \nabla^2 A_f[g,g]]$, and $|v^2\mathcal{O}(f)|(U_s) \le \mathsf{h}_s \Gamma_K(\mathcal{O}(f))(U_s)^{1/2} + \|f\|_\infty[3a_K^{-5}\mathsf{D}(g)^2 + 4c(E^2+\ell^{-2})(J,J)_a(U_s)]$; integrated over s between two points of I, with the Cauchy–Schwarz inequality in s, these are polynomials in E with powers at most 11, times the square root of the length.

Where $a_K E > \frac{1}{2}$, $a_K^{-1} < 2E$, and the crude bounds $|v^2\mathcal{O}(f)| \le 1536\|f\|_\infty \ell^3 a_K^{-8}$ and $|v\mathcal{O}(f)| \le 48\|f\|_\infty \ell^3 a_K^{-6}$ become powers of E, the square of the second one the power 12. As $E \le (4/\sigma_1)^{5/3}\sup_{0<s\le 1} s^{\frac{3}{2}+\kappa}A^a(U_s)$, this gives $|\partial_\sigma H_K^{\sigma''} - \partial_\sigma H_K^{\sigma'}| \le C_I|\sigma'' - \sigma'|^{1/2}(1 + \sup_{0<s\le 1} s^{\frac{3}{2}+\kappa}A^a(U_s))^{12}$ at every field and every cutoff, and the moments of Prop. 16.1(a), by (Adm), give (c).

Step 7: convergence of flowed observables along the full sequence, (C3). Bounded strongly convergent sequences are stable under continuous functions, so $\varphi(\Theta_1,\dots,\Theta_r)$, Θ_i of Prop. 16.1(c), under the proved conclusion (Adm), would converge strongly for f_i applied to the flowed loops once the flow-approximation step is established, and $|H_K^\sigma - \varphi(\Theta_1,\dots,\Theta_r)|$ is at most $\mathrm{Lip}(\varphi)\, r\, \eta$ on $\bigcap_i \mathsf{G}_K^{(i)}$ and at most $2\sup|\varphi|$ elsewhere; let $\eta, \epsilon \to 0$. The joint convergence in law identifies the limit as G_σ, an expression independent of the cutoff; only the Lipschitz constants of the f_i and of φ were used.

By (C2)(b), $\|\mathsf{G}_\sigma - \mathsf{G}_{\sigma'}\| = \lim_K \|H_K^\sigma - H_K^{\sigma'}\| \le C|\sigma - \sigma'|$. For $\dot{\mathsf{G}}_\sigma$: by (C2)(b), (c) the functions $\sigma \mapsto \int \Psi_K \partial_\sigma H_K^\sigma \,\mathrm{d}\mu^K$ are bounded and locally Hölder continuous of exponent $\frac{1}{2}$, uniformly in K; their primitives $\int \Psi_K H_K^\sigma \,\mathrm{d}\mu^K$ converge to $\int \Psi \mathsf{G}_\sigma \,\mathrm{d}\mu$; so the derivatives converge, locally uniformly, to the derivative of the limit, which is then continuously differentiable with a Hölder continuous derivative; the bound in L^2 and the density of the cylinder functions represent the limit as $\int \Psi \dot{\mathsf{G}}_\sigma \,\mathrm{d}\mu$ with $\dot{\mathsf{G}}_\sigma \in L^2_{\mathrm{inv}}$, along the full sequence.

Step 8: condenser cutoffs and the generator limit, (C4), (C5). Let $c_3' = c_3(\kappa/2)$, $R_\flat = 2(2 + c_3')$, $\rho = R/2(2+c_3')$, $q = 4p/\kappa$; $\bar{s}(R) = 2^{-j_0(R)}$ is the largest dyadic number $\bar{s}$ with $\bar{s} \le (c_1'\rho^{-2})^8$, which lies below the time $s_0(\rho)$ of Prop. 16.1(a) at the index $\frac{\kappa}{2}$, $c_1' = c_1(\frac{\kappa}{2})$; $c_{\mathrm{st}} R^2 \bar{s}^{\frac{1}{4}-\frac{\kappa}{2}} \le 1$; and $486R^2\bar{s}^{\frac{1}{2}-\kappa} + 108R\bar{s}^{\frac{1}{4}-\frac{\kappa}{2}} \le 1$, which by Lem. 16.2(e) at $\bar{C} = 9R$ gives $\Lambda_s \le 1$ for $s \le \bar{s}$ on $\mathsf{O}_K(9R,\bar{s})$. $\bar{K}(R)$ is the least integer above the depth d_1 of the conclusion (Adm) at which $a = a_K$ has $a \le (c_2'/\rho)^3$, which lies below $a_0(\rho)$ at the index $\frac{\kappa}{2}$, $c_2' = c_2(\frac{\kappa}{2})$, $c_{\mathrm{st}} R a^{\frac{1}{2}-\kappa} \le 1$, and $4a^2 \le \bar{s}(R)$.

Here c_{st} is an absolute constant of the short-time theory of the gauge-fixed flow; all these conditions are upper bounds of $\bar s$ and of a that decrease in R. Let $g_j = \sup\{\mathsf{m}_s(U_s) : s \in (2^{-j-1}, 2^{-j}] \cap [a_K^2, \bar s(R)]\}$, $g_\flat = a_K^{1/2+\kappa}$ min $\|\mathbf{B}\|_\infty$ over $e^{ia_K\mathbf{B}}$ in the orbit of U, $\mathsf{G}^* = \max\{g_\flat, \max_j g_j\}$, and $\chi_{K,R}$ the average of $\min\{1, \max\{0, 4 - 2\mathsf{G}^*/R\}\}$ against a product of smooth conjugation-invariant approximate identities supported on small rotations of the bond groups. On $\{\mathsf{G}^* \le 3R\}$, $\mathsf{G}^* \le c$ implies $U \in \mathsf{O}_K(3c, \bar s)$ and $\Lambda_s \le 1$ for $s \le \bar s$; there the pieces are locally Lipschitz for the L^2 metric, $\operatorname{lip} g_j \le C_L 2^{(j+1)(1-\kappa)/2}$, $\operatorname{lip} g_\flat \le 2a_K^{-1+\kappa}$, $C_L = 24e^{24}$, because the linearised flow smooths from L^2 modulo gauge: $\mathrm{Ad}(u)D\Phi_s(U)Y = \zeta + a_K^{-1}\mathrm{d}\vartheta$ with $\|\zeta\|_\infty \le 9e^{24}s^{-3/4}\|Y\|_2$ and $\|\nabla\zeta\|_\infty \le 17e^{24}s^{-5/4}\|Y\|_2$.

The rotations are chosen so small that G^* changes by at most $\frac{R}{2}$ under them; so $\chi_{K,R} = 1$ on $\{\mathsf{G}^* \le R\}$, $\chi_{K,R} = 0$ off $\{\mathsf{G}^* \le \frac52 R\} \subset \mathsf{O}_K(8R, \bar s(R))$, and the piece j counts in $\Gamma_K(\chi_{K,R})$ only where $g_j \ge R$. The short-time theory at the index $\frac\kappa2$, which gains $s^{\kappa/4}$, and $\mathsf{M}_q = \mathsf{M}_q(\frac\kappa2) < \infty$, the number of Prop. 16.1(a) at the index $\frac\kappa2$ under (Adm) ((iv) of the moments of the gauge-fixed field), give $\mu^K(g_j \ge R) \le \mathsf{M}_q\rho^{-q}2^{-pj}$ and $\mu^K(g_\flat \ge R) \le \mathsf{M}_q(2e^{12}/R)^q a_K^{2p}$; with $2^{(j+1)(1-\kappa)p - pj} \le 2^p 2^{-\kappa pj}$,

$$\mu^K(\chi_{K,R} < 1) \le \mathsf{M}_q[2\rho^{-q} + (2e^{12}/R)^q], \qquad \int \Gamma_K(\chi_{K,R})^p d\mu^K \le (\tfrac{2}{R})^{2p}\mathsf{M}_q\Big[\frac{C_L^{2p}2^p\rho^{-q}}{1-2^{-\kappa p}} + 4^p(\tfrac{2e^{12}}{R})^q\Big],$$

and we call the first of these bounds $\epsilon_p(R)$ and the second $C_\chi(p,R)$, $q = 4p/\kappa$. As $\Gamma_K(\chi_{K,R})$ vanishes off the shell $\{0 < \chi_{K,R} < 1\}$, Hölder's inequality on the shell bounds the energy, $\mathcal{E}_K(\chi_{K,R}) \le C_\chi(p,R)^{1/p}\epsilon_p(R)^{1-1/p} \le c(p)\mathsf{M}_q R^{-2-q}$, the exponents of R adding up to $-(2+\frac{q}{p}) - (q - \frac{q}{p})$, while the mass is only $\int(1-\chi_{K,R})^2\,\mathrm{d}\mu^K \le \mu^K(\chi_{K,R} < 1) \le \epsilon_p(R) \le c(p)\mathsf{M}_q R^{-q}$. The cutoff $\chi_{K,R}$ does not depend on p, so one cutoff serves all p, and

$$\bar\varkappa(R) := \min_{p\in\mathbb{N},\ p\le R}\Big[C_\chi(p,R)^{1/p}\epsilon_p(R)^{1-1/p} + \epsilon_p(R)\Big] > 0$$

bounds $\mathcal{E}_K(\chi_{K,R}) + \int(1-\chi_{K,R})^2\,\mathrm{d}\mu^K$ for $K \ge \bar K(R)$ and is at most $c(p)\mathsf{M}_{4p/\kappa}R^{-4p/\kappa}$ for every $p \le R$; so $R^{q'}\bar\varkappa(R) \to 0$ for every q'. The numbers $\bar s(R)$, $\bar K(R)$ are monotone in R, and G^* does not increase when $\bar s$ decreases; so for $R' \ge \frac52 R$, $\{\chi_{K,R} > 0\} \subset \{\mathsf{G}^*_{(R)} \le \frac52 R\} \subset \{\mathsf{G}^*_{(R')} \le R'\}$, on which $\chi_{K,R'} = 1$. The condenser cutoff: Lem. 16.5 at $\eta = 1 - \chi_{K,R}$, with $\varkappa \le \mathcal{E}_{K,1}(\eta,\eta) \le \bar\varkappa(R)$. (C5): by (C1) and Lem. 16.5, $\int \chi^{\mathrm{c}}_{K,R}\mathcal{L}_K H\,\mathrm{d}\mu^K = \mathcal{E}_K(w_{K,R}, H)$, so $|\int \chi^{\mathrm{c}}_{K,R}\mathcal{L}_K H^\sigma_K| \le \mathrm{osc}(\varphi)\bar\varkappa(R)$; moreover $|\int \chi^{\mathrm{c}}\mathsf{b}\,\partial_\sigma H - \mathsf{b}\,\partial_\sigma\langle H\rangle| = \mathsf{b}|\int w\,\partial_\sigma H| \le \mathsf{b}C_\partial\bar\varkappa(R)^{1/2}$, which gives the second line of (a).

(b) is the last part of Lem. 16.5, as $q(1-u) = 1 - q(u)$. (c): $\int\chi^{\mathrm{c}}(H'\mathcal{L}_K H - H\mathcal{L}_K H') = \mathcal{E}_K(w, HH') - 2\int H\,\Gamma_K(w,H')$, and $\Gamma_K(w,\cdot)$ vanishes off the shell. (d): by (C1) and Lem. 16.5,

$$\Big|\int\chi^{\mathrm{c}}F\mathcal{L}_K H - \int H\mathcal{L}_K F\Big| \le \sup|H|\,[2\|F\|_\infty\varkappa + (2\mathcal{E}_K(F)^{1/2} + \|\mathcal{L}_K F\|)\varkappa^{1/2}];$$

with a test sequence, $\int H^\sigma_{K_j}\mathcal{L}_{K_j}F_j\,\mathrm{d}\mu^{K_j} \to -\int(A_\star F)\mathsf{G}_\sigma\,\mathrm{d}\mu$ by (C3); the convergence of resolvents in (A3) gives $\alpha(\alpha - \mathcal{L}_{K_j})^{-1}W_j \to \alpha(\alpha + A_\star)^{-1}W$ strongly, bounded by $\sup_j\|W_j\|_\infty$, hence test sequences; c_F uses $\bar\varkappa \le \bar\varkappa^{1/2}$. The flow-time half: $\int\chi^{\mathrm{c}}F_j\partial_\sigma H^\sigma_{K_j}$ differs from $\partial_\sigma\int F_j H^\sigma_{K_j}$ by at most $\sup_j\|F_j\|_\infty C_\partial\bar\varkappa(R)^{1/2}$, and $\int F_j H^\sigma_{K_j} \to (F, \mathsf{G}_\sigma)$, locally Lipschitz in σ uniformly in j; this gives the identity of distributions.

Reversibility: take $F_j = \alpha(\alpha - \mathcal{L}_{K_j})^{-1}H'_{K_j}$, a test sequence for $F = \alpha(\alpha + A_\star)^{-1}\mathsf{G}'$, and note that $A_\star\alpha(\alpha + A_\star)^{-1}$ is self-adjoint. The criteria: for $F^\Lambda = \Lambda(\Lambda + A_\star)^{-1}\mathsf{G}_\sigma$ with its test sequence, $(A_\star F^\Lambda, \mathsf{G}_\sigma) = \int\frac{\Lambda\lambda}{\Lambda+\lambda}d\nu_{\mathsf{G}_\sigma}$ increases to $\mathcal{E}_\star(\mathsf{G}_\sigma)$ as $\Lambda\to\infty$, and is at most $\sup|\varphi|\,C_1$ after $R\to\infty$; in L^2 the same bound with Cauchy–Schwarz holds on a core of $A_\star$.

Step 9: lower energy bounds, (C6). By (Adm), let $\mathbb{P}_K$ be the normalised chain measure from the least top depth d_0 with $\mathsf{R}_{d_0} \le \frac12$ such that every top depth $\ge d_0$ is admissible, as in the head of Lem. 16.7. Take R with $\mathbb{P}_K(\|\mathbf{B}_K\|_{\kappa;a} > R) \le \frac14 p_*$ (by eq. 15.iii at $q = 1$ and Markov's

inequality, $R = \max\{1, 4C(1,\kappa)L^{20d_0}/p_*\}$), and d with $\theta_0 a_{d+1}^2 < \frac{3}{2}\sigma \le \theta_0 a_d^2$. On the complement $\{\|\mathbf{B}_K\|_{\kappa;a} \le R\}$ of this event and on the event of Lem. 16.7(a) at $s = \frac{3}{2}\sigma$, which meet in a $\mathbb{P}_K$-probability at least $\frac{3}{4}p_*$, Lem. 16.7(b) and the flow bounds of Prop. 16.1(a) give, for $\sigma \le \sigma_*$, where $\kappa < \frac{1}{6}$ makes the error of lower order,

$$\Gamma_K(A^a \circ \Phi_\sigma) \ge cR^{-2}\mathsf{b}^{-2}\ell^3\sigma^{-5/2+\kappa}, \qquad A^a \circ \Phi_\sigma \le S_*\sigma^{-3/2-\kappa},$$

on a closed invariant L_K with $\mathbb{P}_K(\mathsf{L}_K) \ge \frac{3}{4}p_*$, so $\mu^K(\mathsf{L}_K) \ge \frac{3}{8}p_*$ (Lem. 15.3(i), $\mathsf{R}_{d_0} \le \frac{1}{2}$); hence $\mu^K(\mathsf{L}_K \cap \{\chi_K = 1\}) \ge \frac{1}{4}p_*$, and $\Gamma_K(\varphi(A^a) \circ \Phi_\sigma) = \varphi'(A^a \circ \Phi_\sigma)^2\,\Gamma_K(A^a \circ \Phi_\sigma)$. The mean flowed action from below is the same argument at $s = \sigma$ with the last inequality of Lem. 16.7(b): $A^a \circ \Phi_\sigma \ge \frac{1}{8}k''_\Sigma \mathsf{b}^{-1}\ell^3\sigma^{-3/2}$, $k''_\Sigma = k_\Sigma\theta_0^{3/2}L^{-3}$, with μ^K-probability $\ge \frac{3}{8}p_*$, so $c_\circ = \frac{3}{64}p_*k''_\Sigma$.

From above, under μ^K and not only under a chain measure: on invariant functions the chain measure σ^K from a top depth d has a density $\bar{\mathfrak{w}} \in [0,1]$ with respect to μ^K, with $\int(1-\bar{\mathfrak{w}})\,\mathrm{d}\mu^K \le \mathsf{R}_d$ (Lem. 15.3(i)), so for invariant $F \ge 0$, by the Cauchy–Schwarz inequality, $\langle F\rangle_{\mu^K} \le \mathbb{E}^{[d]}[F] + \mathsf{R}_d^{1/2}\langle F^2\rangle_{\mu^K}^{1/2}$. Take $F = A^a \circ \Phi_\sigma$, with $\langle F^2\rangle_{\mu^K}^{1/2} \le \mathsf{C}\sigma^{-3/2-\kappa}$ by the moments (iv) of Prop. 16.1(a), under (Adm), and $d = d_\sigma$, the least depth $d \ge d_1$ with $\mathsf{R}_d \le \sigma^{2\kappa}$, an admissible top depth by (Adm); then the second member is at most $\mathsf{C}\sigma^{-3/2}$, and as R_d decays faster than every exponential in d, $L^{d_\sigma} = \sigma^{-o(1)}$ as $\sigma \to 0$.

Under $\mathbb{E}^{[d]}$, d admissible, the centred layers of all depths, with conditional covariances at most $Ca_{d'}^2/\mathsf{b}$, give $\mathbb{E}^{[d]}\|\mathrm{d}_a P_\sigma \mathbf{B}_K\|_2^2 \le c\,\mathsf{b}^{-1}\ell^3\sigma^{-3/2}$ against the heat kernel, with c free of d and K; the top field, the conditional means of the layers and the remainder of the logarithm add a lower power of σ times a number that grows at most like a power of L^d; on $\{\|\mathbf{B}_K\|_{\kappa;a} \le \sigma^{-\epsilon}\}$, $\epsilon > 0$ small, the last inequality of Lem. 16.7(b) passes from $\|\mathrm{d}_a P_\sigma \mathbf{B}_K\|_2^2$ to $2A^a \circ \Phi_\sigma$ at the cost of a lower power of σ; and off this event the bound $A^a \circ \Phi_\sigma \le c_4\ell^3(1 + \|\mathbf{B}_K\|_{\kappa;a})^{24}\sigma^{-3/2-\kappa}$ of Prop. 16.1(a) with eq. 15.iii at a large q costs at most $CL^{pd}\sigma^{-1}$.

So $\mathbb{E}^{[d]}[F] \le c\,\mathsf{b}^{-1}\ell^3\sigma^{-3/2} + CL^{pd}\sigma^{-3/2+\epsilon'}$ for large K, with some $\epsilon' > 0$, and at $d = d_\sigma$ the second member is $o(\sigma^{-3/2})$: with the bound $\mathsf{R}_{d_\sigma}^{1/2}\langle F^2\rangle_{\mu^K}^{1/2} \le \mathsf{C}\sigma^{-3/2}$ this gives $C_\circ$, for $0 < \sigma \le \sigma_{**}$. For $\vartheta < 1$ and for the probability that tends to 1: let $\psi \in C^\infty(\mathbb{R})$ take values in $[0,1]$. By Prop. 16.6(b) the square field of $\psi(\sigma^{3/2}A^a) \circ \Phi_\sigma$ is bounded on $\{\mathscr{N} \le R\}$ uniformly in K and in small σ, so by Prop. 16.6(d), that is, by the key estimate of Step 1, which rests on eq. 15.ii, the function $\chi'_K\,\psi(\sigma^{3/2}A^a \circ \Phi_\sigma)$, χ'_K the cutoff of Prop. 16.6(c), is within a distance in $L^2(\mu^K)$ that is small for large $\hat{d}_0$, uniformly in K and in small σ, of a function of the block field at depth $\hat{d}_0$; under (Adm), every $\hat{d}_0 \ge d_1$ is an admissible top depth, and $\mathsf{R}_{\hat{d}_0} \le \frac{1}{2}$ for large $\hat{d}_0$.

By the last clause of Lem. 16.7(a), at the top depth $\hat{d}_0$ in the place of d_0, off an event of probability τ_d the lower bounds hold, given the block field at depth $\hat{d}_0$, with a conditional probability that is bounded below by a positive number free of K, σ and $\hat{d}_0$; a function that is close to a function of the block field and exceeds a level with conditional probability bounded below exceeds a slightly smaller level with high probability. So the flowed action exceeds a fixed multiple of $\mathsf{b}^{-1}\ell^3\sigma^{-3/2}$ with a probability that tends to 1 as $\sigma \to 0$, uniformly in K; at the flow time $\frac{3}{2}\sigma$ this bounds $\|\mathrm{d}_a P_{3\sigma/2}\mathbf{B}_K\|_2^2$ from below, by the last inequality of Lem. 16.7(b), and the first inequality there, on $\{\|\mathbf{B}_K\|_{\kappa;a} \le R\}$ for a large R, gives the same for $\Gamma_K(A^a \circ \Phi_\sigma)$ and $\sigma^{-5/2+\kappa}$.

By Markov's inequality and the upper bound of the mean flowed action, $\mu^K(A^a \circ \Phi_\sigma > S_*\sigma^{-3/2-\kappa}) \le 2C_\circ\mathsf{b}^{-1}\ell^3\sigma^\kappa/S_*$ for $0 < \sigma \le \sigma_{**}$ and all large K, which tends to 0 with σ. Given $\vartheta < 1$, choose σ_ϑ so that the probability of these lower bounds, together with $A^a \circ \Phi_\sigma \le S_*\sigma^{-3/2-\kappa}$, exceeds $\frac{1}{2}(1+\vartheta)$ for all large K; the set $\{\chi_K = 1\}$, of mass $\ge 1-\vartheta$, meets this event in a mass $\ge \frac{1}{2}(1-\vartheta)$. The current: $\Gamma_K(A^a \circ \Phi_\sigma)(U) \le e^{24\Lambda_\sigma(U)}(J,J)_a(U_\sigma)$ by Lem. 16.2(b), since $\Gamma_K(A^a) = (J,J)_a$; by the tightness of Λ_σ (Prop. 16.1(a), under (Adm)) there is λ with $\mu^K(\Lambda_\sigma > \lambda) \le \frac{1}{8}p_*$ for large K, and on $\mathsf{L}_K \cap \{\Lambda_\sigma \le \lambda\}$, of mass $\ge \frac{1}{4}p_*$, $(J,J)_a(U_\sigma) \ge e^{-24\lambda}cR^{-2}\mathsf{b}^{-2}\ell^3\sigma^{-5/2+\kappa}$.

For small σ the same property of the current follows by a second route from the lower bound of the mean flowed action, through Prop. 16.9(d)(iii); and, by Prop. 16.9(d)(i) it gives back, conversely, the positivity in the limit of the energies $\int \chi_K \Gamma_K(\varphi(A^a)\circ\Phi_\sigma)\,\mathrm{d}\mu^K$, φ as there, for every weight with $\limsup_K \mu^K(\chi_K<1) < \frac14 p_*$.

Step 10: growth of uncut generator images, (C7). Let $U \in \mathsf{O}_K(\bar C,\bar s)$, of μ^K-mass $\ge 1-\epsilon$ (Prop. 16.1(a), by (Adm)). For large K its flow in lattice time satisfies the hypotheses of Lem. 16.4 with $T=\sigma/a_K^2$: by Lem. 16.2(e) at the flow times $s \ge a_K^{9/4}$, where $\kappa<\frac16$ gives $\varpi(U_s)\le (2\bar C+2\bar C^2)a_K^{1/8}$, and, at smaller flow times, by the bound 16 of the speed of the plaquette variables in lattice time, $\sup_{t\le T}\varpi(\Phi_{a_K^2 t}U)\le (4\bar C^2+20)a_K^{1/8}$, $\int_0^T \varpi\,\mathrm{d}t=\Lambda_\sigma$ is bounded, and the action at $T/2$ is small.

Given the other bonds, the law of the three bonds of Lem. 16.4 under μ^K has a density $\ge e^{-20\beta}$ with respect to Haar measure, as they lie in ten plaquettes, and $20\beta = 20\mathsf{b}\,a_K T/\sigma = o(T)$. So, with $\varepsilon=0.002$,

$$\int |\partial(A_K\circ\Phi_\sigma)|^q\,\mathrm{d}\mu^K \ge e^{-20\beta}(1-\epsilon)\,c\,e^{[(q-3)\lambda_1-6\lambda_2-(q+1)\varepsilon]T},$$

and the enclosures of λ_1,λ_2 give (a); at $q=4$, $\Gamma_K(A^a\circ\Phi_\sigma)^2 = a_K^{-6}|\partial(A_K\circ\Phi_\sigma)|^4$ and $\lambda_1-6\lambda_2>1.8$. (b): $G=A^a\circ\Phi_\sigma$ takes its values in $[0,6\ell^3 a_K^{-4}]$, as $A_K\le 6N^3$, and $H=\arctan G$ has $|\partial H| = a_K^{-1}|\partial(A_K\circ\Phi_\sigma)|/(1+G^2)$; so (a) at $q=4$ gives $\int|\partial H|^4\,\mathrm{d}\mu^K \ge c(\ell)\,a_K^{28}e^{1.76\,\sigma/a_K^2}$. Lem. 16.2(g) with $\sup|H|\le\frac\pi2$ gives $\frac\pi2(3\mathsf{m}+14\beta^{1/2}\mathsf{m}^{1/2}) \ge c(\ell)^{1/2}a_K^{14}e^{0.88\,\sigma/a_K^2}$; the right side tends to ∞ and $\beta^{1/2}=(\mathsf{b}/a_K)^{1/2}$, so $\mathsf{m}\ge 1$ for large K and then $\mathsf{m}\ge c\,a_K^{14.5}e^{0.88\,\sigma/a_K^2}$; and $\|\mathcal{L}_K H\| = \mathsf{m}/a_K \ge e^{0.8\,\sigma/a_K^2}$ for large K.

(c): $f=\mathfrak{f}^2$ with $\mathfrak{f}(x)=\sqrt2|\sin(\pi x_1/\ell)|$, of Lipschitz constant $\sqrt2\pi/\ell$. Let b_0 be the bond in the direction 3 at the site $a_K(k,0,0)$, $k\ge1$ an integer fixed below, $\alpha=2\pi a_K/\ell$, $\mathsf{f}_p=f(x(p))$ and $\mathsf{f}_0=1-\cos(\alpha k)\ge\frac{2}{\pi^2}\alpha^2k^2$. For p at the distance j from b_0, $|\mathsf{f}_p-\mathsf{f}_0|\le\alpha^2(j+3)(k+j+3)$, so $(\sum_p|\mathsf{f}_p-\mathsf{f}_0|^2e^{-2\theta|p|})^{1/2}\le C(\theta)\alpha^2(k+1)$; fix k with $C_\sharp C(\theta)(k+1)\le c_\sharp k^2/\pi^2$. Then Lem. 16.4(b) gives $|\partial_{b_0}(\mathcal{O}(f)\circ\Phi_\sigma)(W_\zeta)|\ge a_K^{-1}\frac{c_\sharp}{\pi^2}\alpha^2k^2e^{(\lambda_1-\varepsilon)T}$ for $\zeta\in\mathcal{S}$.

The value: with $\tilde V_t$ of Lem. 16.4 and $\mathcal{A}_f(V)=\sum_p \mathsf{f}_p\varsigma_p a_p(V)$,

$$\mathcal{O}(f)(\Phi_\sigma W_\zeta) = a_K^{-1}\Big[\mathcal{A}_f(\tilde V_T) + 2\sum_{p\ni b_0}\mathsf{f}_p\Big]\ge 0,$$

and the second term is at most $4a_K^{-1}\alpha^2(k+3)^2$, which tends to 0. For the first, a local energy inequality holds along the flow of $\tilde A$ in lattice time: with $\nu=-\partial\tilde A(\tilde V_t)$ its velocity, $f_b=f(a_Kb_-)$ and $a'=3a_K\sqrt2\pi/\ell$,

$$\tfrac{d}{dt}\mathcal{A}_f(\tilde V_t) = -\sum_b f_b|\nu(b)|^2 + \sum_b\Big\langle\nu(b),\sum_{p\ni b}(\mathsf{f}_p-f_b)\varsigma_p\,\partial_b a_p(\tilde V_t)\Big\rangle \le 64a'^2\sum_p a_p(\tilde V_t),$$

since $|\mathsf{f}_p-f_b|\le a'(2|\mathfrak{f}(a_Kb_-)|+a')$ for $b\in p$, $|\partial_b a_p|\le\varpi_p$, $|\nu(b)|\le\sum_{p\ni b}\varpi_p$, and $\sum_b(\sum_{p\ni b}\varpi_p)^2\le 32\sum_p a_p$. So $\mathcal{A}_f(\tilde V_T)\le\mathcal{A}_f(\tilde V_t)+64a'^2\int_t^T\sum_p a_p(\tilde V_u)\,\mathrm{d}u$ for $t\le T$; the mean over $t\in[\frac T2,T]$, $|\mathcal{A}_f|\le 2\sum_p a_p$, Lem. 16.4(c) and $A_K(U^\circ_{T/2})\le a_KE^{\mathrm{a}}_\sigma$ (Lem. 16.2(c), (e)) give

$$\mathcal{A}_f(\tilde V_T)\le\Big(\frac4T+64a'^2\Big)\Big(\frac32 T\,a_KE^{\mathrm{a}}_\sigma+C_\sharp\Big)\le a_K\Big(\frac4\sigma+\frac{11400}{\ell^2}\Big)\Big(\frac32\sigma E^{\mathrm{a}}_\sigma+C_\sharp a_K\Big),$$

as $64a'^2=1152\pi^2a_K^2/\ell^2\le 11400\,a_K^2/\ell^2$. So $0\le\mathcal{O}(f)\circ\Phi_\sigma\le M_\sigma$ on the fields W_ζ, $\zeta\in\mathcal{S}$, for large K, and $\int|\partial\varphi(\mathcal{O}(f)\circ\Phi_\sigma)|^4\,\mathrm{d}\mu^K\ge(\inf_{[0,M_\sigma]}|\varphi'|)^4e^{-20\beta}(1-\epsilon)\,c\,a_K^4e^{(\lambda_1-6\lambda_2-5\varepsilon)T}$; Lem. 16.2(g) as in (b). (d): the last identity of Lem. 16.2(g) gives $|\mathcal{L}_K\cos G|+|\mathcal{L}_K\sin G|\ge\Gamma_K(G)$, and (a) at $q=2p$, whose exponent $(2p-3)\lambda_1-6\lambda_2$ is positive for $p>\frac32+3\lambda_2/\lambda_1$, which is less than 1.8637; for $p>4$ the L^p norm dominates the L^4 norm.

(e): by Lem. 16.2(g) and $\nabla^2 A_K \geq -24$, $a_K^2 M^2 + 24\mathsf{b}\, M \geq \int \|\nabla^2 H\|_{\mathrm{HS}}^2 \,\mathrm{d}\mu^K$ for $M = \|\mathcal{L}_K H\|$ and $\sup|H| \leq 1$, since $\int |\partial H|^2 \,\mathrm{d}\mu^K = -a_K \int H \mathcal{L}_K H \,\mathrm{d}\mu^K$. Let $H = \sin(\mathcal{O}(f) \circ \Phi_\sigma)$; as sin is odd we may replace f by $-f$, so that $f(x_*) = \max|f| > 0$ at some x_*, and we base b_0 at a site nearest to x_*. For large K every $U \in \mathsf{O}_K(\bar{C}, \bar{s})$ satisfies the hypotheses of Lem. 16.4(d) with $\Lambda_0 = \max\{1, \sigma/\ell^2 + (8\bar{C}\sigma^{\frac{1}{4}-\frac{\kappa}{2}} + 4\bar{C}^2\sigma^{\frac{1}{2}-\kappa})/(1-2\kappa)\}$ (Lem. 16.2(e)): the supremum of ϖ along the flow tends to 0 as above, $T/N^2 = \sigma/\ell^2$, and $N^3 T^{-2} = \ell^3 a_K \sigma^{-2} \to 0$.

The fibre $g \mapsto W^{(g)}$ of the bond b_0 is totally geodesic in Ω_K, so $\mathfrak{h}(g) = H(W^{(g)})$ has $\|\nabla^2_{S^3}\mathfrak{h}\|_{\mathrm{HS}}(g) \leq \|\nabla^2 H\|_{\mathrm{HS}}(W^{(g)})$. For $(y_1, y_2) \in \mathsf{Y}$ of Lem. 16.4(d), the function $r \mapsto \mathcal{O}(f)(\Phi_\sigma W^{(g_r)}) = a_K^{-1}\mathsf{v}_f(r)$ falls by at least $f(x_*)\rho_2^2/a_K \geq 2\pi$ on $[0, r_*]$ for large K, so $\mathfrak{h}$ takes the values 1 and -1 at two points g', g'' with $\mathsf{d}(g', g'') \leq r_* \leq \frac{4}{3}\rho_2 e^{-\lambda_1' T}$; the inequalities of Sobolev and Morrey on S^3 give $|\mathfrak{h}(g') - \mathfrak{h}(g'')| \leq C\|\nabla^2_{S^3}\mathfrak{h}\|_{L^2(S^3)}\mathsf{d}(g', g'')^{1/2}$, so $\int \|\nabla^2 H\|_{\mathrm{HS}}^2(W^{(g)})\,\mathrm{d}g \geq c\, e^{\lambda_1' T}$ for the Haar probability measure dg.

The set Y has Lebesgue measure $\geq c_{\mathrm{d}} e^{-6\lambda_2'' T}$, the Haar measure in the chart $e^{iy_j} U(b_0 + \hat{e}_j)$ has a density $\geq (4\pi^2)^{-1}$ for $|y_j| \leq 1$, and given the other bonds the law of the three bonds has a density $\geq e^{-20\beta}$; so $\int \|\nabla^2 H\|_{\mathrm{HS}}^2 \,\mathrm{d}\mu^K \geq c(1-\epsilon)\exp[(\lambda_1' - 6\lambda_2'')T - 20\beta]$, with $\lambda_1' - 6\lambda_2'' > \frac{2}{5}$. This gives $a_K^2 M^2 + 24\mathsf{b} M \geq c\exp[\frac{2}{5}\sigma/a_K^2 - 20\mathsf{b}/a_K]$, hence $M \geq \exp[\frac{\sigma}{5a_K^2} - \frac{10\,\mathsf{b}}{a_K} - C]$ for sin and every $f \not\equiv 0$. For a non-constant periodic φ the same steps hold with φ in the place of sin (and $\varphi(-\,\cdot\,)$ in the place of φ if f was replaced by $-f$): for large K the fall $f(x_*)\rho_2^2/a_K$ exceeds a period of φ, so that φ takes its maximum and its minimum on the fibre within the distance r_*, $\operatorname{osc}\varphi$ replaces 2, and $\sup|\varphi|$ replaces 1 in the first inequality; this gives the exponent $\sigma/20a_K^2$ for large K.

(f): on the fields W_ζ of Lem. 16.4 the four plaquettes at b_0 stay within $\delta \leq \frac{1}{10}$ of $-\mathbf{1}$ during the flow, so $\Lambda_\sigma(W_\zeta) \geq (2-\delta)\sigma/a_K^2$, while their mass is at least $(1-\epsilon)e^{-20\beta} c_\sharp e^{-(3\lambda_1 + 6\lambda_2 + \varepsilon)\sigma/a_K^2}$; and $13(2-\delta) \geq 24.7 > 3\lambda_1 + 6\lambda_2 + \varepsilon$. □

15.1.8. *Uniformity and the order of limits.* Thm. AT holds for every limit, with constants and rates that do not depend on the subsequence. The inequalities of (A4), (A5) and (B2)(c) carry a defect, and their constants depend on ℓ; the constants of Thm. AU that are free of the volume are those of the fine field given a block field: C_e^{fib} and $3\mathsf{M}^2\Pi_e^\flat$ in (B3), in the log-Sobolev inequality of P_W, in the pointwise bound of $\Gamma_e(g_{t'})$ and in the tail under P_W, and the same two numbers at $e = n$ in (B2)(e), whose first inequality is (B3) at $t' = K - n$ integrated over the top law by the chain rule of the entropy.

The tail under μ^K in (B3) adds R_n; the first inequality of (B2)(e) keeps the entropy of the top law, which (B1) bounds at the cost C_n^{t}; and the constants, defects and thresholds of (B1) and (B2)(a)–(c), C_n^{t}, $C_n^\flat$, C_n', $\mathsf{R}_\cdot$, r_n, n_{c}, depend on ℓ. The flowed observables are taken at a fixed positive flow time; the proposed conclusion (C5) would identify the generator on them as a distribution once the flow-approximation step is completed, in the tested outer-R, inner-$\limsup_{K\to\infty}$ error sense of (C5)(d), and (C7) shows that without cutoffs the images under $\mathcal{L}_K$ of some of them are not bounded uniformly in K: for $p > 1.8637$, $\sup_K[\|\mathcal{L}_K \cos(A^a \circ \Phi_\sigma)\|_{L^p(\mu^K)} + \|\mathcal{L}_K \sin(A^a \circ \Phi_\sigma)\|_{L^p(\mu^K)}] = \infty$, so the norm is unbounded at cos or at sin, and at $\cos(\cdot + \theta)$ for all $\theta \in [0, \pi)$ but at most one, since cos and sin are linear combinations of any two of these functions.

15.2. **A uniform gauge on a box.** A comb gauge gives a bond bound proportional to the side of the box. To obtain a bound independent of that side, divide the box into cells of side comparable to the inverse square root of the plaquette bound. First fix the gauge on their edges. Extend it over each face and then each cell, keeping its already prescribed boundary values. For $SU(2)$, the required extensions can be constructed quantitatively on the unit sphere in the quaternions.

The following constants will also fix the numerical conventions in Lem. 15.7:

$$\lambda_{\mathrm{BG},1} = \pi + 2, \qquad \rho_{\mathrm{BG},1} = 1/250, \qquad \lambda_{\mathrm{BG},2} = 2 + 12\sqrt{3}\lambda_{\mathrm{BG},1}\rho_{\mathrm{BG},1}^{-2},$$
$$\lambda'_{\mathrm{BG},2} = \lambda_{\mathrm{BG},2} + 4, \qquad \rho_{\mathrm{BG},2} = (250000\lambda'^{2}_{\mathrm{BG},2})^{-1}, \tag{15.v}$$
$$\lambda_{\mathrm{BG},3} = 4 + 12\sqrt{3}\lambda'_{\mathrm{BG},2}\rho_{\mathrm{BG},2}^{-2}, \qquad C_{\mathrm{BG}} = 2\lambda_{\mathrm{BG},3}.$$

Proposition 15.8. Let U be an $SU(2)$ configuration on the bonds of $\{0,\dots,n\}^3$, where $n \geq 0$. If $0 < \kappa \leq C_{\mathrm{BG}}^{-2}$ and $|\partial U(p) - \mathbf{1}| \leq \kappa$ at every plaquette, then some gauge u satisfies

$$|U^u(b) - \mathbf{1}| \leq C_{\mathrm{BG}}\sqrt{\kappa} \quad \text{at every bond.} \tag{15.vi}$$

The same conclusion holds on $(\mathbb{Z}/n\mathbb{Z})^3$ if $n \geq \kappa^{-1/2}$. ■

Proof. We use the operator norm, which on quaternions is their Euclidean norm, and identify $SU(2)$ with the unit sphere S^3. Unitary multiplication preserves this norm. In particular, reversing a bond does not change its distance from $\mathbf{1}$.

Avoiding a point of the sphere. If a subset $S \subset S^3$ is covered by m closed balls of radius $0 < \rho < 1/8$ and $m < (8\rho)^{-3}$, there is $q \in S^3$ such that $|z + q| > \rho$ for every $z \in S$. Indeed, put $k = \lceil (8\rho)^{-1} \rceil - 1 \geq 1$. The points

$$p_v = \frac{(1, v)}{|(1, v)|}, \qquad v \in \{-1 + 2a/k : 0 \leq a \leq k\}^3,$$

number $(k+1)^3 \geq (8\rho)^{-3} > m$. For distinct grid points v, w, the wedge product of $(1, v)$ and $(1, w)$ has norm at least $|v - w|$, whereas both vectors have norm at most 2. Consequently

$$|p_v - p_w| \geq \sin\angle((1, v), (1, w)) \geq \tfrac{1}{4}|v - w| \geq \frac{1}{2k} > 4\rho.$$

Each of the m ball centres is within distance 2ρ of at most one p_v. Choose a remaining p_v and put $q = -p_v$.

Extending a map which avoids that point. Let Y be a nonempty subset of a finite metric space (X, d). Suppose $h : Y \to S^3$ is a-Lipschitz and $|h + q| \geq \rho$. Then it extends to $H : X \to S^3$ with Lipschitz constant $4\sqrt{3}\rho^{-2}a$. To see this, use the inversion

$$I_q(z) = -q + 2\frac{z + q}{|z + q|^2}, \qquad |I_q(z) - I_q(w)| = \frac{2|z - w|}{|z + q|\,|w + q|}.$$

It is its own inverse, maps $S^3 \setminus \{-q\}$ to $q^\perp$, and maps $q^\perp$ to S^3. Its Lipschitz constants on the two sets in use are $2\rho^{-2}$ and 2, respectively. Each coordinate f of $I_q h$ in an orthonormal basis of $q^\perp$ extends by

$$F(x) = \min_{y \in Y}\{f(y) + 2\rho^{-2}a\, d(x, y)\}.$$

The Lipschitz inequality for f shows that $F = f$ on Y; the triangle inequality shows that F has the same Lipschitz constant. The three coordinate extensions together have Lipschitz constant $2\sqrt{3}\rho^{-2}a$. Composition with I_q gives H.

The cell geometry and the comb. Put $N = \lfloor \kappa^{-1/2} \rfloor$. Then

$$N^2\kappa \leq 1, \qquad N\kappa \leq N^{-1}, \qquad N \geq \lambda_{\mathrm{BG},3}, \qquad N^{-1} \leq 2\sqrt{\kappa}.$$

For a coordinate rectangle or box with side lengths between N and $2N - 1$, any two boundary sites are joined along its boundary by a path of length at most three times their ℓ^1 distance. For sites on one face, or on intersecting faces, a monotone path has exactly that distance. For opposite faces, use either one of the two intervening faces. If their separating direction is μ and the chosen other direction is ν, the shorter detour costs at most $n_\nu + n_\mu$ in those directions; this is at most $3n_\mu$, since

$n_\nu < 2n_\mu$. The remaining coordinate contributes its ordinary difference. The rectangle proof is the same argument with two coordinates.

In a cell with lowest corner y, let $r_y(x)$ be the transport from y to x, first in direction 1, then 2, then 3. For $b = \langle x, x + e_\mu\rangle$ put $m_b = r_y(x)U(b)r_y(x + e_\mu)^{-1}$. Moving the last step through the later directions in the comb exchanges one plaquette at a time. The holonomy of a strip of k plaquettes is a product of k unitary conjugates of those plaquettes, so its distance from $\mathbf{1}$ is at most $k\kappa$. Thus, writing $x - y = (k_1, k_2, k_3)$,

$$|m_b - \mathbf{1}| \le \begin{cases} (k_2 + k_3)\kappa, & \mu = 1, \\ k_3\kappa, & \mu = 2, \\ 0, & \mu = 3. \end{cases}$$

This is the comb calculation of Lem. YM3_I:14.4, with the coordinate order reversed. It proves the estimate on an ordinary coordinate box and on the lift of a periodic cell, without any condition on the ambient torus side. On a face the bound is $2/N$, and on a cell it is $4/N$. If $n < N$ in the nonperiodic case, the same comb on the whole box gives $2n\kappa \le 4\sqrt{\kappa}$, which proves the assertion.

Suppose now $n \ge N$. Divide each coordinate interval into lengths between N and $2N - 1$: take $t_i = iN$ for $0 \le i < \lfloor n/N\rfloor$ and the last endpoint n. Their products give nodes, edges, faces and cells. Each new piece meets the union of lower-dimensional pieces exactly in its boundary; different interiors are disjoint. Every bond is contained in a cell. We can therefore define the gauge successively on nodes, edges, faces and cells.

Edges. Set $u = \mathbf{1}$ at the nodes. On an edge from y to $y' = y + n_c e_\mu$, write $U([y, y']) = e^{iY}$ with $|Y| \le \pi$, and set

$$u(y + ke_\mu) = e^{-ikY/n_c}U([y, y + ke_\mu]), \qquad 0 \le k \le n_c.$$

Both endpoint values are $\mathbf{1}$. At an edge bond the transformed field is e^{iY/n_c}, so its distance from $\mathbf{1}$ is at most π/N.

For the next two steps, write $h = ur_y^{-1}$ on the prescribed part of a piece and $w_b = U^u(b)$. Since $h(b_-)m_b h(b_+)^{-1} = w_b$, we have

$$\begin{aligned} |h(b_+) - h(b_-)| &\le |w_b - \mathbf{1}| + |m_b - \mathbf{1}|, \\ |w_b - \mathbf{1}| &\le |m_b - \mathbf{1}| + |h(b_+) - h(b_-)|. \end{aligned} \tag{15.vii}$$

Faces. On the boundary of a face, the bond differences of h are at most $\lambda_{\mathrm{BG},1}/N$; the boundary-path bound makes h $3\lambda_{\mathrm{BG},1}/N$-Lipschitz in ℓ^1 distance. The boundary cycle has at most $8N$ bonds. Sample it at intervals $s_1 = \lfloor \rho_{\mathrm{BG},1}N/\lambda_{\mathrm{BG},1}\rfloor$. The constants ensure $s_1 \ge \rho_{\mathrm{BG},1}N/(2\lambda_{\mathrm{BG},1}) \ge 1$. The image is covered by balls of radius $\rho_{\mathrm{BG},1}$ whose number is at most

$$16\lambda_{\mathrm{BG},1}/\rho_{\mathrm{BG},1} + 1 \le 17\lambda_{\mathrm{BG},1}/\rho_{\mathrm{BG},1} < 21853 < (8\rho_{\mathrm{BG},1})^{-3}.$$

The avoidance and extension arguments give an extension H over the face with bond differences bounded by $12\sqrt{3}\lambda_{\mathrm{BG},1}\rho_{\mathrm{BG},1}^{-2}/N$. Set $u = Hr_y$ there. It retains the prescribed edge values, and eq. 15.vii gives $|U^u(b) - \mathbf{1}| \le \lambda_{\mathrm{BG},2}/N$ on every face bond.

Cells. On the boundary of a cell, the bond differences of h are at most $\lambda'_{\mathrm{BG},2}/N$, and its ℓ^1 Lipschitz constant is $3\lambda'_{\mathrm{BG},2}/N$. On each face sample both coordinates at multiples of $s_2 = \lfloor \rho_{\mathrm{BG},2}N/(2\lambda'_{\mathrm{BG},2})\rfloor$. Here $s_2 \ge \rho_{\mathrm{BG},2}N/(4\lambda'_{\mathrm{BG},2}) \ge 1$. Lowering the two coordinates to these multiples uses fewer than $2s_2$ steps, so the image lies within $\rho_{\mathrm{BG},2}$ of a sampled value. The number of samples on all six faces is at most

$$m = 486\lambda'^2_{\mathrm{BG},2}\rho_{\mathrm{BG},2}^{-2}, \qquad m(8\rho_{\mathrm{BG},2})^3 \le 248832/250000 < 1.$$

The same extension gives H over the cell, with bond differences at most $12\sqrt{3}\lambda'_{\mathrm{BG},2}\rho_{\mathrm{BG},2}^{-2}/N$. Again set $u = Hr_y$. The boundary values agree, and eq. 15.vii gives

$$|U^u(b) - \mathbf{1}| \le \lambda_{\mathrm{BG},3}/N \le C_{\mathrm{BG}}\sqrt{\kappa}.$$

Every bond belongs to a cell, proving the box assertion.

The periodic lattice. Divide each coordinate circle of length n into the same integer lengths, now identifying its last endpoint with its first. Work on each piece in its coordinate lift. Put $u = \mathbf{1}$ at the periodic nodes and perform the edge, face and cell constructions just given once for each periodic piece. The edge formula agrees at both endpoints even when an edge is a full circle. At every later stage the boundary values are the values of the already defined periodic function u. The auxiliary function $h = ur_y^{-1}$ is defined on the lifted boundary; it need not have equal values on opposite lifted faces, since the comb transports there may differ. After extension, however, Hr_y equals the prescribed u at every boundary point. Thus those values agree at all identified points. No new interior point has two preimages, even when a cell spans an entire coordinate circle. The extensions therefore descend to a single gauge on the torus. Every periodic bond has a lift in one cell, with the same plaquette and comb bounds as above. This proves the periodic assertion. □

For completeness, this also gives the first component assertion of Lem. 15.7(a). Let $0 < \kappa' \le (8\pi C_{\mathrm{BG}})^{-2}$ and use the periodic gauge. Write $V^u = e^{iA}$, choosing the principal logarithm at positive bonds and extending by reversal. Then

$$|A| \le \alpha := \tfrac{\pi}{2} C_{\mathrm{BG}}\sqrt{\kappa'} \le 1/16.$$

For the product of four exponentials around a plaquette, Taylor's formula in t gives $|\partial e^{itA}(p) - \mathbf{1} - it\,\mathrm{d}A(p)| \le 8\alpha^2$: the norm of its second derivative is bounded by $(\sum_{b\in\partial p}|A(b)|)^2 \le 16\alpha^2$. Here $dA(p)$ is the unnormalised oriented sum around p. In particular, the bound $10\alpha^2$ used in Lem. 15.7 holds. Applying it at t and at 1 yields

$$|\partial e^{itA}(p) - \mathbf{1}| \le |\partial V^u(p) - \mathbf{1}| + 20\alpha^2 \le (1 + 5\pi^2 C_{\mathrm{BG}}^2)\kappa' < C''\kappa', \qquad 0 \le t \le 1.$$

The gauge group is a finite product of connected copies of $SU(2)$, so a path of gauge transformations joins V to V^u without changing its plaquette norms. Joining this path to e^{itA} places V in the component of $\mathbf{1}$ in $\{\varpi < C''\kappa'\}$. Taking $\kappa' = r/C''$ gives the shell assertion there. This single-scale construction does not supply the separate multilevel estimate (Multiscale gauge).

15.3. **Response and one-step conventions.** We record the response bound needed when differentiating the normalised measure of a step. Work on a constant torus sequence, at level $j \ge 1$, with the real regular background, geometric thresholds and datum ball of §5.3. Lengths in the following lemma are in level-j units, so the bare spacing is $\eta_j = L^{-j}$ and every terminal pillar has scale 1. Let d_j be the periodic ℓ^1 distance on the terminal lattice. In this setting it is the weighted path distance in equation YM3_I:(838). For a field X on its positive bonds put

$$m_y(X) = \sum_{c>0} e^{-\delta_0 d_j(y,c_-)}|X(c)|, \qquad S_0 = \left(\frac{1+e^{-\delta_0}}{1-e^{-\delta_0}}\right)^3, \qquad \mathsf{S} = 3S_0,$$

where $\delta_0 > 0$ is no larger than the rate in that equation.

Lemma 15.9. There is a constant B, depending only on the fixed construction constants, such that the response $\mathcal{H}_U$ obeys

$$\max\{|\mathcal{H}_U(X)(b)|, |\nabla_U\mathcal{H}_U(X)(b)|\} \le \mathsf{B}m_y(X)$$

on its datum ball, whenever b has an endpoint in the pillar of y. At zero datum, put

$$h = D\mathcal{H}_U(0)X, \qquad j_X = \frac{d}{ds}J^{(j)}(e^{i\eta_j\mathcal{H}_U(sX)}U)\Big|_{s=0}.$$

Then

$$\max\{|h(b)|, |\nabla_U h(b)|, |j_X(b)|\} \le \mathsf{B} m_y(X), \qquad \sum_y m_y(X)^2 \le \mathsf{S}^2 \sum_{c>0} |X(c)|^2. \tag{15.viii}$$

All constants are independent of j and of the torus side. ■

Proof. For one input bond, equation YM3_I:(838) bounds h, $\nabla_U h$ and $D_U^{\mathsf{T}} D_U h$ with exponential decay. Sum this bound over the input bonds. Integrating the same estimate along sX, $0 \le s \le 1$, proves the first assertion, since $\mathcal{H}_U(0) = 0$ and the datum ball is convex.

The current requires one further identity. Let $F(A)$ be the local Wilson action at $e^{i\eta_j A}U$ and set $f(z) = (e^z - 1)/z$, with its power-series value at zero. Prop. YM3_I:13.1 gives, on a complete plaquette star,

$$J^{(j)}(e^{i\eta_j A}U)(b) = f(-i\eta_j \operatorname{ad}_{A(b)})^{-1} F'(A)(b), \qquad F''(0) = D_U^{\mathsf{T}} D_U + \Delta'.$$

Since $f(z)^{-1} = 1 - z/2 + O(z^2)$, differentiation at $A = 0$ gives

$$j_X(b) = (D_U^{\mathsf{T}} D_U h)(b) + (\Delta' h)(b) + \tfrac{i\eta_j}{2}[h(b), J^{(j)}(U)(b)].$$

All stars are complete on the torus. The same proposition bounds $\Delta' h$ by $C\varepsilon$ times the supremum of h on this fixed star, where ε is the background regularity radius. Regularity also gives $|J^{(j)}(U)| \le \varepsilon$. The star meets only pillars at a fixed distance from y; translating the exponential weight over that distance costs a fixed factor. Together with $\eta_j \le 1$ and $|[h, J]| \le 2|h||J|$, the three terms therefore have the asserted bound, after increasing B.

Finally the sum of $e^{-\delta_0 d_j(y,z)}$ over a periodic lattice is at most S_0: choose least coordinate representatives and bound their sum by the sum over $\mathbb{Z}^3$. There are three positive bonds starting at each site. The nonnegative kernel defining m_y has row sums at most $3S_0$ and column sums at most S_0. Cauchy–Schwarz, first with this kernel and then after summing in y, gives an operator norm at most $\sqrt{3}S_0 \le \mathsf{S}$. □

The gauge equation used with this lemma is exactly equation YM3_I:(837). Thus the projection denoted by R^{La} in the dynamics section is the companion's R_{m}: the projection onto $D_U^{\mathsf{T}} D_U \mathcal{N}$, where $\mathcal{N}$ consists of site fields with zero prescribed site averages. This is the mean-Landau choice of Thm. YM3_I:K.

15.3.1. *The local input and its global sum.* At height k, the actual input is the one in Section YM3_I:52.4 and Thm. YM3_I:W. Keep its geometric thresholds, admissible radius system, shift hypotheses, octet condition when $k \ge 2$, numerical ceilings and array bound $N \le N_*$. In particular, $E_0 > 0$ is the fixed size of the output family there; it is chosen before the height, lattice and input array. For the density identity, keep in addition the whole-data response neighbourhood, full-torus core membership and bounded Borel integrand required in that theorem.

A family in the fourth place means the fourth potential of Def. YM3_I:52.1. Its members depend on the represented pair, are gauge invariant, vanish at $B = 0$, and are jointly holomorphic on each core slice and the field polydisc $|B| < C_{\mathcal{A}}\mathfrak{b}(\mathsf{t})$. With additional parameters, joint holomorphy is required in those parameters too. Its size is equation YM3_I:(888). For a parameter space consisting of one point this is the same definition without a parameter.

The phrase that this family *sums to S at W* has the following precise meaning. The averaged background is real, admissible, and has invertible pivots; the real cutoff chart is defined throughout its box, every background over a point of that chart exists, and P_W belongs to the full-torus core. The gauge-invariant function S is defined on both critical orbits. For every real cutoff field,

$$\sum_Y \mathbb{V}'(Y; P_W|_Y, B|_Y) = S(U_k(V_W(B))) - S(U_{k+1}(W)). \tag{15.ix}$$

These are the background and chart conditions in §5.3.1. For a bare-array potential the identity is equation YM3_I:(882). For a source it is the additional sum condition imposed at its entry into the step.

The block field of a triple is $V[P] = \mathcal{M}^k(e^{i\eta_{k+1}A'}U)$ on the level-k bonds of its domain, with the actual complex averaging domains retained. The fine-cube gauge form $\widehat{\mathsf{G}}_\square(P)$ is evaluated at this field by equation YM3_I:(823). Equivalently it is the quadratic form obtained from $\mathfrak{t}\Psi^{\mathrm{G}}(\square; P, B)$ in the proof of Prop. YM3_I:51.4. Def. YM3_I:52.1, item 2, records its pair dependence, slice holomorphy, covariance and compatibility with restrictions; its sum on the full torus is equation YM3_I:(828). At real data the inverse whole covariance differs from its real reference form, with floor γ_{r} and ceiling c_{r}, by at most $\frac{1}{2}u_{\mathrm{G}}(LM)^{-3}$. These are the actual constants of Thm. YM3_I:U, used with the choice $u_{\mathrm{G}} = 4C_{\mathrm{Str}}$ and the radius inequalities of Section YM3_I:52.4. Completeness is Def. YM3_I:47.2, condition (St4).

The expansion numbers $w_0, \mathsf{C}_{\mathrm{ex}}, c_G, c_{\mathrm{v}}, c_{\mathrm{w}}, \lambda_1, \lambda_V, w_\star$ are those defined immediately before and in equation YM3_I:(705); in particular $\mathsf{C}_{\mathrm{ex}} \geq 8e^8$. Their one-step substitution is equation YM3_I:(889), including $\lambda_{\mathrm{out}} = (1 + 4\beta_{\mathrm{s}})\kappa$ and $(LM)^3 u = 3 + c_{\mathrm{r}} + u_{\mathrm{G}}$.

16. Positive-time gradient flow

The deterministic Wilson flow Φ_σ decreases the lattice action. It is related to the Langevin generator, but its continuum identification is a separate problem. At positive time the intended limiting object is a connection modulo periodic gauge transformations, specified by its holonomies.

Sketch O (The proposed continuum flow). The sketch describes a positive-time Yang–Mills gradient flow from almost every block-field thread, with strongly convergent flowed gauge-invariant observables. Its identification requires compactness modulo gauges, passage to the limiting equation, recovery of the initial holonomies and uniqueness. The estimates below provide the preparatory bounds; these four steps remain to be established. ■□

Sketch of the argument. For a smooth lattice observable G, put $H_K^\sigma = G \circ \Phi_\sigma$ and $\Delta_K = a_K^{-1} \sum_{b,\alpha} (\partial_b^\alpha)^2$, the second-order part of the Langevin generator. The finite-dimensional identity

$$\mathcal{L}_K H_K^\sigma = (b\partial_\sigma + \Delta_K) H_K^\sigma$$

is exact. The action drift in the stochastic generator is cancelled by moving along the deterministic flow. Integrating against the stationary measure gives the corresponding identity for means; multiplying by a test observable gives its Dirichlet-form version.

The small-field chain decomposes a gauge-fixed potential into layers. Conditional estimates control the layer means and the part of their colour covariance that is not scalar. Their summation gives rough-field moments. Deterministic heat estimates then control the flow at positive times, producing uniform moments of the flowed curvature and current and high-probability regularity sets. Sufficiently deep layers satisfy the admissibility bounds needed for these estimates.

For the continuum identification, start with minimal backgrounds over converging coarse data. One must choose periodic gauges so that their positive-time potentials have convergent subsequences, locally uniformly in time. Their limit must satisfy the gauge-fixed mild equation

$$\partial_\sigma \mathfrak{A} = -\mathrm{d}_{\mathfrak{A}}^* F_{\mathfrak{A}} + \mathrm{d}_{\mathfrak{A}}(\partial_\nu \mathfrak{A}_\nu),$$

recover the prescribed smoothed holonomies as $\sigma \downarrow 0$, and be unique modulo gauge with those initial holonomies. The source explicitly leaves these linked claims as an additional approximation step. The derivative and moment estimates do not alone complete it.

There is another difficulty even after identifying the flowed observables. Positive flow time does not automatically put them in the domain of the limiting stochastic generator. Some bounded flowed observables have $\|\mathcal{L}_K H_K^\sigma\|_2$ growing exponentially in a_K^{-2}. Insert invariant regularization cutoffs $\chi_{K,R}$ whose lost mass and Dirichlet cost tend to zero as $R \to \infty$. First pass $K \to \infty$ at fixed

R; only afterwards remove R. For resolvent test functions this gives a tested generator identity, and after integrating in σ a distributional one. An unregularized operator-domain claim requires a separate uniform generator bound, which those examples show cannot be assumed for every flowed observable.

16.1. **The identification that the flow sketch requires.** Deterministic smoothing and stochastic evolution act on the same finite lattice, but their continuum limits require different arguments. Let Φ_σ be the Wilson gradient flow and let G be a smooth observable of the lattice field. Write $H^\sigma = G \circ \Phi_\sigma$. With the bond Laplacian $\Delta_K = a_K^{-1} \sum_{b,\alpha} (\partial_b^\alpha)^2$, the finite-dimensional chain rule gives

$$\mathcal{L}_K H^\sigma = (b\partial_\sigma + \Delta_K) H^\sigma.$$

Stationarity and integration by parts therefore imply

$$b\partial_\sigma \langle H^\sigma \rangle_{\mu^K} = -\langle \Delta_K H^\sigma \rangle_{\mu^K}.$$

These are finite-cutoff identities. They describe how flow time enters the observable, without yet identifying a random continuum connection or its deterministic flow.

The prospective continuum flow is most naturally specified modulo periodic gauge transformations. For a fixed admitted block depth D and block field V, choose minimal backgrounds at finer and finer cutoffs over V. The unflowed loop comparison identifies limiting holonomies $w_C^D(V)$ for fixed closed paths C. Positive-time regularity estimates then control the smoothed backgrounds in gauges. To finish the identification, one must obtain compactness modulo periodic gauges, pass the lattice equation to the continuum equation, recover these initial holonomies as flow time decreases to zero, and establish uniqueness of the resulting orbit-valued flow. The detailed estimates below provide the preparatory bounds for these four steps, which remain to be established.

The proposed limiting equation, in a local gauge representative $\mathfrak{A}_s$, is

$$\partial_s \mathfrak{A} = -\mathrm{d}_{\mathfrak{A}}^* F_{\mathfrak{A}} + \mathrm{d}_{\mathfrak{A}}(\partial_\nu \mathfrak{A}_\nu).$$

The last term is an infinitesimal gauge transformation. Thus the object to identify is a path of gauge orbits, with local representatives satisfying this equation, rather than one global choice of potentials. The initial condition is expressed by $W_C(\mathfrak{A}_s) \to w_C^D(V)$ as $s \downarrow 0$. Neither the finite-lattice chain rule nor positive-time moment bounds alone establish uniqueness for that initial condition.

A further limit issue concerns the generator. Smoothness at positive flow time does not give a bound for $\|\mathcal{L}_K H_K^\sigma\|_2$ uniform in K. The source gives bounded flowed observables for which that norm grows exponentially in a_K^{-2}. One therefore tests the generator identity with regularity cutoffs whose Dirichlet cost vanishes. First pass to the continuum with a fixed regularization; then remove that regularization. The resulting identity has the tested or distributional meaning established by this procedure. It cannot be replaced by an assertion that every bounded flowed observable lies in the domain of the limiting generator.

16.2. **The background-flow identification.**
Approximation of the fixed-depth background flow. Fix $0 < \alpha < 1$. For D sufficiently large put $\mathcal{K}_D = \{V \in \Omega_D : \varpi(V) \le \theta_D\}$, and let $U_{K,D}(V)$ be any member of the minimal orbit over V on $\Lambda_{K,\ell}$, $K > D$. The unflowed comparison in the proof of Prop. 16.1(b) defines $w_C^D(V) = \lim_{K\to\infty} W_C(U_{K,D}(V))$ for each closed lattice path C. The remaining approximation step, referred to as *(Flow approximation)*, is to prove the following compactness and identification statement. For each fixed D, every sequence $K_\nu \to \infty$, $V_\nu \to V$ in $\mathcal{K}_D$ and arbitrary minimal backgrounds U_ν over V_ν should have a subsequence whose positive-time flows converge modulo periodic gauges, locally uniformly in time in $\mathcal{O}^\alpha$, to an orbit-valued flow line. More explicitly, on each compact positive time interval, periodic gauges give real bond potentials $A_\nu(s)$ representing $\Phi_s U_\nu$ as $e^{ia_{K_\nu} A_\nu(s)}$ and

local representatives $\mathfrak{A}_s$ of the limit for which

$$\sup_{\tau\le s\le T}\max_b |A_\nu(s,b)-\mathfrak{A}_{s,\mu(b)}(x_b)|\longrightarrow 0,\qquad 0<\tau<T<\infty.$$

Here x_b is the bond midpoint and $\mu(b)$ its direction. The limit must have local mild representatives satisfying

$$\partial_s\mathfrak{A}=-\mathrm{d}^*_{\mathfrak{A}}F_{\mathfrak{A}}+\mathrm{d}_{\mathfrak{A}}(\partial_\nu\mathfrak{A}_\nu),\qquad \lim_{s\downarrow 0}W_C(\mathfrak{A}_s)=w_C^D(V),$$

and one must prove uniqueness of this orbit-valued flow line from those initial holonomies. These are the compactness and identification tasks of the sketch. The positive-time derivative bounds used below are proved separately by the single-scale gauge and the short-time regularisation in the proof of Prop. 16.1(c).

Detailed sketch AV (Flowed estimates and the proposed continuum identification). Assume (E) and $0<\kappa<\frac16$; (C1) holds for all K, m, $\beta>0$, with $\mathsf{b}=a_K\beta$. (C2)(b), (C2)(c) and (C3)–(C7), which read the moments, the good sets or the field $\mathbf{B}_K$ of Prop. 16.1(a), use the consequence (Adm) of (E) proved in Prop. 16.1: every top depth from some depth on, a depth free of K, is admissible in the sense of Prop. 16.1. (C1) and (C2)(a) are free of it. The continuum identifications in (C3) and the part of (C5)(d) involving G_σ remain proposed conclusions until the approximation step above is completed. The assertions in (C7) use the nonlinear defect estimates of Lem. 16.4.

(C1) For $G\in C^\infty(\Omega_K)$, $H^\sigma=G\circ\Phi_\sigma$ and $\sigma\ge 0$: $\mathcal{L}_KH^\sigma=(\mathsf{b}\,\partial_\sigma+\Delta_K)H^\sigma$. Hence $\mathsf{b}\,\partial_\sigma\langle H^\sigma\rangle_{\mu^K}=-\langle\Delta_KH^\sigma\rangle_{\mu^K}$; for $\chi\in D(\mathcal{E}_K)\cap L^\infty$, $\int\chi\,(\mathsf{b}\partial_\sigma+\Delta_K)H^\sigma\,\mathrm{d}\mu^K=-\int\Gamma_K(\chi,H^\sigma)\,\mathrm{d}\mu^K=-\int(1-\chi)\,\mathcal{L}_KH^\sigma\,\mathrm{d}\mu^K$; for $t\ge0$, $P_t^KH^\sigma=H^{\sigma+\mathsf{b}t}+\int_0^tP_s^K\Delta_KH^{\sigma+\mathsf{b}(t-s)}\,\mathrm{d}s$; and for the stationary process and $0\le r\le t$, $H^{\sigma+\mathsf{b}(t-r)}(U_r)-H^{\sigma+\mathsf{b}t}(U_0)-\int_0^r(\Delta_KH^{\sigma+\mathsf{b}(t-s)})(U_s)\,\mathrm{d}s$ is a martingale with the bracket $2\int_0^r\Gamma_K(H^{\sigma+\mathsf{b}(t-s)})(U_s)\,\mathrm{d}s$: in the frame that moves along $\sigma+\mathsf{b}t=\text{const}$ the drift of the action is gone.

(C2) (a) For $\bar C\ge1$, $0<\bar s\le1$ there is K_0 such that for every flowed observable, $0<\sigma\le1$ and $K\ge K_0$: $\Gamma_K(H_K^\sigma)\le C_\Gamma$ and $|\partial_\sigma H_K^\sigma|\le C_\partial$ on $\mathsf{O}_K(\bar C,\bar s)$, with C_Γ,C_∂ depending on $\bar C,\bar s,\ell,\kappa,\sigma$ and the norms of $\nabla\varphi$, f_i, ∇f_i, bounded for σ in compact subsets of $(0,1]$; for $\sigma\le\bar s$ this holds for every K. (b) For $0<\sigma\le1$, $1\le p<\infty$ and all K: $\|\partial_\sigma H_K^\sigma\|_{L^p(\mu^K)}\le C_p(\sigma)\sum_i\|\partial_i\varphi\|_\infty(2\|f_i\|_\infty+4\|\nabla f_i\|_\infty)$, $C_p(\sigma)$ bounded on compact subsets of $(0,1]$; so $\|H_K^\sigma-H_K^{\sigma'}\|_{L^p(\mu^K)}\le C|\sigma-\sigma'|$ locally uniformly in $\sigma,\sigma'\in(0,1]$ and in K, and, by (C1), $\sup_K\|\mathcal{L}_KH_K^\sigma\|_{L^p(\mu^K)}<\infty$ if and only if $\sup_K\|\Delta_KH_K^\sigma\|_{L^p(\mu^K)}<\infty$.

(c) For compact $I\subset(0,1]$, $1\le q<\infty$: $\sup_K\|\partial_\sigma H_K^{\sigma''}-\partial_\sigma H_K^{\sigma'}\|_{L^q(\mu^K)}\le C_I(q)|\sigma''-\sigma'|^{1/2}$ for $\sigma',\sigma''\in I$.

(C3) For every flowed observable and $\sigma>0$, $H_K^\sigma\to\mathsf{G}_\sigma$ strongly along the full sequence of cutoffs, where

$$\mathsf{G}_\sigma(Y)=\varphi\big(\mathcal{O}^0(f_1)(\mathfrak{F}(Y)_\sigma),\dots,\mathcal{O}^0(f_r)(\mathfrak{F}(Y)_\sigma)\big),$$

$\mathfrak{F}$ the map of Prop. 16.1(b); the same holds for real Lipschitz f_i and bounded Lipschitz φ, and $\sigma\mapsto\mathsf{G}_\sigma$ is locally Lipschitz from $(0,1]$ into $L^2(\mu)$. For $0<\sigma<1$ there is $\dot{\mathsf{G}}_\sigma\in L^2_{\mathrm{inv}}$ with $\int\Psi_K\,\partial_\sigma H_K^\sigma\,\mathrm{d}\mu^K\to\int\Psi\,\dot{\mathsf{G}}_\sigma\,\mathrm{d}\mu$ along the full sequence for every invariant cylinder function Ψ; $\sigma\mapsto\int\Psi\dot{\mathsf{G}}_\sigma\,\mathrm{d}\mu$ is locally Hölder continuous of exponent $\frac12$ and is the derivative of the continuously differentiable function $\sigma\mapsto\int\Psi\mathsf{G}_\sigma\,\mathrm{d}\mu$.

(C4) *Regularisation and condenser cutoffs.* There are $R_\flat\ge1$ and, for $R\ge R_\flat$, numbers $\bar s(R)\in(0,1]$, $\bar K(R)$, $\bar\varkappa(R)>0$ with $R^q\bar\varkappa(R)\to0$ for every q, and for $K\ge\bar K(R)$ invariant $\chi_{K,R}\in C^\infty(\Omega_K)$ with values in $[0,1]$ such that $\chi_{K,R}=1$ on $\{\mathsf{G}^*\le R\}$ and $\chi_{K,R}=0$ off $\{\mathsf{G}^*\le\frac52R\}\subset\mathsf{O}_K(8R,\bar s(R))$, G^* the functional of Step 8; $\mathcal{E}_K(\chi_{K,R})+\int(1-\chi_{K,R})^2\,\mathrm{d}\mu^K\le\bar\varkappa(R)$; $\sup_{K\ge\bar K(R)}\int\Gamma_K(\chi_{K,R})^p d\mu^K<\infty$ for every $p<\infty$; and $\mathbf{1}_{\{\chi_{K,R}>0\}}\le\chi_{K,R'}$ for $R'\ge\frac52R$, $K\ge\bar K(R')$.

Let $w_{K,R}$ be the potential of Lem. 16.5 for $\eta = 1 - \chi_{K,R}$, and $\chi^{\mathrm{c}}_{K,R} = 1 - w_{K,R}$, the condenser cutoff. Then $\chi^{\mathrm{c}}_{K,R} \in D(\mathcal{E}_K)$ is invariant, takes values in $[0,1]$, is 1 where $\chi_{K,R} = 1$ and 0 where $\chi_{K,R} = 0$, has $\Gamma_K(\chi^{\mathrm{c}}_{K,R}, \cdot) = 0$ off the shell $\{0 < \chi_{K,R} < 1\}$, $\mathcal{E}_K(\chi^{\mathrm{c}}_{K,R}) + \int (1 - \chi^{\mathrm{c}}_{K,R})^2 \,\mathrm{d}\mu^K \le \bar{\varkappa}(R)$, and $|\int \Gamma_K(\chi^{\mathrm{c}}_{K,R}, \psi)\,\mathrm{d}\mu^K| \le \operatorname{osc}(\psi)\,\bar{\varkappa}(R)$ for $\psi \in D(\mathcal{E}_K) \cap L^\infty$. A second family of smooth invariant cutoffs, defined without choosing a gauge, is given by Prop. 16.6.

(C5) *Static invariance and the generator.* (a) For every flowed observable, $\sigma > 0$, $R \ge R_\flat$ and $K \ge \bar{K}(R)$,

$$\Big| \int \chi^{\mathrm{c}}_{K,R}\, (\mathsf{b}\,\partial_\sigma + \Delta_K) H^\sigma_K \,\mathrm{d}\mu^K \Big| \le \operatorname{osc}(\varphi)\,\bar{\varkappa}(R);$$

for $0 < \sigma \le 1$, with $C_\partial = \sup_K \|\partial_\sigma H^\sigma_K\|_{L^2(\mu^K)}$, $|\int \chi^{\mathrm{c}}_{K,R} \Delta_K H^\sigma_K \,\mathrm{d}\mu^K + \mathsf{b}\,\partial_\sigma \langle H^\sigma_K \rangle_{\mu^K}| \le \operatorname{osc}(\varphi)\bar{\varkappa}(R) + \mathsf{b}\, C_\partial\, \bar{\varkappa}(R)^{1/2}$; and $|\int \chi^{\mathrm{c}}_{K,R} \mathcal{L}_K H \,\mathrm{d}\mu^K| \le \operatorname{osc}(H)\bar{\varkappa}(R)$ for every $H \in C^2(\Omega_K)$. (b) With $q(u) = 3u^2 - 2u^3$, $q(\chi^{\mathrm{c}}_{K,R}) \in D(\mathcal{E}_K)$ is invariant, takes values in $[0,1]$, is 1 where $\chi_{K,R} = 1$ and 0 where $\chi_{K,R} = 0$, has $\mathcal{E}_K(q(\chi^{\mathrm{c}}_{K,R})) \le \frac{9}{4}\bar{\varkappa}(R)$, and its generator is a function: $\int q(\chi^{\mathrm{c}}_{K,R})\, \mathcal{L}_K H \,\mathrm{d}\mu^K = \int H\, \mathsf{I}_{K,R} \,\mathrm{d}\mu^K$ for $H \in C^2(\Omega_K)$, $\|\mathsf{I}_{K,R}\|_{L^1(\mu^K)} \le \frac{15}{2}\bar{\varkappa}(R)$. (c) For $H, H' \in C^2(\Omega_K)$,

$$\begin{aligned} \Big| \int \chi^{\mathrm{c}}_{K,R}\, (H' \mathcal{L}_K H - H \mathcal{L}_K H') \,\mathrm{d}\mu^K \Big| &\le \operatorname{osc}(HH')\,\bar{\varkappa}(R) \\ &\quad + 2 \sup|H|\, \bar{\varkappa}(R)^{1/2} \Big(\int_{\{0 < \chi_{K,R} < 1\}} \Gamma_K(H') \,\mathrm{d}\mu^K \Big)^{1/2}. \end{aligned}$$

(d) Let (K_j) be a limit and $F \in D(A_\star)$ with a test sequence, that is, invariant $F_j \in D(\mathcal{L}_{K_j})$ with $\sup_j \|F_j\|_\infty < \infty$, $F_j \to F$ and $\mathcal{L}_{K_j} F_j \to -A_\star F$ strongly; test sequences exist for $F = \alpha(\alpha + A_\star)^{-1} W$, $\alpha > 0$, whenever W is the strong limit of uniformly bounded invariant W_j (for instance an invariant cylinder function or a G_σ). Then for $R \ge R_\flat$ with $\bar{\varkappa}(R) \le 1$

$$\limsup_{j \to \infty} \Big| \int \chi^{\mathrm{c}}_{K_j,R} F_j\, (\mathsf{b}\,\partial_\sigma + \Delta_{K_j}) H^\sigma_{K_j} \,\mathrm{d}\mu^{K_j} + \int (A_\star F)\, \mathsf{G}_\sigma \,\mathrm{d}\mu \Big| \le c_F\, \bar{\varkappa}(R)^{1/2},$$

$c_F = \sup|\varphi| \sup_j [2\|F_j\|_\infty + 2\mathcal{E}_{K_j}(F_j)^{1/2} + \|\mathcal{L}_{K_j} F_j\|_{L^2}]$: the displayed tested error tends to zero as $R \to \infty$. For every $\tau \in C^\infty_c(0,1)$ the corresponding distributional statement is

$$\begin{aligned} \lim_{R \to \infty} \limsup_{j \to \infty} \Big| \int_0^1 \tau(\sigma) \int \chi^{\mathrm{c}}_{K_j,R} F_j\, \Delta_{K_j} H^\sigma_{K_j} \,\mathrm{d}\mu^{K_j} \,\mathrm{d}\sigma \\ + \int_0^1 [\tau(\sigma)(A_\star F, \mathsf{G}_\sigma) - \mathsf{b}\,\tau'(\sigma)(F, \mathsf{G}_\sigma)] \,\mathrm{d}\sigma \Big| = 0. \end{aligned}$$

For two flowed observables H_K, H'_K at σ, σ' with limits G, G' and $\alpha > 0$,

$$\begin{aligned} \lim_R \limsup_j \Big| \int \chi^{\mathrm{c}}_{K_j,R} [\alpha(\alpha - \mathcal{L}_{K_j})^{-1} H'_{K_j}]\, \mathcal{L}_{K_j} H_{K_j} \,\mathrm{d}\mu^{K_j} \\ + (\alpha A_\star (\alpha + A_\star)^{-1} \mathsf{G}', \mathsf{G}) \Big| = 0, \end{aligned}$$

a limit that is symmetric in the two observables.

If $C_1 = \liminf_R \limsup_j \int \chi^{\mathrm{c}}_{K_j,R} |\mathcal{L}_{K_j} H^\sigma_{K_j}| \,\mathrm{d}\mu^{K_j} < \infty$, then $\mathsf{G}_\sigma \in D(\mathcal{E}_\star)$ and $\mathcal{E}_\star(\mathsf{G}_\sigma) \le \sup|\varphi|\, C_1$; if $C_2 = \liminf_R \limsup_j \|\chi^{\mathrm{c}}_{K_j,R} \mathcal{L}_{K_j} H^\sigma_{K_j}\|_{L^2(\mu^{K_j})} < \infty$, then $\mathsf{G}_\sigma \in D(A_\star)$ and $\|A_\star \mathsf{G}_\sigma\| \le C_2$. Without a cutoff, the criterion of (A3) gives $\mathsf{G}_\sigma \in D(A_\star)$, with $\mathcal{L}_{K_j} H^\sigma_{K_j} \to -A_\star \mathsf{G}_\sigma$ weakly and $\mathcal{E}_{K_j}(H^\sigma_{K_j}) \to \mathcal{E}_\star(\mathsf{G}_\sigma)$, whenever $\sup_K \|\mathcal{L}_K H^\sigma_K\|_{L^2(\mu^K)} < \infty$; this fails at the members of (C7)(b), (c), (e).

(C6) *Lower energy bounds.* There is $p_* > 0$, depending only on the constants of the construction, and there are $\sigma_*, c_* > 0$, $S_* < \infty$ such that for $0 < \sigma \le \sigma_*$, every $\varphi \in C^1(\mathbb{R})$ and every invariant Borel $\chi_K : \Omega_K \to [0,1]$ with $\mu^K(\chi_K < 1) \le p_*/8$,

$$\liminf_{K\to\infty} \int \chi_K \, \Gamma_K(\varphi(A^a) \circ \Phi_\sigma) \, \mathrm{d}\mu^K \;\ge\; c_* \, \sigma^{-\frac{5}{2}+\kappa} \inf_{[0, S_* \sigma^{-3/2-\kappa}]} \varphi'^2.$$

For every $\vartheta < 1$ there is $\sigma_\vartheta > 0$ such that the left side is positive for $0 < \sigma \le \sigma_\vartheta$, every φ with $\varphi' > 0$ and every such χ_K with $\mu^K(\chi_K < 1) \le \vartheta$; in particular $\liminf_K \mathcal{E}_K(\varphi(A^a) \circ \Phi_\sigma) > 0$. There are $\sigma_{**} > 0$ and $0 < c_\circ \le C_\circ$, $c_\circ$ depending only on the constants of the construction, with

$$c_\circ \, \mathsf{b}^{-1} \ell^3 \sigma^{-3/2} \le \liminf_K \langle A^a \circ \Phi_\sigma \rangle_{\mu^K} \le \limsup_K \langle A^a \circ \Phi_\sigma \rangle_{\mu^K} \le C_\circ \, \mathsf{b}^{-1} \ell^3 \sigma^{-3/2} \qquad (0 < \sigma \le \sigma_{**});$$

for every $\varrho \in (0,1)$ there are $c_\varrho, \sigma_\varrho > 0$ such that for $0 < \sigma \le \sigma_\varrho$ and all large K, with μ^K-probability at least $1 - \varrho$, the flowed action exceeds $c_\varrho \mathsf{b}^{-1} \ell^3 \sigma^{-3/2}$ and $\Gamma_K(A^a \circ \Phi_\sigma)$ exceeds $c_\varrho \sigma^{-5/2+\kappa}$; and for $0 < \sigma \le \sigma_*$ the flowed current does not vanish in probability: $\liminf_K \mu^K((J,J)_a(U_\sigma) \ge c_J(\sigma)) \ge \frac{1}{4} p_*$ for some $c_J(\sigma) > 0$.

(C7) *The generator without a regularisation cutoff.* Let $\bar{s}, \bar{C}$ be given by Prop. 16.1(a) for some $0 < \epsilon < 1$, and $0 < \sigma \le \bar{s}$. There is K_1 such that for $K \ge K_1$, $a = a_K$: (a) $\int |\partial(A_K \circ \Phi_\sigma)|^q \, \mathrm{d}\mu^K \ge \exp[(6.6\, q - 24.64)\, \sigma/a^2]$ for $q \in [3.74, 8]$, and $\int \Gamma_K(A^a \circ \Phi_\sigma)^2 \, \mathrm{d}\mu^K \ge e^{1.76\, \sigma/a^2}$; (b) $\|\mathcal{L}_K \arctan(A^a \circ \Phi_\sigma)\|_{L^2(\mu^K)} \ge e^{0.8\, \sigma/a^2}$; (c) for $f(x) = 1 - \cos(2\pi x_1/\ell)$, $E^{\mathrm{a}}_\sigma = \frac{3}{2}\ell^3 (2\bar{C}(\frac{\sigma}{2})^{-\frac{3}{4}-\frac{\kappa}{2}} + 8\bar{C}^2(\frac{\sigma}{2})^{-\frac{1}{2}-\kappa})^2$, $M_\sigma = (\frac{4}{\sigma} + \frac{11400}{\ell^2})(\frac{3}{2}\sigma E^{\mathrm{a}}_\sigma + 1) + 1$ and every $\varphi \in C^\infty(\mathbb{R})$, bounded with all its derivatives, with $\inf_{[0,M_\sigma]} |\varphi'| > 0$ (K_1 depending on φ): $\|\mathcal{L}_K \varphi(\mathcal{O}(f) \circ \Phi_\sigma)\|_{L^2(\mu^K)} \ge e^{0.8\, \sigma/a^2}$; (d) for $p \in [1.87, 4]$: $\|\mathcal{L}_K \cos(A^a \circ \Phi_\sigma)\|_{L^p(\mu^K)} + \|\mathcal{L}_K \sin(A^a \circ \Phi_\sigma)\|_{L^p(\mu^K)} \ge e^{0.04\, \sigma/(p a^2)}$, and for every $p > 1.8637$ the left side is unbounded in K; (e) for every real $f \in C^\infty(T_\ell)$, $f \not\equiv 0$, with K_1 and a constant C depending on f but not on K: $\|\mathcal{L}_K \sin(\mathcal{O}(f) \circ \Phi_\sigma)\|_{L^2(\mu^K)} \ge \exp[\frac{\sigma}{5a^2} - \frac{10\,\mathsf{b}}{a} - C]$, and $\|\mathcal{L}_K \varphi(\mathcal{O}(f) \circ \Phi_\sigma)\|_{L^2(\mu^K)} \ge e^{\sigma/20a^2}$ for every non-constant periodic $\varphi \in C^\infty(\mathbb{R})$, K_1 depending besides on φ; (f) $\sup_K \int e^{13\Lambda_\sigma} \, \mathrm{d}\mu^K = \infty$.

16.3. **Gauge-fixed regularity and the admissibility hypothesis.**

Proposition 16.1 (Gauge-fixed fields and the gradient flow)**.** Let $0 < \kappa < \frac{1}{6}$, and let $\mathsf{N}'(U)$ be the least $\|\mathbf{B}\|_{\kappa;a}$ over the 1-forms $\mathbf{B}$ with $e^{i a_K \mathbf{B}}$ in the orbit of U. *The gauge-fixed flow* is the lattice gradient flow of the action with a gauge term: $V_s = e^{i a_K A_s}$, $A_0 = \mathbf{B}$, moves with the velocity of the Wilson flow Φ plus a gauge direction $\mathrm{d}_{V_s}\lambda_s$, λ_s the lattice form of the divergence of A_s that answers to the member $\mathrm{d}_{\mathfrak{A}}(\partial_\nu \mathfrak{A}_\nu)$ of the flow lines, fixed so that the linear part of the equation is the lattice heat operator. In the chart it reads $\frac{d}{ds} A_s(b) = a_K^{-3} \Theta^{\mathrm{ch}}(a_K A_s|_{\mathsf{N}(b)})$, $\mathsf{N}(b)$ the fifteen bonds near b, Θ^{ch} holomorphic and bounded on $\{|a_K A| \le 1\}$, and $\mathsf{M}_\Theta = \max\{1, \sup|\Theta^{\mathrm{ch}}|\}$, the supremum taken there, an absolute number; the members of Θ^{ch} of the orders one, two and at least three in A give

$$\dot{A} = \Delta_a A + \mathcal{N}(A,A) + \mathcal{R}(A), \qquad \mathcal{N}(A,A') = \sum_j c_j \, (\tau_{h_j} \nabla_{\lambda_j} A_{\nu_j}) \wedge (\tau_{h'_j} A'_{\nu'_j}),$$

a finite sum, with absolute coefficients, over the directions and the fixed finite translation set used in the rough regularity quantity.

Fields in the chain gauge. Assume (E); let $d_0 \ge n_2$ be a top depth, $K > d_0$, $t = K - d_0$, $\mathbb{E}^{[d_0]}$ the normalised chain measure from the top depth d_0, and $V_k = \mathcal{M}^k U$. On a set of full measure: U is a gauge transform of U_0, where $\mathsf{U}_t = U_{\mathrm{top}}$ is a background over the top field V_t and $\mathsf{U}_k = e^{i a_K \mathbf{h}_{K-k}} \mathsf{U}_{k+1}$ ($k < t$) is a gauge transform of the background over V_k, in a gauge that is a function of V_{k+1} (the

gauge of the chain); the layer $\mathbf{h}_d$ of the depth $d = K - k$ is a function of the fluctuation B_k of the chart at V_{k+1}, with $|\mathbf{h}_d| \le c_{\mathsf{h}} L^d \delta(L^d \mathsf{b})$, c_{h} a constant of the construction; its linear part in the fluctuation, carried by $\mathrm{Ad}(\gamma)$ below, is $\mathsf{b}^{-1/2} L^{d/2} \mathsf{J}_d B_k$, with the layer map J_d, a function of V_{k+1}, of the norms $\|\mathsf{J}_d X\|_{L^2(T_\ell)} \le c_{\mathsf{J}} L^{-3d/2} \|X\|$ and $\|\mathsf{J}_d X\|_\infty \le c_{\mathsf{J}} \max |X|$, c_{J} a constant of the construction, and at every point of the box the derivative of $\mathbf{h}_d$ in B_k is $\mathsf{b}^{-1/2} L^{d/2}$ times a map with the same two bounds; in its regular gauge γ the top is $U^\gamma_{\mathrm{top}} = e^{i a_K \mathbf{A}^{\mathrm{top}}}$ with $|\mathbf{A}^{\mathrm{top}}| \le \mathsf{a}_{\mathrm{top}} \le C L^{10 d_0}$, $\mathsf{a}_{\mathrm{top}}$ a number that reads neither K nor the field; and U is a gauge transform of $e^{i a_K \mathbf{B}_K}$,

$$\mathbf{B}_K = \tfrac{1}{i a_K} \log(e^{i a_K \mathbf{h}'_K} \cdots e^{i a_K \mathbf{h}'_{d_0+1}} e^{i a_K \mathbf{A}^{\mathrm{top}}}), \qquad \mathbf{h}'_d = \mathrm{Ad}(\gamma) \mathbf{h}_d,$$

bond by bond, the logarithm being formed by its series if $\sum_d a_K |\mathbf{h}_d| \le \frac14$ and $a_K \mathsf{a}_{\mathrm{top}} \le \frac18$, and otherwise by a fixed Borel $\mathfrak{su}(2)$ logarithm of norm at most π, principal off $-\mathbf{1}$, on positive bonds and extended by reversal. Admissibility and the conclusion (Adm) have the meaning stated before Thm. AV; the layer fields and their conditional estimates are specified in the proof below.

(a) There are $c_1, c_2 \in (0,1]$, $c_{\mathrm{Lip}} \in (0, c_1]$ and c_3, c_4, c_5, depending only on κ, such that for all K, m and $\beta > 0$, every real 1-form $\mathbf{B}$ on $\Lambda_{K,\ell}$ and $R \ge \max\{1, \|\mathbf{B}\|_{\kappa;a}\}$, with $s_0(R) = (c_1 R^{-2})^{4/(1-2\kappa)}$, $s_{\mathrm{Lip}}(R) = (c_{\mathrm{Lip}} R^{-2})^{4/(1-2\kappa)}$ and $a_0(R) = (c_2 R^{-1})^{2/(1-2\kappa)}$, the following hold. If $a_K \le a_0(R)$, the gauge-fixed flow A_s from $A_0 = \mathbf{B}$ exists on the closed interval $[0, s_0(R)]$, $\Phi_s(e^{i a_K \mathbf{B}})$ is gauge equivalent to $e^{i a_K A_s}$, and for $0 < s \le s_0(R)$: $\|A_s - P_s \mathbf{B}\|_\infty \le c_3 R s^{-\kappa}$, $\|\nabla(A_s - P_s \mathbf{B})\|_\infty \le c_3 R s^{-\frac12 - \kappa}$, $\|A_s\|_\infty \le (1 + c_3) R s^{-\frac14 - \frac{\kappa}{2}}$, $\|\nabla A_s\|_\infty \le (2 + c_3) R s^{-\frac34 - \frac{\kappa}{2}}$.

If besides $\mathbf{B}'$ is a real 1-form with $\|\mathbf{B}'\|_{\kappa;a} \le R$, A'_s its gauge-fixed flow and D the rough distance of $\mathbf{B}$ and $\mathbf{B}'$, then for $0 < s \le s_{\mathrm{Lip}}(R)$: $\|(A_s - A'_s) - P_s(\mathbf{B} - \mathbf{B}')\|_\infty \le c_5 \mathsf{D} s^{-\kappa}$, $\|\nabla[(A_s - A'_s) - P_s(\mathbf{B} - \mathbf{B}')]\|_\infty \le c_5 \mathsf{D} s^{-\frac12 - \kappa}$, so $\|A_s - A'_s\|_\infty \le (1 + c_5) \mathsf{D} s^{-\frac14 - \frac{\kappa}{2}}$. For every a_K: $A^a(\Phi_s e^{i a_K \mathbf{B}}) \le c_4 \ell^3 (1 + R)^{24} s^{-\frac32 - \kappa}$ for $0 < s \le 1$. These statements, the short-time theory of the gauge-fixed flow, are deterministic and rest on its equation alone; they hold on every lattice $\Lambda_{K,\ell}$, uniformly in a_K.

Assume (E): for every admissible d_0, $K > d_0$ and $q < \infty$, $\mathbb{E}^{[d_0]}[\|\mathbf{B}_K\|^q_{\kappa;a}]^{1/q} \le C(q,\kappa) L^{20 d_0}$, with $C(q,\kappa)$ free of K and d_0; and for every top depth $d_1 \ge n_2$, $K > d_1$, invariant Borel $F \ge 0$ and $r > 1$,

$$\langle F \rangle_{\mu^K} \le \mathbb{E}^{[d_1]}[F] + \sum_{d_1 \le d \le K-2} \mathsf{R}_d^{1 - 1/r} \, \mathbb{E}^{[d+1]}[F^r]^{1/r} + \mathsf{R}_{K-1} \sup F,$$

where $\sum_d \mathsf{R}_d^{1/2} L^{pd}$ and $\sup_K \mathsf{R}_{K-1} L^{pK}$ are finite for every p. Under (E), the conclusion (Adm) proved below gives $\mathsf{M}_q = \mathsf{M}_q(\kappa) = \sup_K \langle \mathsf{N}'^q \rangle_{\mu^K} < \infty$ for every $q < \infty$, and: for every $\epsilon > 0$ there are $\bar s \in (0,1]$, $\bar C$, $\bar K$ with $\mu^K(\mathsf{O}_K(\bar C, \bar s)) \ge 1 - \epsilon$ for $K \ge \bar K$; $\sup_K \langle (\sup_{0 < s \le 1} s^{\frac32 + \kappa} A^a(U_s))^q \rangle_{\mu^K} < \infty$ for every q; for $0 < \sigma \le 1$ and $1 \le p < \infty$ there is C_3, bounded for σ in compact subsets of $(0,1]$, with $\mu^K(\max_p a_p(U_\sigma) > 10^{-4}) \le C_3 a_K^p$ and $\int [(a_K^{-4} \max_p a_p(U_\sigma))^p + (J,J)_a(U_\sigma)^p] \, \mathrm{d}\mu^K \le C_3$ for all K; and for $0 < \sigma \le 1$ the laws of Λ_σ under μ^K are tight.

(b) Under (E), the flow-approximation task seeks the following conclusion. For every closed path C of bonds of some $\Lambda_{d,\ell}$ and $s > 0$, the flowed Wilson loop $W_C \circ \Phi_s$ (W_C the half trace of the holonomy) converges strongly along the full sequence of cutoffs; there are an invariant Borel set of threads of full measure and a Borel map $\mathfrak{F}$ from it into flow lines, $\mathfrak{F}(Y)_s$ represented by a $C^{1,1}$ connection for $s > 0$, such that the limit is $W_C(\mathfrak{F}(Y)_s)$. For every flowed observable and $\sigma > 0$, with $\Xi^\sigma_{K,D}(V) = H^\sigma_K(U)$ for $V \in \{\varpi < \theta_D\} \subset \Omega_D$, U any element of the minimal orbit over V in Ω_K, and $\Xi^\sigma_{K,D} = 0$ elsewhere:

$$\lim_{D \to \infty} \sup_{K > D} \|H^\sigma_K - \Xi^\sigma_{K,D} \circ \pi_{K,D}\|_{L^2(\mu^K)} = 0, \qquad \lim_{D \to \infty} \limsup_{K \to \infty} \|\Xi^\sigma_{K,D}(Y_D) - \mathsf{G}_\sigma\|_{L^2(\mu)} = 0 :$$

the flowed observable at the background of the block field of a large depth.

(c) The same flow identification is intended to give the following joint convergence under (E). For $s > 0$ and Lipschitz f the joint laws of $\mathcal{O}(f) \circ \Phi_s$ and of the $W_C \circ \Phi_s$ under μ^K converge with all moments along the full sequence to the joint law of $\mathcal{O}^0(f)(\mathfrak{F}(Y)_s)$ and the $W_C(\mathfrak{F}(Y)_s)$ under μ. Separately, under (E) alone, for $\epsilon, \eta > 0$ there are Borel sets G_K with $\mu^K(\mathsf{G}_K) \geq 1 - \epsilon$, closed paths $C_1, \dots, C_q$ and a continuous Θ on $[-1,1]^q$ with $|\mathcal{O}(f)(U_s) - \Theta((W_{C_i}(U_s))_i)| \leq \eta$ on G_K for all large K.

■

Proof sketch. (a)

The gauge-fixed flow. Write $A_s = P_s\mathbf{B} + w_s$; the mild form $w_s = \int_0^s P_{s-r}[\mathcal{N}(A_r, A_r) + \mathcal{R}(A_r)]\,\mathrm{d}r$ has a fixed point in the norm $\sup_{0<s\leq s_0(R)} \max\{s^\kappa \|w_s\|_\infty, s^{\frac{1}{2}+\kappa}\|\nabla w_s\|_\infty\}$. The first iterate $\int_0^s P_{s-r}\mathcal{N}(P_r\mathbf{B}, P_r\mathbf{B})\,\mathrm{d}r$ is bounded through the quadratic member of the rough norm, by $\|P_{s-r}f\|_\infty \leq (s-r)^{-1/4}|f|_{-\frac{1}{2};a}$ and $\int_0^s (s-r)^{-\frac{1}{4}} r^{-\frac{3}{4}-\kappa} dr \leq c\, s^{-\kappa}$; the cross terms $\mathcal{N}(P_r\mathbf{B}, w_r)$, $\mathcal{N}(w_r, P_r\mathbf{B})$, $\mathcal{N}(w_r, w_r)$ give the unweighted factor $s^{\frac{1}{4}-\frac{3}{2}\kappa}$.

This is a positive power because $\kappa < \frac{1}{6}$; multiplication by the weight s^κ in the fixed-point norm gives the contraction condition $R^2 s^{\frac{1}{4}-\frac{\kappa}{2}} \leq c_1$; the members of order at least three are bounded in the chart, $|\mathcal{R}(A)| \leq 2 \sup|\Theta^{\mathrm{ch}}|\, \|A\|_\infty^3$ for $a_K\|A\|_\infty \leq \frac{1}{2}$ by Cauchy's estimate, and the flow does not leave the chart on $[0, s_0(R)]$ for $a_K \leq a_0(R)$, by the choice of c_2, as $a_K\|\mathbf{B}\|_\infty \leq e^{12} R a_K^{\frac{1}{2}-\kappa}$. The other two bounds follow with $s^{\frac{1}{4}+\frac{\kappa}{2}}\|P_s\mathbf{B}\|_\infty \leq R$, $s^{\frac{3}{4}+\frac{\kappa}{2}}\|\nabla P_s\mathbf{B}\|_\infty \leq 2R$.

The velocities of V_s and of $\Phi_s(V_0)$ differ by a gauge direction, so the two are gauge equivalent. For two data, $(A_s - A'_s) - P_s(\mathbf{B} - \mathbf{B}')$ solves the same kind of equation, into which the quadratic member enters through $\mathcal{N}(P_r\mathbf{B}, P_r\mathbf{B}) - \mathcal{N}(P_r\mathbf{B}', P_r\mathbf{B}')$, which the rough distance bounds; the fixed point closes on $(0, s_{\mathrm{Lip}}(R)]$. The action: for $s \leq s_0(R)$ and $a_K \leq a_0(R)$, $A^a \leq \frac{3}{2}\ell^3(a_K^{-2}\varpi)^2$ and $\varpi(e^{ia_K A}) \leq 2a_K^2(\|A\|_\infty^2 + \|\nabla A\|_\infty)$ (Lem. 16.2(c), (e)) give with the four bounds $A^a(\Phi_s e^{ia_K\mathbf{B}}) \leq 6((1+c_3)^2 + 2 + c_3)^2\ell^3 R^4 s^{-\frac{3}{2}-\kappa}$; for $s_0(R) < s \leq 1$ the action does not increase (Lem. 16.2(c)), and its value at $s_0(R)$ is at most $CR^4(R^2/c_1)^{4(\frac{3}{2}+\kappa)/(1-2\kappa)}$, a power of R below 24; for $a_K > a_0(R)$, $A^a \leq 6\ell^3 a_K^{-4} < 6\ell^3(R/c_2)^{8/(1-2\kappa)}$, a power of R below 12.

So c_4 depends only on κ.

The field of the gauge of the chain. Given $\mathcal{F}_{d-1}$, the σ-algebra of V_{K-d+1}, the law of B_{K-d} is p_W, $W = V_{K-d+1}$ (Lem. 15.3(ii)). The layers are made step by step, for $k = t-1, \dots, 0$, starting from $\mathsf{U}_t = U_{\mathrm{top}}$, a background over V_t, and ending at $k = 0$, where $\mathcal{M}^0$ is the identity, so that U is a gauge transform of U_0. At the step k, with $W = V_{k+1}$, let U_+ be a background over W whose block field $\mathcal{M}^k U_+$ is the base point $V_W(0)$ of the chart, a background of the level k as well, over $\mathcal{M}^k U_+$ (the background and chart identification in Prop. YM3_I:52.3), chosen as a Borel function of W, and let g_{k+1}, a function of V_{k+1}, be the gauge with $\mathsf{U}_{k+1}^{\mathsf{g}_{k+1}} = U_+$. The chart writes $V_k = V_W(B_k)$, and $\zeta = x_k^{-1/2} B_k$, on the bonds that are not pivot bonds, has $\sup|\zeta| < \delta(x_k) \leq \frac{1}{6}\varepsilon_{\mathrm{A}}$; by the global shift identification in Prop. YM3_I:51.5, and at $k = 0$ by the pivot chart in equation YM3_I:(800), the background over V_k is a gauge transform of $e^{iL^{-k}\mathbf{A}[U_+;\zeta]}U_+$. As $a_K L^d = L^{-k}$ and $(e^{iX}U)^g = e^{i\mathrm{Ad}(g)X}U^g$, the layer $\mathbf{h}_d = L^d \mathrm{Ad}(\mathsf{g}_{k+1}^{-1})\mathbf{A}[U_+;\zeta]$ makes $\mathsf{U}_k = e^{ia_K\mathbf{h}_d}\mathsf{U}_{k+1}$ the transform of $e^{iL^{-k}\mathbf{A}[U_+;\zeta]}U_+$ by g_{k+1}^{-1}, a function of V_{k+1}; U_k is a function of V_k, and so is the gauge g_k of the next step. The bound $|\mathbf{A}[U_+;\zeta]| \leq c_{\mathsf{h}} \sup|\zeta|$ (Prop. YM3_I:51.5 and the pivot estimate YM3_I:(800)) gives $|\mathbf{h}_d| \leq c_{\mathsf{h}} L^d \delta(L^d \mathsf{b})$. The product that defines $\mathbf{B}_K$ lies within $\frac{3}{8}$ of $\mathbf{1}$ when $\sum_d a_K|\mathbf{h}_d| \leq \frac{1}{4}$ and $a_K \mathsf{a}_{\mathrm{top}} \leq \frac{1}{8}$.

The regular gauge of the top. The regularity number of the level k of a configuration U' on the bare lattice is $L^{2k}\max_p|\partial U'(p) - \mathbf{1}|$, the maximum over the bare plaquettes p ([7, Def. P.3]); at the level 0 it is $\varpi(U')$, and at the level k it is L^{2k} times its value at the level 0 (by that definition

in the two units). For $k \geq 1$, Cut_k consists of the block fields of the level k whose backgrounds exist and have regularity numbers of the level k below $c_\rho\varepsilon(x_k)$ (the definition of the field cut). As $V_t \in \mathsf{I}_{d_0} \subset \mathsf{Cut}_t$ and $x_t = L^{d_0}\mathsf{b}$, every background U' over V_t has $L^{2t}\varpi(U') < c_\rho\varepsilon(L^{d_0}\mathsf{b})$, so $\varpi(U') < c_\rho\varepsilon(L^{d_0}\mathsf{b})L^{-2t} = c_\rho\varepsilon(L^{d_0}\mathsf{b})L^{2d_0}a_K^2$. Lem. 15.7(a) with $\mathfrak{n} = N$, at $\kappa' = \max\{c_\rho\varepsilon(L^{d_0}\mathsf{b})L^{2d_0}, \ell^{-2}\}a_K^2$, for which $N \geq \kappa'^{-1/2}$, gives a gauge γ, which a measurable selection makes depend on V_t alone in a Borel way, with $|U^\gamma_{\mathrm{top}}(b) - \mathbf{1}| \leq C_{\mathrm{BG}}\sqrt{\kappa'} \leq C_{\mathrm{BG}} \max\{(c_\rho\varepsilon(L^{d_0}\mathsf{b}))^{1/2}, \ell^{-1}\}L^{d_0}a_K \leq CL^{d_0}a_K$ at every bond; at the finitely many K with $\kappa' > \kappa_0$ or $N < \lambda_{\mathrm{BG},3}$ we take $\gamma = \mathbf{1}$, and there $\pi/a_K \leq CL^{d_0}$. So $U^\gamma_{\mathrm{top}} = e^{ia_K\mathbf{A}^{\mathrm{top}}}$, with $ia_K\mathbf{A}^{\mathrm{top}}$ a fixed Borel $\mathfrak{su}(2)$ logarithm of norm at most π, equal to the principal logarithm off $-\mathbf{1}$, at each positive bond, and extended by reversal, so that $\mathbf{A}^{\mathrm{top}}$ too depends on V_t alone in a Borel way, and $|\mathbf{A}^{\mathrm{top}}| \leq \frac{\pi}{2}a_K^{-1}|U^\gamma_{\mathrm{top}} - \mathbf{1}|$ gives $|\mathbf{A}^{\mathrm{top}}| \leq \mathsf{a}_{\mathrm{top}} = CL^{d_0} \leq CL^{10d_0}$. The bounds of J_d, and those of the derivative of the layer on the box, come from the locality of the shift. Let $\mathfrak{n}$ be the distance, in the maximum norm and in units of their side, of the cubes of π^M_{k+1} that hold β_- and b_-, for a bare bond β and a bond b of the level k, and $e^{\bar\kappa}$ the radius of the polydisc $\mathbb{D}(Y)$ of the parameters of the shift systems (Prop. YM3_I:51.5 and the hypotheses preceding it). For $\mathfrak{n} \geq 3$ the value of $\mathbf{A}[U_+;\zeta]$ at β differs from that of the shift of the cube of $(2\mathfrak{n}-1)^3$ cubes about the cube of β_-, which does not read $\zeta(b)$, by at most $2c_{\mathsf{h}} \sup|\zeta| e^{-\bar\kappa(\mathfrak{n}-2)}$: let every fine cube, that is every cube of π^M_k, in the shell of the cubes of this cube at the distance j from the cube of β_-, $2 \leq j \leq \mathfrak{n}-1$, one of its $\mathfrak{n}-2$ outer shells, carry a single variable s_j, $|s_j| < e^{\bar\kappa}$, and every fine cube outside these shells the value 1; by the holomorphy, support and restriction properties of Prop. YM3_I:51.5 the difference is then the value at $s_2 = \cdots = s_{\mathfrak{n}-1} = 1$ of a holomorphic function of these $\mathfrak{n}-2$ variables, of modulus at most $2c_{\mathsf{h}} \sup|\zeta|$ on their polydisc, and zero as soon as some s_j is zero, since that shell then separates the cubes nearer than it to the cube of β_-, among them those that hold the two ends of β, from the cubes beyond it; and Schwarz's lemma in the s_j gives the bound. So, by Cauchy's estimate, for $\sup|\zeta| \leq \frac{1}{2}\varepsilon_{\mathrm{A}}$ the derivative of $\mathbf{A}[U_+;\zeta]$ at β in the value of ζ at b is at most $4c_{\mathsf{h}}e^{-\bar\kappa(\mathfrak{n}-2)_+}$, and for $k = 0$ it vanishes unless $\mathfrak{n} \leq 1$ (the double-block dependence of the pivot chart YM3_I:(800)). As at most 125 cubes lie at a distance ≤ 2 from a given one and at most $24\mathfrak{n}^2 + 2$ at the distance $\mathfrak{n}$, Schur's test gives the two norms of J_d, and the same bounds for the derivative of the layer on the box, with $c_{\mathsf{J}} = \sqrt{27}(LM)^3 \cdot 4c_{\mathsf{h}}[125 + \sum_{\mathfrak{n}\geq 3}(24\mathfrak{n}^2+2)e^{-\bar\kappa(\mathfrak{n}-2)}]$, and $\|\mathsf{J}_d^* f\| \leq c_{\mathsf{J}} \min\{L^{-3d/2}\|f\|_2, \|f\|_1\}$.

Each layer splits as $\mathbf{h}'_d = \mathbf{n}_d + u_{(d)} + e_{(d)}$: $\mathbf{n}_d$ its conditional mean given $\mathcal{F}_{d-1}$; $u_{(d)} = \mathsf{b}^{-1/2}L^{d/2}\mathrm{Ad}(\gamma)\mathsf{J}_d\tilde B_d$, linear in the centred fluctuation $\tilde B_d = B_{K-d} - \int B\,\mathrm{d}p_W$ with a predictable coefficient; $e_{(d)}$ the centred rest, which carries besides the factor $\delta(L^d\mathsf{b})$. So $\mathbf{B}_K = u + \rho$, $u = \sum_d u_{(d)}$, ρ the sum of the $e_{(d)}$, of the $\mathbf{n}_d$, of $\mathbf{A}^{\mathrm{top}}$ and of the remainder of the ordered product beyond the sum of its factors.

The linear fluctuation. By Lem. 15.3(iv), given $\mathcal{F}_{d-1}$ every Lipschitz function of B_{K-d} has Gaussian tails, with the variance proxy $\frac{8}{\gamma_{\mathrm{r}}}$ times the square of its Lipschitz constant; for $\langle u_{(d)}, f\rangle$ this square is at most $c_{\mathsf{J}}^2\mathsf{b}^{-1}L^d \min\{\|f\|_1^2, L^{-3d}\|f\|_2^2\}$, so $(P_s u_{(d)})(x)$, $f = k_s(x,\cdot)$ the heat kernel, has the proxy $C\mathsf{b}^{-1}L^d\min\{1, L^{-3d}s^{-3/2}\}$, whose sum over d is $\leq C\mathsf{b}^{-1}s^{-1/2}$. Exponential supermartingales over the depths, with test functions that are functions of $\mathcal{F}_{d-1}$, and a union over dyadic grids of times and sites, through the grid lemma for $|\cdot|_{\eta;a}$ and the bounds of the heat kernel, give Gaussian tails of $|u|_{-\frac{1}{2}-\kappa;a}$.

The quadratic fluctuation and colour cancellation. Sort the pairs in $\mathcal{N}_s[u,u]$ by the finer index. A pair of different depths is linear in the finer layer with a predictable coefficient: a martingale difference, with Gaussian tails as before. The diagonal $\mathcal{N}_s[u_{(d)}, u_{(d)}]$, after P_r at a point, is a quadratic form $(\tilde B_d, \mathcal{Q}_d\tilde B_d)$ of the centred fluctuation, $\|\mathcal{Q}_d\|_{\mathrm{tr}} \leq C\mathsf{b}^{-1}L^d s^{-1/2}\min\{1, L^{-3d}s^{-3/2}\}$; its centred part has exponential moments by (Q), through the norm and the Hilbert–Schmidt norm of $\mathcal{Q}_d$. Its compensator, the conditional mean $\mathrm{tr}(\mathcal{Q}_d\mathrm{Cov}_W)$, would sum by the sizes to the order

$\mathsf{b}^{-1}s^{-1}$, beyond the weight $s^{\frac{3}{4}+\kappa}$; but it reads the conditional covariance of the layer on the bare lattice, in the gauge of the chain, only through its part that is antisymmetric in colour, as $X \wedge Y$ is antisymmetric.

By (Col) the scalar part drops out, and almost surely

$$|\mathrm{tr}(\mathcal{Q}_d \mathrm{Cov}_W)| \le C s^{-1/2} \min\{1, L^{-3d} s^{-3/2}\} [L^{d/2} (\log x)^{\mathfrak{p}_0+6} + \mathsf{a}_{\mathrm{top}}],$$

$x = L^d \mathsf{b}$, whose sum over d is $\le C(1+\mathsf{a}_{\mathrm{top}}) s^{-\frac{3}{4}-\frac{\kappa}{2}}$, which the weight $s^{\frac{3}{4}+\kappa}$ admits: the cancellation in colour.

Means and nonlinear remainders. The $e_{(d)}$ by the bounds of the linear part, with the factor $\delta(L^d\mathsf{b})$; the means by (M), summable in $|\cdot|_{-\kappa;a}$ through $\|\cdot\|_{L^p}$, $p = \lceil 3/\kappa \rceil$; $\mathbf{A}^{\mathrm{top}}$ by $\mathsf{a}_{\mathrm{top}}$; the ordered product, at the second order linear in the finer factor with a predictable coefficient, at the third order small; each with $|\cdot|_{-\kappa;a} \le C(1+\mathsf{a}_{\mathrm{top}})$ in every L^q. The cross members of u and ρ by the sizes, as $(-\frac{1}{2}-\kappa)+(-\kappa) \ge -\frac{1}{2}-2\kappa$. Together $\mathbb{E}^{[d_0]}[\|\mathbf{B}_K\|_{\kappa;a}^q]^{1/q} \le C(q,\kappa)(1+\mathsf{a}_{\mathrm{top}})^2$, every constant reading d_0 only through $\mathsf{a}_{\mathrm{top}}$; with $\mathsf{a}_{\mathrm{top}} \le C L^{10 d_0}$ this is the bound of the statement; for the finitely many K with $a_K \mathsf{a}_{\mathrm{top}} > \frac{1}{8}$ the principal logarithm has $\|\mathbf{B}_K\|_\infty < 8\pi \mathsf{a}_{\mathrm{top}}$.

The statements on one fluctuation integral that enter, besides Lem. 15.3(iv), the bounds of the response, the bounds of the heat kernel and the grid lemma, are, with C free of K and d_0: (M) $\|\mathbf{n}_d\|_\infty \le C\mathsf{b}^{-1}(\log L^d\mathsf{b})^{2\mathfrak{p}_0}$ and $\|\mathbf{n}_d\|_{L^2}^2 \le C\ell^3\mathsf{b}^{-3}L^{-d}(\log L^d\mathsf{b})^{8\mathfrak{p}_0+12}$; (Col) in the gauge of the chain the kernel of $\mathrm{Ad}(\gamma)\mathsf{J}_d\mathsf{A}_W^{-1}\mathsf{J}_d^*\mathrm{Ad}(\gamma)^{\mathsf{T}}$ at two bare bonds whose partition cubes are at distance N is a number times the identity in colour up to w_N, $\sum_N (24N^2+2)\mathsf{w}_N \le C[x^{-1/2}(\log x)^{\mathfrak{p}_0+6} + \mathsf{a}_{\mathrm{top}} L^{-d}]$, the number being formed at the trivial background, where the Gaussian form and the response commute with the adjoint action; and $\|\mathrm{Cov}_W - \mathsf{A}_W^{-1}\| \le C x^{-1/2}(\log x)^{\mathfrak{p}_0+3}$, A_W the Gaussian form of p_W.

(Q) There are universal constants $C_{\mathrm{HW}}, c_{\mathrm{HW}} > 0$ with the following property. Let the real symmetric $\mathcal{Q}_d$ be predictable, that is, functions of $\mathcal{F}_{d-1}$, and assume almost surely the deterministic bounds $\|\mathcal{Q}_d\| \le \mathsf{q}$ and $C_{\mathrm{HW}}\gamma_{\mathrm{r}}^{-2}\sum_d \|\mathcal{Q}_d\|_{\mathrm{HS}}^2 \le \Sigma^2$. For the actual conditional covariance set $\mathsf{X}_d = (\tilde{B}_d, \mathcal{Q}_d\tilde{B}_d) - \mathrm{tr}(\mathcal{Q}_d\mathrm{Cov}_W)$. Then $\mathbb{E}^{[d_0]} e^{\epsilon\sum_d \mathsf{X}_d} \le e^{\epsilon^2\Sigma^2}$ for $|\epsilon|\mathsf{q} \le c_{\mathrm{HW}}\gamma_{\mathrm{r}}$.

Indeed the conditional box law has Hessian at least $\gamma_{\mathrm{r}}/4$ and log-Sobolev constant $8/\gamma_{\mathrm{r}}$ (Lem. 15.3(iv)); the convex-domain criterion [4, Thm. 2.1] applies. For nonzero $\mathcal{Q}$, Adamczak's dependent-vector inequality [3, Thm. 2.3] gives the centred quadratic form Y the conditional tail $2\exp[-c\min\{\gamma_{\mathrm{r}}^2 t^2/\|\mathcal{Q}\|_{\mathrm{HS}}^2, \gamma_{\mathrm{r}} t/\|\mathcal{Q}\|\}]$. For $\epsilon > 0$, centering gives

$$\mathbb{E}e^{\epsilon Y} - 1 = \epsilon \int_0^\infty [(e^{\epsilon t}-1)\mathbb{P}(Y > t) + (1-e^{-\epsilon t})\mathbb{P}(Y < -t)]\,dt.$$

Integrating the Gaussian and exponential tails bounds the conditional logarithmic moment by $C_{\mathrm{HW}}\epsilon^2\gamma_{\mathrm{r}}^{-2}\|\mathcal{Q}\|_{\mathrm{HS}}^2$ for $|\epsilon|\|\mathcal{Q}\| \le c_{\mathrm{HW}}\gamma_{\mathrm{r}}$; apply the same argument to $-Y$. Consequently $\exp[\epsilon\sum_{j\le d}\mathsf{X}_j - C_{\mathrm{HW}}\epsilon^2\gamma_{\mathrm{r}}^{-2}\sum_{j\le d}\|\mathcal{Q}_j\|_{\mathrm{HS}}^2]$ is a conditional supermartingale. Iteration and the pathwise budget prove (Q); independence of the layers is unnecessary.

The proof of (Adm). Here $d_0 < d \le K$, $k = K-d$, $x = L^d\mathsf{b}$, $g = x^{-1/2}$, $N_k = (\ell L^d)^3$, $W \in \mathsf{Cut}_{k+1}$, U_+ is as above, $\bar{B}_W = \int B\, p_W(\,\mathrm{d}B)$, and v is the sum of the potentials, so that $\Psi_W = \frac{1}{2}(B, \mathsf{A}_W B) - v$ up to a constant (Prop. 15.4(b)). (1)

Conditions on numbers. Besides the chain, the bounds of (2) use only the following conditions on numbers. At the top depth there are six,

$$1 \le d_0 < K, \qquad L^{d_0}\mathsf{b} \ge \mathsf{t}_\natural,$$
$$\mathsf{R}_{d_0} \le \tfrac{1}{2}, \qquad C_{\mathrm{hs}}\,\delta(L^{d_0}\mathsf{b}) \le \tfrac{1}{4}\gamma_{\mathrm{r}},$$
$$4c_{\mathsf{h}}\delta(L^{d_0}\mathsf{b}) \le \tfrac{1}{4}, \qquad c_\rho \varepsilon(L^{d_0}\mathsf{b}) \le C_{\mathrm{BG}}^{-2},$$

with $C_{\rm hs} = C_{\rm E,1}[338K_P + \frac{1}{2}K_\Lambda(1+\beta_{\rm s})N_\star^{\rm s}/\alpha_0]$, formed from $C_{\rm E,1}$ and the numbers that make up C_V in the setting; the fifth then holds at every depth $d > d_0$ too, δ being decreasing from the reciprocal of the squared coupling floor on, a number that b does not fall below under (E) (the decreasing cutoff functions in §2.3.1). Together with them, (2) uses at the depths $d > d_0$ the bound $C_{\rm Hs}\delta(L^d\mathsf{b}) \le \frac{1}{4}\gamma_{\rm r}$, with the constant $C_{\rm Hs} = 144\,C_{\rm E,1}C_V$ of the setting, which exceeds $C_{\rm hs}$, as $3\cdot 144 > 338$ and $144 > \frac{1}{2}$, so that at d_0 this bound contains the fourth of the six; by the choice of n_2 it holds at every depth $d \ge n_2$, and $n_2 \le n_{\rm a} \le d_{\rm adm}$, so that it holds at d_0 and at every depth $d > d_0$ as soon as $d_0 \ge d_{\rm adm}$ and asks nothing of $d_{\rm adm}$ beyond its member $n_{\rm a}$. At each depth $d > d_0$, with $x = L^d\mathsf{b}$ as above, $\bar\kappa \ge 1$ (Def. YM3_I:47.2) and

$$\nu_0 = \Big\lceil \frac{\log x}{2\bar\kappa} \Big\rceil, \qquad \nu_1 = \Big\lceil \frac{\lceil \log x \rceil + 2}{L} \Big\rceil,$$
$$\nu_2 = \max\Big\{\nu_1, \Big\lceil \frac{3\log x}{2\bar\kappa} \Big\rceil + 1\Big\}, \qquad \nu_3 = \max\Big\{\nu_1, 2\Big\lceil \frac{2\log x}{\bar\kappa} \Big\rceil + 19\Big\},$$

there are three conditions on cubes, at each of the three inner radii $\nu = \nu_1, \nu_2, \nu_3$:

$$2M(2\nu + 2\nu_0 + 3)^3 + 4 < L^{m+d-1},$$
$$4M(2\nu + 2\nu_0 + 3)^3\,\theta_{d-1} \le \varepsilon_{\mathcal W}\, c_{*,\rm rg},$$
$$4B_*M(2\nu + 2\nu_0 + 3)^3\,\theta_{d-1} \le \tfrac{1}{2}\varepsilon_{\mathcal W}\, a^{\rm us}(\alpha_0, \alpha_1),$$

with $\theta_{d-1} = 2c_\rho\varepsilon(x/L)$, the absolute numbers $B_* \ge 1$ and $c_{*,\rm rg} \in (0,1]$ of the local regular-gauge Thm. YM3_I:F, and the usable radius $a^{\rm us}(\alpha_0,\alpha_1)$ in equation YM3_I:(933) at the fixed radii. $(2\nu + 2\nu_0 + 3)^3$ is the number of the cubes of π^M_{k+1} at distances up to $\nu + \nu_0 + 1$ from a given one, in units of their side; they form the cube Q_ν about it, of side $(2\nu + 2\nu_0 + 3)M$ in the units of the level $k+1$, whose cubes at distances up to ν form its *inner cube*, parted from the cubes outside Q_ν by its *collar*, the ν_0 shells of the cubes at the distances $\nu + 2, \dots, \nu + \nu_0 + 1$. The *trivial triple* on a polymer Y is $P[0] = (\mathbf{1}, 0, 0)$, the value at 0 of the chart $P[\omega] = (\mathbf{1}, A, \mathbf{J})$ at the trivial pair, $\omega = (A, \mathbf{J})$, whose pair is $\mathbf{p}(P[\omega]) = (e^{iL^{-k-1}A}, \mathbf{J})$ (the triple and pair conventions of Def. YM3_I:49.1); a triple P on Y is *within r of the trivial triple in a gauge* $\mathfrak{v}$ if $P^{\mathfrak{v}}$ has the pair of $P[\omega]$ for a real ω with $\|\omega\|_Y < r$, the triple norm, namely the largest of $|A|$, $|\nabla_{\mathbf{1}}A|$ and $|\mathbf{J}|$ on $\mathrm{Bd}(Y)$. Every term of the exponent of p_W reads a triple through its pair alone (proof of Prop. 15.4(c)), and so do the structure of the step and the shift (Thm. YM3_I:U, Prop. YM3_I:51.5, and the actual-core verification in the proof of Thm. YM3_I:W). Under the three conditions Q_ν is small against the side of the torus of the level, and Thm. YM3_I:F at the level $k+1$, on Q_ν with $\mathsf{l} = (2\nu + 2\nu_0 + 3)M$ and at $\alpha = 2\theta_{d-1}/\varepsilon_{\mathcal W}$ (the first two conditions give its conditions on the sides and on $\mathsf{l}\alpha$), gives a gauge $\mathfrak{v}$ and a real 1-form A' with $U_+^{\mathfrak{v}} = e^{iL^{-k-1}A'}$ on the bare bonds of the concentric cube of side $\mathsf{l}+4$ and $|A'|, |\nabla_{\mathbf{1}}A'| < B_*\mathsf{l}\alpha = 2B_*(2\nu + 2\nu_0 + 3)M\theta_{d-1}/\varepsilon_{\mathcal W}$ on $\mathrm{Bd}(Q_\nu)$ (the potential and first-difference estimates of that theorem). Its hypotheses on U_+, at the spacing $\eta = \eta_{k+1}$, are the bounds $|\partial U_+(p) - \mathbf{1}| < \alpha\eta^2$ at the bare plaquettes p with a corner in the concentric cube of side $\mathsf{l}+4$ and $|(D^{\mathsf T}_{U_+}\partial U_+)(b)| < \alpha\eta^2$ at the bare bonds b with an end point in that cube; here, for a configuration U, $D^{\mathsf T}_U\partial U$ is the 1-form whose value at $b = \langle x, x+\eta e_\mu\rangle$ is $\eta^{-1}\sum_{\nu\ne\mu}[X_{\mu\nu}(x) - \mathrm{Ad}(U(\langle x, x-\eta e_\nu\rangle))X_{\mu\nu}(x-\eta e_\nu)]$, with $X_{\mu\nu}(y)$ the value of ∂U at the plaquette of the directions $\mu < \nu$ based at y and $X_{\nu\mu} = -X_{\mu\nu}$ (the covariant-difference convention of Section YM3_I:22), that is, the transpose, at the spacing η and at U, of the covariant exterior derivative of 1-forms into 2-forms, applied to the matrix-valued 2-form $p \mapsto \partial U(p)$. Both bounds hold at all the bare plaquettes and bonds of the torus: U_+, a background over $W \in \mathsf{Cut}_{k+1}$, has regularity number of the level $k+1$ less than $c_\rho\varepsilon(x/L) = \frac{1}{2}\theta_{d-1}$ (the definition of the field cut), so $|\partial U_+ - \mathbf{1}| < \frac{1}{2}\theta_{d-1}\eta_{k+1}^2 < \alpha\eta_{k+1}^2$; its current $\mathbf{J}_+$ is below $\theta_{d-1}/\varepsilon_{\mathcal W}$ at every bare bond, as $\varpi(W) < \theta_{d-1}$ admits the plain-core verification in the proof of Prop. YM3_I:52.3 at the free radii $\theta_{d-1}/\varepsilon_{\mathcal W}$, α_1 (as in the proof of Prop. 15.4(a)), which puts P_W in the core with these radii, and

the condition (iii) of its simple set bounds the current by the first radius (Def. YM3_I:49.1); so $|D^{\mathsf T}_{U_+}\partial U_+| \le \eta_{k+1}^2|\mathbf J_+| + \frac14\eta_{k+1}^3\theta_{d-1}^2 < \alpha\eta_{k+1}^2$ (equation YM3_I:(579)). As $|\mathrm{Ad}(\mathfrak v)\mathbf J_+| = |\mathbf J_+|$, P_W is within $r_\nu := 4B_*M(2\nu{+}2\nu_0{+}3)^3\theta_{d-1}/\varepsilon_{\mathcal W}$ of the trivial triple in the gauge $\mathfrak v$, with $\omega = (A', \mathrm{Ad}(\mathfrak v)\mathbf J_+)$, on Q_ν and on every polymer in it; r_ν is below a multiple of $x^{-1/2}(\log x)^{\mathfrak p_0+3}$ and below half the usable radius, so that the chart carries the ball of radius $2r_\nu$ into the analyticity cores. The cubes Q_{ν_1}, Q_{ν_2}, Q_{ν_3} serve (i), (ii), (iii) of (2) in turn; in each the collar is the room in which $\mathsf A_W^{-1}$ on the inner cube forgets the cubes outside, up to a multiple of $x^{-1/2}$ (see (i)). The six conditions at the top depth and the conditions on cubes hold for every integer $d_0 \ge d_{\mathrm{num}}(\ell,\mathsf b)$, every $K > d_0$ and every depth $d > d_0$, where

$$
\begin{aligned}
d_{\mathrm{num}}(\ell,\mathsf b) := \max\Big\{1,\ &\Big\lceil\frac{\log(\mathsf t_{\mathrm{adm}}/\mathsf b)}{\log L}\Big\rceil,\\
&\Big\lceil\frac{\mathsf y_{\mathsf R}(\ell,\mathsf b)-\log\mathsf b}{\log L}\Big\rceil,\\
&\Big\lceil\frac{2}{\log L}\log\frac{12\cdot10^5\,LM(\log\mathsf b)^3}{\ell}\Big\rceil\Big\},
\end{aligned}
$$

$$
\begin{aligned}
\mathsf t_{\mathrm{adm}} = \max\Big\{&\mathsf t_\natural,\\
&\Big(\frac{4\mathfrak p_0}{e}\Big)^{4\mathfrak p_0}\max\Big\{\frac{4C_{\mathrm{hs}}A_1}{\gamma_{\mathrm r}},\,16c_{\mathsf h}A_1,\,C_{\mathrm{BG}}^2c_\rho A_0\Big\}^4,\\
&\Big(\frac{125000\,c_\rho A_0L^{1/2}M}{\varepsilon_{\mathcal W}}\Big)^4\Big(\frac{4\mathfrak p_0+12}{e}\Big)^{4\mathfrak p_0+12}\\
&\qquad\max\Big\{\frac{1}{c_{*,\mathrm{rg}}},\,\frac{2B_*}{a^{\mathrm{us}}(\alpha_0,\alpha_1)}\Big\}^4\Big\},
\end{aligned}
$$

$$
\mathsf y_{\mathsf R}(\ell,\mathsf b) = \max\Big\{\Big(\frac{6}{c'A_0^2}\Big)^{\frac{1}{2\mathfrak p_0-1}},\ \Big(\frac{2\,\mathsf E(\ell,\mathsf b)}{c'A_0^2}\Big)^{\frac{1}{2\mathfrak p_0}}\Big\},
$$

$$
\mathsf E(\ell,\mathsf b) = \log 4 + 3\log\frac{\ell}{M} + \max\{\mathsf k(\mathsf b),0\}\,\ell^3,
$$

with the rate $c'>0$ in the bound defining $\mathsf R_d$ and $\mathsf k(\mathsf b) = \mathsf C^{\Sigma}_{\mathrm{maj}}+2+C_{\mathrm{low}}(\mathsf b)$, the factor of ℓ^3 in the last exponent of the definition of $\mathsf R_d$; $\mathsf E(\ell,\mathsf b)>0$, as $\ell = 2L^m \ge 2MR(\mathsf b) \ge 2M$ under (E). $\mathsf t_{\mathrm{adm}}$ is formed from the constants alone, and $d_{\mathrm{num}}(\ell,\mathsf b)$ from ℓ, $\mathsf b$ and the constants of the construction; it reads neither K nor a level nor a field. For the proof: for $\mathsf t>1$ and $r>0$, $\mathsf t^{-1/2}(\log\mathsf t)^r \le (4r/e)^r\mathsf t^{-1/4}$, as $r\log z - \frac{z}{4}$ is largest at $z=4r$. Let $d_0 \ge d_{\mathrm{num}}(\ell,\mathsf b)$ and $K>d_0$, which is the first of the six. Then $L^{d_0}\mathsf b \ge \mathsf t_{\mathrm{adm}}$, which gives the second and, as $\delta(\mathsf t)$ and $\varepsilon(\mathsf t)$ are A_1 and A_0 times $\mathsf t^{-1/2}(\log\mathsf t)^{\mathfrak p_0}$, by that inequality at $r=\mathfrak p_0$ the last three; and $z_0 = \log L^{d_0}\mathsf b \ge \mathsf y_{\mathsf R}(\ell,\mathsf b)$, so that half of $c'A_0^2z_0^{2\mathfrak p_0}$ is at least $3z_0$ and at least $\mathsf E(\ell,\mathsf b)$, while the definition of $\mathsf R_{d_0}$, at the $(\ell L^{d_0})^3$ sites of the depth d_0 and with $3d_0\log L < 3z_0$, gives $\log 2\mathsf R_{d_0} = \log 4 + 3\log\frac{\ell}{M} + 3d_0\log L + \mathsf k(\mathsf b)\ell^3 - c'A_0^2z_0^{2\mathfrak p_0} < \mathsf E(\ell,\mathsf b) + 3z_0 - c'A_0^2z_0^{2\mathfrak p_0} \le 0$: the third. At a depth $d>d_0$, $x \ge L\mathsf t_{\mathrm{adm}}$, and $\log x > 3$, as $\log\mathsf b > 2$ (the label floor of §2.3.1); as $\lceil z\rceil < z+1$, $L\ge13$ and $\bar\kappa\ge1$, each of ν_1,ν_2,ν_3 is less than $4\log x + 21$ and $\nu_0 < \frac12\log x + 1$, so that $(2\nu+2\nu_0+3)^3 < (9\log x+47)^3 < 15625(\log x)^3$. With $\theta_{d-1} < 2c_\rho A_0L^{1/2}x^{-1/2}(\log x)^{\mathfrak p_0}$ and that inequality at $r=\mathfrak p_0+3$, the left member of the second condition on cubes is less than $125000\,c_\rho A_0L^{1/2}M(\frac{4\mathfrak p_0+12}{e})^{\mathfrak p_0+3}x^{-1/4}$ and that of the third less than B_* times this number; and $x\ge\mathsf t_{\mathrm{adm}}$ makes these two bounds at most $\varepsilon_{\mathcal W}c_{*,\mathrm{rg}}$ and $\frac12\varepsilon_{\mathcal W}a^{\mathrm{us}}(\alpha_0,\alpha_1)$. And as $\log x \le \log\mathsf b\,(1+d\log L)$ and $(1+z)^3 < 17.74\,e^{z/2}$ for $z\ge0$, the left member of the first is less than $31251M(\log x)^3 < 6\cdot10^5M(\log\mathsf b)^3L^{d/2}$, which is below L^{m+d-1}, as $L^{d/2} > L^{d_0/2} \ge 6\cdot10^5L^{1-m}M(\log\mathsf b)^3$ by the last member of $d_{\mathrm{num}}(\ell,\mathsf b)$, ℓ being $2L^m$.

A uniform second moment. For the fluctuation fields the bound holds under p_W at every W. Fix W and a bond b_0. At a bond b, the divergence theorem in the variable $B(b)$ on the ball $\{|B(b)| < \mathfrak{b}(x_k)\}$ of the box, applied to $B(b)e^{-\Psi_W}$, gives the flux $\mathfrak{b}(x_k)\int_{|B(b)|=\mathfrak{b}(x_k)} e^{-\Psi_W} \geq 0$, so $\int B(b)\cdot\nabla_b\Psi_W \,\mathrm{d}p_W \leq 3$. By Prop. 15.4(b), $\Psi_W = \frac{1}{2}(B, \mathsf{A}_W B) - v$ up to a constant, v the sum of the potentials; $\mathsf{A}_W \geq \frac{1}{2}\gamma_{\mathrm{r}}$, and Cauchy's estimate gives $|\nabla_b v| \leq C\delta(x_k)\mathfrak{b}(x_k) \leq \eta$ on the box, η a number free of x_k (the proof of Lem. 15.3(iv)). Take the weights $w_b = e^{-\mu\,\mathrm{dist}(b,b_0)}$, dist the distance in the units of the level k. The entries of A_W fall off exponentially with the distance of the bonds, as A_W is a sum of local terms with the bounds of the polymers (Prop. 15.4(b), Prop. YM3_I:51.4 and its proof), so Schur's test gives $\|w^{1/2}\mathsf{A}_W w^{-1/2} - \mathsf{A}_W\| \leq \frac{1}{4}\gamma_{\mathrm{r}}$ for a small $\mu > 0$ that reads neither K, d nor W. Then $\frac{1}{4}\gamma_{\mathrm{r}}\sum_b w_b \int |B(b)|^2 \,\mathrm{d}p_W \leq \sum_b w_b \int (3 + \eta|B(b)|)\,\mathrm{d}p_W$, and $\eta|B(b)| \leq 2\eta^2/\gamma_{\mathrm{r}} + \frac{1}{8}\gamma_{\mathrm{r}}|B(b)|^2$ gives $\int |B(b_0)|^2 \,\mathrm{d}p_W \leq m_2 = \frac{8}{\gamma_{\mathrm{r}}}(3 + \frac{2\eta^2}{\gamma_{\mathrm{r}}})\sum_b w_b$, which reads neither K, d, d_0 nor W, as $\sum_b w_b \leq C\mu^{-3}$. The log-Sobolev bound of Lem. 15.3(iv), together with this second moment, gives Gaussian tails about a uniformly bounded mean. Consequently the boundary layers used below have mass smaller than every power of x. (2)

The bounds on one integral, for $d_0 \geq d_{\mathrm{adm}}$; C stands for numbers formed from $\ell/\mathfrak{b}$ and the constants of the construction. (i)

The mean of the fluctuation. Integration by parts in each variable of the box, against a cut-off that vanishes on its boundary, gives $\mathsf{A}_W\bar{B}_W$ as the mean of ∇v up to terms carried by $\{|B(b)| \geq \frac{1}{2}\mathfrak{b}(x)\}$, whose mass under p_W is at most a multiple of $e^{-c\,\mathfrak{b}(x)^2}$, $c > 0$, and so smaller than every power of x; ∇v is at most a multiple of $\delta(x)\mathfrak{b}(x) = A_1^2 x^{-1/2}(\log x)^{2\mathfrak{p}_0}$ at each bond; and the kernel of A_W^{-1} decays at the rate $\bar{\kappa}$: $\|\mathsf{A}_W^{-1}(b,b')\| \leq c_{\mathbf{K}} e^{-\bar{\kappa}(\mathfrak{n}-3)_+}$, $\mathfrak{n}$ the distance of the cubes of π_{k+1}^M that hold b_- and b'_-, with $c_{\mathbf{K}} = \frac{2}{\gamma_{\mathrm{r}}} + \frac{4}{\gamma_{\mathrm{r}}^2}(c_{\mathrm{r}} + \gamma_{\mathrm{r}})^2$, formed from γ_{r} and c_{r} alone. Indeed A_W^{-1} is the whole covariance of the complete structure of the step at P_W, a decoupled Gaussian structure with the constants $(\bar{\kappa}; \gamma_{\mathrm{r}}, c_{\mathrm{r}}, \hat{\varepsilon})$, $\hat{\varepsilon} = \frac{1}{2}\mathsf{u}_{\mathrm{G}}(LM)^{-3} \leq \frac{1}{2}\gamma_{\mathrm{r}}$ (Def. YM3_I:47.2, Thm. YM3_I:U, and the actual-core verification in Thm. YM3_I:W); on the union of the two cubes it is $\mathbf{C}+\mathbf{C}\Gamma\Gamma^{\mathsf{T}}\mathbf{C}$ at the decoupling parameters 1 (the conditioning identity in Thm. YM3_I:U), where $\mathbf{C} = \mathbf{C}(Z_\circ, s)$ and $\Gamma = \mathbf{\Gamma}(Z_\circ, s)$ are the conditioned covariance and the connecting operator, the two families of operators that the structure assigns to a region $Z_\circ$, here the union of the two cubes, and to the decoupling parameters s (Def. YM3_I:47.2); at all parameters s of the polydisc of radius $e^{\bar{\kappa}}$ this is an operator of norm at most $c_{\mathbf{K}}$, as (St3) with $\hat{\varepsilon} \leq \frac{1}{2}\gamma_{\mathrm{r}}$ gives $\|\mathbf{C}\| \leq 2/\gamma_{\mathrm{r}}$ and $\|\Gamma^{\mathsf{T}}\| = \|\Gamma\| \leq c_{\mathrm{r}} + \hat{\varepsilon} \leq c_{\mathrm{r}} + \gamma_{\mathrm{r}}$; for $\mathfrak{n} \geq 4$ its block between the two cubes is holomorphic in $\mathfrak{n} - 3$ variables, each the parameter of all the cubes of one of the shells at the distances $2, \dots, \mathfrak{n} - 2$ from the cube of b_-, the other parameters being 1 ((St1)), and vanishes as soon as one of them is 0, since that shell then parts the two cubes into different wall-components ((St2)); Schwarz's lemma in these variables gives the factor $e^{-\bar{\kappa}(\mathfrak{n}-3)}$, and for $\mathfrak{n} \leq 3$ the bound is $\|\mathsf{A}_W^{-1}\| \leq \frac{2}{\gamma_{\mathrm{r}}}$. As at most $24\mathfrak{n}^2 + 2$ cubes lie at the distance $\mathfrak{n}$ from a given one and $\bar{\kappa} \geq 1$, the rows of A_W^{-1} have bounded sums: so $\sup|\bar{B}_W| \leq Cx^{-1/2}(\log x)^{2\mathfrak{p}_0}$. The same argument, with one variable for each of the ν_0 shells of the collar of a cube Q_ν of (1), compares the parameters 1 and 0 on the cubes outside Q_ν: as $\nu_0\bar{\kappa} \geq \frac{1}{2}\log x$, on the inner cube A_W^{-1} lies within $2c_{\mathbf{K}}x^{-1/2}$ of the operator at the parameters 1 on the collar and 0 outside Q_ν, which is that of the structure on Q_ν at the restriction of P_W (restriction consistency in Thm. YM3_I:U); carried by the gauge $\mathfrak{v}$ of Q_ν it is that of the structure at $P[\omega]$ (gauge covariance and dependence on the pair), which at $P[z\omega]$ is holomorphic in z for $|z| < a^{\mathrm{us}}(\alpha_0, \alpha_1)/r_\nu$, by joint holomorphy in $(s, A', \mathbf{J})$ at a fixed real factor, taken at the real factor $\mathbf{1}$, as the chart carries the ball of radius $a^{\mathrm{us}}(\alpha_0, \alpha_1)$ into the cores (equation YM3_I:(933) and its proof), and at most $c_{\mathbf{K}}$ there, by (St3) as above, since Thm. YM3_I:U gives at every triple of the cores a structure with the same constants; so Schwarz's lemma in z puts A_W^{-1} on the inner cube, carried by $\mathfrak{v}$, within $2c_{\mathbf{K}}(x^{-1/2} + r_\nu/a^{\mathrm{us}}(\alpha_0, \alpha_1)) \leq Cx^{-1/2}(\log x)^{\mathfrak{p}_0+3}$ of the operator formed at the trivial triple on Q_ν, which commutes with the constant gauge transformations, as these fix

$P[0]$ (gauge covariance). In the ℓ^2 norm a further factor $x^{-1/2}$ comes, up to powers of $\log x$: along the laws proportional to $e^{-\frac12(B,\mathsf{A}_W B)+\tau v}$ on the box, $0\le\tau\le1$, whose exponents have Hessians $\ge\frac14\gamma_{\rm r}$, the Poincaré inequality makes the means of ∇v at $\tau=0$ and at $\tau=1$ differ in ℓ^2 by at most $\frac{4}{\gamma_{\rm r}}C_{\rm Hs}\delta(x)\sup\|\nabla v\|$; and at $\tau=0$, the Gaussian law of covariance A_W^{-1} conditioned on the box, the gradient at a bond b of each potential v_Y with $b_-\in Y$ and $d(Y)<\lceil\log x\rceil$ has a mean smaller than its size by a factor $Cx^{-1/2}(\log x)^{\mathfrak{p}_0+3}$: such a Y lies within $(\lceil\log x\rceil+2)M\le\nu_1 LM$ of b_- in the units of the level k, so in the inner cube of Q_{ν_1} about the cube of b_-; in the gauge $\mathfrak{v}$ of Q_{ν_1} the triple is within r_{ν_1} of the trivial triple, at which the potentials are invariant under the constant gauge transformations; carried by $\mathfrak{v}$, the covariance lies on the inner cube within $Cx^{-1/2}(\log x)^{\mathfrak{p}_0+3}$ of an operator that commutes with these (above); and $\mathfrak{g}$ holds no non-zero vector fixed by the adjoint action. The potentials with $d(Y)\ge\lceil\log x\rceil$ add at most $C\delta(x)\mathfrak{b}(x)x^{-1}$ at b, by the sum over polymers [7, eq. 320] at $p=1$. So $\|\bar B_W\|\le CN_k^{1/2}x^{-1}(\log x)^{3\mathfrak{p}_0+3}$. (ii)

The mean of the shift. At a bare bond β the parts of $\mathbf{A}[U_+;gB](\beta)$ of degree two and of higher degree in B are at most $c_{\mathfrak{h}}\delta(x)^2/\varepsilon_{\rm A}$ and $2c_{\mathfrak{h}}\delta(x)^3/\varepsilon_{\rm A}^2$, by Cauchy's estimate; the mean of the part of degree two is its value at $g\bar B_W$, at most a multiple of $g^2\sup|\bar B_W|^2$, plus its contraction with $g^2{\rm Cov}_W$, and the latter is smaller than the size of that part by a factor $x^{-1/2}$, up to powers of $\log x$: by the locality of the shift at $\mathfrak{n}=\nu_2+1$ (above), as $\bar\kappa(\nu_2-1)\ge\frac32\log x$, it may be replaced, at a cost below $4c_{\mathfrak{h}}\delta(x)x^{-3/2}$, by the shift of the inner cube of Q_{ν_2} about the cube of β_-, of $(2\nu_2+1)^3$ cubes of π^M_{k+1}; by gauge covariance in Prop. YM3_I:51.5 it may be formed in the gauge $\mathfrak{v}$ of Q_{ν_2}, in which the triple is within $r_{\nu_2}\le Cx^{-1/2}(\log x)^{\mathfrak{p}_0+3}$ of the trivial one, and by pair dependence and slice holomorphy its part of degree two then differs from the one formed at the trivial triple by a multiple of r_{ν_2} times its size; at the trivial triple the part of degree two is covariant under the adjoint action of the constant gauge transformations, by covariance under constant gauges, so that its contraction with an operator that commutes with them is an element of $\mathfrak{g}^c=\mathfrak{g}\otimes\mathbb{C}$ fixed by the adjoint action, hence 0; and on the inner cube the covariance of p_W, carried by $\mathfrak{v}$, lies within $\epsilon_d^{\rm cv}+2c_{\mathbf{K}}(x^{-1/2}+r_{\nu_2}/a^{\rm us}(\alpha_0,\alpha_1))\le Cx^{-1/2}(\log x)^{\mathfrak{p}_0+3}$ of such an operator, by (i) and (iv). Hence $|\int\mathbf{A}[U_+;gB](\beta)\,p_W(\,{\rm d}B)-(D\mathbf{A}[U_+;0]g\bar B_W)(\beta)|\le\epsilon_d^{\rm s}\le Cx^{-3/2}(\log x)^{4\mathfrak{p}_0+6}$ at every bare bond; and as $|D\mathbf{A}[U_+;0]X|\le c_{\mathfrak{h}}\sup|X|$, and by the kernel bound of $D\mathbf{A}[U_+;0]$ above, which reads β only through its cube, with Schur's test, $\sup_\beta|\int\mathbf{A}[U_+;gB](\beta)\,p_W(\,{\rm d}B)|\le\epsilon_d^{\rm m}$ and $\sum_y\max_{\beta_-\in B^k(y)}|\int\mathbf{A}[U_+;gB](\beta)\,p_W(\,{\rm d}B)|^2\le\epsilon_d^{\rm q}$, the sum over the sites y of the level k, where $\epsilon_d^{\rm m}$ is $c_{\mathfrak{h}}g$ times the bound of $\sup|\bar B_W|$ in (i) plus $\epsilon_d^{\rm s}$, and $\epsilon_d^{\rm q}$ is $2c_{\mathfrak{J}}^2g^2$ times the square of the bound of $\|\bar B_W\|$ in (i) plus $2N_k(\epsilon_d^{\rm s})^2$. (iii)

The kernel. The kernel of $D\mathbf{A}[U_+;0]\mathsf{A}_W^{-1}D\mathbf{A}[U_+;0]^*$ at two bare bonds β,β' is

$$\sum_{b,b'}\partial_b\mathbf{A}[U_+;0](\beta)\,\mathsf{A}_W^{-1}(b,b')\,\partial_{b'}\mathbf{A}[U_+;0](\beta')^{\mathsf{T}},$$

with the kernel $\mathsf{A}_W^{-1}(b,b')\in{\rm End}\,\mathfrak{g}$ of A_W^{-1}, and its outer factors decay at the rate $\bar\kappa$ in the distances of the cubes (above), and so does its middle one, by (i); so, by the triangle inequality for these distances, it is at most $Ce^{-\bar\kappa\mathfrak{n}/2}$, $\mathfrak{n}$ the distance of the cubes of β_- and β'_-. Let $\mathfrak{n}\le n_\flat:=\lceil2\log x/\bar\kappa\rceil+9$, so that $\nu_3=\max\{\nu_1,2n_\flat+1\}$, and let $\mathfrak{v}$ be the gauge of Q_{ν_3} about the cube of β_-, in which P_W is within $r_{\nu_3}\le Cx^{-1/2}(\log x)^{\mathfrak{p}_0+3}$ of the trivial triple; the inner cube of Q_{ν_3} holds every cube within $n_\flat$ of the cubes of β_- and β'_-, and the bonds b, b' farther than $n_\flat$ from these add at most $Cx^{-2}(\log x)^2$, as $\bar\kappa(n_\flat-2)\ge2\log x$. There both factors lie within $Cx^{-1/2}(\log x)^{\mathfrak{p}_0+3}$ of the operators formed at the trivial triple, which commute with the adjoint action of the constant gauge transformations, and a linear map of $\mathfrak{g}$ that commutes with it is a multiple of $\mathbf{1}$; so, up to that error, the factors are numbers formed at the trivial triple times ${\rm Ad}(\mathfrak{v}(\beta_-)^{-1}\mathfrak{v}(b_-))$ and ${\rm Ad}(\mathfrak{v}(b_-)^{-1}\mathfrak{v}(b'_-))$, the inner factors cancel, and the kernel is $\mathsf{s}_0(\beta,\beta'){\rm Ad}(\mathfrak{v}(\beta_-)^{-1}\mathfrak{v}(\beta'_-))$ up to $Cx^{-1/2}(\log x)^{\mathfrak{p}_0+3}$, with a number $\mathsf{s}_0(\beta,\beta')$ formed at the trivial triple. In the gauge of the chain the kernel is multiplied

on the left by $\mathrm{Ad}((\gamma \mathsf{g}_{k+1}^{-1})(\beta_-))$ and on the right by the transpose of $\mathrm{Ad}((\gamma \mathsf{g}_{k+1}^{-1})(\beta'_-))$, which turns $\mathrm{Ad}(\mathfrak{v}(\beta_-)^{-1}\mathfrak{v}(\beta'_-))$ into $\mathrm{Ad}(\mathfrak{u}(\beta_-)^{-1}\mathfrak{u}(\beta'_-))$, $\mathfrak{u} = \mathfrak{v}\mathsf{g}_{k+1}\gamma^{-1}$. As $(\mathsf{U}_{k+1}^{\gamma})^{\mathfrak{u}} = U_+^{\mathfrak{v}} = e^{iL^{-k-1}A'}$ with $|A'| \le Cx^{-1/2}(\log x)^{\mathfrak{p}_0+3}$ on the cube, the ordered product of the values of $\mathsf{U}_{k+1}^{\gamma}$ along a path of bare bonds from β_- to β'_- of length at most $3(\mathfrak{n}+1)LML^{-d}$ lies within $3(\mathfrak{n}+1)M \sup|A'|$ of $\mathfrak{u}(\beta_-)^{-1}\mathfrak{u}(\beta'_-)$, and within $3(\mathfrak{n}+1)LM[c_{\mathsf{h}}\delta(x) + L^{-d}\mathsf{a}_{\mathrm{top}}]$ of $\mathbf{1}$, as $\mathsf{U}_{k+1}^{\gamma}$ is the ordered product of the layers of the depths below d and of the top field, which in its regular gauge has $|\mathbf{A}^{\mathrm{top}}| \le \mathsf{a}_{\mathrm{top}}$ at each bare bond. So in the gauge of the chain the kernel at β, β' is a number times $\mathbf{1}$ up to a $\mathsf{w}_{\mathfrak{n}}$ that is affine in $\mathsf{a}_{\mathrm{top}}L^{-d}$; for the pairs at distances $\mathfrak{n} > n_\flat$ the number is taken 0 and $\mathsf{w}_{\mathfrak{n}}$ is the bound $Ce^{-\bar\kappa \mathfrak{n}/2} \le Cx^{-1}e^{-\bar\kappa(\mathfrak{n}-n_\flat)/2}$ of the kernel; and $\sum_{\mathfrak{n}}(24\mathfrak{n}^2+2)\mathsf{w}_{\mathfrak{n}} \le \epsilon_d^{\Sigma}$, a number formed from x, the constants and $\mathsf{a}_{\mathrm{top}}L^{-d}$. For $k=0$, where no shift system enters, (ii) and (iii) use the local pivot construction and its holomorphy and gauge covariance in equations YM3_I:(800)–YM3_I:(803) in place of the corresponding shift properties: off the pivot bonds $\mathbf{A}[U_+;\zeta] = \zeta$ is linear in ζ and free of the triple; at the pivot bond $b_0(c)$ of a cube c the pivot value $\beta_c(P,\zeta)$ depends on the block field and on ζ through their values on P_c alone, so on the triple through its pair alone, the block field being formed from the configuration of the pair; for $\sup|\zeta| < r_P^\circ$ and a fixed real factor it is holomorphic in $(A', \mathbf{J}, \zeta)$ on the simple chart set, which contains the cores by the common-domain verification in the proof of Thm. YM3_I:W, with $|\beta_c| \le 2C_P \sup|\zeta|$; and $\beta_c(P^u, \mathrm{Ad}(u)\zeta) = \mathrm{Ad}(u(b_0(c)_-))\,\beta_c(P,\zeta)$ for every gauge transformation u of the bare sites, constant or not. Carried by the gauge $\mathfrak{v}$ of Q_ν, the pivot value is therefore the one formed at $P[\omega]$, and $z \mapsto \beta_c(P[z\omega],\zeta)$ is holomorphic and at most $2C_P\sup|\zeta|$ for $|z| < a^{\mathrm{us}}(\alpha_0,\alpha_1)/r_\nu$, where $P[z\omega]$ lies in the cores; Schwarz's lemma in z, with Cauchy's estimate in ζ, puts its parts of degree one and two in ζ within a multiple of r_ν times their size of the parts formed at the trivial triple, as pair dependence and slice holomorphy do for $k \ge 1$. (iv)

The covariance. On the convex box $\mathsf{A}_W - C_{\mathrm{Hs}}\delta(x) \le D^2\Psi_W \le \mathsf{A}_W + C_{\mathrm{Hs}}\delta(x)$, with $C_{\mathrm{Hs}}\delta(x) \le \frac{1}{4}\gamma_{\mathrm{r}}$ as $d > d_0 \ge n_2$ (the bound $C_{\mathrm{Hs}}\delta(x)$ of the Hessians of the potentials in the proof of Lem. 15.3(iv), which Cauchy's estimate draws from their bound on the whole product of the analyticity cores and the polydisc of radius $C_A\mathfrak{b}(x)$, and which so holds at the triple P_W of every $W \in \mathsf{Cut}_{k+1}$ and at every point of the box); the Brascamp–Lieb inequality gives $\mathrm{Cov}_W \le (\mathsf{A}_W - C_{\mathrm{Hs}}\delta(x))^{-1}$, and integration by parts and the Cauchy–Schwarz inequality against linear functions give $\mathrm{Cov}_W \ge (1-\iota_d)(\mathsf{A}_W + C_{\mathrm{Hs}}\delta(x))^{-1}$, with a share ι_d of the boundary of the box that is smaller than every power of x; so $\|\mathrm{Cov}_W - \mathsf{A}_W^{-1}\| \le \epsilon_d^{\mathrm{cv}} = \frac{8}{\gamma_{\mathrm{r}}^2}C_{\mathrm{Hs}}\delta(x) + \frac{2}{\gamma_{\mathrm{r}}}\iota_d$. (3)

One constant. The numbers of (2) are formed from $x = L^d\mathsf{b}$, ℓL^d and the constants of the construction, ϵ_d^{Σ} besides from $\mathsf{a}_{\mathrm{top}}L^{-d}$, in which it is affine; save for the factor $N_k = (\ell L^d)^3$ that multiplies both members of ϵ_d^{q} and stays in its bound below, $\ell L^d = (\ell/\mathsf{b})x$ enters only through counts of bonds that multiply masses of boundary layers of the box, which fall faster than every power of x. Collecting the multiples of (2) gives four numbers C_6, C_6', C_Σ, C_{cv}, formed from ℓ, b and the constants, which read neither K, d_0, d, W, a gauge nor $\mathsf{a}_{\mathrm{top}}$, with $\epsilon_d^{\mathrm{m}} \le C_6x^{-1}(\log x)^{2\mathfrak{p}_0}$, $\epsilon_d^{\mathrm{q}} \le C_6'N_kx^{-3}(\log x)^{8\mathfrak{p}_0+12}$, $\epsilon_d^{\Sigma} \le C_\Sigma[x^{-1/2}(\log x)^{\mathfrak{p}_0+6} + \mathsf{a}_{\mathrm{top}}L^{-d}]$ and $\epsilon_d^{\mathrm{cv}} \le C_{\mathrm{cv}}x^{-1/2}(\log x)^{\mathfrak{p}_0+3}$ at $x = L^d\mathsf{b}$. From these, (M) and (Col): given $\mathcal{F}_{d-1}$ the law of B_k is p_W, $W = V_{k+1}$, and γ and g_{k+1} are functions of V_{k+1} that act at each bond by isometries, so $|\mathbf{n}_d(\beta)| = L^d|\int \mathbf{A}[U_+;gB](\beta)\,p_W(\,\mathrm{d}B)|$; the factor L^d, with $L^dx^{-1} = \mathsf{b}^{-1}$, gives $C_6\mathsf{b}^{-1}(\log L^d\mathsf{b})^{2\mathfrak{p}_0}$ as a bound of $|\mathbf{n}_d(\beta)|$ for every bare bond β; three bare bonds start at every bare site, and the norm of (M) takes at a site the euclidean norm of the three values, so $\|\mathbf{n}_d\|_\infty \le \sqrt{3}\,C_6\mathsf{b}^{-1}(\log L^d\mathsf{b})^{2\mathfrak{p}_0}$; and as $\|\mathbf{n}_d\|_{L^2}^2 = a_K^3\sum_\beta|\mathbf{n}_d(\beta)|^2$ and $B^k(y)$ holds L^{3k} bare sites, each the initial point of three bare bonds, the sum over the blocks gives $\|\mathbf{n}_d\|_{L^2}^2 \le 3a_K^3L^{3k}L^{2d}\epsilon_d^{\mathrm{q}} \le 3C_6'\ell^3\mathsf{b}^{-3}L^{-d}(\log L^d\mathsf{b})^{8\mathfrak{p}_0+12}$, as $a_K^3L^{3k} = L^{-3d}$. The kernel of $\mathrm{Ad}(\gamma)\mathsf{J}_d\mathsf{A}_W^{-1}\mathsf{J}_d^*\mathrm{Ad}(\gamma)^{\mathsf{T}}$ is that of (iii) in the gauge of the chain, in which the top field is at most $\mathsf{a}_{\mathrm{top}}$ at each bare bond; so the first two clauses of (Col) hold with C_Σ, $\mathbb{E}^{[d_0]}$-almost surely and at all pairs of bare bonds, and the third holds with C_{cv} at every W. With the four explicit

conditions, of which $d_0 \ge n_{\mathrm{a}}$ and $d_0 \ge d_{\mathrm{num}}(\ell, \mathsf{b})$ follow from $d_0 \ge d_{\mathrm{adm}} = \max\{n_{\mathrm{a}}, d_{\mathrm{num}}(\ell, \mathsf{b})\}$ and the bounds of $c_\rho \varepsilon(L^{d_0}\mathsf{b})$ and of $4c_{\mathsf{h}}\delta(L^{d_0}\mathsf{b})$ from (1), every top depth $d_0 \ge d_{\mathrm{adm}}$ is admissible with $C_{\mathrm{adm}} = \max\{\sqrt{3}\, C_6, 3C_6', C_\Sigma, C_{\mathrm{cv}}\}$: this is (Adm).

Layer estimates. At an admissible d_0, with C free of K and d_0, the chain and these statements give: (L1) for $d_0 < d \le K$ the ordered product $e^{ia_K \mathbf{h}'_d} \cdots e^{ia_K \mathbf{h}'_{d_0+1}} e^{ia_K \mathbf{A}^{\mathrm{top}}}$ of the top field and of the layers of the depths $\le d$ is $\mathsf{U}^{\gamma}_{K-d}$, a gauge transform of a background over the block field V_{K-d} at depth d; (L2) $|\mathbf{h}_d| \le c_{\mathsf{h}} L^d \delta(L^d \mathsf{b})$ at every bond, and $\sum_d a_K |\mathbf{h}_d| \le \frac{1}{4}$; (L3) for a real bond function f, every component ξ of $\langle f, \mathbf{h}'_d - \mathbf{n}_d\rangle$ has $\mathbb{E}^{[d_0]}[e^{\lambda\xi}|\mathcal{F}_{d-1}] \le e^{4\lambda^2 G_d(f)^2/\gamma_{\mathrm{r}}}$ for real λ, $G_d(f)^2 = c_{\mathsf{J}}^2 \mathsf{b}^{-1} L^d \min\{\|f\|_1^2, L^{-3d}\|f\|_2^2\}$, by Lem. 15.3(iv), as the derivative of $\mathbf{h}'_d$ in the fluctuation obeys on the box the bounds of $\mathsf{b}^{-1/2} L^{d/2} \mathsf{J}_d$; (L4) $\sup|\mathbf{n}_d| \le C\mathsf{b}^{-1}(\log L^d \mathsf{b})^{2\mathfrak{p}_0}$ by (M), a bound whose sums over $d_0 < d' \le d$, times $L^{-d/2}$, tend to 0 as $d \to \infty$, and almost surely $\|\sum_{d_0 < d \le K} \mathbf{n}_d\|_{L^{12}(T_\ell)} \le \mathsf{c}_{12}$, a number free of K and d_0, as $\|\mathbf{n}_d\|_{L^{12}(T_\ell)} \le \|\mathbf{n}_d\|_\infty^{5/6} \|\mathbf{n}_d\|_{L^2}^{1/6}$ is summable over d by (M); (L5) the moments of the fluctuation fields and of the layers: at every bond b, $\mathbb{E}^{[d_0]}|B_{K-d}(b)|^2 \le m_2$, and for $q < \infty$, $\|a_K(\sum_d |\mathbf{h}_d(b)|)^2\|_{L^q(\mathbb{E}^{[d_0]})} \le \mathsf{c}_{(q)}\mathsf{b}^{-1}$, with m_2 and $\mathsf{c}_{(q)}$ free of K, d and d_0.

The fluctuation-field second moment was proved above before the mean and covariance estimates. For the layers: (L3) at $f = a_K^{-3}\delta_b$, for which $\langle f, \cdot\rangle$ is the value at b and $G_d(f)^2 = c_{\mathsf{J}}^2 \mathsf{b}^{-1} L^d$, bounds the centred layers at b in $L^{2q}(\mathbb{E}^{[d_0]})$ by $C\sqrt{q}\, \mathsf{b}^{-1/2} L^{d/2}$, whose sum over $d \le K$ is at most $C\sqrt{q}\, \mathsf{b}^{-1/2} a_K^{-1/2}$, and the means add at most $2a_K(\sum_{d \le K} C\mathsf{b}^{-1}(\log L^d \mathsf{b})^{2\mathfrak{p}_0})^2$, a number free of K times b^{-1}.

In its regular gauge the top field is bounded by $\mathsf{a}_{\mathrm{top}} \le CL^{10 d_0}$.

Passage from the chain measure to the Wilson measure. The inequality over the top depths: on invariant functions the chain measure from the top depth d has a density $\bar{\mathfrak{w}}_d \in [0,1]$ with respect to μ^K, with $\int(1 - \bar{\mathfrak{w}}_d)\, \mathrm{d}\mu^K \le \mathsf{R}_d$ (Lem. 15.3(i)); split $1 = \bar{\mathfrak{w}}_{d_1} + \sum_{d_1 < d \le K-1}(1 - \bar{\mathfrak{w}}_{d_1}) \cdots (1 - \bar{\mathfrak{w}}_{d-1})\bar{\mathfrak{w}}_d + (1 - \bar{\mathfrak{w}}_{d_1}) \cdots (1 - \bar{\mathfrak{w}}_{K-1})$, bound each product of the sum by its last two factors and the last product by its last factor, and use Hölder's inequality; $\sum_d \mathsf{R}_d^{1/2} L^{pd}$ and $\sup_K \mathsf{R}_{K-1} L^{pK}$ are finite, as R_d decays faster than every exponential in d.

By (Adm) let d_{adm} be a depth, free of K, such that every top depth $\ge d_{\mathrm{adm}}$ is admissible. At $d_1 = d_{\mathrm{adm}}$ the moment bound applies at every top depth $d+1$ of the inequality, and $\mathsf{N}' \le \|\mathbf{B}_K\|_{\kappa;a}$, $\mathsf{N}' \le 23 L^{3K}$: this gives $\mathsf{M}_q < \infty$. The bound of the action at $R = \max\{1, \mathsf{N}'\}$ and M_{24q} give the moments of $\sup_s s^{\frac{3}{2}+\kappa} A^a(U_s)$. The good sets: at an admissible d_0 with $\mathsf{R}_{d_0} \le \frac{1}{2}\epsilon$, on $\{\|\mathbf{B}_K\|_{\kappa;a} \le R\}$ and for $a_K \le a_0(R)$ the four bounds put U in $\mathsf{O}_K(\bar{C}, \bar{s})$, $\bar{C} = (2 + c_3)R$, $\bar{s} = s_0(R)$, and Chebyshev's inequality with Lem. 15.3(i) gives $\mu^K(\mathsf{O}_K(\bar{C}, \bar{s})^{\mathrm{c}}) \le \mathsf{R}_{d_0} + C(1,\kappa)L^{20 d_0}/R$.

With $E = A^a(U_{\sigma/2})$, Lem. 16.2(f) bounds $a_K^{-4} \max_p a_p(U_\sigma)$ and $(J,J)_a(U_\sigma)$ by polynomials in E if $a_K E \le e_0$, and otherwise by $2a_K^{-4}$ and $48\ell^3 a_K^{-6}$, against $\mu^K(a_K E > e_0) \le (a_K/e_0)^{6p}\langle E^{6p}\rangle_{\mu^K}$. Tightness of Λ_σ: on $\mathsf{O}_K(\bar{C}, \bar{s})$, which has mass $\ge 1 - \epsilon$, Λ_σ is bounded by a number free of K (Step 6).

(b) Choose D_* so that for $D \ge D_*$

$$L^{m+D} \ge 3R_1 \mathfrak{M}, \qquad L^{m+D} > 6\rho_*, \qquad 2\theta_D \le \bar{\varepsilon}, \qquad 2B_3\theta_D \le \alpha_*,$$
$$2B_3\theta_D L^{-4} < \min\{\omega_M, (\kappa_2^{\mathrm{SO}})^{-1}\},$$

where α_*, ρ_* are from Prop. 16.10. All these constants are fixed, so the conditions eventually hold because $\theta_D \to 0$. For $V \in \mathcal{K}_D$, set $\eta = L^{-(K-D)}$ and $N_D = (2L^{m+D})^3$. Take the minimal backgrounds $U^{\mathrm{A}} = U_{K,D}(V)$ and $U^{\mathrm{B}} = U_{K+1,D}(V)$. Their regularity on the larger open ball $\{\varpi < 2\theta_D\}$ and the proposition give

$$(U^{\mathrm{A}})^g = e^{i\eta A}\mathcal{M}(U^{\mathrm{B}}), \qquad \sup|A| \le 2CB_3\theta_D N_D^{1/5}\eta^{1/5}, \qquad \varpi(U^{\mathrm{B}}) \le 2B_3\theta_D(\eta/L)^2.$$

The one-step contour estimate, Lem. YM3_I:14.6(iii), gives $\mathcal{M}(U^{\mathrm{B}})(c) = e^{iY_c}U^{\mathrm{B}}[c]$, $|Y_c| \le \kappa_3\varpi(U^{\mathrm{B}})$, where $[c]$ subdivides c into its L fine bonds. A path C of physical length at most R uses at most RL^D/η bonds of the first lattice. Telescoping the products therefore gives

$$|W_C(U^{\mathrm{A}}) - W_C(U^{\mathrm{B}})| \le 2RL^D B_3\theta_D \left(CN_D^{1/5}\eta^{1/5} + \frac{\kappa_3}{L^2}\eta\right).$$

For each fixed D this is summable in K, uniformly in $V \in \mathcal{K}_D$ and in the closed paths of length at most R defined at that cutoff. Its constant may depend on D through N_D; no uniformity in D is used in this step. Thus the unflowed loops have limits $w_C^D(V)$. The positive-time assertion remains a sketch at (Flow approximation). Its proposed approximation step, together with compactness of $\mathcal{K}_D$, would give a convergent subsequence of any sequence of top data and background flows; its limit solves the specified equation with the specified initial holonomies. Uniqueness identifies the limiting orbit curve. Uniform convergence of the potential representatives gives convergence of flowed holonomies: the difference of their path products is bounded by the path length times their supremum discrepancy. The sequential assertion and compactness of $\mathcal{K}_D$ make this convergence uniform over V and bounded-length paths on compact positive time intervals. The cutoff-uniform comparison between the bare field and the background is proved separately below.

The bare field and the background over $\pi_{K,D}U$. By Lem. 15.3(i) at an admissible $d_0 < D$ with R_{d_0} small, which the proved conclusion (Adm) provides, the comparison is made under $\mathbb{E}^{[d_0]}$. There U is a gauge transform of $e^{ia_K\mathbf{B}_K}$; and $e^{ia_K\mathbf{B}_K^{\le D}}$, with $\mathbf{B}_K^{\le D}$ the logarithm of the ordered product of the top and of the layers of the depths $\le D$, the field cut at the depth D, a function of $\pi_{K,D}U$, is a gauge transform of U_{K-D}, that is of the background over $\pi_{K,D}U$. (i) $\mathbf{B}_K - \mathbf{B}_K^{\le D}$ is small in the rough distance, in every L^q uniformly in K, at the rate $L^{-\kappa D/8}$: its linear part is the sum of the martingale differences of the depths beyond D, its bilinear members are those of (a) with a factor of a depth beyond D, and its means and the remainders of the product are small in L^p.

(ii) The rough norm of the cut field has moments free of K and D: its martingale part $u_{\le D} = \sum_{d\le D} u_{(d)}$ is the conditional mean $\mathbb{E}[u|\mathcal{F}_D]$ of that of the whole field, so $|u_{\le D}|_{-\frac12-\kappa;a} \le \mathbb{E}[|u|_{-\frac12-\kappa;a}|\mathcal{F}_D]$; for a bilinear member Υ of the rough norm (one tuple of directions and translations, one colour, one time, one point) the pairs of different depths whose finer depth exceeds D have vanishing conditional means given $\mathcal{F}_D$, so $\mathbb{E}[\Upsilon(u,u)|\mathcal{F}_D] = \Upsilon(u_{\le D}, u_{\le D}) + \sum_{d>D}\mathbb{E}[\mathsf{c}_d|\mathcal{F}_D]$, $\mathsf{c}_d = \mathbb{E}[\Upsilon(u_{(d)},u_{(d)})|\mathcal{F}_{d-1}]$ the compensators of (a), whose sum is bounded almost surely by $C(1+\mathsf{a}_{\mathrm{top}})s^{-\frac34-\frac{\kappa}{2}}$; with the rest as in (a) and Jensen's inequality, $\mathbb{E}[\|\mathbf{B}_K^{\le D}\|_{\kappa;a}^q]^{1/q} \le C(q,\kappa)(1+\mathsf{a}_{\mathrm{top}})^2$.

So for a large R and a large D, off a probability that is small uniformly in K, the two fields have rough norms $\le R$ and the rough distance $\le \eta$: they are the two data of the Lipschitz bound of (a).

From the short time to the time s. Let $s_* = \min\{s_{\mathrm{Lip}}(R), \frac12 s\}$ and $a_K \le a_0(R)$. At s_* the two flowed fields are gauge transforms of e^{ia_KA}, $e^{ia_KA'}$ with the four bounds and $\|A - A'\|_\infty \le (1+c_5)\eta s_*^{-\frac14-\frac{\kappa}{2}}$; by Lem. 16.2(c), (e) the actions of the flowed fields at $\frac12 s_*$, and those of the fields $e^{ia_K((1-r)A+rA')}$, $0 \le r \le 1$, are at most $E = 6(2+c_3)^4\ell^3R^4(\frac12 s_*)^{-\frac32-\kappa}$. For $a_KE \le e_0$, Lem. 16.2(f), started at $\frac12 s_*$, bounds the curvature $a_K^{-2}\varpi$ of the flow of the bare field on $[s_*, s]$ by a number F_1, and, started at the time 0 of the fields of the segment, bounds the number Λ_{s-s_*} of their flows by a number Λ_1; both read E and s alone.

For a flowed observable H of the flow time s: by Lem. 16.2(b), (d), the square field of $H\circ\Phi_{s-s_*}$ is at most L^2, L free of K, at the fields of the segment, whose ℓ^2 length is at most $\sqrt{3}\ell^{3/2}a_K^{-1/2}\|A'-A\|_\infty$; so the two values of H differ by at most $\sqrt{3}\ell^{3/2}\mathsf{L}\|A'-A\|_\infty$. With (i), (ii) this gives the first display: the mean squared difference is at most $3\ell^3\mathsf{L}^2(1+c_5)^2\eta^2 s_*^{-\frac12-\kappa}$ plus $4\sup|\varphi|^2$ times a small probability, uniformly in K. For the loops, whose square field is of the order of the length times a_K^{-2}, the comparison is made in the supremum distance modulo gauge, in the units of a_K, which is

at most $\|A-A'\|_\infty$ at s_*: by Lem. 15.7(a) at $\kappa' = F_1 a_K^2$ the flowed bare field has at every time of $[s_*, s]$ a gauge with a potential bounded by a number $C_0(F_1, \ell)$; the short-time theory of (a), restarted from these bounded data in steps of a length $\sigma_1(F_1, \ell, \kappa)$, multiplies the distance by at most a factor C_1 in each step, and asks nothing of the second field; after $m = \lceil (s-s_*)/\sigma_1 \rceil$ steps the factor is C_1^m, free of K; and $|W_C(V) - W_C(V')|$ is at most the length of C times the distance.

Hence $\lim_D \limsup_K \|W_C \circ \Phi_s - \Psi_D \circ \pi_{K,D}\|_{L^1(\mu^K)} = 0$ with Ψ_D free of K, which is strong convergence. Two configurations with equal loops are gauge equivalent (characters of SU(2)), and the orbits with $\|\mathfrak{A}\|_\infty + \operatorname{Lip}\mathfrak{A} \le C$ form a compact set on which the loops give the topology: this gives $\mathfrak{F}$. The second display follows from the first, from (C3), and from total variation at the depth D.

(c) The good sets at the time s: by the moments of the action in (a) and Lem. 16.2(f), started at $\frac14 s$, for $\epsilon > 0$ there is F_1, free of K, such that the closed invariant set $\mathsf{G}_K = \{a_K^{-2}\varpi(\Phi_r U) \le F_1 \text{ for } \frac12 s \le r \le s\}$ has $\mu^K(\mathsf{G}_K) \ge 1-\epsilon$ for all large K. On G_K, Lem. 15.7(a) at $\kappa' = F_1 a_K^2$ gives at the time $s - \sigma_1$, $\sigma_1 = \min\{s_0''(R_1), \frac12 s\}$, where $s_0''(R) = (c_1'' R^{-2})^{4/(1-2\kappa)} \le s_0(R)$ and $c_1'' \in (0, c_1]$ depends only on κ, a gauge with a potential bounded by $C_0(F_1, \ell)$, of rough norm at most $R_1 = \max\{1, C_0 + C_0^2\}$, as $\|\mathbf{B}\|_{\kappa;a} \le \|\mathbf{B}\|_\infty + \|\mathbf{B}\|_\infty^2$; the short-time theory of (a) restarted from it gives at the time s a gauge transform $e^{ia_K A}$ of the flowed field with $\|A\|_\infty + \|\nabla A\|_\infty + \|\nabla\nabla A\|_\infty \le C$, a number $C \ge 1$ free of K: the first two members by the bounds of (a) at the time $\sigma_1 \le s_0(R_1)$ after the restart, the second differences by the same fixed point with one more derivative, which closes up to the time $s_0''(R_1)$ and gives $\|\nabla\nabla A_\sigma\|_\infty \le c_8 R_1 \sigma^{-\frac54 - \frac\kappa2}$ for $0 < \sigma \le s_0''(R_1)$, σ the time after the restart, c_8 depending only on κ; here $\sigma = \sigma_1 \le s_0''(R_1)$.

For $a_K C \le \frac{1}{24}$ and Lipschitz f, $|\mathcal{O}(f)(e^{ia_K A}) - \mathcal{O}^0(f)(\mathfrak{A})| \le c\,\ell^3 C^5 (\|f\|_\infty + \operatorname{Lip} f)\, a_K$ for the interpolated connection $\mathfrak{A}$; $\mathcal{O}^0(f)$ is continuous on the compact set of these orbits, so the theorems of Stone and Weierstrass and of Tietze give Θ; the moments come from (a). □

16.4. **Deterministic estimates along the Wilson flow.**

Lemma 16.2 (Deterministic bounds)**.** For all K, m, $\beta > 0$, every U and real X; $\partial U(p) = c_p \mathbf{1} + i\mathsf{s}_p$, $Y_1, \dots, Y_4$ the values of X at the four bonds of p carried to its base point by the parallel transport of U, with the signs $\epsilon = (+,+,-,-)$, and $Z_p(X) = \sum_i \epsilon_i Y_i$:

(a) $\langle X, \partial a_p\rangle = \langle Z_p(X), \mathsf{s}_p\rangle$, so $|\partial_b a_p| = |\mathsf{s}_p|$ for $b \in p$;

$$\nabla^2 a_p[X,X] = c_p |Z_p(X)|^2 + \sum_{i<j} \epsilon_i \epsilon_j \langle i[Y_i, Y_j], \mathsf{s}_p\rangle,$$

$$-3\varpi_p \sum_{b\in p} |X(b)|^2 \le \nabla^2 a_p[X,X] \le (4 + 3\varpi_p) \sum_{b\in p} |X(b)|^2,$$

and

$$-12\varpi(U)\|X\|^2 \le \nabla^2 A_K(U)[X,X] \le 40\|X\|^2$$

(second derivatives along $e^{isX}U$);

(b) with $w_s = D\Phi_s(U)X$: $\frac{d}{ds}\|w_s\|^2 = -2a_K^{-2}\nabla^2 A_K(U_s)[w_s, w_s]$; so $\|D\Phi_\sigma(U)\| \le e^{12\Lambda_\sigma(U)}$ and $\Gamma_K(G\circ\Phi_\sigma)(U) \le e^{24\Lambda_\sigma(U)}\Gamma_K(G)(U_\sigma)$ for $G \in C^1(\Omega_K)$; $D\Phi_s(U)\mathrm{d}_U\lambda = \mathrm{d}_{U_s}\lambda$ and $D\Phi_s(U)J(U) = J(U_s)$, and $D\Phi_\sigma(U)^{\mathsf{T}}$ maps horizontal vectors at U_σ to horizontal vectors at U;

(c) $\partial_\sigma A^a(U_\sigma) = -(J,J)_a(U_\sigma)$; $(J,J)_a(U_\sigma) \le e^{24(\Lambda_\sigma - \Lambda_s)(U)}(J,J)_a(U_s)$ for $s \le \sigma$; $A^a(V) \le \frac32 \ell^3 (a_K^{-2}\varpi(V))^2$; $A^a(U_{\sigma/2}) \le 24\ell^3 \Lambda_\sigma(U)^2 \sigma^{-2}$; and $(J,J)_a(U_\sigma) \le \frac{2}{\sigma} e^{24\Lambda_\sigma(U)} A^a(U_{\sigma/2})$;

(d) $\Gamma_K(\mathcal{O}(f)) \le 2\|f\|_\infty^2 (J,J)_a + 256\|\nabla f\|_\infty^2 A^a$ and $|v\,\mathcal{O}(f)| \le ((J,J)_a \Gamma_K(\mathcal{O}(f)))^{1/2}$;

(e) on $\mathsf{O}_K(\bar C, \bar s)$, $a_K^{-2}\varpi(U_s) \le 2\bar C s^{-\frac34 - \frac\kappa2} + 2\bar C^2 s^{-\frac12 - \kappa}$ for $0 < s \le \bar s$, and so $\Lambda_\sigma \le (8\bar C \sigma^{\frac14 - \frac\kappa2} + 4\bar C^2 \sigma^{\frac12 - \kappa})/(1-2\kappa)$ for $\sigma \le \bar s$;

(f) let $e_0 = 10^{-4}$, $c_{10} = 5.1 \cdot 10^4$, $x_0 = (1440 c_{10})^{-1}$, $E = A^a(U_{s_1})$ and $a_K E \le e_0$; at $E = 0$ set $E^{-2} = +\infty$, the flat field being stationary. Then for $s \ge s_1$, $a_p(U_s) \le e_0$, and $z_p = a_K^{-4} a_p(U_s)$ satisfies $\partial_s z_p \le \Delta_a z_p + c_{10} \bar z_p z_p^{1/2}$ (Δ_a the Laplacian on parallel plaquettes, $\bar z_p$ the largest z on a box of plaquettes about p); $a_K^{-4} \max_p a_p(U_s) \le \frac{5}{2} E \min\{s - s_1, x_0^4 E^{-2}, 1\}^{-3/2}$ for $s > s_1$; and at $s_1 = \frac{\sigma}{2} \le \frac{1}{2}$, $(J,J)_a(U_\sigma) \le e^{48}[\frac{4E}{\sigma} + 7E^{3/2}\sigma^{-3/4} + 3x_0^{-3}E^3]$;

(g) (Bochner.) For $H \in C^\infty(\Omega_K)$, with ∇^2 the Hessian of the bi-invariant metric of Ω_K, a product of unit spheres S^3 of Ricci curvature 2,

$$\|\mathcal{L}_K H\|^2_{L^2(\mu^K)} = a_K^{-2} \int \|\nabla^2 H\|^2_{\mathrm{HS}} \,\mathrm{d}\mu^K + 2a_K^{-1} \mathcal{E}_K(H) + a_K^{-2}\beta \int \nabla^2 A_K(\partial H, \partial H)\,\mathrm{d}\mu^K;$$

consequently $(\int |\partial H|^4 \,\mathrm{d}\mu^K)^{1/2} \le \sup|H|\,(3\mathsf{m} + 2(28\beta \sup|H|\,\mathsf{m})^{1/2})$, $\mathsf{m} = a_K \|\mathcal{L}_K H\|_{L^2(\mu^K)}$, and $H_K \in C^\infty(\Omega_K)$ with $\sup_K \|\mathcal{L}_K H_K\|_{L^2(\mu^K)} < \infty$ and $\liminf_K \mathcal{E}_K(H_K) > 0$ have $a_K^{-2}\beta \int \nabla^2 A_K(\partial H_K, \partial H_K)\,\mathrm{d}\mu^K \to -\infty$; and $(\mathcal{L}_K \cos G)^2 + (\mathcal{L}_K \sin G)^2 = (\mathcal{L}_K G)^2 + \Gamma_K(G)^2$ for real $G \in C^\infty(\Omega_K)$;

(h) (Weitzenböck and Kato.) $\nabla^2 A_K(U)[z,z] = \langle z, (\nabla_U^{\mathsf{T}} \nabla_U + R_U) z\rangle$ for horizontal z at U, where $(\nabla_U^{\mathsf{T}} \nabla_U z)(b) = \sum_{b' \sim b} (z(b) - \tau_{bb'} z(b'))$, the sum over the six parallel neighbours with the parallel transports $\tau_{bb'}$ of U, and $\|R_U(b,b')\| \le 4\varpi(U)\mathsf{n}(b,b')$, $\mathsf{n}(b,b') = 1$ if $b = b'$ or b, b' lie in a common plaquette and 0 otherwise. For invariant $G \in C^1(\Omega_K)$ and every bond b,

$$|\partial_b(G \circ \Phi_\sigma)(U)| \le \big[e^{4\Lambda_\sigma(U)\mathsf{n}}\, e^{-\sigma a_K^{-2}\Delta_0}\, |\partial G|(U_\sigma)\big](b),$$

Δ_0 the free Laplacian on the bonds (six parallel neighbours) and $|\partial G|(V)$ the function $b \mapsto |\partial_b G(V)|$; so $\|\partial(G \circ \Phi_\sigma)(U)\|_{\ell^q} \le e^{52\Lambda_\sigma(U)} \|\partial G(U_\sigma)\|_{\ell^q}$ for $1 \le q \le \infty$, and $\sup_b |J(U_\sigma)(b)| \le e^{52(\Lambda_\sigma - \Lambda_s)(U)} \sup_b |J(U_s)(b)|$ for $s \le \sigma$;

(i) (One-bond fibres.) For $N \ge 3$, $p \ni b_0$, $s \ge 0$, the map $g \mapsto \partial(\Phi_s U^{(g)})(p)$ of G to itself, $U^{(g)}$ the field U with the value g at b_0, is onto; so $\sup_U \varpi(U_s) = 2$, and $\sup_U \mathcal{O}(f)(U_s) \ge 2f(x(p))/a_K$ for $f \ge 0$, at every flow time. At a field with values in the centre $\{\pm\mathbf{1}\}$, $\partial A_K = 0$ and $\nabla^2 A_K[X,X] = \sum_p c_p |Z_p(X)|^2$, $c_p = \pm 1$; at the field that is $-\mathbf{1}$ at one bond and $\mathbf{1}$ elsewhere, $\|D\Phi_\sigma\| \ge e^{4\sigma/a_K^2}$.

■

Proof sketch. (a) Expand $\partial(e^{itX}U)(p)$ to second order in t, with the values of X carried to the base point of p; the bounds follow from $|\mathsf{s}_p| \le \varpi_p$, $|c_p| \le 1$, $|Z_p|^2 \le 4\sum_{b \in p} |X(b)|^2$, and four plaquettes at each bond. (b) $\frac{d}{ds}\|D\Phi_s X\|^2 = -2a_K^{-2}\nabla^2 A_K(U_s)[D\Phi_s X, D\Phi_s X]$ and Gronwall; the flow commutes with gauge transformations and moves along the current. (c) The current solves the linearised flow; A^a is non-increasing along the flow, ϖ bounds a_p, and averaging the bound of the current over $[\frac{\sigma}{2}, \sigma]$ gives the last inequality. (d) $\partial_b \mathcal{O}(f) = a_K^{-1} f(x_b)\partial_b A_K + a_K^{-1} \sum_{p \ni b} (f(x(p)) - f(x_b))\partial_b a_p$, x_b a point of b, so that $|x(p) - x_b| \le 2a_K$ for $p \ni b$, and $\sum_b (\sum_{p \ni b} \varpi_p)^2 \le 32 A_K$.

(e) $\varpi(e^{iaA}) \le 2a^2(\|A\|_\infty^2 + \|\nabla A\|_\infty)$, integrated in s. (f) The lattice Bianchi identity in a gauge near p gives the differential inequality where $a_K^4 \bar z_p \le e_0$; Duhamel's formula with $\|P_t z\|_\infty \le t^{-3/2}E$ bounds $\sup_t t^{3/2} \max_p z_p$ as long as $t^{1/4}E^{1/2} \le x_0$, and the action does not increase; then (c) on an interval before σ on which Λ grows by at most 1. (g) Bochner's formula with the drift; the limit follows from the formula, as its first member on the right is ≥ 0 and the second, $2a_K^{-1}\mathcal{E}_K(H_K)$, tends to ∞; the bound follows from $\int \langle \partial H, \partial F\rangle \,\mathrm{d}\mu^K = -a_K \int F\, \mathcal{L}_K H \,\mathrm{d}\mu^K$ at $F = H|\partial H|^2$ and using $\nabla^2 A_K \ge -28$; the identity is the chain rule $\mathcal{L}_K \phi(G) = \phi'(G)\mathcal{L}_K G + \phi''(G)\Gamma_K(G)$.

(h) Expanding $\sum_p |Z_p(X)|^2 + \sum_x |(\mathrm{d}_U^{\mathsf{T}} X)(x)|^2$, the products of parallel bonds give the covariant Laplacian and those of the corners of a plaquette cancel but for $2\sum_p \langle X_1, (1 - \mathrm{Ad}\,\partial U(p)) X_4\rangle$; with (a) this is the identity. The adjoint of the linearised flow keeps horizontal vectors horizontal, and $|z(b)|$ is then a subsolution of the parabolic system with the off-diagonal entries ≥ 0; the comparison principle and the commutation of Δ_0 with n (Δ_0 is the same scalar parallel-neighbour convolution

in every bond direction) give the bound; $e^{-t\Delta_0}$ is doubly stochastic and n has row sums 13. The current is a forward horizontal solution, whence its maximum principle.

(i) $s \mapsto (g \mapsto \partial(\Phi_s U^{(g)})(p))$ is a homotopy from a translation of S^3, or a translation composed with $g \mapsto g^{-1}$, and a map of S^3 to itself that misses a point is homotopic to a constant; at the centre fields $\mathsf{s}_p = 0$, and $X = e\,\delta_{b_0}$ gives $\langle X, \nabla^2 A_K X\rangle = -4|e|^2$ at the flipped field. □

Lemma 16.3 (Exact identities for the Laplacian along the flow)**.** For all K, m, $\beta > 0$:

(a) for $f \in C^\infty(\Omega_K)$, $[\Delta_K, v]f = -8a_K^{-1} v f - 2a_K^{-3}\langle \nabla^2 A_K, \nabla^2 f\rangle_{\mathrm{HS}}$, and the diagonal blocks of $\nabla^2 A_K$ are $\delta_{\alpha\beta}\sum_{p\ni b}(1 - a_p)$;

(b) Φ_σ is a diffeomorphism of Ω_K, and $\log\det D\Phi_\sigma(U) = -12 a_K^{-2}\int_0^\sigma (3N^3 - A_K(U_s))\,\mathrm{d}s$;

(c) at every U at which d_U is injective on the site functions (all U off a closed null set), with $\mathsf{G}_U = (\mathrm{d}_U^*\mathrm{d}_U)^{-1}$, $\mathsf{I}(U) = \frac{1}{2}\log\det \mathrm{d}_U^*\mathrm{d}_U$ and $\mathsf{j}^{\mathrm{gh}}_U(b) = i\sum_{\alpha,\gamma}\mathsf{G}_U((b_-,\alpha),(b_+,\gamma))[\sigma_\alpha, \mathrm{Ad}(U(b))\sigma_\gamma]$: $\mathsf{j}^{\mathrm{gh}}_U = \partial\mathsf{I}(U)$, and for invariant $f \in C^2(\Omega_K)$

$$\Delta_K f(U) = a_K^{-1}\sum_e \frac{d^2}{dt^2} f(e^{ite}U)\Big|_{t=0} + a_K^{-1}\sum_b \langle \mathsf{j}^{\mathrm{gh}}_U(b), \partial_b f(U)\rangle = \Delta_K^{\mathrm{hor}} f + \Gamma_K(\mathsf{I}, f),$$

(e) an orthonormal basis of the horizontal vectors at U; for a site function λ,

$$\frac{d^2}{dt^2} f(e^{it\,\mathrm{d}_U\lambda}U)|_0 = \sum_b \langle i[\lambda(b_-), \mathrm{Ad}(U(b))\lambda(b_+)], \partial_b f(U)\rangle;$$

and at $f = G\circ\Phi_\sigma$ the second member is $a_K^{-1}\langle D\Phi_\sigma(U)\mathsf{j}^{\mathrm{gh}}_U, \partial G(U_\sigma)\rangle$: the gauge term is evaluated once, at the bare field, and then carried by the linearised flow.

■

Proof sketch. (a) On a Riemannian manifold, $[\Delta, \langle\nabla\phi, \nabla\cdot\rangle]f = \langle\nabla\Delta\phi, \nabla f\rangle + 2\langle\nabla^2\phi, \nabla^2 f\rangle + 2\,\mathrm{Ric}(\nabla\phi, \nabla f)$; here $\mathrm{Ric} = 2$, and $a_K\Delta_K A_K = \sum_{b,\alpha}(\partial_b^\alpha)^2 A_K = 12(3N^3 - A_K)$, because each bond variable enters a plaquette through a matrix coefficient of the fundamental representation, an eigenfunction of the Laplacian of S^3 of eigenvalue -3, and four bonds enter each of the $3N^3$ plaquettes. (b) Liouville's formula $\frac{d}{ds}\log\det D\Phi_s = (\mathrm{div}\, v)\circ\Phi_s = -a_K^{-1}(\Delta_K A_K)\circ\Phi_s$. (c) The trace of the Hessian over an orthonormal basis splits into the horizontal part and the part along the gauge directions; along $\mathrm{d}_U\lambda$ the curve $e^{it\mathrm{d}_U\lambda}U$ differs from the gauge orbit at second order, which gives the formula for one site function by invariance of f; summing over a basis orthonormal for $\mathrm{d}_U^*\mathrm{d}_U$ gives j^{gh}, and differentiating $\log\det$ identifies it with $\partial\mathsf{I}$.

The last statement is the chain rule with (b) of Lem. 16.2. □

16.5. **The lattice defect in generator estimates.**

Lemma 16.4 (A lattice defect)**.** On $(\mathbb{Z}/N)^3$ let $\varsigma_p = -1$ on the four plaquettes that contain a bond b_0 and $+1$ elsewhere. For $N \ge N_0$ the operator $\mathrm{d}^{\mathsf{T}}\varsigma\,\mathrm{d}$ on real 1-forms, per colour the Hessian of A_K at the field that is $-\mathbf{1}$ on b_0 and $\mathbf{1}$ elsewhere, has exactly three negative eigenvalues, $-\lambda_1$ simple and $-\lambda_2$ double, $6.6 < \lambda_1 < 6.62$, $0.79 < \lambda_2 < 0.8$, with orthonormal eigenvectors e_1 (of $-\lambda_1$) and e_2, e_3 (of $-\lambda_2$) that decay exponentially away from b_0. Let $\hat e_1, \hat e_2$ be the lattice unit vectors of the two axes orthogonal to b_0, so that $b_0 + \hat e_1$, $b_0 + \hat e_2$ are the two translates of b_0 parallel to it that share a plaquette with it, and the three bonds b_0, $b_0 + \hat e_1$, $b_0 + \hat e_2$ lie in ten plaquettes; the matrix $[e_i(b_0 + \hat e_j)]_{i=1,2,3;\, j=0,1,2}$, $\hat e_0 := 0$, is upper triangular and invertible, with an inverse bounded by an absolute constant. And $\langle X, \mathrm{d}^{\mathsf{T}}\varsigma\,\mathrm{d}X\rangle \ge c_1|\mathrm{d}X|^2 - 7\sum_i\langle e_i, X\rangle^2$ with an absolute $c_1 > 0$. For $\varepsilon \in (0,1]$ and $\Lambda_0 \ge 1$ there are $N_*, T_* < \infty$ and $\delta_*, \rho_0, \theta, c_\sharp > 0$, $0 < \delta \le \frac{1}{10}$, $C_\sharp < \infty$, depending only on ε and Λ_0, such that for $N = \ell/a_K \ge N_*$, $T \ge T_*$, every bond b_0 and every U whose flow in lattice time, $U_t^\circ = \Phi_{a_K^2 t}U$, has $\sup_{t\le T}\varpi(U_t^\circ) \le \delta_*$, $\int_0^T \varpi(U_t^\circ)\,\mathrm{d}t \le \Lambda_0$, $T \le \Lambda_0 N^2$ and $A_K(U^\circ_{T/2}) \le \delta_*^2$, there is a Borel set $\mathcal{S}$ of $\zeta = (\zeta_0, \zeta_1, \zeta_2) \in \mathfrak{g}^3$, $|\zeta| \le \rho_0 \le 1$, of Lebesgue measure $\ge c_\sharp e^{-(3\lambda_1 + 6\lambda_2 + \varepsilon)T}$, such that

the field W_ζ, equal to U but for $W_\zeta(b_0) = -e^{i\zeta_0}U(b_0)$ and $W_\zeta(b_0+\hat e_j) = e^{i\zeta_j}U(b_0+\hat e_j)$ $(j=1,2)$, and the fields $\tilde V_t$, equal to $\Phi_{a_K^2 t}W_\zeta$ but for the sign of their value at b_0, have the properties (a)–(c) below. Here $a_p(\Phi_{a_K^2 t}W_\zeta) = \varsigma_p a_p(\tilde V_t) + 1 - \varsigma_p$ for every plaquette p, so that $A_K(\Phi_{a_K^2 t}W_\zeta) = 8 + \sum_p \varsigma_p a_p(\tilde V_t)$, and $t \mapsto \tilde V_t$ is the gradient flow, in lattice time, of $\tilde A = \sum_p \varsigma_p a_p + 8$. (a) $\varpi(\tilde V_t) \le \delta$ for $0 \le t \le T$: the four plaquettes of $\Phi_{a_K^2 t}W_\zeta$ at b_0 lie within δ of $-\mathbf{1}$ and all the others within δ of $\mathbf{1}$; (b) for every real function $\mathsf f$ of the plaquettes and real $\mathsf f_0$,

$$\big|\partial_{b_0}\big(\textstyle\sum_p \mathsf f_p\, a_p \circ \Phi_{a_K^2 T}\big)(W_\zeta)\big| \ge \Big[c_\sharp|\mathsf f_0| - C_\sharp\Big(\textstyle\sum_p |\mathsf f_p - \mathsf f_0|^2 e^{-2\theta|p|}\Big)^{1/2}\Big]e^{(\lambda_1-\varepsilon)T},$$

$|p|$ the distance of p from b_0; in particular $|\partial_{b_0}(A_K \circ \Phi_{a_K^2 T})(W_\zeta)| \ge c_\sharp e^{(\lambda_1-\varepsilon)T}$; (c) $\int_{T/2}^T \sum_p a_p(\tilde V_t)\,\mathrm dt \le \frac{3}{2}T\,A_K(U^\circ_{T/2}) + C_\sharp$.

(d) (Traversing the fibre of one bond.) Let $\lambda_1' = \lambda_1 - 0.027$ and $\lambda_2'' = \lambda_2 + \frac{1}{700}(\lambda_1 - \lambda_2) + 10^{-3}$; then $\lambda_1' - 6\lambda_2'' > \frac{2}{5}$. For $\Lambda_0 \ge 1$ there are $\epsilon_{\mathrm d}, \rho_2, c_{\mathrm d} > 0$ and $N_{\mathrm d} < \infty$, depending only on Λ_0, such that the following holds for $N \ge N_{\mathrm d}$, $T \ge N_{\mathrm d}$ with $N^3 \le c_{\mathrm d}T^2$, every bond b_0 and every U with $\int_0^T \varpi(U_t^\circ)\,\mathrm dt + T/N^2 \le \Lambda_0$ and $\sup_{t\le T}\varpi(U_t^\circ) \le \epsilon_{\mathrm d}$. There is a compact set $\mathsf Y \subset \mathfrak g^2$ of Lebesgue measure $\ge c_{\mathrm d}e^{-6\lambda_2'' T}$ such that for every $(y_1,y_2) \in \mathsf Y$, with W the field equal to U but for $W(b_0+\hat e_j) = e^{iy_j}U(b_0+\hat e_j)$ $(j=1,2)$ and $W^{(g)}$ the field W with the value g at b_0, and for every unit vector $e \in \mathfrak g$, there are $x_0 \in \mathfrak g$, with $|(x_0,y_1,y_2)| \le 30C_\triangle\rho_2 \le 1$, where $C_\triangle = 4c_\triangle$ and $c_\triangle$ is the absolute constant that bounds the inverse of the matrix $[e_i(b_0+\hat e_j)]$, and $r_* \in (0, \frac{4}{3}\rho_2 e^{-\lambda_1' T}]$ for which $\mathsf v(r) = A_K(\Phi_{a_K^2 T}W^{(g_r)})$, $g_r = -e^{ire}e^{ix_0}U(b_0)$, has $\mathsf v(0) \in [7,9]$ and $\mathsf v(0) - \mathsf v(r_*) \ge 2\rho_2^2$. If $f \in C^\infty(T_\ell)$ is real, $f(x_*) = \max|f| > 0$ and b_0 is based at a site nearest to x_*, the same holds, with constants that depend besides on f and for $a_K \le c_{\mathrm d}(f)$, for $\mathsf v_f(r) = \sum_p f(x(p))\,a_p(\Phi_{a_K^2 T}W^{(g_r)})$ in the place of $\mathsf v$, and with the single condition $\mathsf v_f(0) - \mathsf v_f(r_*) \ge f(x_*)\rho_2^2$ in the place of the two conditions on $\mathsf v$. ∎

Sketch. Flipping the sign of $U(b_0)$ conjugates the flow of A_K to that of $\tilde A = \sum_p \varsigma_p a_p + 8$, whose Hessian at small fields is close to $\mathrm d^{\mathsf T}\varsigma\,\mathrm d$. The number of negative eigenvalues is found exactly. For $E > 0$, with $S = (\mathrm d^{\mathsf T}\mathrm d + E)^{1/2}$ and Π_4 the projection onto the four plaquettes, $\mathrm d^{\mathsf T}\varsigma\,\mathrm d + E = S(1 - 2R^{\mathsf T}R)S$, $R = \Pi_4 \mathrm d S^{-1}$; by Sylvester's law of inertia the number of eigenvalues below $-E$ is the number of eigenvalues > 1 of $2RR^{\mathsf T} = K(E) = 2\Pi_4[\frac{-\Delta}{-\Delta+E} - \mathrm d_2^{\mathsf T}G_E\mathrm d_2]\Pi_4$, $\mathrm d_2$ the coboundary of 2-forms and $G_E = (-\Delta+E)^{-1}$, which decreases in E. On $\mathbb Z^3$, $K(E)$ is diagonal in three patterns of signs on the four plaquettes, taken relative to the signs of $\mathrm d\delta_{b_0}$: $(1,1,1,1)$, the doublet $(1,0,-1,0)$, $(0,1,0,-1)$, and $(1,-1,1,-1)$, with the entries

$$K_1 = 2 - \tfrac{E}{3}(1 - EG_E(0)), \qquad K_2 = 2 - F_2, \qquad F_2 = 2E\big(G_E(0) + G_E(e_1)\big) + 4\big(G_E(0) - G_E(e_1+e_2)\big),$$
$$K_3 = 2\big[1 - E\big(G_E(0) - G_E(e_1)\big) - 4G_E(0) + 8G_E(e_1) - 4G_E(e_1+e_2)\big],$$

where $G_E(x) = (2\pi)^{-3}\int_{[-\pi,\pi]^3} e^{ik\cdot x}\big(E + \sum_\mu 2(1-\cos k_\mu)\big)^{-1}dk$ is the Green function of $-\Delta + E$ on the sites of $\mathbb Z^3$. Its Neumann series $G_E(x) = \sum_{m\ge 0} c_m(x)(6+E)^{-m-1}$, with the number $c_m(x) = \sum_n \binom{m}{n}\binom{n}{(n+x_1+x_2)/2}\binom{n}{(n+x_1-x_2)/2}\binom{m-n}{(m-n+x_3)/2}$ of the walks of m steps from 0 to x (a binomial coefficient whose lower entry is not an integer between 0 and its upper entry read as 0), encloses $G_E(x)$ between its partial sum up to $m = M$ and that sum plus $E^{-1}(\frac{6}{6+E})^{M+1}$; at $M = 240$ the width is below 10^{-12} at the four energies 6.6, 6.62, 0.79, 0.8. This gives, to the digits shown, $E(1 - EG_E(0)) = 2.997958$ at $E = 6.6$ and 3.002351 at $E = 6.62$, and $F_2 = 0.99944880$ at $E = 0.79$ and 1.00144415 at $E = 0.8$; so $K_1(6.6) > 1 > K_1(6.62)$ and $K_2(0.79) > 1 > K_2(0.8)$. As $E \to 0$, $K_1 \to 2$, $K_2 \to 2 - 4(g_0 - g_2)$ and $K_3 \to 8(g_0 - g_2) - \frac{2}{3}$, $g_0 - g_2 = G_0(0) - G_0(e_1+e_2)$; since $0 \le 1 - \cos k_1\cos k_2 \le (1-\cos k_1) + (1-\cos k_2)$, the symmetry of the axes gives $0 \le g_0 - g_2 - [G_E(0) - G_E(e_1+e_2)] \le \frac{E}{3}G_E(0)$, and the series at $E = \frac{1}{10}$

with $M = 700$, of width $\le 9.3 \cdot 10^{-5}$, give $0.19195 < g_0 - g_2 < 0.19970$; so $K_2(0+) > 1.2$ and $K_3(0+) < 0.94$. As the entries decrease in E, the third pattern gives no negative eigenvalue, the first gives the simple $-\lambda_1 \in (-6.62, -6.6)$, the doublet gives the double $-\lambda_2 \in (-0.8, -0.79)$, and there is no other. On $(\mathbb{Z}/N)^3$ the Green function is $\sum_{k\in\mathbb{Z}^3} G_E(x+Nk)$, which differs from $G_E(x)$ by at most $E^{-1}\sum_{k\neq 0}(\frac{6}{6+E})^{|x+Nk|_1}$, uniformly small for $E \ge 0.7$ and $|x|_1 \le 2$, and the entries at $E \to 0$ are Riemann sums of those on $\mathbb{Z}^3$: the strict inequalities persist for $N \ge N_0$. The eigenvectors: $e_i \propto \mathrm{d}^{\mathsf{T}} G_{\lambda_i}\eta_i$, η_i the pattern of the mode on the four plaquettes, so they decay at the rate of $G_E(x) \le E^{-1}(\frac{6}{6+E})^{|x|_1}$: as $\frac{6}{6+\lambda_i} \le \frac{6}{6.79} < e^{-0.12}$, $|e_i(b)| \le C_e e^{-c_e|b|}$ with $c_e = 0.12$, an absolute number C_e and $|b|$ the distance of the bond b from b_0; $e_1(b_0)^2 \ge 2/\lambda_1$; the doublet patterns are odd under the reflections across the two planes through b_0 that contain $\hat e_2$, resp. $\hat e_1$, which fix b_0 and $b_0 + \hat e_2$, resp. b_0 and $b_0 + \hat e_1$, so $e_2(b_0) = e_2(b_0+\hat e_2) = 0 = e_3(b_0) = e_3(b_0+\hat e_1)$, while $|e_2(b_0+\hat e_1)| = |e_3(b_0+\hat e_2)| \ge 0.049$: the matrix is triangular. *The coercivity.* On the range of d the form $\langle \eta, \varsigma\eta'\rangle$ is that of $B = 1 - 2\mathsf{P}\Pi_4\mathsf{P}$, P the projection onto the range of d; the non-zero eigenvalues of $\mathsf{P}\Pi_4\mathsf{P}$ are those of $\frac12 K(0+)$, so the spectrum of B lies in $\{-1, 1-K_2(0+), 1-K_3(0+), 1\}$: $\|B\| \le 1$, $|B| \ge c_B = 0.06$ for $N \ge N_0$, and B has three negative eigenvalues. On the span of the $\mathrm{d}e_i$, three-dimensional, $B \le -\frac{\lambda_2}{12}$, as $\langle \mathrm{d}e_i, \varsigma\,\mathrm{d}e_j\rangle = -\lambda_j\delta_{ij}$ and $|\mathrm{d}Y|^2 \le 12|Y|^2$. A self-adjoint B with $\|B\| \le 1$, $|B| \ge c_B$ and an n-dimensional negative spectral subspace is $\ge c_- c_B$ on the B-orthogonal complement of every n-dimensional subspace on which $B \le -c_-$ (compare the two spectral parts in the norm of $|B|$). For $X = \sum_i a_i e_i + X'$, $a_i = \langle e_i, X\rangle$, one has $\langle \mathrm{d}X', \varsigma\,\mathrm{d}e_i\rangle = -\lambda_i\langle X', e_i\rangle = 0$, so $\langle X, \mathrm{d}^{\mathsf{T}}\varsigma\,\mathrm{d}X\rangle = -\sum_i \lambda_i a_i^2 + \langle \mathrm{d}X', \varsigma\,\mathrm{d}X'\rangle \ge -\lambda_1\sum_i a_i^2 + 0.0039(\frac12|\mathrm{d}X|^2 - 12\sum_i a_i^2)$: the bound with $c_1 = 0.0019$, as $\lambda_1 + 0.05 \le 7$. *The unstable coordinates.* Let $\tilde\Phi_t$ be the flow of $\tilde A$ in lattice time, $\tilde V_t = \tilde\Phi_t \tilde V_0$, $\tilde V_0$ the field W_ζ with the sign of its value at b_0 reversed. The nine coordinates $\xi_i(V) = \sum_p \omega_i(p)\,\mathrm{Ad}(T_p(V))\,\mathsf{s}_p(V) \in \mathfrak{g}$, $i = 1,2,3$, are the curvature paired with $\omega_i = -\lambda_i^{-1}\varsigma\,\mathrm{d}e_i$ (so $\mathrm{d}^{\mathsf{T}}\omega_i = e_i$, and $|\omega_i(p)| \le C_e e^{-c_e|p|}$ once C_e is enlarged by an absolute factor), cut off at the distance $\frac14 N$ from b_0 and carried to one root along a comb of paths: $T_x(V)$ is the ordered product of the values of V along the path of the comb from the root to the site x, and $T_p = T_x$, $T_b = T_x$ for a plaquette p and a bond b based at x; along a flow line of $\tilde A$, $\dot\xi_i = \lambda_i\xi_i + r_i$ with $|r_i| \le C(q(\tilde V_t) + N^2 e^{-c_e N/4})$, $q(V) = \sum_p e^{-c|p|}\varpi_p(V)^2$ with $c = \frac12 c_e$, a weighted sum of the plaquettes, at most $C_q\varpi(V)^2$ with an absolute C_q. The other directions are controlled by the coercivity bound in the rough field, through a lattice Weitzenböck identity and Kato's inequality, as long as the nine coordinates stay in the box $\mathfrak{B} = \{\max_i|\xi_i| \le \delta_u\}$, with the number $\delta_u > 0$ fixed below, say on $[0, t_1]$, $t_1 \le T$; the bound does not grow with T, as the unstable coordinates are integrated backwards in time. Let $D(t)$ be the ℓ^2 distance of the gauge orbits of $\tilde V_t$ and U_t°, an absolutely continuous function with $D(0) \le |\zeta| \le \rho_0$; at a minimising gauge $\tilde V_t = e^{iY_t}U_t^\circ$, Y_t horizontal at U_t°; let $\mathcal{D}_t = \sum_p |Z_p(Y_t)|^2$ be the energy of the difference and $\varpi_t^\circ = \varpi(U_t^\circ)$. (i) While $D \le \bar D$, a radius $\le \frac12$, half the derivative of D^2 is at most $-\sum_p \varsigma_p|Z_p(Y_t)|^2$ plus the source $2\sum_{p\ni b_0}\langle Z_p(Y_t), \mathsf{s}_p(U_t^\circ)\rangle$ of the four plaquettes at b_0, a member $28\varpi_t^\circ D^2$ and members of the orders three and four in Y_t; the coercivity bound applies to the first member, the three $\mathfrak{g}$-valued linear coordinates of Y_t that it leaves free equal the $\xi_i(\tilde V_t)$ up to errors bounded by $C\varpi_t^\circ$ and by $C(\varpi_t^\circ + D)(\mathcal{D}_t + (\varpi_t^\circ + N^{-2})D^2)^{1/2}$, and the Weitzenböck identity with Kato's inequality bounds $\sum_b |Y_t(b)|^4$ by $CD^2(\mathcal{D}_t + (\varpi_t^\circ + N^{-2})D^2)$; for $\bar D$ and δ_* small this gives, with absolute numbers $c' > 0$ and C, $\frac12\frac{d}{dt}D^2 \le -c'\mathcal{D}_t + C|\xi(\tilde V_t)|^2 + C(\varpi_t^\circ + N^{-2})D^2 + C(\varpi_t^\circ)^2$. (ii) Here the hypotheses $\int_0^T \varpi_t^\circ\,\mathrm{d}t \le \Lambda_0$ and $T \le \Lambda_0 N^2$ enter: they give $\int_0^T(\varpi_t^\circ + N^{-2})\,\mathrm{d}t \le 2\Lambda_0$, and with $\varpi_t^\circ \le \delta_*$ also $\int_0^T(\varpi_t^\circ)^2\,\mathrm{d}t \le \delta_*\Lambda_0$; so Gronwall's lemma gives, with $t_2 \le t_1$ the largest time with $D \le \bar D$ on $[0, t_2]$, $D(t)^2 + 2c'\int_0^t \mathcal{D}_s\,\mathrm{d}s \le e^{4C\Lambda_0}[\rho_0^2 + 2C\int_0^{t_2}|\xi(\tilde V_s)|^2 ds + 2C\delta_*\Lambda_0]$ for $t \le t_2$. (iii) The equation $\dot\xi_i = \lambda_i\xi_i + r_i$ is integrated backwards from t_2: $\xi_i(t) = e^{-\lambda_i(t_2-t)}\xi_i(t_2) - \int_t^{t_2} e^{-\lambda_i(u-t)}r_i(u)\,\mathrm{d}u$ with $|\xi_i(t_2)| \le \delta_u$, and Young's inequality gives $\int_0^{t_2}|\xi_i|^2 \le \delta_u^2/\lambda_i + 2\lambda_i^{-2}\int_0^{t_2}|r_i|^2$, a bound that does not grow with t_2. (iv) By the bound of r_i, $\int_0^{t_2}|r_i|^2 \le C[\sup_{[0,t_2]} q\int_0^{t_2} q + N^4 e^{-c_e N/2}T]$ with $q = q(\tilde V_t)$,

where $q(\tilde V_t)\le C(\mathcal D_t+(\varpi_t^\circ)^2+(\varpi_t^\circ+N^{-2})D^2)$, $\sup q\le C(\delta_*+\bar D)^2$ and $N^4e^{-c_eN/2}T\le\Lambda_0N^6e^{-c_eN/2}$. (v) Inserting (iii) and (iv) into (ii), $\mathcal J=\sup_{[0,t_2]}D^2+2c'\int_0^{t_2}\mathcal D_t\,\mathrm dt$ obeys $\mathcal J\le e^{C\Lambda_0}[\rho_0^2+\delta_u^2+\delta_*+N^6e^{-c_eN/2}]+e^{C\Lambda_0}(\delta_*+\bar D)^2\mathcal J$; for $\bar D$ and δ_* small with Λ_0, and N large with δ_*, this gives $\mathcal J\le\frac14\rho^2$ with $\rho^2=C_*(\rho_0^2+\delta_u^2+\delta_*)$, C_* depending only on Λ_0, and if $\rho\le\bar D$ the continuity of D gives $t_2=t_1$. So on $[0,t_1]$ the distance of the two flows modulo gauge stays below ρ, small with ρ_0, δ_u and δ_*, and the energy of the difference is integrable in time, $\int_0^{t_1}\mathcal D_t\,\mathrm dt\le\rho^2/c'$. *The numbers.* Given ε and Λ_0, the numbers are fixed in this order. First C_* and $\bar D$, which read Λ_0 alone, and $C_{**}=(C_*(64C_{\mathsf E}^2+2))^{1/2}$, with $C_{\mathsf E}$ the absolute bound of the inverse of the triangular matrix. Next θ and a ceiling $\bar\delta\le\frac{1}{10}$ for δ, small with ε and Λ_0, such that along flows with $\varpi(\tilde V_t)\le\bar\delta$, for N and T large, $\|\Lambda^9D\tilde\Phi_T\|\le e^{(3\lambda_1+6\lambda_2+\varepsilon)T}$, and the cone condition of (b) holds with the loss ε in the rate and leaves outside the strongest mode a part of w_T that is small against $|x_T|/(1+C_{**})$. Next δ_u, small with all these. Then $\delta_*=\delta_u^2$ and $\rho_0=8C_{\mathsf E}\delta_u$, so that the radius of (v) is $\rho=C_{**}\delta_u\le\bar D$ and $\delta=\delta_*+4\rho\le(1+4C_{**})\delta_u\le\bar\delta$. Last N_* and T_*, large with all these, so that for $N\ge N_*$ the number $N^2e^{-c_eN/4}$ is small against δ_u and $N^6e^{-c_eN/2}\le\delta_*$. These choices serve three steps below: on the faces of $\mathfrak B$, $|r_i|\le C(C_q\delta^2+N^2e^{-c_eN/4})\le\frac12\lambda_2\delta_u$, so that the exit is strict; at $t=0$ the map $\zeta\mapsto\xi(\tilde V_0)$ differs from its linear part, on the ball $|\zeta|\le\rho_0$, by a map with a Lipschitz constant at most $1/(2C_{\mathsf E})$, so that its image holds the ball of radius $\rho_0/(2C_{\mathsf E})=4\delta_u$ about $\xi(U)$, which holds $\mathfrak B$ as $|\xi(U)|\le C\delta_*\le\delta_u$; and at the end $|\partial\tilde A(\tilde V_T)|\le C(\delta_*+\rho)\le C(1+C_{**})\delta_u$, so that the errors in (b) are small multiples of $\delta_u|x_T|$. *The set.* Let $\mathcal K_T$ be the set of the ζ, $|\zeta|\le\rho_0=8C_{\mathsf E}\delta_u$, $C_{\mathsf E}$ the bound of the inverse of the triangular matrix, whose nine coordinates stay in $\mathfrak B$ up to the time T. At $t=0$ the map $\zeta\mapsto\xi(\tilde V_0)$ is close to the linear map $\zeta\mapsto(\sum_j e_i(b_0+\hat e_j)\mathrm{Ad}(T_{b_0+\hat e_j}(U))\zeta_j)_i$, invertible by the triangular matrix; on the faces of $\mathfrak B$ the exit is strict, as $\frac{d}{dt}\frac12|\xi_i|^2\ge\delta_u(\lambda_2\delta_u-|r_i|)>0$ there; so by a degree argument the end map $\Xi_T(\zeta)=\xi(\tilde V_T)$ carries $\mathcal K_T$ onto the interior of $\mathfrak B$. Put $\mathcal S=\mathcal K_T\cap\Xi_T^{-1}(\mathsf S)$, $\mathsf S=\{\frac12\delta_u<|\xi_1|<\delta_u,\ |\xi_2|,|\xi_3|<\delta_u\}$: its image under Ξ_T is the shell $\mathsf S$, of the volume $c\,\delta_u^9$, and the area formula with $\|\Lambda^9D\tilde\Phi_T\|\le e^{(3\lambda_1+6\lambda_2+\varepsilon)T}$ bounds the measure of $\mathcal S$ from below. (a) holds on $\mathcal K_T$, with $\delta=\delta_*+4\rho$. *(b) on $\mathcal S$.* With $w_T=D\tilde\Phi_T(\tilde V_0)[e\,\delta_{b_0}]$, $e\in\mathfrak g$,

$$\langle e,\partial_{b_0}(\textstyle\sum_p\mathsf f_pa_p\circ\Phi_{a_K^2T})(W_\zeta)\rangle=\mathsf f_0\langle\partial\tilde A(\tilde V_T),w_T\rangle+\sum_p(\mathsf f_p-\mathsf f_0)\varsigma_p\langle Z_p(w_T),\mathsf s_p(\tilde V_T)\rangle.$$

By a cone condition, also with the weight $e^{\theta|b|}$, w_T follows the strongest mode: $|w_T|^2\le3.4|x_T|^2$, x_T its coordinate along e_1 carried to the root, the rest of w_T small against $|x_T|$, and $|x_T|\ge\frac12|e|e^{(\lambda_1-\varepsilon)T}$. At the end the gradient is small, $|\partial\tilde A(\tilde V_T)|\le C(\delta_*+\rho)$, as $A_K(U^\circ_{T/2})\le\delta_*^2$, and, since $\varsigma\,\mathrm de_1=-\lambda_1\omega_1$, $\langle\partial\tilde A(\tilde V_T),w_T\rangle=-\lambda_1\langle\xi_1(\tilde V_T),x_T\rangle$ up to a small multiple of $\delta_u|x_T|$. The map $e\mapsto x_T(e)$ is onto; for e with $x_T(e)$ a positive multiple of $\xi_1(\tilde V_T)$, of modulus $>\frac12\delta_u$ on $\mathcal S$: $|\langle\partial\tilde A(\tilde V_T),w_T\rangle|\ge\frac14\lambda_1\delta_u|x_T|$, while the second sum is at most $21\,\delta(\sum_p|\mathsf f_p-\mathsf f_0|^2e^{-2\theta|p|})^{1/2}|x_T|$; divide by $|e|$. (c): on $\mathcal S$, up to a gauge, $\tilde V_t=e^{iY_t}U_t^\circ$ with Y_t horizontal at U_t° and small, and the energy $\mathcal D_t=\sum_p|Z_p(Y_t)|^2$ of the difference has $\int_0^T\mathcal D_t\,\mathrm dt$ bounded by a number that depends only on ε and Λ_0; as $\sum_pa_p(e^{iY}U)\le3A_K(U)+\frac32\sum_p|Z_p(Y)|^2+6\sum_p(\sum_{b\in p}|Y(b)|^2)^2$, with a quartic member that is integrable in t by the same bound and the inequality of Sobolev on the discrete torus, and as $A_K(U_t^\circ)$ does not increase, the integral over $[\frac T2,T]$ gives (c). (d): here the unstable part is read through nine coordinates of its own, taken from the velocity of the flow and cut off at a fixed radius. Let R be a radius that reads ε_c and Λ_0 alone, χ_R a cutoff of the bonds with values in $[0,1]$, equal to 1 within the distance $\frac R2$ of b_0 and to 0 beyond R, which varies by at most π/R across a plaquette, and $\mathsf t_x(V)$ the transport from the root to the site x along the comb of the coordinates ξ_i; with (σ_α) an orthonormal basis of $\mathfrak g$, $\lambda_3=\lambda_2$ and $i,\alpha=1,2,3$, let $e_{i\alpha}(V)(b)=\chi_R(b)\,e_i(b)\,\mathrm{Ad}(\mathsf t_{b_-}(V))^{-1}\sigma_\alpha$ and $u_{i\alpha}(V)=\lambda_i^{-1}\langle e_{i\alpha}(V),-\partial\tilde A(V)\rangle$. These nine numbers read the velocity of the flow along the cut eigenvectors, and they are the nine unstable coordinates of (d): $u_1=(u_{1\alpha})_\alpha\in\mathbb R^3$ is the coordinate in the strongest mode, and $(u_2,u_3)\in\mathbb R^6$ are the six slow coordinates. Along a flow line of $\tilde A$ the velocity solves the linearised

flow exactly, as the current does in Lem. 16.2(c), so that $\frac{d}{ds}u_{i\alpha}(\tilde V_s) = \lambda_i u_{i\alpha}(\tilde V_s) + \mathrm{err}_{i\alpha}(\tilde V_s)$ with $|\mathrm{err}_{i\alpha}(V)| \le C_R q_R(V) + 4\lambda_2^{-1}\epsilon_R q_R(V)^{1/2}$; here $q_R(V)$ is the sum of $\varpi_p(V)^2$ over the plaquettes within the distance $R+1$ of b_0, $\epsilon_R = \max_i \|(\mathrm{d}^\mathsf{T}\varsigma\,\mathrm{d} + \lambda_i)\chi_R e_i\| + \max_i \|(1-\chi_R)e_i\|_{\ell^{6/5}} \le CR^{5/2}(\frac{6}{6+\lambda_2})^{R/2}$ is the defect of the cut eigenvectors, and the numbers C_R read R and Λ_0 alone. For $V' = e^{i\eta}V$ with $\varpi(V)$ and $\|\eta\|$ small with R, $|\mathrm{err}_{i\alpha}(V') - \mathrm{err}_{i\alpha}(V)| \le [C_R(\varpi(V) + \|\eta\|) + 44\lambda_2^{-1}\epsilon_R]\|\eta\|$, and $|u_{i\alpha}(V') - u_{i\alpha}(V) - \langle e_{i\alpha}(V), \eta\rangle| \le \frac{\varepsilon_c}{100}\|\eta\|$ if $\varpi(V), \|\eta\| \le \epsilon_\sharp$, a number that reads R and ε_c. Let $\tilde V_s$ and $\tilde V'_s = e^{i\eta_s}\tilde V_s$ be two flow lines of $\tilde A$ in lattice time along which $\varpi \le \epsilon_\sharp$ and $n_s = \|\eta_s\| \le \epsilon_\sharp$, and $p_s = |u_1(\tilde V'_s) - u_1(\tilde V_s)|$ the difference of their coordinates in the strongest mode. They obey the cone inequalities $\frac{d}{ds}\frac12 n^2 \le \lambda_2 n^2 + (\lambda_1 - \lambda_2)p^2 + \varepsilon_c n^2$ and $\frac{d}{ds}\frac12 p^2 \ge \lambda_1 p^2 - \varepsilon_c pn$, $\varepsilon_c \le 10^{-3}$; so where $n^2 \le 700p^2$ the difference p grows at the rate $\ge \lambda_1 - \varepsilon_c\sqrt{700} \ge \lambda'_1$, and this cone is never left, while where $n^2 > 700p^2$ or $p = 0$ the distance n grows at the rate $\le \lambda_2 + \frac{1}{700}(\lambda_1 - \lambda_2) + \varepsilon_c \le \lambda''_2$. As long as the nine unstable coordinates stay in the ball $\{|u| \le \rho_1\}$, the flow of $\tilde A$ from the three changed bonds stays near the flow of A_K from U, modulo gauge and in ℓ^2 of all the bonds: by an energy inequality, which holds while the distance $D(s)$ of the two flows modulo gauge is at most a number D_0, $D(s) \le C'(\Lambda_0)\rho_1 + C_R\epsilon_{\mathrm d}^{1/2}$, with $C'(\Lambda_0)$ free of ε_c and of the radii; so $\varpi(\tilde V_s) \le \epsilon_{\mathrm d} + 4D(s) \le 5C'(\Lambda_0)\rho_1 \le \epsilon_\sharp$ and $|\mathrm{err}(\tilde V_s)| \le \frac{1}{12}\lambda_2\rho_1$ in $\mathbb{R}^9$ there. The values $(x, y_1, y_2) \in \mathfrak{g}^3$ at b_0 and at the two neighbouring bonds parametrise the nine unstable coordinates at the time 0 by a map close to an invertible linear one, triangular through the matrix $[e_i(b_0 + \hat e_j)]$, whose inverse has the norm at most $c_\triangle$. The data are taken in the ball $\{|(x, y_1, y_2)| \le 30C_\triangle\rho_2\}$, of radius $C_\triangle\rho_1 = 4c_\triangle\rho_1$: there ϖ and the changes stay below $\epsilon_\sharp$, and the bound on $u_{i\alpha}(V') - u_{i\alpha}(V)$ above, with the change of the $e_{i\alpha}(V)$ over the ball, small with ρ_1, leaves to the difference of the map and its linearisation at the centre a Lipschitz constant at most $\frac{1}{2c_\triangle}$ on the ball; so the map carries the ball homeomorphically onto its image, the images of the points of the boundary sphere lie at the distance $\ge \frac{C_\triangle\rho_1}{2c_\triangle} = 2\rho_1$ from $u(U)$, the image of the centre, and as $|u(U)| \le C_R\epsilon_{\mathrm d} \le \rho_1$ the image holds the ball $\{|u| \le \rho_1\}$, $\rho_1 = 30\rho_2$; on the sphere $\{|u| = \rho_1\}$ the exit is strict, as $\frac{d}{ds}\frac12|u|^2 \ge \lambda_2\rho_1^2 - \frac{1}{12}\lambda_2\rho_1^2 > 0$ there; so by a shooting argument with Brouwer's theorem, for every $\mathsf w \in \mathbb{R}^6$ with $|\mathsf w| \le \frac14\rho_1$ there are data in the ball $\{|(x, y_1, y_2)| \le 30C_\triangle\rho_2\}$ whose nine coordinates stay in the ball $\{|u| \le \rho_1\}$ up to T, whose coordinate in the strongest mode vanishes at T, and whose six slow coordinates at T equal $\mathsf w$. Here $e_1(b_0)^2 \ge 4/\lambda_1 > 0.604$: as $e_2(b_0) = e_3(b_0) = 0$, $\delta_{b_0} = e_1(b_0)e_1 + z$ with z in the orthogonal complement of e_1, e_2, e_3, on which the form of $\mathrm{d}^\mathsf{T}\varsigma\,\mathrm{d}$ is ≥ 0, as it has no other negative eigenvalue, and the cross term vanishes, e_1 being an eigenvector; so $-4 = \langle\delta_{b_0}, \mathrm{d}^\mathsf{T}\varsigma\,\mathrm{d}\,\delta_{b_0}\rangle \ge -\lambda_1 e_1(b_0)^2$, the value -4 coming from the four plaquettes at b_0; thus $|e_1(b_0)| > 0.777$. For two such data let $s_1 \le T$ be the last time up to which $n \le \epsilon_\sharp$. On $[0, s_1]$ the pair stays out of the cone: inside it p would grow from then on, against $p_T = 0$ if $s_1 = T$, as the coordinates in the strongest mode both vanish at T, and against $p_{s_1} \ge \epsilon_\sharp/\sqrt{700} > 2\rho_1 \ge p_{s_1}$ if $s_1 < T$. Hence $n_{s_1} \le e^{\lambda''_2 s_1}n_0$, and the slow coordinates at T differ by at most $3e^{\lambda''_2 T}n_0$, by $\sqrt6 \cdot 1.01\,n_T$ if $s_1 = T$ and by $2\rho_1 < \epsilon_\sharp = n_{s_1}$ if $s_1 < T$. At the time 0 the difference η_0 lives on the three changed bonds; $p_0 \le n_0/\sqrt{700}$, $n_0 \le |\eta_0(b_0)| + |\eta_0(b_0+\hat e_1)| + |\eta_0(b_0+\hat e_2)|$ and $p_0 \ge |e_1(b_0)||\eta_0(b_0)| - |\eta_0(b_0+\hat e_1)| - |\eta_0(b_0+\hat e_2)| - \varepsilon_c n_0$, so $0.73|\eta_0(b_0)| \le 1.04(|\eta_0(b_0+\hat e_1)| + |\eta_0(b_0+\hat e_2)|)$ and $n_0 \le 2.5(|\eta_0(b_0+\hat e_1)| + |\eta_0(b_0+\hat e_2)|) \le 4|y - y'|$, y, y' the values of the data at the two neighbouring bonds: the slow coordinates at T differ by at most $12e^{\lambda''_2 T}|y - y'|$; a Lipschitz map changes Lebesgue measure at most by the sixth power of its constant, which gives the measure of $\mathsf Y$. On the fibre of b_0 through such a datum, along the geodesic g_r, the two flows differ at the time 0 by $\eta_0 = re\,\delta_{b_0}$, so $p_0 \ge (|e_1(b_0)| - \varepsilon_c)r \ge 0.75\,r \ge 0.75\,n_0$: the difference in the strongest mode starts at $\ge 0.75\,r$, inside the cone, and grows at the rate $\ge \lambda'_1$, with $n_s \le 1.35p_s$ by the same two inequalities; let r_* be the first r at which it reaches ρ_2 at the time T (meanwhile $n_s \le 1.35\rho_2 < \epsilon_\sharp$, and $|u| \le \frac13\rho_1 + 3.1n_s < \frac12\rho_1$, where $\frac13\rho_1$ bounds $|u|$ along the datum by the equation of u read backwards from T), so that $r_* \le \frac43\rho_2 e^{-\lambda'_1 T}$. At the time T

the velocity of the flow is orthogonal to the strongest mode, $\langle \partial\tilde{A}(\tilde{V}_T), e_{1\alpha}(\tilde{V}_T)\rangle = -\lambda_1 u_{1\alpha}(\tilde{V}_T) = 0$, as the coordinate of the datum in that mode vanishes there, and it is of the order ρ_2 with a constant of Λ_0 alone: $\|\partial\tilde{A}(\tilde{V}_T)\| \le \|\partial A_K(U_T^\circ)\| + 16\epsilon_{\mathrm{d}} + 44D(T)$, $D(T)$ the distance of the two flows modulo gauge, where $\|\partial A_K(U_T^\circ)\|^2 \le 48e^{24\Lambda_0}\Lambda_0^2 N^3 T^{-3}$ (the condition $N^3 \le c_{\mathrm{d}} T^2$ enters here as well) and $D(T) \le C'(\Lambda_0)\rho_1 + C_R\epsilon_{\mathrm{d}}^{1/2}$; so $\|\partial\tilde{A}(\tilde{V}_T)\| \le 45\,C'(\Lambda_0)\rho_1 = 1350\,C'(\Lambda_0)\rho_2$, $\rho_2 = \rho_1/30$, by the last condition on ϵ_{d} below. The numbers are chosen in this order: $C'(\Lambda_0)$; $\varepsilon_c = \min\{10^{-3}, (4000\,C'(\Lambda_0))^{-2}\}$; the radius R, which reads ε_c and Λ_0; $\epsilon_\sharp$, which bounds ϖ and n wherever the cone inequalities are used, and D_0, the distance modulo gauge up to which the energy inequality holds, both depending on R and ε_c; ρ_1, small with R, with $5C'(\Lambda_0)\rho_1 \le \epsilon_\sharp$, $2\sqrt{700}\,\rho_1 < \epsilon_\sharp$ and $5C_\triangle\rho_1 \le \min\{1, \epsilon_\sharp\}$, so that $30C_\triangle\rho_2 \le 1$ and, as $\epsilon_{\mathrm{d}} \le \frac{1}{5}\epsilon_\sharp$ by the conditions on ϵ_{d} below, ϖ and the changes stay below $\epsilon_\sharp$ on the ball of the data; $\rho_2 = \rho_1/30$; and last ϵ_{d}, N_{d} and c_{d}, which depend on everything chosen before: small enough for the energy inequality, and such that $C_R\epsilon_{\mathrm{d}} \le \rho_1$, $\epsilon_{\mathrm{d}} + 4C_R\epsilon_{\mathrm{d}}^{1/2} \le C'(\Lambda_0)\rho_1$, $\|\partial A_K(U_T^\circ)\| + 16\epsilon_{\mathrm{d}} + 44C_R\epsilon_{\mathrm{d}}^{1/2} \le C'(\Lambda_0)\rho_1$ and $0.8\,e^{-11N_{\mathrm{d}}} \le \varepsilon_c$. At $r = r_*$ the ratio $\theta_s = n_s^2/p_s^2$ is defined on $[0,T]$, as $p_s > 0$ there, and the cone inequalities give $\theta' \le -2(\lambda_1 - \lambda_2)(\theta - 1) + 2\varepsilon_c\theta(1 + \theta^{1/2})$; as $\lambda_1 - \lambda_2 > 5.8$, the right side is at most $-11(\theta - 1) + 10\varepsilon_c$ where $1 \le \theta \le 2$, and $\theta_0 \le 0.75^{-2} < 1.8$, so that θ stays below 1.8 and $\theta_T - 1 \le 0.8\,e^{-11T} + \varepsilon_c \le 2\varepsilon_c$, by $T \ge N_{\mathrm{d}}$ and the last condition on N_{d}. Let $\hat{e}_\alpha = e_{1\alpha}(\tilde{V}_T)/\|\chi_R e_1\|$, three orthonormal vectors, and $\eta_T = \sum_\alpha c_\alpha\hat{e}_\alpha + \eta_T^\perp$ with $\eta_T^\perp$ orthogonal to them; the bound on $u_{i\alpha}(V') - u_{i\alpha}(V) - \langle e_{i\alpha}(V), \eta\rangle$ above, with $\|\chi_R e_1\| \le 1$, gives $|c| \ge p_T - \varepsilon_c n_T$, whence $\|\eta_T^\perp\|^2 = n_T^2 - |c|^2 \le (\theta_T - 1)p_T^2 + 2\varepsilon_c p_T n_T \le 5\varepsilon_c p_T^2$, and $p_T = \rho_2$ at $r = r_*$. Thus the displacement η_T at $r = r_*$ lies along the strongest mode up to the part $\eta_T^\perp$, of norm $\le (5\varepsilon_c)^{1/2}\rho_2$, so the member of the first order of the Taylor expansion of $\tilde{A}$ at the end of the flow, which sees only that part, is at most $1350\,C'(\Lambda_0)\rho_2\,(5\varepsilon_c)^{1/2}\rho_2 \le 0.76\,\rho_2^2$; the Hessian of $\tilde{A}$ on that mode is close to $-\lambda_1$, and its quadratic form at every X is at most $40\|X\|^2$, by the bounds of Lem. 16.2(a) at each plaquette, so that $\eta_T^\perp$ moves the member of the second order by at most $0.2\,\rho_2^2$, and this member is at most $-3\rho_2^2$: the fall is at least $2\rho_2^2$. The value $\mathsf{v}(0)$ is 8 plus a number of modulus at most $\sum_p a_p$ of the field with the reversed sign at b_0, and this sum is ≤ 1 by the bound used for (c), as the two flows are close and $A_K(U_T^\circ) \le 24\Lambda_0^2 N^3 T^{-2} \le 24\Lambda_0^2 c_{\mathrm{d}}$, the action being non-increasing and $\varpi(U_s^\circ) \le 4\Lambda_0/T$ at some $s \in [\frac{T}{4}, \frac{T}{2}]$. For a general f the same steps hold, with 8000 in the place of 4000 in ε_c: the plaquettes within a fixed distance of b_0 change $f(x(p))$ by $O(a_K)$ from $f(x_*)$, and the others see only the part of η_T outside the strongest mode, which is small; this gives the fall $f(x_*)\rho_2^2$. □

16.6. **Regularisation cutoffs and lower energy bounds.**

Lemma 16.5 (Condenser cutoffs)**.** For all K, m, $\beta > 0$, let $\eta \in D(\mathcal{E}_K)$, $0 \le \eta \le 1$, $\mathsf{A} = \{\eta = 0\}$, $\mathsf{B} = \{\eta = 1\}$, $D_0 = \{\phi \in D(\mathcal{E}_K) : \phi = 0 \text{ a.e. on } \mathsf{A}\cup\mathsf{B}\}$, $\mathcal{E}_{K,1}(\phi,\psi) = \mathcal{E}_K(\phi,\psi) + \int \phi\psi\,\mathrm{d}\mu^K$. There is exactly one $w \in \eta + D_0$ with $\mathcal{E}_{K,1}(w,\phi) = 0$ for $\phi \in D_0$; with $\varkappa = \mathcal{E}_{K,1}(w,w)$: $0 \le w \le 1$, $w = 0$ on A, $w = 1$ on B, $\Gamma_K(w,\cdot) = 0$ a.e. on $\mathsf{A}\cup\mathsf{B}$, $\varkappa \le \mathcal{E}_{K,1}(\eta,\eta)$, $\int w\,\mathrm{d}\mu^K \le \varkappa$, and $|\mathcal{E}_K(w,\phi)| \le \operatorname{osc}(\phi)\,\varkappa$ for every $\phi \in D(\mathcal{E}_K) \cap L^\infty$; w is invariant if η is.

With $q(u) = 3u^2 - 2u^3$: $q(w) \in D(\mathcal{E}_K)$, $q(w) = 0$ on A, $q(w) = 1$ on B, $\mathcal{E}_K(q(w)) \le \frac{9}{4}\varkappa$, and $\mathcal{E}_K(q(w),\phi) = -\int \mathsf{I}\,\phi\,\mathrm{d}\mu^K$ for $\phi \in D(\mathcal{E}_K) \cap L^\infty$, with $\mathsf{I} = 6w^2(1-w) + 6(1-2w)\Gamma_K(w)$, $\|\mathsf{I}\|_{L^1(\mu^K)} \le \frac{15}{2}\varkappa$. ■

Proof sketch. w is the element of least norm of the closed convex set $\{v \ge 1 \text{ on } \mathsf{B},\ v \le 0 \text{ on } \mathsf{A}\}$; truncation does not raise the norm, so $0 \le w \le 1$. The variational inequality $\mathcal{E}_{K,1}(w,\psi) \ge 0$ for $\psi \ge 0$ on B, $\psi \le 0$ on A, applied to $\psi = \phi\eta$, $(M-\phi)\eta$, $-\phi(1-\eta)$, $-(M-\phi)(1-\eta)$ for $0 \le \phi \le M = \operatorname{osc}\phi$, gives

$$M\Big(\int w\,\mathrm{d}\mu^K - \varkappa\Big) \le \mathcal{E}_{K,1}(w,\phi) \le M\varkappa, \qquad 0 \le \int w\phi\,\mathrm{d}\mu^K \le M\int w\,\mathrm{d}\mu^K,$$

so $|\mathcal{E}_K(w,\phi)| = |\mathcal{E}_{K,1}(w,\phi) - \int w\phi \,\mathrm{d}\mu^K| \le M\varkappa$. Gauge transformations preserve μ^K, Γ_K and the constraint set, so uniqueness gives invariance. For $q(w)$, apply the equation of w to $6w(1-w)\phi \in D_0$: $\Gamma_K(w, 6w(1-w)\phi) = 6w(1-w)\Gamma_K(w,\phi) + 6(1-2w)\phi\,\Gamma_K(w)$; and $6w^2(1-w) \le \frac{3}{2}w$, $\int \Gamma_K(w) \le \varkappa$. □

Proposition 16.6 (Gauge-invariant regularisation cutoffs)**.** For all K, m: let $0 < \bar{s} \le 1$ with $64\bar{s}^{7/16} \le \ell$ and $4a_K^2 \le \bar{s}$. For a site y and an integer $k \ge 1$ let $Q(y,k)$ be the cube of k^3 sites with lowest corner y, $\mathsf{e}_k(V;y) = a_K^{-1}\sum \varpi_p(V)^2$ over the plaquettes with base point in $Q(y,k)$, $\mathsf{e}_k^* = \max_y \mathsf{e}_k(\cdot;y)$, $\mathfrak{s}_k(V) = a_K^3 \sum_y \mathsf{e}_k(V;y)^8$, $k(r) = \lceil r^{7/16}/a_K \rceil$, and

$$\mathscr{N}(U) = \int_{a_K^2}^{\bar{s}} r\,\mathfrak{s}_{16k(r)}(U_r)\,\mathrm{d}r,$$

a smooth invariant function defined without choosing a gauge.

(a) If $\varpi(V) \le 1$, $1 \le k < N$ and X is horizontal at V, then $\nabla^2 A_K(V)[X,X] \ge \frac{1}{4}\sum_p |Z_p(X)|^2 - \hat{\lambda}_k(V)\|X\|^2$ with $a_K^{-2}\hat{\lambda}_k(V) = 16[16(144C)^3 \mathsf{e}_{k+1}^*(V)^2 + (144(a_K k)^2)^{-1}]$, C absolute: on horizontal vectors the Hessian is bounded below by the square of the energy in windows of side $a_K k$, with no supremum of the curvature and no gauge.

(b) Let $R > 0$ and K so large that $e^{64}(C_1 R)^{1/8} a_K^{11/64} \le \frac{1}{144}$, C_1 absolute. If $\mathscr{N}(U) \le R$, then $\varpi(U_r) \le \frac{1}{12}$ for $0 \le r \le \bar{s}$; $\Gamma_K(G\circ\Phi_\sigma)(U) \le e^{2\bar{\Lambda}(R)}\Gamma_K(G)(U_\sigma)$ for invariant $G \in C^2(\Omega_K)$ and $\sigma \le \bar{s}$, $\bar{\Lambda}(R) = 1 + c_\Lambda \bar{s}^{11/64} R^{1/4} + \bar{s}^{1/8}$, c_Λ absolute; for $4a_K^2 \le \sigma \le \bar{s}$, $A^a(U_{\sigma/2}) \le \mathsf{A}_\sigma(R) = \frac{1}{2}\cdot 16^{-3}(\frac{\sigma}{4})^{-25/16}\ell^{21/8}R^{1/8}$ and $(J,J)_a(U_\sigma) \le \frac{2}{\sigma}e^{2\bar{\Lambda}(R)}\mathsf{A}_\sigma(R)$; so $\Gamma_K(H_K^\sigma)$ and $|\partial_\sigma H_K^\sigma|$ are bounded on $\{\mathscr{N} \le R\}$ by numbers free of K for $4a_K^2 \le \sigma \le \bar{s}$, and for all $\sigma \ge 4a_K^2$ if besides $2a_K \mathsf{A}_{\bar{s}}(R) \le 1$; and $\Gamma_K(\mathscr{N}) \le 512\, e^{2\bar{\Lambda}(R)}\mathscr{N}'$, with $\mathscr{N}'$ the same integral with $r^2(16\rho(r))^3 a_K^3 \sum_y \mathsf{e}_{16k(r)}(\cdot;y)^{15}$, $\rho(r) = a_K k(r)$, in the place of $r\,\mathfrak{s}_{16k(r)}$.

(c) Assume (E), so that (Adm) of Prop. 16.1 holds, and let $\epsilon > 0$. There are $\bar{s}$, R, $\bar{K}$, and for every $q < \infty$ a number C_q, none depending on K, such that for $K \ge \bar{K}$ the function $\chi_K = \chi_0(\mathscr{N}/R)$, $\chi_0 \in C^\infty(\mathbb{R})$, $\chi_0 = 1$ on $(-\infty, \frac{1}{2}]$, $\chi_0 = 0$ on $[1,\infty)$, $0 \le -\chi_0' \le 3$, is smooth and invariant, vanishes off $\{\mathscr{N} \le R\}$, is 1 on the set $\mathsf{O}_K(\bar{C},\bar{s})$ of Prop. 16.1(a) formed at $\kappa = \frac{1}{64}$ and this ϵ, so that $\mu^K(\chi_K < 1) \le \epsilon$, and has $\int \Gamma_K(\chi_K)^q d\mu^K \le \mathsf{C}_q$.

(d) In the setting of (c), for a flowed observable $H = H_K^\sigma$ at a fixed $\sigma > 0$, $K \ge \bar{K}(\epsilon,\sigma)$, $\mathsf{h} = \sup_{\{\mathscr{N}\le R\}}\Gamma_K(H)$, $\mathsf{h}' = \sup_{\{\mathscr{N}\le R\}}|\partial_\sigma H|$: the vector field $\zeta_K = \chi_K \partial H$ has $a_K^{-1}\int |\zeta_K|^2\,\mathrm{d}\mu^K \le \mathsf{h}$ and the divergence $\chi_K\Delta_K H + \mathsf{b}\,\chi_K\partial_\sigma H + \Gamma_K(\chi_K, H)$; for $F \in C^1(\Omega_K)$, $|\int F\chi_K\Delta_K H\,\mathrm{d}\mu^K| \le \mathsf{h}^{1/2}\mathcal{E}_K(F)^{1/2} + [(\mathsf{hC}_1)^{1/2} + \mathsf{bh}']\|F\|_{L^2(\mu^K)}$; $|\int \chi_K(\mathsf{b}\partial_\sigma + \Delta_K)H\,\mathrm{d}\mu^K| \le (\mathsf{hC}_1)^{1/2}\mu^K(\frac{1}{2}R < \mathscr{N} < R)^{1/2}$; every sequence of cutoffs has a subsequence along which $\chi_K H_K^\sigma$ converges strongly to an element of $D(\mathcal{E}_\star)$; and $\|\chi_K H - g_n^K \circ \pi_{K,n}\|^2_{L^2(\mu^K)} \le C\,a_n^2/\mathsf{b} + 4\sup|\varphi|^2\mathsf{R}_n$ uniformly in K, g_n^K the top of the tower of $\chi_K H$, $n \ge n''$.

■

Proof sketch. (a) As $\varpi(V) \le 1$, $c_p \ge \frac{1}{2}$, and Lem. 16.2(a) gives $\nabla^2 A_K(V)[X,X] \ge \frac{1}{2}\sum_p |Z_p(X)|^2 - 3\sum_p |\mathsf{s}_p|\,|X|_p^2$, $|X|_p^2 = \sum_{b\in p}|X(b)|^2$. With $f(x) = (\sum_\mu |X_\mu(x)|^2)^{1/2}$ and $t(x)$ the largest $|\mathsf{s}_p|$ over the plaquettes with the corner x, the remainder is at most $12\mathcal{T}$, $\mathcal{T} = \sum_x t(x)f(x)^2$. For horizontal X the lattice Weitzenböck identity of Lem. 16.2(h), its remainder bounded plaquette by plaquette, gives $\|\nabla X\|^2 \le 2\sum_p |Z_p(X)|^2 + 36\mathcal{T}$, and Kato's inequality $\|\nabla f\| \le \|\nabla X\|$. In the windows $Q(y,k)$, each site lying in k^3 of them: Hölder's inequality and the inequality of Sobolev on a discrete cube, $\|f\|^2_{\ell^6(Q)} \le C_{\mathrm{Sob}}(\|\nabla f\|^2_{2,Q} + k^{-2}\|f\|^2_{\ell^2(Q)})$, $C_{\mathrm{Sob}} = 864$, give $\mathcal{T} \le E^{1/2}\|f\|^{1/2}\mathsf{B}^{3/4}$, $E = 4a_K\mathsf{e}_{k+1}^*(V)$, $\mathsf{B} = C_{\mathrm{Sob}}(\|\nabla f\|^2 + k^{-2}\|f\|^2) \le C_{\mathrm{Sob}}(2\sum_p |Z_p(X)|^2 + 36\mathcal{T} + k^{-2}\|X\|^2)$; the ℓ^2 member of the inequality of Sobolev is the source of the term $(144(a_K k)^2)^{-1}$.

Young's inequality at $(144C_{\mathrm{Sob}})^{-1}$ gives $\frac34\mathcal{T}\le\frac{1}{72}\sum_p|Z_p(X)|^2+[(144C_{\mathrm{Sob}})^3E^2+(144k^2)^{-1}]\|X\|^2$, so $12\mathcal{T}\le\frac29\sum_p|Z_p(X)|^2+\hat\lambda_k(V)\|X\|^2$, and $\frac12-\frac29>\frac14$; the absolute C of the statement is C_{Sob}. (b) Let $\mathscr{N}(U)\le R$.

The window energies. At every field a local energy inequality holds, from the derivative of a cut-off window energy along the flow: $\mathsf{e}_k(U_r;y)\le\mathsf{e}_{k+2h}(U_{r'};y-h)+64(a_Kh)^{-2}\int_{r'}^r\mathsf{e}_{k+2h}(U_\tau;y-h)\,\mathrm{d}\tau$ for $r'<r$, $y-h=y-a_Kh(1,1,1)$. At $k=16k(r)$, $h=8k(r)$, the mean over $r'\in[\frac r2,r]$, the bound $\mathsf{e}_k^*(V)^8\le8^9(a_Kk)^{-3}\mathfrak{s}_k(V)$ (a window is covered by eight windows of the same side whose corners run over a sub-cube of side $\frac k2$) and Jensen's inequality give $\mathsf{e}^*_{16k(r)}(U_r)^8\le C_1r^{-53/16}R$ for $2a_K^2\le r\le\bar s$, directly from $\mathscr{N}(U)\le R$. So $\varpi(U_r)^2\le a_K\mathsf{e}^*_{16k(r)}(U_r)\le(C_1R)^{1/8}a_K^{11/64}$ there, and for $r<2a_K^2$, as $\varpi(U_{r'})^2\le e^{32|r-r'|/a_K^2}\varpi(U_r)^2$, with the factor e^{64}: by the condition on K, $\varpi(U_r)\le\frac{1}{12}$ on $[0,\bar s]$.

The floor in two regimes. For horizontal X at U_r, $a_K^{-2}\nabla^2A_K(U_r)[X,X]\ge\frac14a_K^{-2}\sum_p|Z_p(X)|^2-\lambda(r)\|X\|^2$ with $\lambda(r)=12a_K^{-2}\varpi(U_r)$ for $r<a_K^2$ (Lem. 16.2(a), with $c_p\ge\frac12$; its integral over $[0,a_K^2]$ is ≤1) and $\lambda(r)=a_K^{-2}\hat\lambda_{k(r)}(U_r)$ for $a_K^2\le r\le\bar s$ (by (a)); Hölder's inequality with the exponents $4,\frac43$ in r bounds the integral of the window member by $c_\Lambda\bar s^{11/64}R^{1/4}$, and the member $(144\rho(r)^2)^{-1}$, $\rho(r)=a_Kk(r)\ge r^{7/16}$, contributes $\frac89\bar s^{1/8}\le\bar s^{1/8}$: $\int_0^{\bar s}\lambda(r)\,\mathrm{d}r\le\bar\Lambda(R)$.

The bounds. Lem. 16.2(b)–(d), read on horizontal vectors with λ in the place of $12a_K^{-2}\varpi$, give the bounds of $\Gamma_K(G\circ\Phi_\sigma)$, of $(J,J)_a$, of $\Gamma_K(H_K^\sigma)$ and of $\partial_\sigma H_K^\sigma$; $\mathsf{A}_\sigma(R)$ comes from $A^a=\frac12(16\rho)^{-3}a_K^3\sum_y\mathsf{e}_{16k}$, Hölder's inequality in y, the monotonicity of A^a along the flow and the mean over $[\frac\sigma4,\frac\sigma2]$. For continuation at later fixed times use the action-only horizontal Hessian bound from Prop. 16.6(a), as in Step 6 below: $a_KE\le\frac12$ gives $\max_p a_p\le\frac12$ along the later flow and a lower Hessian bound by $-c(E^2+\ell^{-2})$. This is distinct from the smaller small-action threshold in Lem. 16.2(f).

The square field of $\mathscr{N}$. With $M_r(V)=\int_r^{\bar s}w(\tau)\,\mathfrak{s}_{16k(\tau)}(\Phi_{\tau-r}V)\,\mathrm{d}\tau$, $w(\tau)=\tau\mathbf{1}_{\tau\ge a_K^2}$, and $\Xi_r=\partial M_r(U_r)$, horizontal, $\Xi_0=\partial\mathscr{N}(U)$, $\Xi_{\bar s}=0$: $\frac{d}{dr}\|\Xi_r\|^2=2a_K^{-2}\nabla^2A_K(U_r)[\Xi_r,\Xi_r]-2w(r)\langle\Xi_r,\partial\mathfrak{s}_{16k(r)}(U_r)\rangle$. The gradient of $\mathfrak{s}_{\hat k}$ is a covariant divergence: $\langle\Xi,\partial\mathfrak{s}_{\hat k}\rangle=\sum_p\mathsf{f}(p)\langle\mathfrak{s}_p,Z_p(\Xi)\rangle\le\mathsf{G}_r^{1/2}(\sum_p|Z_p(\Xi)|^2)^{1/2}$, $\mathsf{f}(p)=16a_K^2\sum_{y:\,\mathrm{base}(p)\in Q(y,\hat k)}\mathsf{e}_{\hat k}(\cdot;y)^7$, $\mathsf{G}_r\le256a_K^{-1}(16\rho)^3a_K^3\sum_y\mathsf{e}_{\hat k}(\cdot;y)^{15}$; it is paid by the member $\frac14\sum_p|Z_p|^2$ of the floor, $2w\mathsf{G}_r^{1/2}(\sum_p|Z_p(\Xi)|^2)^{1/2}\le\frac12a_K^{-2}\sum_p|Z_p(\Xi)|^2+2a_K^2w^2\mathsf{G}_r$.

Gronwall's inequality from $\bar s$ back to 0 gives

$$\|\partial\mathscr{N}(U)\|^2\le2a_K^2e^{2\bar\Lambda(R)}\int w^2\mathsf{G}_r\,\mathrm{d}r\le512\,a_Ke^{2\bar\Lambda(R)}\mathscr{N}'(U),$$

that is $\Gamma_K(\mathscr{N})\le512\,e^{2\bar\Lambda(R)}\mathscr{N}'$. (c) $\{\mathscr{N}\le R\}$ contains O_K, on which the window energies are bounded by the sizes of the flowed field; at each dyadic scale r_j the square field of the functional is bounded on the good set of that scale by a positive power of r_j, and off it crudely by r_j^{-1} (by a_K^{-12} at the last scale) against a mass $\le t_Mr_j^M$ for every M, from the moments of Prop. 16.1(a) and the super-exponential decay of R_d; the sum over the dyadic scales converges in every L^q.

(d) The divergence is the product rule and (C1) of Thm. AV; the bounds are Cauchy–Schwarz; the convergence is (A2) applied to χ_KH, whose energy is at most $2\mathsf{h}+2\sup|\varphi|^2\mathsf{C}_1$; the last bound is the key estimate of Step 1 applied to χ_KH. □

Lemma 16.7 (Lower bounds for the flowed action)**.** Assume (E), so that (Adm) of Prop. 16.1 holds; let $\mathbb{P}_K$ be the normalised chain measure from the least top depth d_0 with $\mathsf{R}_{d_0}\le\frac12$ such that every top depth $\ge d_0$ is admissible, $\mathbb{E}_K$ its mean, $\mathbf{B}_K$ and $\mathsf{a}_{\mathrm{top}}$ as in Prop. 16.1, and $\|\cdot\|_2$ the norm of $L^2(T_\ell)$. For a real function f and a $\mathfrak{g}$-valued function h of the bare bonds, $\langle f,h\rangle=a_K^3\sum_b f(b)h(b)\in\mathfrak{g}$, $\|f\|_1=a_K^3\sum_b|f(b)|$, $\|f\|_2^2=a_K^3\sum_b|f(b)|^2$. For a function Y of the bonds, $\mathrm{d}Y(p)=Y(b_1)+Y(b_2)-Y(b_3)-Y(b_4)$ is the plain sum around the plaquette p, with the signs $(+,+,-,-)$ of Lem. 16.2 and no factor of length; for a 1-form A per unit length, $\mathrm{d}_aA=a_K^{-2}\mathrm{d}(a_KA)$

is its lattice curl, $(\mathrm{d}_a A)(p) = \partial^+_\mu A_\nu(x) - \partial^+_\nu A_\mu(x)$ for $p = (x;\mu\nu)$, $\|\mathrm{d}_a A\|_2^2 = a_K^3 \sum_p |\mathrm{d}_a A(p)|^2$, and $\mathrm{d}_a P_s = P_s \mathrm{d}_a$.

(a) There are $k_4 = 100\, c_{\mathsf{J}} \gamma_{\mathrm{r}}^{-1/2}$, c_{J} the constant of the layer maps of Prop. 16.1, $p_* = 9/(64\Lambda_+^2 k_4^4)$, $k_\Sigma = 15/(16\Lambda_+)$ and $\theta_0 > 0$, depending only on the constants of the construction, and d_L, free of K, with $\mathbb{P}_K(\|\mathrm{d}_a P_s \mathbf{B}_K\|_2^2 \geq k_\Sigma \mathsf{b}^{-1} \ell^3 a_d^{-3}) \geq p_*$ for $d \geq d_L$, $K > d$ with $a_K \mathsf{a}_{\mathrm{top}} \leq \frac{1}{8}$, and $0 \leq s \leq \theta_0 a_d^2$. Let $k = K - d$ and $\mathbf{Q}_k^{\mathrm{lin}}$ the k-fold linear average at $\mathbf{1}$ from the bare bonds to the bonds of depth d, the composite of k maps YM3_I:(42).

For a plaquette P of depth d none of whose bonds is a pivot bond,

$$X_P = \mathrm{d}\, \mathbf{Q}_k^{\mathrm{lin}}(a_K P_s \mathbf{B}_K)(P) \in \mathfrak{g},$$

the plain sum around P, with no factor of length, is $\langle P_s f_P, \mathbf{B}_K \rangle$ with the real bond function $f_P = a_K^{-2} q_P$, q_P the kernel of $\mathsf{a} \mapsto \mathrm{d}\, \mathbf{Q}_k^{\mathrm{lin}} \mathsf{a}(P)$, $\|f_P\|_1 \leq 4a_d$, $\|f_P\|_2^2 \leq 4a_d^{-1}$; and X_P has $\mathbb{E}_K |X_P|^2 \geq \frac{3}{4\Lambda_+} x_k^{-1}$ and $\mathbb{E}_K |X_P|^4 \leq k_4^4 x_k^{-2}$; at least $3(1 - 4L^{-3})(\ell L^d)^3$ of the plaquettes of depth d have no pivot bond. Conditionally: let d_0 be any admissible top depth with $\mathsf{R}_{d_0} \leq \frac{1}{2}$, $\mathbb{P}_K$ the normalised chain measure from d_0, and $\mathbb{E}_K^0$ its conditional mean given the block field at depth d_0.

There are $d_L' > d_0$ and numbers $\tau_d \to 0$, which depend on d_0 but not on K, such that for $d \geq d_L'$, $K > d$ with $a_K \mathsf{a}_{\mathrm{top}} \leq \frac{1}{8}$ and $0 \leq s \leq \theta_0 a_d^2$ there is an event $\mathcal{T}_d$ of the block field at depth d_0 with $\mathbb{P}_K(\mathcal{T}_d) \geq 1 - \tau_d$ on which, N_P being the number of the plaquettes of depth d without pivot bond and the sums running over them, $N_P^{-1} \sum_P \mathbb{E}_K^0 |X_P|^2 \geq \frac{3}{4\Lambda_+} x_k^{-1}$, $N_P^{-1} \sum_P \mathbb{E}_K^0 |X_P|^4 \leq k_4^4 x_k^{-2}$, and

$$\mathbb{P}_K(\|\mathrm{d}_a P_s \mathbf{B}_K\|_2^2 \geq k_\Sigma \mathsf{b}^{-1} \ell^3 a_d^{-3} \,|\, \text{block field at depth } d_0) \geq p_*.$$

(b) Let $R \geq \max\{1, \|\mathbf{B}\|_{\kappa;a}\}$, $\bar{C} = (2 + c_3)R$, $a_K \leq a_1(R)$, $0 < \sigma \leq \min\{s_0(R), s_{\mathrm{lin}}(R)\}$, $a_K \bar{C} \sigma^{-1/4-\kappa/2} \leq \frac{1}{8}$, $P_\sigma \mathbf{B} \neq 0$, $U = e^{i a_K \mathbf{B}}$, where c_3, $s_0(R)$, $a_0(R)$ are those of Prop. 16.1(a) and M_Θ that of its head, $s_{\mathrm{lin}}(R) = (2c_6 \bar{C}^2)^{-4/(1-2\kappa)}$, $a_1(R) = \min\{a_0(R), (8e^{12}R)^{-2/(1-2\kappa)}, (8(4\mathsf{M}_\Theta)^{1/6} c_3 R)^{-1/(1-2\kappa)}\}$, a positive number that reads R and κ alone, and c_6, c', c_g are absolute. For $a_K \leq a_1(R)$ the gauge-fixed flow A_s from $\mathbf{B}$ has $a_K \|A_s\|_\infty \leq \frac{1}{2}$ on the closed interval $[0, s_0(R)]$, so that the chart and the linearised equation serve from $s = 0$ on: $a_K \|\mathbf{B}\|_\infty \leq e^{12} R a_K^{\frac{1}{2}-\kappa} \leq \frac{1}{8}$, as $\|f\|_\infty \leq e^{12} \|P_{a_K^2} f\|_\infty$; on $[0, a_K^2/(4\mathsf{M}_\Theta)]$ the chart variable $a_K A_s$ moves at most at the speed $a_K^{-2} \mathsf{M}_\Theta$, so that $a_K \|A_s\|_\infty \leq \frac{1}{8} + \frac{1}{4}$ there; later the first bound of Prop. 16.1(a) gives

$$\begin{aligned} a_K \|A_s - P_s \mathbf{B}\|_\infty &\leq (4\mathsf{M}_\Theta)^\kappa c_3 R a_K^{1-2\kappa} \\ &\leq (4\mathsf{M}_\Theta)^{1/6} c_3 R a_K^{1-2\kappa} \leq \frac{1}{8}. \end{aligned}$$

, and with $\|P_s \mathbf{B}\|_\infty \leq \|\mathbf{B}\|_\infty$, $a_K \|A_s\|_\infty \leq \frac{1}{4}$.

Then

$$\Gamma_K(A^a \circ \Phi_\sigma)(U)^{1/2} \geq \frac{\|\mathrm{d}_a P_{3\sigma/2} \mathbf{B}\|_2^2}{\|P_\sigma \mathbf{B}\|_2} - c' \ell^{3/2} \bar{C}^3 \sigma^{-1-\kappa}, \qquad \|P_\sigma \mathbf{B}\|_2 \leq \sqrt{3} \ell^{3/2} R \sigma^{-\frac{1}{4}-\frac{\kappa}{2}},$$

$\Gamma_K(A^a \circ \Phi_\sigma)(U)^{1/2} \leq \frac{8}{7}[\sqrt{2} c_g \sigma^{-1/2} \|\mathrm{d}_a P_\sigma \mathbf{B}\|_2 + c' \ell^{3/2} \bar{C}^3 \sigma^{-1-\kappa}]$, and $|(2A^a(U_\sigma))^{1/2} - \|\mathrm{d}_a P_\sigma \mathbf{B}\|_2| \leq \sqrt{3} \ell^{3/2} (2\bar{C} + 8\bar{C}^2) \sigma^{-\frac{1}{2}-\kappa}$.

(c) Let $\mathfrak{b} > 0$, $p = e^{-\Psi} dB$ a probability measure on the box $\prod_b \{|B(b)| < \mathfrak{b}\}$ with $\Psi \in C^2$ and $0 \leq D^2\Psi \leq \Lambda_+$, ∂_e the derivative in one coordinate of one bond b_1, and $\eta(B) = \phi(|B(b_1)|/\mathfrak{b})$ with $\phi = 1$ on $[0, \frac{1}{2}]$ and $\phi(t) = \cos^2(\pi(t - \frac{1}{2}))$ on $[\frac{1}{2}, 1]$. Then $\mathrm{Var}_p(u) \geq (\int \eta\, \partial_e u\, \mathrm{d}p)^2 / (\Lambda_+ + \pi^2 \mathfrak{b}^{-2})$ for every bounded Lipschitz u.

■

Proof sketch. (c) Integrate by parts against η, which vanishes at the faces in the direction e, so there is no boundary term: $\int \eta\, \partial_e u \,\mathrm{d}p = \int (u-\bar u)(\eta \partial_e \Psi - \partial_e \eta)\,\mathrm{d}p$, and bound the second factor in $L^2(p)$ through $D^2\Psi \le \Lambda_+$ (one more integration by parts) and $|\partial_e \eta| \le \pi/\mathfrak{b}$. (a)

Signs. They are those of the head of the lemma: the pairing $\langle f, \mathbf{h}\rangle = a_K^3 \sum_b f(b)\mathbf{h}(b) \in \mathfrak{g}$ of a real bond function f with a $\mathfrak{g}$-valued $\mathbf{h}$ on $\Lambda_{K,\ell}$; for a bond function Y without a factor of length, its plain sum $\mathrm{d}Y(p) = Y(b_1)+Y(b_2)-Y(b_3)-Y(b_4)$ around the plaquette p, with the signs of Lem. 16.2, the bonds taken as in $\partial U(p)$; and for a 1-form A per unit length, its lattice curl $\mathrm{d}_a A = a_K^{-2}\mathrm{d}(a_K A)$, with $\|\mathrm{d}_a A\|_2^2 = a_K^3 \sum_p |\mathrm{d}_a A(p)|^2$ and $\mathrm{d}_a P_s = P_s \mathrm{d}_a$. Besides, $\|f\|_r^r = a_K^3 \sum_b |f(b)|^r$ for $1 \le r < \infty$.

The roman d and d_a are these sums around a plaquette, and the italic d is a depth. For a plaquette P of depth d, $k = K-d$, X_P and f_P are those of (a): $X_P = \mathrm{d}\,\mathbf{Q}_k^{\mathrm{lin}}(a_K P_s \mathbf{B}_K)(P)$ is the sum around P of the k-fold linear average $\mathbf{Q}_k^{\mathrm{lin}}$ of equation YM3_I:(42), YM3_I:(42), applied to the bond function $a_K P_s \mathbf{B}_K$, which carries no factor of length, and f_P is the real bond function with $\mathrm{d}\,\mathbf{Q}_k^{\mathrm{lin}}(a_K A)(P) = \langle f_P, A\rangle$ for every 1-form A, so that $X_P = \langle P_s f_P, \mathbf{B}_K\rangle$. The numbers k_4, p_*, k_Σ of (a), and the number θ_0 with k_1, are

$$\theta_0 = \frac{3}{16\Lambda_+ k_1^2}, \qquad k_4 = 100\, c_{\mathsf{J}} \gamma_{\mathrm{r}}^{-1/2}, \qquad p_* = \frac{9}{64\Lambda_+^2 k_4^4}, \qquad k_\Sigma = \frac{15}{16\Lambda_+}, \qquad k_1 = 48\, c_\nabla \Big(\frac{24\, c_{\mathsf{J}}^2}{\gamma_{\mathrm{r}}(1-L^{-1})}\Big)^{1/2},$$

with the absolute constant c_∇ of the bound $\|\partial_\nu^{\pm} P_s f\|_1 \le c_\nabla s^{-1/2}\|f\|_1$ of the heat kernel and the constant c_{J} of the layer maps of Prop. 16.1, which enters (L3) below; they depend only on the constants of the construction.

The linear average. In the sum of YM3_I:(42) around a coarse plaquette the contour averages cancel, so one step maps the curl of a fine bond function to L^{-3} times the sum, over the sites x of the block, of its curls at the L^2 fine plaquettes of the square of side L with the corner x: a matrix with the row sums L^2 and the column sums L^{-1}. By the Cauchy–Schwarz inequality, $\sum_P |\mathrm{d}\,\mathbf{Q}_k^{\mathrm{lin}}\mathsf{a}(P)|^2 \le L^k \sum_p |\mathrm{d}\mathsf{a}(p)|^2$, and at $\mathsf{a} = a_K A$, as $\sum_p |\mathrm{d}(a_K A)(p)|^2 = a_K \|\mathrm{d}_a A\|_2^2$ and $L^k a_K = a_d$,

$$\|\mathrm{d}_a A\|_2^2 \;\ge\; a_d^{-1} \sum_P \big|\mathrm{d}\,\mathbf{Q}_k^{\mathrm{lin}}(a_K A)(P)\big|^2 : \tag{16.i}$$

the curls of the linear averages bound $\|\mathrm{d}_a A\|_2^2$ from below, with the constant one between the L^2 norms at the spacings a_K and a_d. Iterated, $\mathrm{d}\,\mathbf{Q}_k^{\mathrm{lin}}\mathsf{a}(P)$ is the mean, over the L^{3k} sites u of the block, of the sum of a around the square of side L^k with the corner u; so $a_K^2 f_P$ is a signed sum of four tents along the bonds of P, $\|f_P\|_1 \le 4a_d$, $\|f_P\|_2^2 \le 4a_d^{-1}$ and $\sum_\nu \|\partial_\nu^+ f_P\|_1 \le 24$; these norms do not grow under P_s, $\|P_s f_P\|_{12/11} \le \|P_s f_P\|_1^{5/6}\|P_s f_P\|_2^{1/6} \le 4a_d^{3/4}$, and $(1-P_s)f = -\int_0^s \sum_\nu \partial_\nu^- P_r \partial_\nu^+ f\,\mathrm{d}r$ gives $\|(1-P_s)f_P\|_1 \le 48 c_\nabla \sqrt{s}$.

The plaquette of a block field, by (c). Let $W \in \mathsf{Cut}_{k+1}$ and let P be a plaquette of level k none of whose bonds is a pivot bond, b_1 its first bond. Its four bonds are coordinates of the chart, so $\partial V_W(B)(P) = e^{i x_k^{-1/2} B(b_1)} C$ with C free of $B(b_1)$. Write $\partial V_W(B)(P) = c_P \mathbf{1} + i\mathsf{s}_P$, let (t_α) be an orthonormal basis of $\mathfrak{g}$ and $\mathsf{E} = \int_0^1 \mathrm{Ad}(e^{iu x_k^{-1/2} B(b_1)})\,\mathrm{d}u$; the derivative of $\langle \mathsf{s}_P, t_\alpha\rangle$ in the coordinate $B(b_1)^\alpha$ is $x_k^{-1/2}\,\frac12 \mathrm{tr}(t_\alpha(\mathsf{E}t_\alpha)\,\partial V_W(B)(P)) \ge x_k^{-1/2}(1-\delta(x_k)-\theta_d)$, as $|\mathsf{E}t_\alpha - t_\alpha| \le x_k^{-1/2}|B(b_1)| < \delta(x_k)$ on the box and $|\partial V_W(B)(P) - \mathbf{1}| < \theta_d$ on the cut: in the variable B of p_W, in which $D^2\Psi_W \le \Lambda_+$ holds (Lem. 15.3(iv)), the derivative carries the chart factor $x_k^{-1/2}$.

(c) at $p = p_W$, $\mathfrak{b} = \mathfrak{b}(x_k)$ and $u = \langle \mathsf{s}_P, t_\alpha\rangle$, with $\int \eta\,\mathrm{d}p_W \ge p_W(|B(b_1)| \le \frac12 \mathfrak{b}(x_k))$, summed over the three α and integrated over $W = V_{k+1}$ with Jensen's inequality, and $\mathbb{P}_K(|B_k(b_1)| > \frac12 \mathfrak{b}(x_k)) \le 4m_2 \mathfrak{b}(x_k)^{-2}$, m_2 the bound, free of k, of the second moments of one fluctuation field in (L5) of the proof of Prop. 16.1(a), recalled below (its Gaussian tails, Lem. 15.3(iv)), give, as

$|\partial V_W(B)(P)-\mathbf{1}|\ge|\mathsf{s}_P|$,

$$\mathbb{E}_K|\partial V_k(P)-\mathbf{1}|^2\ \ge\ \frac{3x_k^{-1}\varsigma_d^2}{\Lambda_+ +\pi^2\mathfrak{b}(x_k)^{-2}},\qquad \varsigma_d=\big(1-\delta(x_k)-\theta_d\big)_+\big(1-4m_2\mathfrak{b}(x_k)^{-2}\big)_+\to 1\quad(d\to\infty):$$

the upper bound of the Hessian of one fluctuation integral keeps the plaquette of the block field from degenerating. There are $3(\ell L^{d-1})^3$ pivot bonds, each in four plaquettes, so at most $12L^{-3}(\ell L^d)^3$ of the $3(\ell L^d)^3$ plaquettes of level k hold one.

The layers. By (Adm), as in the head of the lemma, d_0 and every larger top depth are admissible. By Prop. 16.1 (the field of the gauge of the chain), $\mathbf{B}_K=\frac{1}{ia_K}\log(e^{ia_K\mathbf{h}'_K}\cdots e^{ia_K\mathbf{h}'_{d_0+1}}e^{ia_K\mathbf{A}^{\mathrm{top}}})$, the logarithm of the ordered product of the top field, $|\mathbf{A}^{\mathrm{top}}|\le\mathsf{a}_{\mathrm{top}}$, and of the layers $\mathbf{h}'_{d'}=\mathrm{Ad}(\gamma)\mathbf{h}_{d'}$, $d_0<d'\le K$, with the regular gauge γ of the top, a function of the top field, and $\mathbf{h}_{d'}$ a function of the block field at depth d'; let $\mathcal{F}_{d'}$ be the σ-algebra of that block field, which increases with d', and $\mathbf{n}_{d'}=\mathbb{E}_K[\mathbf{h}'_{d'}|\mathcal{F}_{d'-1}]$.

The facts on the layers in the proof of Prop. 16.1(a) give: (L1) the ordered product of the top field and of the layers of the depths $\le d$ is a gauge transform of a background over the block field V_k, $k=K-d$, and the k-fold average of a background over V_k is V_k (Defs. YM3_I:9.3 and YM3_I:9.5, §5.2); (L2) $|\mathbf{h}'_{d'}|=|\mathbf{h}_{d'}|\le c_{\mathsf{h}}L^{d'}\delta(L^{d'}\mathsf{b})$ at every bond, with the constant c_{h} of the construction, and $\sum_{d'}a_K|\mathbf{h}'_{d'}|\le\frac14$, as d_0 is admissible; (L3) for a real bond function f, every component ξ of $\langle f,\mathbf{h}'_{d'}-\mathbf{n}_{d'}\rangle$ has $\mathbb{E}_K[e^{\lambda\xi}|\mathcal{F}_{d'-1}]\le e^{4\lambda^2G_{d'}(f)^2/\gamma_{\mathrm{r}}}$ for real λ, $G_{d'}(f)^2=c_{\mathsf{J}}^2\mathsf{b}^{-1}L^{d'}\min\{\|f\|_1^2,L^{-3d'}\|f\|_2^2\}$: the log-Sobolev inequality of one fluctuation integral (Lem. 15.3(iv)), carried by the map from the fluctuation field to the layer, whose derivative on the box obeys the bounds of the layer map with the constant c_{J}; on $L^2(T_\ell)$ this is the covariance bound $Ca_{d'}^2/\mathsf{b}$; (L4) $\sup|\mathbf{n}_{d'}|\le\mathsf{n}_{d'}=C\mathsf{b}^{-1}(\log L^{d'}\mathsf{b})^{2\mathfrak{p}_0}$, by the bounds (M), with $L^{-d/2}\mathsf{s}_d\to0$, $\mathsf{s}_d=\sum_{d_0<d'\le d}\mathsf{n}_{d'}$, and almost surely $\|\sum_{d_0<d'\le K}\mathbf{n}_{d'}\|_{L^{12}(T_\ell)}\le\mathsf{c}_{12}$, a number free of K; (L5) at every bond b, $\mathbb{E}_K|B_{K-d'}(b)|^2\le m_2$, and the moments of the layers are bounded so that $\|a_K(\sum_{d'}|\mathbf{h}'_{d'}(b)|)^2\|_{L^q(\mathbb{P}_K)}\le\mathsf{c}_{(q)}\mathsf{b}^{-1}$, with m_2 and $\mathsf{c}_{(q)}$ free of K and d'.

For $\sum_j|x_j|=s'\le\frac12$ the product $e^{ix_1}\cdots e^{ix_m}$ of exponentials of elements of $\mathfrak{g}$ is e^{iy} with $|y|\le1.02s'$ and $|y-\sum_j x_j|\le1.02s'^2$; so, with $a_K\mathsf{a}_{\mathrm{top}}\le\frac18$ and (L2), the remainder of the product formula, $\mathbf{B}_K-\mathbf{A}^{\mathrm{top}}-\sum_{d'}\mathbf{h}'_{d'}$, is at most $10a_K[(\sum_{d'}|\mathbf{h}'_{d'}|)^2+\mathsf{a}_{\mathrm{top}}^2]$ at every bond.

The field of the depths $\le d$. Let $d>d_0$ and let $\mathbf{B}^{\le d}$ be the logarithm of the ordered product of the top field and of the layers of the depths $\le d$. At every bare bond the arguments of the exponentials have the sum $s'=a_K\mathsf{a}_{\mathrm{top}}+a_K\sum_{d'\le d}|\mathbf{h}'_{d'}|\le L^{-k}\bar y_d$, $\bar y_d=a_d\mathsf{a}_{\mathrm{top}}+c_{\mathsf{h}}\delta(L^d\mathsf{b})/(1-L^{-1/2})$, by (L2) and $L^{d'}\delta(L^{d'}\mathsf{b})\le L^{-(d-d')/2}L^d\delta(L^d\mathsf{b})$ for $d'\le d$; so $y=L^k\sup a_K|\mathbf{B}^{\le d}|\le2\bar y_d$, and the remainder $\mathbf{B}^{\le d}-\mathbf{A}^{\mathrm{top}}-\sum_{d'\le d}\mathbf{h}'_{d'}$ is at most $1.02a_d^{-1}\bar y_d^2$ at every bond.

By (L1) and the gauge covariance of the average, $\mathcal{M}(U^u)=\mathcal{M}(U)^{u|}$ (Prop. YM3_I:4.5, YM3_I:(40)), $\mathcal{M}^k(e^{ia_K\mathbf{B}^{\le d}})$ is a gauge transform of V_k, so its plaquette at P has the modulus $|\partial V_k(P)-\mathbf{1}|$. For $L^k\sup|\mathsf{a}|<c_Q$, $\mathcal{M}^k(e^{i\mathsf{a}})(c)=e^{iQ_k(\mathsf{a})(c)}$ with $|Q_k(\mathsf{a})(c)|\le C_QL^k\sup|\mathsf{a}|$ and $|Q_k(\mathsf{a})(c)-\mathbf{Q}_k^{\mathrm{lin}}\mathsf{a}(c)|\le4C_Qc_Q^{-1}(L^k\sup|\mathsf{a}|)^2$: the linearisation of the average, with constants that depend on L alone (Prop. YM3_I:51.1 and Lem. 5.30).

At $\mathsf{a}=a_K\mathbf{B}^{\le d}$, with the product formula for the four factors around P,

$$\big|\langle f_P,\mathbf{B}^{\le d}\rangle\big|\ \ge\ |\partial V_k(P)-\mathbf{1}|-4\big(8C_Q^2+16C_Qc_Q^{-1}\big)\,\bar y_d^2,$$

a bound of the modulus alone, which is the quantity that (c) bounds from below; the error tends to 0 as $d\to\infty$, uniformly in K.

The heat kernel at the depths $\le d$. Let $f^1=(1-P_s)f_P$, $\|f^1\|_1\le48c_\nabla\sqrt{s}$. Of the parts of $\mathbf{B}^{\le d}$, the top field, the conditional means $\mathbf{n}_{d'}$ and the remainder are bounded at every bond by $\mathsf{a}_{\mathrm{top}}$, s_d and $1.02a_d^{-1}\bar y_d^2$, and pair with f^1 to at most $\|f^1\|_1$ times these; the centred layers $\mathbf{h}'_{d'}-\mathbf{n}_{d'}$, $d'\le d$, are martingale differences for $(\mathcal{F}_{d'})$, so orthogonal, and by (L3) at $f=f^1$ their pairing with f^1 has

the $L^2(\mathbb{P}_K)$ norm at most

$$\Big(3\cdot\frac{8}{\gamma_{\mathrm{r}}}\,c_{\mathsf{J}}^2\mathsf{b}^{-1}\|f^1\|_1^2\sum_{d'\le d}L^{d'}\Big)^{1/2}\;\le\;k_1\Big(\frac{s}{a_d^2}\Big)^{1/2}x_k^{-1/2},$$

as $\mathsf{b}^{-1}L^d=x_k^{-1}a_d^{-2}$. This cost does not vanish as d grows: at $s=\theta_0a_d^2$ it is $\frac14(3/\Lambda_+)^{1/2}x_k^{-1/2}$, and the range $0\le s\le\theta_0a_d^2$ of (a) is made for it.

The finer layers. Let $f=P_sf_P$. $\mathbf{B}_K-\mathbf{B}^{\le d}$ is the sum of the centred layers of the depths $d'>d$, of their conditional means and of the difference of the two remainders. $Y_P=\langle f,\mathbf{B}^{\le d}\rangle$ is $\mathcal{F}_d$-measurable and bounded, and $Z_P=\sum_{d'>d}\langle f,\mathbf{h}'_{d'}-\mathbf{n}_{d'}\rangle$ has $\mathbb{E}_K[Z_P|\mathcal{F}_d]=0$, so $\mathbb{E}_K|Y_P+Z_P|^2=\mathbb{E}_K|Y_P|^2+\mathbb{E}_K|Z_P|^2\ge\mathbb{E}_K|Y_P|^2$: in the second moment the finer layers can only add. The conditional means of the depths $>d$ pair with f to at most $4a_d^{3/4}\mathsf{c}_{12}+4a_d\mathsf{s}_d$, by Hölder's inequality and (L4), and the remainders, by (L5), to at most $40a_d(\mathsf{c}_{(4)}\mathsf{b}^{-1}+a_K\mathsf{a}_{\mathrm{top}}^2)+4.08\,\bar y_d^2$ in $L^4(\mathbb{P}_K)$.

(a). All these errors are at most $\mathsf{z}_dx_k^{-1/2}$ with $\mathsf{z}_d\to0$ uniformly in K, as $\bar y_d^2x_k^{1/2}\to0$, $a_dx_k^{1/2}=(a_d\mathsf{b})^{1/2}\to0$, $a_dx_k^{1/2}\mathsf{s}_d\to0$ by (L4) and $a_d^{3/4}x_k^{1/2}\to0$; d_L is the least depth $>d_0$ beyond which $\bar y_d\le\min\{\frac12,\frac{1}{16C_Q},\frac14c_Q\}$, $[3/(\Lambda_++\pi^2\mathsf{b}(L^d\mathsf{b})^{-2})]^{1/2}\varsigma_d-\mathsf{z}_d\ge\frac34(3/\Lambda_+)^{1/2}$ and $\mathsf{z}_d\le15c_{\mathsf{J}}\gamma_{\mathrm{r}}^{-1/2}$, a depth free of K. For P without pivot bond, $d\ge d_L$ and $0\le s\le\theta_0a_d^2$,

$$\|X_P\|_{L^2(\mathbb{P}_K)}\;\ge\;x_k^{-1/2}\Big\{\Big[\frac{3}{\Lambda_++\pi^2\mathfrak{b}(x_k)^{-2}}\Big]^{1/2}\varsigma_d-k_1\Big(\frac{s}{a_d^2}\Big)^{1/2}-\mathsf{z}_d\Big\}\;\ge\;x_k^{-1/2}\Big(\frac34-\frac14\Big)\Big(\frac{3}{\Lambda_+}\Big)^{1/2},$$

as $k_1\theta_0^{1/2}=\frac14(3/\Lambda_+)^{1/2}$; since $(\frac34-\frac14)^2\frac{3}{\Lambda_+}=\frac{3}{4\Lambda_+}$, this is $\mathbb{E}_K|X_P|^2\ge\frac{3}{4\Lambda_+}x_k^{-1}$. For the fourth moment, the centred layers of all depths form a martingale whose components have, by (L3) at $f=P_sf_P$ with $\|f\|_1\le4a_d$ at the depths $d'\le d$ and $\|f\|_2^2\le4a_{d'}^{-1}$ at the depths $d'>d$, the total variance proxy $v=\frac{4}{\gamma_{\mathrm{r}}}\sum_{d'}G_{d'}(f)^2\le\frac{4c_{\mathsf{J}}^2}{\gamma_{\mathrm{r}}}x_k^{-1}[\frac{16}{1-L^{-1}}+\frac{4}{L^2-1}]\le\frac{100\,c_{\mathsf{J}}^2}{\gamma_{\mathrm{r}}}x_k^{-1}$ $(L\ge3)$; so each component M^α has $\mathbb{E}_K|M^\alpha|^4\le64v^2$, the martingale has the $L^4(\mathbb{P}_K)$ norm at most $60\sqrt2\,c_{\mathsf{J}}\gamma_{\mathrm{r}}^{-1/2}x_k^{-1/2}$, the other members at most $\mathsf{z}_dx_k^{-1/2}$, and $\mathbb{E}_K|X_P|^4\le k_4^4x_k^{-2}$, for every P.

Paley and Zygmund. Let $\Sigma=a_d^{-1}\sum_P|X_P|^2$, the sum over the $N_P\ge3(1-4L^{-3})(\ell L^d)^3\ge\frac52(\ell/a_d)^3$ plaquettes without pivot bond $(L\ge3)$. By eq. 16.i at $A=P_s\mathbf{B}_K$, $\|\mathrm{d}_aP_s\mathbf{B}_K\|_2^2\ge\Sigma$; $\mathbb{E}_K\Sigma\ge a_d^{-1}N_P\frac{3}{4\Lambda_+}x_k^{-1}$, and by the Cauchy–Schwarz inequality for the pairs of plaquettes $\mathbb{E}_K\Sigma^2\le a_d^{-2}N_P^2k_4^4x_k^{-2}$; so $\mathbb{P}_K(\Sigma\ge\frac12\mathbb{E}_K\Sigma)\ge(\mathbb{E}_K\Sigma)^2/4\mathbb{E}_K\Sigma^2\ge\frac14(3/4\Lambda_+k_4^2)^2=p_*$, and $\frac12\mathbb{E}_K\Sigma\ge\frac12\cdot\frac52\cdot\frac{3}{4\Lambda_+}\,\ell^3a_d^{-3}\,x_k^{-1}a_d^{-1}=k_\Sigma\mathsf{b}^{-1}\ell^3a_d^{-3}$, as $x_k^{-1}a_d^{-1}=\mathsf{b}^{-1}$.

This is (a). The conditional form: the bounds that hold at every bond or almost surely, and the martingale structure of the layers, are conditional on the block field at depth d_0 as they stand, so the argument goes through under $\mathbb{E}_K^0$ with the norms $(N_P^{-1}\sum_P\mathbb{E}_K^0|\cdot|^r)^{1/r}$, $r=2,4$, but for the two places where unconditional moments of one layer enter, the bound m_2 and (L5); there Markov's inequality bounds their conditional means off an event of probability at most τ_d, and the inequality of Paley and Zygmund under $\mathbb{E}_K^0$, with the Cauchy–Schwarz inequality over P for the second moment of Σ, gives the last bound.

(b) By Duhamel's formula the linearised gauge-fixed flow from an L^2 datum z is a small perturbation of the heat flow, $\|w_s-P_sz\|_2\le2\epsilon(s)\|z\|_2$ with $\epsilon(s)=c_6\bar C^2s^{\frac14-\frac\kappa2}$; differentiating $A^a\circ\Phi_\sigma$ along $e^{ia_K(\mathbf{B}+rz)}$ at $z=P_\sigma\mathbf{B}$ and using $(\mathrm{d}_aP_\sigma\mathbf{B},\mathrm{d}_aP_\sigma P_\sigma\mathbf{B})=\|\mathrm{d}_aP_{3\sigma/2}\mathbf{B}\|_2^2$ and $\Gamma_K(F)^{1/2}\ge|\frac{d}{dr}F(e^{ia_K(\mathbf{B}+rz)})|/\|z\|_2$ gives the lower bound; the upper bound and the last inequality are the same expansion. □

The lower bound requires control of the frequency of the terminal gradient. For the action this frequency is controlled by the change in the squared current between two positive times. The following estimate makes this control uniform in the lattice spacing.

Lemma 16.8 (Lower propagation on a regular time interval)**.** Let $a = a_K$, $U_s = \Phi_s U$, $0 < \kappa < \frac{1}{2}$, and put

$$r = \frac{3}{4} + \frac{\kappa}{2}, \qquad \theta = 1 - r = \frac{1}{4} - \frac{\kappa}{2}.$$

Suppose that $C_0 > 0$, $\sigma > 0$, and

$$a^{-2}\varpi(U_s) \le C_0 s^{-r} \quad (0 < s \le \sigma). \tag{16.ii}$$

Write $g(s) = (J, J)_a(U_s)$ and assume $g(\sigma) > 0$. For $x \ge 0$ and $j > 0$ define

$$c_\kappa(x, j) = e^{8x/\theta}\left(\log \max\{1, j\} + \frac{64x}{\theta} + 1072x^2\right) + 32x,$$

$$E_\kappa(x, c) = 64x(1 + \theta^{-1}) + 16e^{8x/\theta}x(c + 32x) + \frac{672}{\theta}x^2 + \frac{7168}{\theta}e^{8x/\theta}x^3.$$

If $j \ge g(\sigma/2)/g(\sigma)$ and $x = C_0\sigma^\theta$, then

$$\Gamma_K(A^a \circ \Phi_\sigma)(U) \ge g(\sigma) \exp\left[-2c_\kappa(x, j) - E_\kappa(x, c_\kappa(x, j))\right]. \tag{16.iii}$$

The factor on the right is positive, decreases as j increases, and depends only on κ, C_0, σ, j. ∎

Proof. All the operators in the proof act on the finite periodic lattice at spacing a. Use the scalar product $(X, Y)_a = a^3 \sum_b \langle X(b), Y(b)\rangle$ on positive bonds. Thus $\mathrm{grad}_a F = a^{-2}\partial F$ satisfies $\|\mathrm{grad}_a F\|_a^2 = \Gamma_K(F)$, and $\mathrm{grad}_a A^a = J$. At a field V, let

$$T_\mu h(x) = \mathrm{Ad}(V_\mu(x))h(x + ae_\mu), \qquad \nabla_\mu = a^{-1}(T_\mu - 1), \qquad (DX)_{\mu\nu} = \nabla_\mu X_\nu - \nabla_\nu X_\mu.$$

Here $D_0^* X = \sum_\mu \nabla_\mu^* X_\mu$. In this proof $\Delta = \sum_\mu \nabla_\mu^* \nabla_\mu$ is positive and acts on each component; it is distinct from the heat operator Δ_a of Prop. 16.1. Set

$$\phi(V) = a^{-2}\varpi(V), \qquad \mathcal{F}(p) = \frac{\partial V(p) - \partial V(p)^*}{2ia^2}.$$

The orientations and base points of $\mathcal{F}$ agree with those of D. Differentiating the plaquette action gives $J = D^*\mathcal{F}$ and $a|J|_\infty \le 4\phi$.

We first compare the action Hessian with Δ. Define the symmetric operator H by

$$(X, HX)_a = \frac{d^2}{dt^2} A^a(e^{iatX}V)\Big|_{t=0}.$$

For $p = p_{\mu\nu}(x)$ put $\alpha_p = (-T_\nu X_\mu, -X_\nu, X_\mu, T_\mu X_\nu)$ and $S_p = \sum_{i<j}[\alpha_{p,i}, \alpha_{p,j}]$. The four perturbed factors in the plaquette can be transported to x; their sum is $a(DX)(p)$. For $P_t = \prod_i e^{it\alpha_{p,i}}$,

$$P_0'' = -\left(\sum_i \alpha_{p,i}\right)^2 - S_p.$$

Every traceless Hermitian 2×2 matrix Z has $Z^2 = |Z|^2\mathbf{1}$. Since $\partial V(p) = (1 - a_p)\mathbf{1} + ia^2\mathcal{F}(p)$, taking the trace in the second variation gives

$$(X, HX)_a = a^3 \sum_p \left((1 - a_p)|(DX)(p)|^2 + \langle \mathcal{F}(p), iS_p\rangle\right). \tag{16.iv}$$

Expansion of the squares also gives

$$\|DX\|_a^2 + \|D_0^* X\|_a^2 = (X, \Delta X)_a + w(X), \qquad w(X) = \sum_{\mu\neq\nu} (X_\mu, [\nabla_\mu, \nabla_\nu^*]X_\nu)_a.$$

The commutator compares the two transports around a plaquette, so its norm is at most 2ϕ. Thus $|w(X)| \le 4\phi\|X\|_a^2$. Moreover, $|\mathcal{F}(p)| \le \phi$, $|S_p| \le 3\sum_i |\alpha_{p,i}|^2$, and every bond belongs to four

plaquettes. Consequently the second term of eq. 16.iv has modulus at most $12\phi\|X\|_a^2$. Finally, $a_p = \frac{1}{2}|\partial V(p) - \mathbf{1}|^2$, $|\partial V(p) - \mathbf{1}| \le 2$, and $|DX(p)|^2 \le 4a^{-2}\sum_{b\in p}|X(b)|^2$ imply

$$0 \le a^3 \sum_p a_p |DX(p)|^2 \le 16\phi \|X\|_a^2.$$

It follows that

$$H + D_0 D_0^* = \Delta + \mathcal{U}, \qquad \|\mathcal{U}\| \le 32\phi. \tag{16.v}$$

In particular, $H = \Delta + \mathcal{U}$ on divergence-free forms.

We next record the two evolution equations used below. If Y_s is the differential of the flow, in the frame $\delta U_s = iaY_s U_s$, then

$$Y_s' = -H_s Y_s - \frac{a}{2} i[J_s, Y_s].$$

Indeed, for $R_X F = \frac{d}{dt} F(e^{iatX} V)\Big|_0$ one has $[R_X, R_Y] = -aR_{i[X,Y]}$. The symmetric part of the second derivative is the Hessian, and hence $R_Y J = HY - \frac{a}{2} i[J, Y]$. Differentiating $\dot U = -iaJU$ now gives the displayed equation. For a smooth gauge-invariant G with $\Gamma_K(G)(U_\sigma) > 0$, put

$$\xi(s) = \operatorname{grad}_a (G \circ \Phi_{\sigma - s})(U_s), \qquad n(s) = \frac{(\xi, H_s \xi)_a}{\|\xi\|_a^2}.$$

The pairing $(\xi(s), Y_s)_a$ is constant. Since $D\Phi_s$ is invertible, this gives

$$\xi' = H_s \xi - \frac{a}{2} i[J_s, \xi], \qquad \Gamma_K(G \circ \Phi_\sigma)(U) = \Gamma_K(G)(U_\sigma) \exp\left[-2\int_0^\sigma n(s)\,\mathrm{d}s\right]. \tag{16.vi}$$

Here ξ never vanishes, and $D_0^* \xi = 0$ because the flow is gauge covariant. The current $j(s) = J(U_s)$ satisfies

$$j' = -H_s j, \qquad D_0^* j = 0, \qquad g' = -2(j, H_s j)_a. \tag{16.vii}$$

Thus g vanishes at one time only if it vanishes identically.

The derivative of Δ has a useful cancellation. For fixed X, $\partial_s \nabla_\mu X_\nu = -i[J_\mu, T_\mu X_\nu]$. The part containing $a\nabla_\mu X_\nu$ pairs to zero with $\nabla_\mu X_\nu$. Setting $Y_\mu = \sum_\nu i[X_\nu, \nabla_\mu X_\nu]$ therefore gives

$$(X, \Delta' X)_a = -2(J, Y)_a = -2(\mathcal{F}, DY)_a.$$

The discrete product rule $\nabla_\mu [A, B] = [\nabla_\mu A, T_\mu B] + [A, \nabla_\mu B]$ shows explicitly that

$$(DY)_{\mu\lambda} = \sum_\nu i([\nabla_\mu X_\nu, T_\mu \nabla_\lambda X_\nu] - [\nabla_\lambda X_\nu, T_\lambda \nabla_\mu X_\nu] + [X_\nu, [\nabla_\mu, \nabla_\lambda] X_\nu]).$$

The first two terms contain only first differences. Translations are isometries, $|[A, B]| \le 2|A||B|$, and the sum over the three pairs of directions is bounded by twice the sum of the squared first differences. The last term uses $\|[\nabla_\mu, \nabla_\lambda]\| \le 2\phi$. Multiplying by $2|\mathcal{F}|$ and summing gives

$$|(X, \Delta' X)_a| \le 8\phi (X, \Delta X)_a + 24\phi^2 \|X\|_a^2. \tag{16.viii}$$

For either $\eta = \xi$ or $\eta = j$, let $h = (\eta, \Delta\eta)_a / \|\eta\|_a^2$ and $n_\eta = (\eta, H\eta)_a / \|\eta\|_a^2$. Then $h \ge 0$, $|h - n_\eta| \le 32\phi$, and

$$h' = \frac{2(\eta', (\Delta - h)\eta)_a + (\eta, \Delta'\eta)_a}{\|\eta\|_a^2}.$$

For ξ the leading term is $2\|(\Delta - h)\xi\|_a^2$, whereas for j it is its negative. The remaining part of ξ' has norm at most $(32 + 4)\phi\|\xi\|_a$, using $a|J|_\infty \le 4\phi$. The inequality $72\phi\|\xi\|_a \|(\Delta - h)\xi\|_a \le 2\|(\Delta - h)\xi\|_a^2 + 648\phi^2\|\xi\|_a^2$ and the corresponding bound with 64 and 512 for j give

$$h' \ge -8\phi h - 672\phi^2 \quad (\eta = \xi), \qquad h' \le 8\phi h + 536\phi^2 \quad (\eta = j). \tag{16.ix}$$

Put $\psi(s) = C_0 s^{-r}$, so $\int_0^\sigma \psi = x/\theta$. For the adjoint solution, backward integration of eq. 16.ix yields

$$h(s) \le e^{8x/\theta}\left(h(\sigma) + 1344 C_0^2 s^{1-2r}\right), \qquad 0 < s \le \sigma,$$

because $2r - 1 \ge \frac{1}{2}$. The square ψ^2 is not integrable at zero, but $s\psi^2$ is. Accordingly, integrate against the weight s:

$$\int_0^\sigma h = \sigma h(\sigma) - \int_0^\sigma s h' \le \sigma h(\sigma) + \int_0^\sigma s(8\psi h + 672\psi^2).$$

There is no boundary term at zero: for each fixed lattice the flow, the operators, and the nonzero adjoint solution are smooth there. If $c \ge \sigma n(\sigma)$, then $0 \le \sigma h(\sigma) \le c + 32x$. Combining the last two inequalities with $|n - h| \le 32\psi$ gives

$$2\int_0^\sigma n(s)\,\mathrm{d}s \le 2\sigma n(\sigma) + E_\kappa(x, c). \tag{16.x}$$

Indeed, the endpoint and $n - h$ terms give $64x(1 + \theta^{-1})$; the constant part of $h(s)$ gives at most $16e^{8x/\theta}x(c + 32x)$, since $2 - r \ge 1$; and the two remaining integrals are

$$1344 C_0^2 \int_0^\sigma s^{1-2r}\,\mathrm{d}s = \frac{672}{\theta}x^2, \qquad 21504 C_0^3 e^{8x/\theta}\int_0^\sigma s^{2-3r}\,\mathrm{d}s = \frac{7168}{\theta}e^{8x/\theta}x^3.$$

It remains to control the terminal frequency when $G = A^a$. Apply the second inequality of eq. 16.ix to the current and integrate forward from s to σ. Averaging over $\sigma/2 \le s \le \sigma$ gives

$$\frac{\sigma}{2}h(\sigma) \le e^{8x/\theta}\left(\int_{\sigma/2}^\sigma h(s)\,\mathrm{d}s + \frac{\sigma}{2}536\int_{\sigma/2}^\sigma \psi(s)^2\,\mathrm{d}s\right).$$

By eq. 16.vii,

$$\int_{\sigma/2}^\sigma h(s)\,\mathrm{d}s \le \frac{1}{2}\log\frac{g(\sigma/2)}{g(\sigma)} + 32\int_{\sigma/2}^\sigma \psi(s)\,\mathrm{d}s, \qquad \int_{\sigma/2}^\sigma \psi(s)^2\,\mathrm{d}s \le 2C_0^2\sigma^{1-2r}.$$

Consequently

$$0 \le \sigma h(\sigma) \le e^{8x/\theta}\left(\log\frac{g(\sigma/2)}{g(\sigma)} + \frac{64x}{\theta} + 1072x^2\right).$$

The terminal adjoint vector for $G = A^a$ is the current itself. Thus its terminal frequency satisfies $\sigma n(\sigma) \le c_\kappa(x, j)$. Equations eq. 16.vi and eq. 16.x prove eq. 16.iii. □

Proposition 16.9 (Lower energy bounds for flowed observables)**.** For all K, m, $\beta > 0$, with $a = a_K$, the lattice time $\tau = s/a^2$, $T = \sigma/a^2$ and $U_\tau^\circ = \Phi_{a^2\tau}U$: let $|X|_\infty = \max_b |X(b)|$, let $\nabla^3 A_K(V)$ be the symmetric trilinear form with $\nabla^3 A_K(V)[X, X, X] = \frac{d^3}{dt^3}A_K(e^{itX}V)|_{t=0}$, and let Z_p be as in Lem. 16.2, taken at the field V.

(a) (Log-convexity with a defect.) Let $G \in C^2(\Omega_K)$ be invariant, $U \in \Omega_K$, $\sigma > 0$ and $\partial G(U_\sigma) \ne 0$; for $0 \le \tau \le T$ let $\gamma_\tau = \partial(G \circ \Phi_{a^2(T-\tau)})(U_\tau^\circ)$, $N(\tau) = \|\gamma_\tau\|^2$, $\mathsf{q}(\tau) = \nabla^2 A_K(U_\tau^\circ)[\gamma_\tau, \gamma_\tau]$ and $\mathsf{f}_\tau = \partial A_K(U_\tau^\circ)$. Then $N > 0$, $\dot N = 2\mathsf{q}$, $(\log N)'' \ge -\eta$ with $\eta(\tau) = 2|\nabla^3 A_K(U_\tau^\circ)[\mathsf{f}_\tau, \gamma_\tau, \gamma_\tau]|/N(\tau)$, and

$$\Gamma_K(G \circ \Phi_\sigma)(U) \;\ge\; \Gamma_K(G)(U_\sigma)\,\exp\Big[-2\nu - \int_0^T \tau\,\eta(\tau)\,\mathrm{d}\tau\Big], \qquad \nu = \frac{T\,\mathsf{q}(T)}{N(T)},$$

ν the frequency of the gradient at the flowed field. For all V and real β, γ:

$$|\nabla^3 A_K(V)[\beta, \gamma, \gamma]| \le |\gamma|_\infty\{4(\sum_p |Z_p(\beta)|^2)^{1/2}\|\gamma\| + 8(\sum_p |Z_p(\gamma)|^2)^{1/2}\|\beta\| + 64\,\varpi(V)\|\gamma\|\|\beta\|\}.$$

(b) (An effective form.) In (a) let besides $0<\kappa<\frac16$, $C_F\ge1$, $0<\sigma\le1$ and $a^{-2}\varpi(U_s)\le C_F s^{-\frac34-\frac{\kappa}{2}}$ for $0<s\le\sigma$. Put $\lambda_F=6C_F$, $\mathsf{e}_1=(1+56\lambda_F e^{56\lambda_F})^{1/2}$,

$$\mathsf{r}=(\ell/a)^{3/2}|\partial G(U_\sigma)|_\infty/\|\partial G(U_\sigma)\|,$$

$\nu_+=\max\{\nu,0\}$, $\varrho_F=3.5\,e^{80\lambda_F}C_F\mathsf{r}$ and

$$\mathsf{k}_A=28e^{56\lambda_F}C_F+e^{28\lambda_F}\varrho_F(7\mathsf{e}_1+256C_F).$$

If

$$4e^{2\nu_++1}\varrho_F\big[48\mathsf{e}_1+384C_F+12\nu_+^{1/2}+32\mathsf{k}_A^{1/2}+768\varrho_F\big]\sigma^{\frac14-\frac{\kappa}{2}}\le1,$$

then $\Gamma_K(G\circ\Phi_\sigma)(U)\ge e^{-2\nu_+-\frac12}\,\Gamma_K(G)(U_\sigma)$. At $G=A^a$: $\Gamma_K(A^a)(U_\sigma)=(J,J)_a(U_\sigma)$ and $\nu=-\frac{\sigma}{2}\,\partial_\sigma\log(J,J)_a(U_\sigma)$.

(c) (Lower propagation at every time.) Let $0<\kappa<\frac16$, $\mathbf{B}$ a real 1-form, $R\ge\max\{1,\|\mathbf{B}\|_{\kappa;a}\}$ and

$$a\le a_2(R):=\min\big\{a_1(R),\ (16e^{12}R)^{-2/(1-2\kappa)},\ \big(8(16\mathsf{M}_\Theta)^{1/6}c_3R\big)^{-1/(1-2\kappa)}\big\},$$

a positive number that depends on R and κ alone, with c_3, $a_0(R)$, $s_0(R)$ of the short-time theory of the gauge-fixed flow in Prop. 16.1(a), $a_1(R)\le a_0(R)$ the threshold of Lem. 16.7(b), and $\mathsf{M}_\Theta=\max\{1,\sup|\Theta^{\mathrm{ch}}|\}$, the absolute number of the head of Prop. 16.1, with the chart equation $\frac{d}{ds}A_s(b)=a^{-3}\Theta^{\mathrm{ch}}(aA_s|_{\mathsf{N}(b)})$ of the gauge-fixed flow set there and the supremum taken where $|aA|\le1$; so $a_2(R)\le a_1(R)$, and $a\le a_2(R)$ serves both Lem. 16.7(b) and (c); let U be gauge equivalent to $e^{ia\mathbf{B}}$, $\sigma>0$, $\sigma'=\min\{\sigma,s_0(R)\}$, $(J,J)_a(U_\sigma)>0$, $\Lambda\ge\Lambda_\sigma(U)$ and $\mathsf{j}_\sharp\ge(J,J)_a(U_{\sigma'/2})/(J,J)_a(U_\sigma)$.

Put $r=3/4+\kappa/2$, $\theta=1-r$ and $C_0(R)=4((2+c_3)R)^2$. For $0<\sigma\le s_0(R)$ set $x=C_0(R)\sigma^\theta$ and

$$\mathsf{G}_\kappa^{\mathrm{short}}(R,\sigma,\mathsf{j}_\sharp)=\exp\left[-2c_\kappa(x,\mathsf{j}_\sharp)-E_\kappa(x,c_\kappa(x,\mathsf{j}_\sharp))\right],$$

where c_κ and E_κ are defined in Lem. 16.8. Then

$$\Gamma_K(A^a\circ\Phi_\sigma)(U)\ge(J,J)_a(U_\sigma)\mathsf{G}_\kappa^{\mathrm{short}}(R,\sigma,\mathsf{j}_\sharp).\tag{16.xi}$$

This positive factor is independent of K, ℓ, and b, and decreases as $\mathsf{j}_\sharp$ increases.

For arbitrary $\sigma>0$, set $s=\sigma'$, $\tau=s/2$, $x=C_0(R)s^\theta$ and $j=\max\{1,\mathsf{j}_\sharp\}$. Put

$$c_*=e^{8x/\theta}(\log j+64\Lambda+672x^2)+32x,\qquad \mathsf{G}_\kappa(R,s,\Lambda,\mathsf{j}_\sharp)=j^{-1}\exp[-2c_*-E_\kappa(x,c_*)].$$

Then

$$\Gamma_K(A^a\circ\Phi_\sigma)(U)\ge(J,J)_a(U_\sigma)\mathsf{G}_\kappa(R,\sigma',\Lambda,\mathsf{j}_\sharp).$$

The factor is positive, decreases in Λ and $\mathsf{j}_\sharp$, and is independent of the cutoff, side and label.

The upper bound $\Gamma_K(A^a\circ\Phi_\sigma)(U)\le e^{24\Lambda_\sigma(U)}(J,J)_a(U_\sigma)$ holds as well.

(d) (Positive energies and the flowed current.) Assume (E) and $0<\kappa<\frac16$; let $\varphi\in C^\infty(\mathbb{R})$ be bounded with all its derivatives and $\varphi'>0$ on $[0,\infty)$, and $0<\sigma<\sigma_2\le1$. Say that (J_σ) holds if there is $c_0>0$ with $p_0:=\liminf_K\mu^K((J,J)_a(U_\sigma)\ge c_0)>0$, and $(\mathrm{D}_{\sigma,\sigma_2})$ if $\liminf_K\langle A^a\circ\Phi_\sigma-A^a\circ\Phi_{\sigma_2}\rangle_{\mu^K}>0$. In (i) and in the first two implications of (iii) use the consequence (Adm) of (E) proved in Prop. 16.1. (i) If (J_σ) holds, then $\liminf_K\int\chi_K\Gamma_K(\varphi(A^a)\circ\Phi_\sigma)\,\mathrm{d}\mu^K>0$ for every sequence of Borel $\chi_K:\Omega_K\to[0,1]$ with $\limsup_K\mu^K(\chi_K<1)<p_0$.

(ii) Conversely, if $R\ge R_\flat$, the Borel $\chi_K:\Omega_K\to[0,1]$ vanish off $\mathsf{O}_K(8R,\bar s(R))$ and $\liminf_K\int\chi_K\Gamma_K(\varphi(A^a)\circ\Phi_\sigma)\,\mathrm{d}\mu^K>0$, then (J_σ) holds. (iii) (J_{σ_2}) implies $(\mathrm{D}_{\sigma,\sigma_2})$, and $(\mathrm{D}_{\sigma,\sigma_2})$ implies (J_σ); and $\liminf_K\langle A^a\circ\Phi_\sigma\rangle_{\mu^K}>\sup_K\langle A^a\circ\Phi_1\rangle_{\mu^K}$ implies $(\mathrm{D}_{\sigma,1})$.

■

Proof sketch. (a) $N > 0$ because $D\Phi$ is invertible. As G is invariant, γ_τ is horizontal, and along the trajectory $\dot\gamma_\tau = \nabla^2 A_K(U_\tau^\circ)\gamma_\tau - \frac{i}{2}[\mathsf{f}_\tau, \gamma_\tau]$, the Hessian taken as a symmetric operator; since $\langle \gamma, i[\mathsf{f},\gamma]\rangle = 0$, $\dot N = 2\mathsf{q}$, and a second differentiation, in which the Hessians cancel, gives $\dot{\mathsf{q}} = 2\|\nabla^2 A_K\gamma\|^2 - \nabla^3 A_K[\mathsf{f},\gamma,\gamma] + \frac{1}{6}\|i[\mathsf{f},\gamma]\|^2$. So

$$(\log N)'' = \frac{4}{N^2}(\|\nabla^2 A_K\gamma\|^2\|\gamma\|^2 - \langle\gamma, \nabla^2 A_K\gamma\rangle^2) + \frac{2}{N}\Big(\tfrac{1}{6}\|i[\mathsf{f},\gamma]\|^2 - \nabla^3 A_K[\mathsf{f},\gamma,\gamma]\Big) \geq -\eta$$

by the Cauchy–Schwarz inequality. Integrating twice from T, $\log\frac{N(\tau_1)}{N(T)} \geq -2(T-\tau_1)\frac{\mathsf{q}(T)}{N(T)} - \int_{\tau_1}^T(\tau - \tau_1)\eta(\tau)\,\mathrm{d}\tau$ for $0 \leq \tau_1 \leq T$; at $\tau_1 = 0$, $N(0) = a\Gamma_K(G\circ\Phi_\sigma)(U)$ and $N(T) = a\Gamma_K(G)(U_\sigma)$. The weight τ under the integral keeps the defect finite at rough fields. The bound of $\nabla^3 A_K$ follows from the expansion of the third derivative plaquette by plaquette, as in Lem. 16.2(a), and the Cauchy–Schwarz inequality over the plaquettes. (b) The hypothesis gives $\Lambda_\sigma \leq \lambda_F$; by Lem. 16.2(b), (c), (h), $(J,J)_a(U_s)^{1/2} \leq \mathsf{j}_0 s^{-\frac{5}{4}-\frac{\kappa}{2}}$ with $\mathsf{j}_0 = 3.5\,e^{28\lambda_F}\ell^{3/2}C_F$, and $|\gamma_\tau|_\infty \leq e^{52\lambda_F}|\gamma_T|_\infty$, $\|\gamma_\tau\| \leq e^{28\lambda_F}\|\gamma_T\|$.

Lem. 16.2(a) gives $\sum_p |Z_p(X)|^2 \leq \nabla^2 A_K(V)[X,X] + 28\varpi(V)\|X\|^2$ for all X; with $\frac{d}{d\tau}\|\mathsf{f}_\tau\|^2 = -2\nabla^2 A_K[\mathsf{f}_\tau,\mathsf{f}_\tau]$ this makes the energy $\sum_p|Z_p(\mathsf{f}_\tau)|^2$ of the current integrable in τ, $\int_0^T\sum_p|Z_p(\mathsf{f}_\tau)|^2 d\tau \leq \frac{1}{2}\|\mathsf{f}_0\|^2 + 28\lambda_F\sup_\tau\|\mathsf{f}_\tau\|^2$, and with (a) it bounds the energy $\sum_p|Z_p(\gamma_\tau)|^2 \leq \mathsf{q} + 28\varpi N$ of γ_τ. On the largest interval $[\tau_1, T]$ on which $N \geq e^{-2\nu_+ - 1}N(T)$, the bound of $\nabla^3 A_K$ and these estimates give $\int_{\tau_1}^T(\tau-\tau_1)\eta \leq \frac{1}{2}$ under the displayed condition; so (a) gives $\log\frac{N(\tau_1)}{N(T)} \geq -2\nu_+ - \frac{1}{2}$, and $\tau_1 = 0$ by continuity.

At $G = A^a$, $\partial A^a = a^{-1}\mathsf{f}$, and $\frac{d}{d\tau}\|\mathsf{f}_\tau\|^2 = -2\langle\mathsf{f}_\tau, \nabla^2 A_K\mathsf{f}_\tau\rangle$. (c) First suppose $0 < \sigma \leq s_0(R)$. Since $a \leq a_2(R) \leq a_0(R)$, Prop. 16.1(a) gives a gauge-fixed representative e^{iaA_s} of U_s for $0 \leq s \leq s_0(R)$, with

$$\|A_s\|_\infty \leq (1+c_3)Rs^{-1/4-\kappa/2}, \qquad \|\nabla A_s\|_\infty \leq (2+c_3)Rs^{-3/4-\kappa/2}.$$

For a plaquette, split its holonomy into the two differences between opposite bond potentials and the group commutator of two adjacent bond exponentials. The exponential is Lipschitz on Hermitian matrices, and the group commutator has norm at most twice the product of their norms. This gives

$$a^{-2}\varpi(e^{iaA_s}) \leq 2\left(\|\nabla A_s\|_\infty + \|A_s\|_\infty^2\right),$$

as in Lem. 16.2(e). Put $\bar C = (2+c_3)R \geq 1$. Since $s_0(R) \leq 1$ and $1/2 + \kappa \leq 3/4 + \kappa/2$, the right side is at most $4\bar C^2 s^{-3/4-\kappa/2}$. Curvature is gauge invariant, so eq. 16.ii holds with $C_0 = C_0(R)$. Here $\sigma' = \sigma$, and the ratio assumed in (c) is exactly the ratio required in Lem. 16.8. That lemma proves eq. 16.xi. Now let $\sigma > 0$ be arbitrary and put $s = \sigma'$ and $\tau = s/2$. Use the adjoint solution

$$\xi(t) = \mathrm{grad}_a(A^a \circ \Phi_{\sigma-t})(U_t), \qquad g(t) = \|J(U_t)\|_a^2.$$

It is horizontal and nonzero. The adjoint identity eq. 16.vi and $D\Phi_{\sigma-t}(U_t)J(U_t) = J(U_\sigma)$ give

$$(\xi(t), J(U_t))_a = g(\sigma), \qquad \|\xi(\tau)\|_a^2 \geq \frac{g(\sigma)^2}{g(\tau)} \geq \frac{g(\sigma)}{j}.$$

For this same solution put $h(t) = (\xi(t), \Delta_t\xi(t))_a/\|\xi(t)\|_a^2$ and $n(t) = (\xi(t), H_t\xi(t))_a/\|\xi(t)\|_a^2$. Since $h \geq 0$ and $|n-h| \leq 32\phi$,

$$\|\xi(s)\|_a^2 \leq e^{64(\Lambda_\sigma - \Lambda_s)}g(\sigma), \qquad \int_\tau^s h(t)\,\mathrm{d}t \leq \tfrac{1}{2}\log j + 32\Lambda.$$

Indeed, integrate $(\log\|\xi\|_a^2)' = 2n$ first on $[s,\sigma]$ and then on $[\tau,s]$, using the lower bound at τ. Only the integrated curvature up to σ enters here.

On $[0,s]$ the short-time estimate gives $\phi(t) \leq C_0(R)t^{-r}$. Backward integration of the adjoint inequality in eq. 16.ix, followed by averaging over $[\tau,s]$, yields

$$\tau h(\tau) \leq e^{8x/\theta}\left(\int_\tau^s h(t)\,\mathrm{d}t + 672\tau\int_\tau^s C_0(R)^2 t^{-2r}\,\mathrm{d}t\right).$$

Here $\tau\int_\tau^{2\tau} C_0(R)^2 t^{-2r}\,\mathrm{d}t \le C_0(R)^2\tau^{2\theta} \le x^2$. Consequently $\tau n(\tau) \le c_*$. The integrated adjoint estimate eq. 16.x, applied on $[0,\tau]$ to this solution, gives

$$2\int_0^\tau n(t)\,\mathrm{d}t \le 2c_* + E_\kappa(x, c_*).$$

We used $C_0(R)\tau^\theta \le x$ and monotonicity of E_κ in its nonnegative arguments. Finally,

$$\Gamma_K(A^a\circ\Phi_\sigma)(U) = \|\xi(0)\|_a^2 = \|\xi(\tau)\|_a^2 \exp\left[-2\int_0^\tau n(t)\,\mathrm{d}t\right] \ge \frac{g(\sigma)}{j} e^{-2c_* - E_\kappa(x,c_*)}.$$

Thus no power-law curvature estimate beyond the regular interval $[0,s]$ is needed. The upper bound follows as before from Lem. 16.2(b).

(d) (i): fix R, R' and s_+ such that, for large K, the regularised fields $\mathsf{O}_K(8R,\bar s(R))$ of (C4), the event that the gauge orbit holds a 1-form of rough norm $\le R'$ at the index $\frac{\kappa}{2}$, and $\{A^a\circ\Phi_\sigma \le s_+\}$ all have probability close to 1 (Prop. 16.1(a), by (Adm), and Chebyshev's inequality).

On their intersection with $\{\chi_K = 1\}\cap\{(J,J)_a(U_\sigma)\ge c_0\}$, whose mass has lower limit > 0, the proof of (C2)(a) bounds Λ_σ and $(J,J)_a(U_{\sigma'/2})$, the proved lower bound of (c) at the index $\frac{\kappa}{2}$, for $a_K \le a_2(R')$, bounds $\Gamma_K(A^a\circ\Phi_\sigma)$ below by c_0 times a positive number free of K, and $\Gamma_K(\varphi(A^a)\circ\Phi_\sigma) = \varphi'(A^a\circ\Phi_\sigma)^2\Gamma_K(A^a\circ\Phi_\sigma) \ge (\min_{[0,s_+]}\varphi')^2\Gamma_K(A^a\circ\Phi_\sigma)$. (ii): on $\mathsf{O}_K(8R,\bar s(R))$, for large K, the proof of (C2)(a) gives $\Lambda_\sigma \le \lambda_\sharp$ and $(J,J)_a(U_\sigma)\le \mathsf{j}_\sigma$ with numbers free of K, and $\Gamma_K(\varphi(A^a)\circ\Phi_\sigma) \le \|\varphi'\|_\infty^2 e^{24\lambda_\sharp}(J,J)_a(U_\sigma)$ (Lem. 16.2(b)); splitting at a level c, $\int\chi_K\Gamma_K \le \|\varphi'\|_\infty^2 e^{24\lambda_\sharp}[c + \mathsf{j}_\sigma\mu^K((J,J)_a(U_\sigma)\ge c)]$.

(iii): $A^a\circ\Phi_\sigma - A^a\circ\Phi_{\sigma_2} = \int_\sigma^{\sigma_2}(J,J)_a(U_s)\,\mathrm{d}s$ (Lem. 16.2(c)), and $(J,J)_a(U_{s'}) \le e^{24\lambda_\sharp}(J,J)_a(U_s)$ for $s\le s'$ on $\mathsf{O}_K(8R,\bar s(R))$, whose complement has small mass for large R by (Adm) (Step 8); in the second arrow the moments of $(J,J)_a(U_s)$ of Prop. 16.1(a), under (Adm), and the Cauchy–Schwarz inequality give $\langle(J,J)_a(U_\sigma)\rangle_{\mu^K} \ge 2c_0$, hence $\mu^K((J,J)_a(U_\sigma)\ge c_0) \ge c_0^2/\sup_K\langle(J,J)_a(U_\sigma)^2\rangle_{\mu^K}$. The last arrow is $\liminf_K(x_K - y_K) \ge \liminf_K x_K - \limsup_K y_K$. □

16.7. **Comparison of backgrounds at consecutive cutoffs.** The convergence argument in Prop. 16.1(b) first fixes the coarse lattice and then removes the ultraviolet cutoff. For this step a comparison whose constant depends on the coarse volume is sufficient. We prove that comparison here. The separate estimate between a rough field and its background, used subsequently in that proposition, remains uniform in the cutoff.

We measure lengths in units of the fixed coarse lattice. Its torus has side $2L^n$ and volume $N = (2L^n)^3$. Let $\eta = L^{-j}$, $j\ge 1$, and $\eta' = \eta/L$. The two fine lattices have spacings η and η'. For a configuration U at spacing ξ, write

$$F_U(p) = \frac{\partial U(p) - \partial U(p)^{-1}}{2i\xi^2}, \qquad J(U) = D_U^* F_U, \qquad \mathcal{A}^\xi(U) = \xi^{-1}\sum_p \left(1 - \tfrac{1}{2}\operatorname{tr}\partial U(p)\right).$$

For quaternionic matrices we use the real scalar product $\operatorname{Re}\operatorname{tr}(X^*Y)/2$; its norm agrees with the operator norm and restricts to the stated norm on the Lie algebra. All sums over bonds and plaquettes below use positive orientations. The pairing and L^p norms at spacing ξ include the measure ξ^3. The notation D_U denotes the covariant exterior derivative. We call U regular at radius α when

$$\sup_p|\partial U(p) - 1| < \alpha\xi^2, \qquad \sup_b|J(U)(b)| < \alpha.$$

These are the constant-scale regularity conditions used in the background construction. All constants in this subsection depend only on the fixed blocking factor L. We use the Hölder exponent $1/2$.

Proposition 16.10 (Comparison at a fixed coarse lattice)**.** There are $\alpha_* > 0$, $C < \infty$ and a fixed room radius ρ_* with the following property. Suppose the constant-torus background setting is admitted, $L^n \ge 3L\mathfrak{M}$ and $L^n > 6\rho_*$, where $\mathfrak{M}$ is its fixed analytic block size. Suppose that U^A and

U^B are regular real critical backgrounds, at radius $0 < \alpha \le \alpha_*$, on the lattices of spacings η and η', respectively, and that they have the same coarse datum:

$$\mathcal{M}^j U^A = \mathcal{M}^{j+1} U^B.$$

Then there are a gauge transformation g and a real one-form A on the η lattice such that

$$(U^A)^g = e^{i\eta A}\mathcal{M}(U^B), \qquad \|A\|_\infty \le C\alpha N^{1/5}\eta^{1/5}. \tag{16.xii}$$

The constants α_*, C, ρ_* are independent of n, j and of the coarse datum. The factor $N^{1/5}$ is retained in the estimate. ■

The proof compares the first variations of the actions on the two lattices. The average of a critical field need not be critical. Its failure of criticality is small when tested against a coarse variation and a compatible fine variation. We first quantify this fact.

Lemma 16.11 (One-step regularity and the action defect)**.** Suppose U is regular at radius α on the η' lattice, with α sufficiently small and $L^n > 6\rho_*$. Put $W = \mathcal{M}(U)$. Then W is regular at radius $C\alpha$ on the η lattice. For every real fine one-form h,

$$\left| \frac{d}{dt}\Big[\mathcal{A}^{\eta'}(e^{it\eta' h}U) - \mathcal{A}^{\eta}(\mathcal{M}(e^{it\eta' h}U))\Big]_{t=0} \right| \le C\alpha\eta^{1/2}\|D_U h\|_1 + C\alpha\eta'\|h\|_{1,\sup}. \tag{16.xiii}$$

Here $\|h\|_{1,\sup} = \eta^3 \sum_{p'} \sup_{b\subset Y(p')} |h(b)|$; $Y(p')$ is the union of the four fine blocks at the corners of the coarse plaquette p'. ■

Proof. Choose ρ_* to be a fixed multiple of the radius in [7, Thm. BT], large enough to contain each averaging stencil with a collar of width four. At every coarse site that theorem, with constant level, supplies a gauge $U = e^{i\eta' P}$ on this cube with

$$|P| + |\nabla P| + |D_1^* D_1 P| + |\Delta P| \le C\alpha, \qquad |\nabla P(x) - \nabla P(y)| \le C\alpha |x-y|^{1/2}. \tag{16.xiv}$$

The enlarged cube fits in the torus by $L^n > 6\rho_*$. Its radius is fixed, so the smallness condition in that theorem follows by reducing α_*. In particular the constants in eq. 16.xiv do not depend on η or N.

We give the local estimates needed for averaging. On the fixed stencil of a coarse bond write

$$\Phi(a) = \frac{1}{i}\log \mathcal{M}(e^{ia}), \qquad \Phi(0) = 0, \qquad \Phi'(0) = Q_{\mathrm{lin}}.$$

The exponential and logarithmic formulas defining $\mathcal{M}$ are holomorphic on a ball of fixed radius, since each path contains a bounded number, depending only on L, of factors. Their first three derivatives are bounded on a smaller fixed ball by Cauchy's formula. The differential Q_{lin} is the block mean of straight path sums. Summing the oriented boundary of each path surface gives

$$dQ_{\mathrm{lin}} a(p') = L^2 \langle da\rangle_{p'}, \qquad \langle f\rangle_{p'} = L^{-5} \sum_{x\in B(p'_-)} \sum_{p\in S_x(p')} f(p). \tag{16.xv}$$

The interior edges cancel in each surface $S_x(p')$; its remaining four edges are precisely the four path sums in the left member. The mean has total mass one. Every fine plaquette occurs with total weight L^{-3} when p' is summed, and hence

$$\eta^3 \sum_{p'} \langle f\rangle_{p'} = \eta'^3 \sum_{p} f(p). \tag{16.xvi}$$

For later use we also record the elementary nonlinear curvature bounds. If $V = e^{i\xi P}$, $|P| \le a \le 1$ and $\xi \le 1/13$, then

$$F_V = D_1 P + \mathsf{n}(P), \qquad |\mathsf{n}(P)| \le 16 a^2.$$

Indeed, expand the four exponentials of a plaquette to first order; the remainder is at most the square of the sum of the four angles. Cauchy's formula applied to this quadratic remainder gives

$|\mathsf{n}(P') - \mathsf{n}(P)| \le 64a \max|P' - P|$. In the current, the difference of the two nonlinear remainders on neighboring plaquettes contributes at most $64a^2$ per direction when $|\nabla P| \le a$. The parallel transport in the other term differs from the identity by at most $2\xi a$, while $|F_V| \le 2a + 16a^2$. Thus

$$|J(V) - D_1^* D_1 P| \le 200a^2. \tag{16.xvii}$$

Let $P^M = \eta^{-1}\Phi(\eta' P)$ in the gauge eq. 16.xiv. The derivative bounds for Φ give $|P^M| + |\nabla P^M| \le C\alpha$. Split it into $P^{\mathrm{lin}} = \eta^{-1} Q_{\mathrm{lin}}(\eta' P)$ and P^{nl}. For $\Psi = \Phi - \Phi'(0)$, $|\Psi'(a)| \le C|a|$ and $|\Psi''(a)| \le C$. A mixed second difference of $\Psi(\eta' P)$ is the double integral of

$$\Psi''(a(s,t))[\partial_s a, \partial_t a] + \Psi'(a(s,t))\partial_s\partial_t a,$$

where $a(s,t)$ is the bilinear interpolation of its four translated arguments. Here $|a| \le C\eta'\alpha$, $|\partial_s a| + |\partial_t a| \le C\eta'\eta\alpha$ and $|\partial_s\partial_t a| \le C\eta'\eta\alpha$. After division by η^3 this bounds $|D_1^* D_1 P^{\mathrm{nl}}|$ by $C\alpha^2$.

There is a cancellation needed to bound the linear term without a negative power of η. Fix distinct directions μ, ν, λ, put $F_{\mu\sigma} = \nabla'_\mu P_\sigma - \nabla'_\sigma P_\mu$ and $g_\sigma(w) = \eta'^{-1}[F_{\mu\sigma}(w) - F_{\mu\sigma}(w - \eta' e_\sigma)]$. The linear Stokes identity gives

$$(D_1^* D_1 P^{\mathrm{lin}})_\mu = K_\lambda(g_\nu + g_\lambda) + (K_\nu - K_\lambda) g_\nu,$$

where

$$K_\sigma f(x) = L^{-6} \sum_{z \in B(x)} \sum_{0 \le i, i', r < L} f(z + i\eta' e_\mu + (i' - r)\eta' e_\sigma).$$

The first term is bounded by $C\alpha$ because $g_\nu + g_\lambda = (D_1^* D_1 P)_\mu$ and K_λ is a positive average. To treat the second, multiply P by a product cutoff equal to one on the stencil, supported in its collar, whose first and second differences are bounded independently of the mesh, and extend it by zero. The product rule and eq. 16.xiv give $\|\Delta' \widetilde{P}\|_\infty \le C\alpha$. The two Fourier multipliers expressing $(K_\nu - K_\lambda) g_\nu$ in terms of $\Delta' \widetilde{P}_\nu, \Delta' \widetilde{P}_\mu$ are

$$-\kappa(\vartheta) \frac{\overline{d}_\nu d_\mu}{\sum_\sigma |d_\sigma|^2}, \qquad \kappa(\vartheta) \frac{|d_\nu|^2}{\sum_\sigma |d_\sigma|^2},$$

where $d_\sigma = e^{i\vartheta_\sigma} - 1$, $s(t) = L^{-1} \sum_{|q| \le (L-1)/2} e^{iqt}$, $e_L(t) = L^{-1} \sum_{q=0}^{L-1} e^{iqt}$ and

$$\kappa = s(\vartheta_\mu) e_L(\vartheta_\mu) s(\vartheta_\nu) s(\vartheta_\lambda) [s(\vartheta_\nu)^2 - s(\vartheta_\lambda)^2].$$

The last bracket vanishes to second order at zero. Each multiplier m therefore satisfies $|\partial^r m(\vartheta)| \le C|\vartheta|^{2-r}$ for $0 \le r \le 2$ near zero and is smooth elsewhere. These are also weak derivative bounds: the boundary terms on a sphere of radius δ tend to zero as $\delta \downarrow 0$. Twice integrating by parts and using Bessel's inequality gives

$$\sum_{z \in \mathbb{Z}^3} |\widehat{m}(z)| \le \left(\sum_z (1 + |z|^2)^{-2} \right)^{1/2} \|m - \Delta_\vartheta m\|_{L^2} < \infty.$$

The convolution kernels thus have ℓ^1 norms bounded only in terms of L. This bounds the second term by $C\alpha$. Together with eq. 16.xvii it proves $|J(W)| \le C\alpha$.

We prove the curvature bound and the action estimate together. In $Y(p')$ take the comb gauge based at p'_-. A comb comparison with the elementary plaquettes gives $U = e^{ia_0}$ in this gauge with $|a_0| \le C\varpi$, where $\varpi = \sup|\partial U - 1| \le \alpha\eta'^2$. Put $G_p = \partial U(p) - 1$ in this fixed gauge and $\bar{G} = \langle G \rangle_{p'}$. By eq. 16.xv, the map

$$R(a) = \partial \mathcal{M}(e^{ia})(p') - 1 - L^2 \langle \partial e^{ia} - 1 \rangle_{p'}$$

has zero value and derivative at zero. The holomorphic bounds above imply

$$|R(a_0)| \le C\varpi^2, \qquad |R'(a_0)\dot{a}| \le C\varpi|\dot{a}|. \tag{16.xviii}$$

Consequently $|\partial W - 1| \le L^2\varpi + C\varpi^2 \le C\alpha\eta^2$, completing regularity of W.

In the gauge eq. 16.xiv, curvature varies across a stencil by $C\alpha\eta^{1/2}$ in physical units: this follows from the Hölder bound for ∇P and the Lipschitz bound for $\mathsf{n}(P)$. Passing to the comb gauge changes the comparison of two curvatures by at most $C\alpha^2\eta$ in those units. Indeed, each comb has length $C\eta$, each bond angle is at most $C\eta'\alpha$, and $|\operatorname{Ad}(v)-1| \le 2|v-1|$. Thus

$$|G_p - \bar G| \le C\alpha\eta'^2\eta^{1/2}. \tag{16.xix}$$

The identity $1-\frac{1}{2}\operatorname{tr} v = |v-1|^2/2$ for $v \in SU(2)$ and eq. 16.xvi give the exact defect

$$\mathcal{A}^{\eta'}(U) - \mathcal{A}^{\eta}(W) = \eta^{-1}\sum_{p'} \delta_{p'}, \qquad \delta_{p'} = \frac{L^4}{2}\langle |G-\bar G|^2\rangle - L^2(\bar G, R) - \frac{1}{2}|R|^2.$$

Differentiate at $U_t = e^{it\eta' h}U$, retaining the comb gauge chosen at $t=0$. If $s_{p'} = \sup_{Y(p')}|h|$, the product rule on a plaquette and the derivative of the local logarithm give

$$|\dot G_p| \le \eta'^2 |D_U h(p)| + 4\varpi\eta' s_{p'}, \qquad |\dot a| \le 2\eta' s_{p'}, \qquad |\dot R| \le C\varpi\eta' s_{p'}.$$

In the derivative of the variance, the term containing $\dot{\bar G}$ vanishes because $\langle G - \bar G\rangle = 0$. Therefore

$$\dot\delta_{p'} = L^4\langle (G-\bar G, \dot G)\rangle - L^2(\bar G, \dot R) - L^2(R, \langle \dot G\rangle) - (R, \dot R).$$

Substitute eq. 16.xviii and eq. 16.xix, use $\eta' = \eta/L$ and $\alpha \le 1$, and divide by η. This yields

$$\eta^{-1}|\dot\delta_{p'}| \le C\eta^3\big[\alpha\eta^{1/2}\langle |D_U h|\rangle_{p'} + \alpha\eta' s_{p'}\big].$$

Summing and applying eq. 16.xvi proves eq. 16.xiii. □

Proof of Prop. 16.10. Put $W = \mathcal{M}(U^B)$. The preceding lemma makes W regular at radius $C\alpha$, and it has the same reduced datum as U^A. We check the setting of the companion's chart results. Take $\mathfrak{M} = M_{\mathrm{ps}}$ and choose once and for all $R_1 \ge L$ with $R_1\mathfrak{M} \ge w_S$. At depths $0,\dots,j$ let every region be the whole torus, and let the next region be empty. The required $\mathfrak{M}$-cubes exist since $\mathfrak{M} \le L^n$; the separation distances are infinite. Every layer below j is empty, so both its full and its reduced determining rows are empty. At level j all bonds are interior determining rows. There are no inward or outward rows, seam nodes or edge rows. Thus both determining maps are exactly $\mathcal{M}^j$, and both row spaces are the one-forms on the unit lattice. The local scale is one everywhere, so every weighted norm is the corresponding supremum. The same conclusions hold at the finer cutoff with depth $j+1$.

The companion's chart uses the matrix divergence regularity class. The current bound implies that class with radius $r + r^2$ when the curvature radius is r: the traceless part of the plaquette divergence is the current, and its scalar part is a difference of $1-\frac{1}{2}|\partial U - 1|^2$ at neighboring plaquettes. This is the real $SU(2)$ conversion of Lem. YM3_I:9.4. It costs only a fixed multiple of α here. The terminal torus has $2L^n \ge 6LM_{\mathrm{ps}}$ sites per direction. All geometric and regularity hypotheses of the common-chart argument in the proof of Prop. YM3_I:37.3 are therefore satisfied. After reducing α_* it gives

$$(U^A)^g = e^{i\eta A}W, \qquad RD_W^* A = 0, \qquad q(A) = 0, \qquad \|A\|_X \le C\alpha, \tag{16.xx}$$

where $\|A\|_X$ controls both $\sup|A|$ and the covariant first differences. Write $F(a) = \mathcal{A}^{\eta}(e^{i\eta a}W)$ and $F_B(b) = \mathcal{A}^{\eta'}(e^{i\eta' b}U^B)$. Here q is the nonlinear coarse constraint and $K_a = q'(a)$. Lem. YM3_I:30.8 converts criticality on the actual averaging fiber into the multiplier equation. Applying Prop. YM3_I:30.9 with zero constraint value bounds its multiplier, first at the reference W and then at U^B. Its gradient at the reference is bounded by $C\alpha$ in both cases, by regularity. It follows that on the common unit lattice

$$F'(A) = K_A^*\omega_A, \qquad F_B'(0) = (K_0^B)^*\omega_B, \qquad \|\omega_A\|_\infty + \|\omega_B\|_\infty \le C\alpha. \tag{16.xxi}$$

Here the two constraints are the actual relative constraints, before any orthogonal change of row frame. Their averaging recursions agree after the first fine step, as checked below.

We recall the precise linear and nonlinear estimates needed from Props. YM3_I:29.1 and YM3_I:30.5. With Q the corner linear constraint and T its fixed orthogonal row transport, $T^{-1}q(a) = Qa + \mathsf{C}(a)$, $\mathsf{C}(0) = 0$, and

$$\|\mathsf{C}'(a)\|_{2\to 2} \le C\alpha, \|\mathsf{C}'(a)^*\chi - \mathsf{C}'(b)^*\chi\|_\infty \le C\|a-b\|_\infty\|\chi\|_\infty \tag{16.xxii}$$

on a fixed multiple of the α ball containing the segment $[0, A]$. The first inequality follows also directly from the stated row and column bounds by applying them to the symmetric operator $\mathsf{C}'(a)^*\mathsf{C}'(a)$. Put $\Delta_R = F''(0) + D_W R D_W^*$ and $G = (\Delta_R + Q^*Q)^{-1}$, $M = QGQ^*$, $H = GQ^*M^{-1}$ and $\widetilde{G} = G - GQ^*M^{-1}QG$. These operators obey

$$QH = 1, \quad \widetilde{G}\Delta_R = 1 - HQ, \quad \Delta_R H = Q^*(M^{-1} - 1), \quad \|H\|_{2\to 2} + \|\widetilde{G}\|_{2\to 2} \le C. \tag{16.xxiii}$$

Thm. YM3_I:I gives positivity of G in this real regular setting, and Prop. YM3_I:29.1 gives positivity of M. Thus both M and G are positive definite, and $\widetilde{G}$ is positive semidefinite. To see the last assertion directly, complete the square in $(f, Gf) - (QGf, M^{-1}QGf)$. The L^2 bounds follow from the sup bounds for $\widetilde{G}, H, H^*$: a symmetric operator bounded by C in any norm has all eigenvalues bounded by C, and one applies this also to H^*H.

These facts imply coercivity along A. For $Qa = 0$, $a = \widetilde{G}\Delta_R a$ and the spectral inequality $\widetilde{G}^2 \le C\widetilde{G}$ give $(a, \Delta_R a) \ge c\|a\|_2^2$. For arbitrary h, set $a = h - HQh$. The mixed term in its quadratic form vanishes by eq. 16.xxiii, whereas the remaining HQh term is at least $-\|Qh\|_2^2$. Hence, whenever $C\|Qh\|_2 \le \|h\|_2$,

$$(h, \Delta_R h) \ge c(\|h\|_2 - C\|Qh\|_2)^2 - \|Qh\|_2^2.$$

The constraint in eq. 16.xx gives $QA = -\mathsf{C}(A)$, so eq. 16.xxii implies $\|QA\|_2 \le C\alpha\|A\|_2$. The gauge term vanishes on A. Finally $F''(0) = D_W^* D_W + \Delta'$ with $\|\Delta'\|_{2\to 2} \le C\alpha$ by the real Hessian bounds in the same results. Combining the two resulting lower bounds and reducing α_* proves

$$F''(0)[A, A] \ge cx^2, \qquad x^2 = \|D_W A\|_2^2 + \|A\|_2^2. \tag{16.xxiv}$$

We next construct the fine test form used to compare first variations. For a fine bond $b = (x, \mu)$, let Y be the lower corner of its coarse cell and $r = x - Y$, $0 \le r_\sigma < \eta$. Interpolate the four parallel coarse bonds c_s, with initial points $Y + \eta s$, $s \in \{0,1\}^{\{\nu:\nu\neq\mu\}}$, using the weights

$$w_s(x) = \prod_{\nu\neq\mu} (r_\nu/\eta)^{s_\nu}(1 - r_\nu/\eta)^{1-s_\nu}.$$

Transport their values to x along the coordinate combs in U^B and denote their weighted mean by $h^\uparrow(b)$. There is no length factor in this definition: h and $h^\uparrow$ are potentials in the same physical units. Define $h^\downarrow$ by

$$\eta h^\downarrow = Q_{\mathsf{m}}(U^B)(\eta' h^\uparrow),$$

where Q_{m} is the derivative of the relative one-step average, including its straightening gauge. The elementary interpolation estimates are

$$\begin{aligned} \|D_{U^B} h^\uparrow\|_1 &\le \|D_W h\|_1 + C\alpha\eta N\|h\|_\infty, \\ \|h^\uparrow\|_{1,\sup} &\le 3N\|h\|_\infty, \\ \|h - h^\downarrow\|_1 &\le C\eta N\|h\|_X. \end{aligned} \tag{16.xxv}$$

Here is the finite-stencil verification. In a comb gauge on the box containing the relevant neighboring cells, the fine angles are bounded by $C\alpha\eta\eta'$. Every comparison path has at most CL bonds. Replacing its transport by the identity changes the interpolated value by $C\alpha\eta^2 \sup|h|$ and its covariant curl by $C\alpha\eta \sup|h|$. Without these errors, subtracting the two linear interpolants in a plaquette gives the linear interpolation of $D_W h$ in the one transverse direction. Its weights are nonnegative; their total fine mass over each coarse plaquette is L^3. This proves the first estimate on multiplying by η'^3 and summing. The second follows from $|h^\uparrow| \le \|h\|_\infty$ and the $3N\eta^{-3}$ coarse

plaquettes. At zero fine angles the relative derivative Q_{m} is straight path averaging; applied to the interpolant it is a convex mean of neighboring values of h. At the given fine angles its derivative differs by $C\alpha\eta^2 \sup|h|$ after division by η, by the bounded second derivative of the relative average. Neighbors differ by at most $3\eta\|\nabla^W h\|_\infty + C\alpha\eta^2\|h\|_\infty$. This gives the last inequality in eq. 16.xxv.

Let $a_1(t)$ be the relative logarithm of the first average of $e^{it\eta' h^\uparrow}U^B$. It has derivative $a_1'(0) = \eta h^\downarrow$. After this first step, the reference configurations in the two averaging recursions are identical. Their subsequent relative logarithms therefore agree, by induction over the remaining j steps. Differentiating the final constraint gives

$$K_0^B h^\uparrow = K_0 h^\downarrow. \tag{16.xxvi}$$

Gauge invariance of the action removes the straightening gauge at the first step. Thus its action defect is exactly

$$E(h) = F_B'(0)[h^\uparrow] - F'(0)[h^\downarrow].$$

Put $d = F'(0) - K_0^*\omega_B$. From eq. 16.xxi and eq. 16.xxvi, $(d, h^\downarrow) = -E(h)$, and hence

$$F'(0)[h] = (d, h - h^\downarrow) + (\omega_B, K_0 h) - E(h). \tag{16.xxvii}$$

Regularity of W, the transpose row bound for K_0 and eq. 16.xxi give $\|d\|_\infty \le C\alpha$. Apply eq. 16.xiii and eq. 16.xxv with $h = A$, using $\|A\|_X \le C\alpha$ and $\|D_W A\|_1 \le (3N)^{1/2}\|D_W A\|_2$. We obtain

$$|(d, A - A^\downarrow)| + |E(A)| \le C\alpha\eta^{1/2}N^{1/2}x + C\alpha^2\eta N. \tag{16.xxviii}$$

The constraint multipliers contribute only quadratically. To see this, for fixed χ the Hessian of $(\chi, \mathsf{C}(a))$ is symmetric and has sup operator norm at most $C\|\chi\|_\infty$ by eq. 16.xxii. Its L^2 operator norm has the same bound, by the eigenvalue argument used above. Since $q(0) = q(A) = 0$, the fundamental theorem of calculus gives

$$T^{-1}K_0 A = -\int_0^1 [\mathsf{C}'(tA) - \mathsf{C}'(0)]A\,\mathrm{d}t, \qquad T^{-1}K_A A = \int_0^1 [\mathsf{C}'(A) - \mathsf{C}'(tA)]A\,\mathrm{d}t.$$

Pair these identities with $T^{-1}\omega_B$ and $T^{-1}\omega_A$, whose suprema are unchanged by the orthogonal row transport. Consequently

$$|(\omega_B, K_0 A)| + |F'(A)[A]| \le C\alpha\|A\|_2^2. \tag{16.xxix}$$

For completeness we bound the third derivative of the action; a bound on four separate bond derivatives would lose powers of the mesh. Put $\phi(t) = F(tA)$. At a plaquette with reference holonomy P, its varied holonomy has the form $Z(t) = e^{tX_1}\cdots e^{tX_4}P$, where $|X_i| \le \eta a_p$ and a_p is the largest $|A|$ on its boundary. Write $Z' = \Sigma Z$. Differentiating the four partial products gives

$$|\Sigma'| \le 12\eta^2 a_p^2, \qquad |\Sigma''| \le 72\eta^3 a_p^3, \qquad \Sigma(0) = i\eta^2 Y, \quad |Y - D_W A(p)| \le C\alpha\eta a_p.$$

The last error is precisely the transport around P rather than the identity; $|P - 1| \le C\alpha\eta^2$. Set $y_p = |Y| + 12a_p^2$. Then $|\Sigma(t)| \le \eta^2 y_p$ and $|Z(t) - 1| \le \eta^2(C\alpha + y_p)$ for $0 \le t \le 1$. Both Σ'' and Σ^3 are traceless, while $\Sigma^2 = -|\Sigma|^2 1$, since $\Sigma \in \mathfrak{su}(2)$. In

$$\frac{d^3}{dt^3}\left(1 - \tfrac{1}{2}\operatorname{tr} Z\right) = -\tfrac{1}{2}\operatorname{tr}[\Sigma'' + 2\Sigma'\Sigma + \Sigma\Sigma' + \Sigma^3]Z$$

one may therefore replace Z by $Z - 1$ in the first and last terms. With $a_p + |D_W A(p)| \le C\alpha$ the displayed bounds give

$$\left|\frac{d^3}{dt^3}\left(1 - \tfrac{1}{2}\operatorname{tr} Z\right)\right| \le C\eta^4\alpha(|D_W A(p)|^2 + a_p^2).$$

Each bond belongs to four plaquettes. Multiplication by η^{-1} and summation therefore prove $|\phi'''(t)| \le C\alpha x^2$.

Taylor's formula, eq. 16.xxiv, eq. 16.xxvii, eq. 16.xxviii and eq. 16.xxix now imply

$$cx^2 \le C\alpha x^2 + C\alpha\eta^{1/2}N^{1/2}x + C\alpha^2\eta N.$$

Choose α_* so the first term is absorbed. Young's inequality absorbs half of the remaining left member and yields

$$\|A\|_2^2 + \|D_W A\|_2^2 \le C\alpha^2 \eta N. \tag{16.xxx}$$

Finally let $s = \|A\|_\infty$ and choose $r = C\alpha$ so that $\|A\|_X \le r/2$. The norm of a component changes by at most $\eta r/2$ across an adjacent site: parallel transport is an isometry. If $s/r < \eta$, then $s < r\eta$. Otherwise set $R = \lfloor s/(r\eta) \rfloor \ge s/(2r\eta)$. On the lattice ℓ^1 ball of radius R about a maximizing site, that component has norm at least $s/2$. Its physical radius is at most $1/2$, so its sites are distinct on the torus. This ball has more than $4R^3/3$ sites, giving

$$\|A\|_2^2 \ge \eta^3 \frac{4R^3}{3} \frac{s^2}{4} \ge \frac{s^5}{24 r^3}.$$

Thus $s \le \max\{r\eta, (24r^3\|A\|_2^2)^{1/5}\}$. Substitution of eq. 16.xxx, with $N \ge 1$ and $\eta \le 1$, proves eq. 16.xii. □

17. A finite-size criterion for confinement

Let $Z(n_1, n_2, n_3; \beta)$ be the Wilson partition function on the periodic lattice box with the indicated integer sides. Its free-energy defect on a half box is

$$\mathsf{e}(l) = 2 \log Z(l, 2l, 2l; \beta) - \log Z(2l, 2l, 2l; \beta).$$

The following implication isolates the remaining quantitative confinement problem in one explicit inequality.

Sketch P (A uniform finite-size criterion). Suppose that for some physical side ℓ_0, label $b > 0$, and $0 < x_0 \le 0.069$,

$$\mathsf{e}(l_K) \le x_0, \qquad l_K = \frac{\ell_0}{2a_K}, \qquad \beta = L^K b,$$

at every sufficiently large cutoff, with $l_K \in \mathbb{N}$. Put $\theta = 12.9 x_0 < 1$. Then the periodic Gibbs limit and its continuum limit are unique, the vacuum is unique, and the reconstructed scalar action-density theory has a positive gap. The characteristic gap and area constants are

$$m_* = \frac{2\log(1/\theta)}{\ell_0}, \qquad \sigma_* = \frac{2\log(1/\theta) + 1.67}{\ell_0^2},$$

and the cutoff states obey $0 \le \nu_K(W_{R\times T}) \le e^{-\sigma_* RT}$ for coordinate rectangles with physical sides $R, T \in a_K\mathbb{N}$. The gap and continuum assertions are understood in the construction's admitted label range. ■□

Sketch of the argument. On one lattice, trace the transfer operator over a fixed section. The defect compares the trace at one height with the trace at twice that height, and hence controls the thermal eigenvalue weights above the largest eigenvalue. Change the time direction to compare the necessary transverse sections. Successive doublings give

$$\mathsf{e}(2l) \le 12.9\, \mathsf{e}(l)^2, \qquad \mathsf{e}(2^j l) \le \theta^{2^j}/12.9.$$

This is the decisive improvement: a small initial defect becomes exponentially small in the linear size.

The cube defect is a positive sum of the three one-direction defects. Summing its dyadic relation to the pressure bounds the finite-volume excess. The resulting thermal estimates give a simple transfer top and a lower bound for the excited levels. They also compare the local laws on successive tori in total variation, producing the unique periodic Gibbs state and exponential clustering.

The vortex-tube recursion bounds the small electric-flux weight. Resolving the transfer space into flux sectors then gives an asymptotically linear lower bound for electric-flux energies. Cutting a rectangular Wilson loop into layers and applying the transfer estimates gives the area bound. The constants survive the physical scaling because the assumed criterion uses one ℓ_0 and one x_0 for

every large cutoff. Uniform volume comparison then permits the cutoff and volume limits to be interchanged, and carries the gap to the reconstructed continuum theory.

This is a genuine conditional implication. Establishing the displayed box inequality at a physical scale is still the outstanding confinement step. The source's small-torus estimates can exclude it at small sides. A test at one cutoff proves a uniform criterion only when its explicit cutoff-comparison error fits inside the margin below the threshold. Finally, the cutoff area law does not construct a nonzero random sharp-loop observable in the continuum; that is distinct from the expectation renormalization in the Wilson-loop sketch.

17.1. **A finite-lattice criterion for confinement.** Let $Z(n_1, n_2, n_3)$ be the periodic partition function at coupling $\beta > 0$. We prove a fixed-lattice implication from

$$2 \log Z(l, 2l, 2l) - \log Z(2l, 2l, 2l) \le x_0, \qquad l \ge 3, \qquad 0 < x_0 \le 0.069.$$

The transfer spectrum controls the doubling defect. A vortex-tube recursion then gives area laws, electric-flux bounds and a gap over finite sections; excess-pressure estimates give uniqueness among periodic Gibbs states and convergence of periodic boxes of arbitrary shape.

All constants and parity restrictions are stated below. Physical conclusions uniform in the cutoff require the criterion at a fixed physical side for every sufficiently large cutoff. The stronger numerical tension and the simpler tension of Prop. 17.8 are kept separate.

17.1.1. *Notation and hypotheses. Boxes.* A *box* is a triple $\underline{n} = (n_1, n_2, n_3)$ of integers ≥ 3, $|\underline{n}| = n_1 n_2 n_3$; the cube of side n is (n, n, n). On the periodic lattice of a box a configuration U gives each bond b an element $U(b)$ of $G = \mathrm{SU}(2)$, with $U(\bar{b}) = U(b)^{-1}$ for the reversed bond; dU is the product of the Haar probability measures, $\partial U(p)$ the ordered product along the boundary of a plaquette p, and $a_p = 1 - \frac{1}{2} \operatorname{tr} \partial U(p) \in [0, 2]$. For $\beta \ge 0$ we write $Z(\underline{n}) = \int e^{-\beta \sum_p a_p} \, \mathrm{d}U$, which lies in $[e^{-6\beta|\underline{n}|}, 1]$, $F = \log Z$, and $\langle \cdot \rangle_{\underline{n}}$ for the mean under $Z^{-1} e^{-\beta \sum_p a_p} dU$. The pressure is $P = \inf_{\underline{n}} F(\underline{n})/|\underline{n}| \in [-6\beta, 0]$, the *excess* of a box is $\delta(\underline{n}) = F(\underline{n}) - |\underline{n}| P \ge 0$, and $\delta_{\mathrm{c}}(n) = \delta(n, n, n)$. For integers $l \ge 3$ we put

$$\mathsf{e}(l) = 2F(l, 2l, 2l) - F(2l, 2l, 2l), \quad d_1(l) = 2F(l, l, l) - F(2l, l, l), \quad d_2(l) = 2F(l, 2l, l) - F(2l, 2l, l), \quad X(l) = 8F(l, l, l) - F(2l, 2l, 2l).$$

Twists. For directions $\mu < \nu$ with third direction ρ, a *column* of the pair $\mu\nu$ is a set of plaquettes $p_{\mu\nu}(x + j e_\rho)$, $0 \le j < n_\rho$. For $z = (z_{12}, z_{13}, z_{23}) \in \{0, 1\}^3$, Z^z is Z with the sign of $\operatorname{tr} \partial U(p)$ reversed on one column of each pair $\mu\nu$ with $z_{\mu\nu} = 1$, and the *twisted box law* is the probability measure with this weight; $|z| = z_{12} + z_{13} + z_{23}$. We write $Z^- = Z^{(0,1,0)}$, $a_\pm = \frac{1}{2}(Z \pm Z^-)$ and $z_\pm = a_\pm / Z$; z_- is the *flux weight*. On a cube, r_j is the quotient Z^z/Z for $|z| = j$ (Lem. 17.10(c)); so $r_1 = Z^-/Z = 1 - 2z_-$.

Sections. A direction μ_0 taken as time has the side $t = n_{\mu_0}$; the two others, $\nu_1 < \nu_2$, span the *section* $\Sigma = (N_1, N_2) = (n_{\nu_1}, n_{\nu_2})$, and $Z(t, \Sigma) = Z(t, N_1, N_2)$, likewise for F and δ; by Lem. 17.10 these numbers do not depend on the order of the sides. Over Σ, $\lambda_0 > \lambda_1 \ge \lambda_2 \ge \cdots \ge 0$ are the eigenvalues of the transfer operator of Lem. 17.10, with $Z(t, \Sigma) = \sum_i \lambda_i^t$ for $t \ge 3$; λ_0 is the *vacuum*, $\mathsf{r}_t(\Sigma) = \sum_{i \ge 1} (\lambda_i/\lambda_0)^t$ the *thermal number*, and a number $y > 0$ *lies at least η above the vacuum* if $\log(\lambda_0/y) \ge \eta$.

The eigenvalues fall into four flux sectors $e \in \{0, 1\}^2$ (Lem. 17.10); Λ_e is the top of the sector e, the sectors $e \ne 00$ are those with electric flux, and over a section (N_2, N), with the first direction as time, so that $\nu_1 = 2$ runs along the side N_2 and $\nu_2 = 3$ along the side N, $\Lambda_- = \max\{\Lambda_{01}, \Lambda_{11}\}$ is the top of the sectors that are odd under J_2, that is, under the *flip of the side N*: the map ι_2 of Lem. 17.10, which changes the sign of the bonds along the side N that start on one line along the side N_2. These sectors carry an electric flux along the side N, a flux line of the length N. With $\lambda_-(t, N) = \lim_s Z^-(t, s, N)^{1/s}$, the number $\varepsilon_{\mathrm{v}}(t, N) = \log(\lambda_0(t, N)/\lambda_-(t, N)) \ge 0$ is the free

energy per unit length of the vortex line that runs along the second direction of the box (t, s, N); $\varepsilon_{\mathrm{v}}(l') = \varepsilon_{\mathrm{v}}(l', l')$.

Functions. $\varpi(x) = x/(1+\sqrt{1-x^2})$ on $[0,1]$; $\omega(D) = 2\varpi(e^D-1)^2$ on $[0, \log 2]$; $Y_1(x) = 2x + \omega(x)$, $Y_2 = 2Y_1 + \omega(Y_1)$, $\Psi = \omega(Y_2)$ and $\Phi = 4\omega + 2\omega(Y_1) + \omega(Y_2)$, where the arguments lie in $[0, \log 2]$.

Cells. For an integer $h \geq 2$, $N = 2h$, and a point $c \in (\mathbb{Z} + \frac{1}{2})^3$, the *cell* $\mathsf{C}_h(c)$ is the cube of the h layers below c, formed by the sites x with $c_\mu - h < x_\mu < c_\mu$, $\mu = 1, 2, 3$; a *function of the cell* is a bounded Borel function of the bonds with both ends in it. On the cube (N, N, N) the reflections $\mathfrak{r}_\mu \colon x_\mu \mapsto 2c_\mu - x_\mu$ map the lattice onto itself, each fixing the two planes $x_\mu = c_\mu$ and $x_\mu = c_\mu + h$; for a function A of the cell and $\epsilon \in \{0,1\}^3$ the *copy* $A^{[\epsilon]}$ is A composed with the $\mathfrak{r}_\mu$ with $\epsilon_\mu = 1$ and complex conjugated if $|\epsilon|$ is odd, and

$$\|\!| A |\!\|_N = \Big\langle \prod_{\epsilon \in \{0,1\}^3} A^{[\epsilon]} \Big\rangle^{1/8}_{(N,N,N)},$$

the mean being a number ≥ 0 by Lem. 17.21.

The infinite lattice. $\Omega = G^{\mathbb{B}}$, $\mathbb{B}$ the bonds of $\mathbb{Z}^3$; local functions are bounded Borel functions of finitely many bonds. A *cube of h layers* is $Q(x_0, h) = \{x_0 + (j_1, j_2, j_3) : 1 \leq j_\mu \leq h\}$; a function of the bonds with both ends in Q is a function on the configurations of every box with sides $\geq h+1$ through the projection of $\mathbb{Z}^3$, which is injective on Q, and box laws are laws on Ω by periodic extension. A *Gibbs state* is a probability measure on Ω under which, given the bonds outside a finite set $\mathfrak{A}$, those of $\mathfrak{A}$ have the density proportional to $e^{-\beta \sum a_p}$, the sum over the plaquettes that meet $\mathfrak{A}$; it is *periodic* if it is invariant under a subgroup of finite index of the translations.

The *symmetries of the lattice* are the maps $x \mapsto Ox + v$, O a signed permutation and $v \in \mathbb{Z}^3$. A *lattice mirror* is a plane $\{x_\mu = c\}$, $c \in \frac{1}{2}\mathbb{Z}$ (a *site mirror* if $c \in \mathbb{Z}$, a *bond mirror* otherwise), or a plane $\{x_\mu \pm x_\nu = c\}$, $\mu \neq \nu$, $c \in \mathbb{Z}$ (a *diagonal mirror*); a state s is *reflection positive* at it if $s(\overline{\mathfrak{r}A}\, A) \geq 0$ for every local A of the bonds in one closed side of the mirror, $\mathfrak{r}$ the reflection in it (bonds in a site mirror or a diagonal mirror are admitted; at a bond mirror the bonds that cross it lie in neither closed side). For a closed lattice path C, $W_C = \frac{1}{2}\operatorname{tr} U(C)$, $U(C)$ the ordered product along C; W_C is real, $|W_C| \leq 1$, and it depends neither on the starting point nor on the sense; $|C|$ is the number of bonds of C, and W_p is the loop along the boundary of one plaquette.

A *rectangle* $R \times T$ of the (μ, ν)-plane runs R steps along e_μ, T along e_ν, and back.

Hypotheses. The *criterion at the side l* is the condition: $\beta > 0$, $l \geq 3$ is an integer of either parity, $0 < x_0 \leq 0.069$, and $\mathsf{e}(l) \leq x_0$. Its numbers are $\theta = 12.9\, x_0 \leq 0.8901$, $\Lambda = \log \frac{1}{\theta} \geq 0.11642$, $\varsigma = 2\Lambda + 1.67$, $\mathsf{q} = \varsigma/2\Lambda = 1 + 0.835/\Lambda \leq 8.173$, and

$$\sigma^+ = \frac{\varsigma}{4l^2} = \frac{\log \frac{1}{\theta} + 0.835}{2l^2}, \qquad \sigma^+ l^2 = \frac{1}{2} \log \frac{e^{0.835}}{12.9 x_0} \geq 0.4757. \tag{17.i}$$

The *cube condition at the side l_0* is $X(l_0) \leq \frac{1}{20}$. For the physical scale let $L \geq 2$ be an integer and $a_K = L^{-K}$. The *uniform criterion* holds if there are $\mathsf{b} > 0$, $l_* > 0$, an integer K_0 and one $x_0 \in (0, 0.069]$ such that for every integer $K \geq K_0$ the number $l_* L^K$ is an integer ≥ 3 and the criterion holds at the side $l_* L^K$ and the coupling $L^K \mathsf{b}$ with this x_0. In the frame L is the blocking factor, a_K the spacing at the cutoff K, $\mathsf{b} = a_K \beta$ the label, and $\ell_0 = 2l_*$ the physical side of the cube of the criterion. In Lem. 17.24, in the steps of proofs that use it, and in Prop. 17.6, L is the blocking factor, an odd integer ≥ 13; the L of the uniform criterion is any integer ≥ 2, independent of it. We write x/yz for $x/(yz)$.

17.1.2. *Why doubling turns the box test into a gap.* The box defect cancels the extensive part of the free energy. At a fixed transverse section Σ, write the transfer eigenvalues as $\lambda_0 \geq \lambda_1 \geq \cdots \geq 0$ and put

$$\mathsf{r}_l(\Sigma) = \sum_{i \geq 1} (\lambda_i/\lambda_0)^l.$$

This includes any multiplicity of the largest eigenvalue. Factoring λ_0^l out of the transfer trace isolates the thermal correction $1 + \mathsf{r}_l$. The difference between twice the log trace at height l and the log trace at height $2l$ is therefore a function of these corrections, with the largest-eigenvalue contribution cancelled. The source proves

$$\log(1 + \mathsf{r}_l(\Sigma)) \le d(l; \Sigma) \le 2\log(1 + \mathsf{r}_l(\Sigma)).$$

Small defect thus controls all excited thermal weights together, including a possible top multiplicity. This is stronger than a comparison with one selected eigenvector.

Doubling time squares the eigenvalue ratios. To make a statement about larger cubes, however, one must also enlarge the transverse section. The proof alternates these two operations and changes which coordinate is time. It tracks the three sections (l, l), $(2l, l)$ and $(2l, 2l)$, bounds the intermediate defects, and closes the resulting scalar recursion. The numerical estimate that matters is

$$\mathsf{e}(2l) \le 12.9\mathsf{e}(l)^2, \qquad 0 < \mathsf{e}(l) \le 0.069.$$

With $\theta = 12.9x_0 < 1$, induction gives $\mathsf{e}(2^j l) \le \theta^{2^j}/12.9$. The exponent grows like the linear size, although the argument proceeds by doubling. This is the source of the exponential estimates that follow from a successful finite-size test.

The cube excess is controlled by a dyadic identity. If $\delta_{\mathrm{c}}(n)$ is the cube's finite-volume excess and $X(n)$ is the sum of its three directional defects, the source has

$$X(n) = 8\delta_{\mathrm{c}}(n) - \delta_{\mathrm{c}}(2n), \qquad \delta_{\mathrm{c}}(n) = \sum_{j\ge 0} 8^{-j-1} X(2^j n).$$

The pressure term cancels in the first relation. The recursion makes the second sum converge with an exponential bound. The transfer comparison then yields a simple top, a quantitative gap and rapid comparison of local laws on successive tori. In parallel, the vortex-tube estimates control the small electric-flux weight. Resolving the transfer trace into its flux sectors turns that bound into an energy cost for a long flux tube and then a rectangular Wilson area law. The gap and area law are two uses of the same small finite-volume excess, through different transfer observables.

For the continuum implication the tested box must have one physical side. Its lattice side is $l_K = \ell_0/(2a_K)$ and its coupling is $\beta_K = L^K b$. The criterion requires the same bound with the same x_0 for every sufficiently large K. This is exactly the uniformity that carries the finite-lattice gap and area constants to physical units. It also makes the volume-comparison error uniform while the cutoff is removed, allowing the volume and cutoff limits in this implication to commute.

Testing one cutoff is a different assertion. It can certify the uniform criterion only if the proved cutoff-comparison error fits within the available margin below the threshold. The detailed statement retains that margin. Likewise, small-torus asymptotics can rule out the criterion at small physical sides; a statement that the test is finite does not verify it at some larger side. Establishing it on the desired continuum trajectory remains the uncompleted confinement step.

17.1.3. *Principal results.*

Theorem AW (One lattice)**.** Assume the criterion at the side l.

(a) *The state.* For $n = 2^k l$, $k \ge 1$, and every bounded Borel function A of the bonds of a cube of h layers, $1 \le h \le n/2 - 1$,

$$|\langle A\rangle_{(n,n,n)} - \langle A\rangle_{(2n,2n,2n)}| \le 1.29 \sup|A|\, \theta^{n/2l}.$$

So $\nu(A) = \lim_k \langle A\rangle_{(2^k l, 2^k l, 2^k l)}$ exists for every local A; and for $n = 2^k l$, $k \ge 1$, and A a bounded Borel function of the bonds of a cube of h layers with $1 \le h \le n/2 - 1$, the n and A of the first bound, $|\nu(A) - \langle A\rangle_{(n,n,n)}| \le 1.29 \sup|A|\, \theta^{n/2l}/(1 - \theta^{n/2l})$. The measure ν is a Gibbs state, invariant under the symmetries of the lattice, reflection positive at every lattice mirror and ergodic under the translations; it is the only periodic Gibbs state, and the laws of the periodic boxes converge weakly to ν as their three sides tend to infinity.

(b) *Rectangles.* For integers $R, T \geq 1$ and every rectangle C of sides $R \times T$ in a coordinate plane,

$$0 \leq \nu(W_C) \leq e^{-\sigma^+ RT}; \tag{17.ii}$$

on the cube of every integer side $n \geq 2\mathsf{q}l$, for $R \leq n/2$ and $T \leq n-1$,

$$0 \leq \langle W_C \rangle_{(n,n,n)} \leq 8^{T/n} \exp\Big[-\sigma^+ RT + \frac{2\mathsf{q}RT}{ln}\Big(\frac{1}{2}\log\frac{2\mathsf{q}n}{l} + 0.86\Big)\Big];$$

and, if $R, T \geq 2$, also $\nu(W_C) \leq (\frac{8\beta}{8\beta+3})^{2(R+T)-4}$, a bound that holds in every Gibbs state.

(c) *Closed paths.* Let C be a closed lattice path that runs a bond of the direction ρ, and $\rho' \neq \rho$; let $\mathsf{A}_{\rho'\rho}(C)$ be the number of unit squares of the (ρ', ρ)-plane about which the projection of C to that plane winds an odd number of times, and $c_\rho(C)$ the number of changes from "down" to "up" in the cyclic sequence of the senses in which C runs its bonds of the direction ρ. Then $|\nu(W_C)| \leq 2^{c_\rho(C)-1} e^{-\sigma^+ \mathsf{A}_{\rho'\rho}(C)}$. More generally, for a gap τ between neighbouring layers of the direction ρ let $\ell^{\rho'}_\tau(C)$ be the number of integers α such that an odd number of the bonds of the direction ρ that C runs in that gap have the ρ'-coordinate $\leq \alpha$, so that $\sum_\tau \ell^{\rho'}_\tau(C) = \mathsf{A}_{\rho'\rho}(C)$; let $\mathsf{A}_\rho(C) = \sum_\tau \max_{\rho' \neq \rho} \ell^{\rho'}_\tau(C)$, the larger of the two counts taken gap by gap, so that $\mathsf{A}_\rho(C) \geq \max_{\rho' \neq \rho} \mathsf{A}_{\rho'\rho}(C)$; and let D be a continuous unitary representation of G on $\mathbb{C}^d$ with $D(-\mathbf{1}) = -\mathbf{1}$, and $W^D_C = d^{-1} \operatorname{tr} D(U(C))$.

Then $|\nu(W^D_C)| \leq d^{c_\rho(C)-1} e^{-\sigma^+ \mathsf{A}_\rho(C)}$; at $D(g) = g$, $d = 2$, this is the first bound with $\mathsf{A}_\rho(C)$ in the place of $\mathsf{A}_{\rho'\rho}(C)$. In particular a closed path that in each such gap runs either no bond of the direction ρ or exactly two, at the sites o_τ, r_τ of the section, has $c_\rho(C) = 1$, as its height in the direction ρ has one maximum, and $|\nu(W_C)| \leq \exp[-\sigma^+ \sum_\tau |r_\tau - o_\tau|_\infty]$. So $|\nu(W_C)| \leq e^{-\sigma^+ \sum_j |r_j - o_j|}$ for every *staircase loop*, a closed path in a coordinate plane that, in each gap between neighbouring layers of one direction ρ of the plane, runs either no bond of the direction ρ or exactly two, in opposite senses, at the ρ'-coordinates o_j and r_j; for a simple loop $\sum_j |r_j - o_j|$ is the enclosed area.

On every periodic box, of any parity, the staircase loops of a $(1,3)$-plane described in Lem. 17.12(f), with $\rho = 3$ and their bonds of the direction 3 in at most $n_3 - 2$ gaps, have the bound stated there. For a simple closed curve in a coordinate plane $4c_\rho(C) \leq |C|$, so that $|\nu(W_C)| \leq \frac{1}{2}\exp[-\sigma^+ \mathsf{A}_{\rho'\rho}(C) + 0.174\,|C|]$.

(d) *Twisted cubes.* For every integer $n \geq 2\mathsf{q}l$ and the seven $z \neq 0$, on (n, n, n):

$$z_- \leq \exp\Big[-\sigma^+ n^2 + \frac{2\mathsf{q}n}{l}\Big(\frac{1}{2}\log\frac{2\mathsf{q}n}{l} + 0.86\Big)\Big], \qquad 0 \leq 1 - Z^z/Z \leq 6z_-.$$

(e) *Flux sectors and static charges.* For the same n, over the section $n \times n$ the top of every sector with electric flux lies at least $\sigma^+ n - \frac{2\mathsf{q}}{l}(\frac{1}{2}\log\frac{2\mathsf{q}n}{l} + 0.86) - \frac{g_n}{n}$ above the vacuum, with $g_n = 0.0017$ if $n = 2^i l$ and $g_n = 0.105$ for every other n; and for $1 \leq R \leq n/2$ the transfer operator $\hat{\mathsf{T}}_{o,r}$ with two static charges at the distance R (Lem. 17.12) has

$$\|\hat{\mathsf{T}}_{o,r}\| \leq \lambda_0(n,n)\,\big[8(1 + \mathsf{r}_n(n,n))\big]^{1/n} \exp\Big[-\sigma^+ R + \frac{2\mathsf{q}R}{ln}\Big(\frac{1}{2}\log\frac{2\mathsf{q}n}{l} + 0.86\Big)\Big].$$

The same bound holds for any two sites $o \neq r$ of the section, with $R = |r - o|_\infty$, the larger of the distances of their two coordinates on the circle of n sites (Lem. 17.12(e)). So for any two sites $o \neq r$ of $\mathbb{Z}^2$, projected to the sections $n \times n$: $\limsup_{i \to \infty} \|\hat{\mathsf{T}}_{o,r}\|/\lambda_0(n,n) \leq e^{-\sigma^+ |r-o|_\infty}$ along $n = 2^i l$.

(f) *Gap.* Over every section $N_1 \times N_2$ with integers $N_1, N_2 \geq 2l$ the vacuum is simple, its eigenvector lies in the sector 00, and every λ_i, $i \geq 1$, the tops of the sectors with electric flux among them, lies at least $\frac{\Lambda}{l} + \frac{1.021}{n_0}$ above it, n_0 the largest $2^k l \leq \min\{N_1, N_2\}$. Over $N_2 \times n$, $n = 2^k l$, $k \geq 1$, and every integer $N_2 \geq n$ the same holds with $\frac{\Lambda}{l} + \frac{3.5065}{n}$, and over

$n\times n$ with $\frac{\Lambda}{l}+\frac{6.42}{n}$. For integers $N_1,N_2\ge n=2^k l$, $k\ge 1$, with $0.01655\,N_1N_2\,\theta^{n/l}\le n^2\log 2$: $\mathsf{r}_n(N_1,N_2)\le \frac{N_1N_2}{41.8\,n^2}\,\theta^{n/l}$.

(g) *Flux lines.* Over a section (N_2,N), with the first direction as time, $\Lambda_-=\max\{\Lambda_{01},\Lambda_{11}\}$ is the top of the sectors that are odd under the flip of the side N, the map ι_2 of Lem. 17.10 that changes the sign of the bonds along the side N starting on one line along the side N_2; these sectors carry a flux line of the length N.

(g1) Let $N=2wl$, $w\ge 2$ a power of two, $\chi=0.03\,\theta^{N/l}$, $\hat N=\lceil 2\sigma^+N^2/\log\frac{1}{\chi}\rceil$ and $\mathsf{g}=\log\hat N+1.71$. Then $4\le\hat N\le \mathsf{q}N/l+1$. For every integer $N_2\ge \hat N N/2$, Λ_- lies at least $\sigma^+N-(2\log\hat N+1.86)/N$ above the vacuum, and the lower limit of $\log(\lambda_0/\Lambda_-)$ as $N_2\to\infty$ is at least $\sigma^+N-\mathsf{g}/N$. For every integer N_2 with $\max\{N,2\mathsf{q}l\}\le N_2<\hat N N/2$, Λ_- lies at least $\sigma^+N-\frac{2\mathsf{q}}{l}(\log\frac{2\mathsf{q}N}{l}+0.86)$ above the vacuum. For integers N' with $N\le N'<2N$ and $N_2\ge\hat N N/2$, over (N_2,N') the top of the sectors odd under the flip of the side N' lies at least $\sigma^+N'-(4\log\hat N+3.72)/N-(2N_2/N^2)\,0.01655\,\theta^{N/l}$ above the vacuum; the last term is at most $0.0331/N$ for $N_2\le N\theta^{-N/l}$.

(g2) Let $N\ge 4l$ be any integer, $n_0=2wl$, $w\ge 2$ a power of two, the dyadic multiple of l with $n_0\le N<2n_0$, $\kappa=N/n_0$, $\tau=\theta^{n_0/l}$, $\chi_0=0.3602\,\tau$, $\mathsf{E}_0=\sigma^+n_0N$, $\hat N'$ the least even integer $\ge 2\mathsf{E}_0/\log\frac{1}{\chi_0}$, $\mathsf{h}=0.01655\,\hat N'\tau$ and $\mathsf{g}'=\kappa\log\hat N'+3.22+(3\kappa+0.68)\mathsf{h}$. Then $6\le\hat N'<\mathsf{q}N/l+2$; for every integer $N_2\ge\hat N'n_0/2$, Λ_- lies at least $\sigma^+N-\kappa\mathsf{g}'/N\ge\sigma^+N-(4\log\hat N'+18.2)/N$ above the vacuum; and for every integer N_2 with $\max\{N,2\mathsf{q}l\}\le N_2<\hat N'n_0/2$ it lies at least $\sigma^+N-\frac{2\mathsf{q}}{l}(\log\frac{2\mathsf{q}N}{l}+0.86)$ above it. Consequently, with

$$C(\theta)=\max\Big\{\frac{\mathsf{q}}{2}+\frac{1}{4},\ 4\log\Big(\mathsf{q}+\frac{1}{2}\Big)+18.2\Big\}\le 27,$$

for all integers $N\ge 4l$ and $N_2\ge C(\theta)N^2/l$ the top Λ_- lies at least $\sigma^+N-C(\theta)(1+\log\frac{N}{l})/N$ above the vacuum. If moreover $w\ge 4$ and $\tau\le 0.087$, then with $\hat N''=\lceil 4\sigma^+n_0^2/\log\frac{1}{0.2728\,\tau}\rceil$ it lies at least $\sigma^+N-(4\log\hat N''+10.8)/n_0$ above the vacuum for every integer $N_2\ge\hat N''n_0/2$.

(g3) For every integer $N\ge 4l$, every integer $N_2\ge\hat N'n_0/2$ and every rectangle C of sides $R\times T$, $T\le N-1$, in a plane spanned by the first and the third direction,

$$\limsup_{L_1\to\infty}\langle W_C\rangle_{(L_1,N_2,N)}\le 4^{T/N}\exp\Big[-\sigma^+RT+\frac{RT}{N^2}(4\log\hat N'+18.2)\Big].$$

(h) *Boxes of every shape, cylinders and twisted boxes.* For every even $N\ge 2l$, every bounded real Borel function A of the bonds of a cube of $N/2$ layers and every periodic box with all sides $\ge N$,

$$|\langle A\rangle_{\underline{n}}-\nu(A)|\le 5.42\,\theta^{N/4l}\sup|A|;$$

for the events of these bonds the bound is $2.71\,\theta^{N/4l}$. In particular $|\langle A\rangle_{(m,m,m)}-\nu(A)|\le 5.42\,\theta^{\lfloor m/2\rfloor/2l}\sup|A|$ for every integer $m\ge 2l$ and every such A of a cube of $\lfloor m/2\rfloor$ layers. Over every section Σ the laws of the boxes (t,Σ) converge as $t\to\infty$, on the bounded Borel functions of finitely many layers, to the law of the infinite cylinder over Σ; for every even $N'\ge 2l$, every $N\ge N'$ and every A as above of a cube of $N'/2$ layers, the cylinder over $N\times N$ satisfies the bound with N', so that these laws converge to ν as $N\to\infty$; and on the cylinder over $n\times n$, $n\ge 2l$, every rectangle with the side $R\le n/2$ across the axis and the side T along it has a mean of modulus at most $[(1+\mathsf{r}_n(n,n))\,z_-(n,n,n)]^{RT/n^2}$. The laws of twisted boxes whose three sides tend to infinity and whose columns recede, in the sense that every finite set of plaquettes meets the columns of only finitely many members, converge weakly to ν, and so do the mixtures, with any weights, of finitely many such sequences; if a

column passes through a fixed plaquette p_0 in every member, the law of $\operatorname{tr}\partial U(p_0)$ tends to the law of $-\operatorname{tr}\partial U(p_0)$ under ν, which is another law.

(i) *The pressure.* There is an open interval U containing β on which the criterion holds at the side $2l$ with $x_0 = 0.069$; on U the pressure is continuously differentiable, with $P'(\beta') = -3\,\nu_{\beta'}(a_p)$, $\nu_{\beta'}$ the state of (a) at β'; and $\nu(a_p) \le 1 - \frac{\beta}{4(\beta+1)} < 1$.

All constants are absolute; σ^+ and q depend only on l and x_0. Decimal upper and lower bounds used in the finite recursions are understood in their indicated directions. The interval bounds recorded in the proof of Prop. 17.17 verify the numerical part of the stronger tension estimate. ■□

Theorem AX (The criterion and the cube condition)**.** Let $\beta \ge 0$ and let $l \ge 3$ be an integer of either parity.

(a) $X(l) = \mathsf{e}(l) + 2d_2(l) + 4d_1(l)$, and $\log(1+\mathsf{r}_l(\Sigma_j)) \le d_j(l) \le 2\log(1+\mathsf{r}_l(\Sigma_j))$ for $\Sigma_1 = (l,l)$, $\Sigma_2 = (2l,l)$, $\Sigma_3 = (2l,2l)$ and $(d_1,d_2,d_3) = (d_1,d_2,\mathsf{e})$; so the three terms are ≥ 0, and the cube condition at l_0 is the inequality $\mathsf{e}(l_0) \le \frac{1}{20} - 2d_2(l_0) - 4d_1(l_0)$. If $\beta > 0$, the cube condition at l_0 gives the criterion at the same side l_0, with every $x_0 \in [X(l_0), \frac{1}{20}]$, $x_0 > 0$, and $\theta \le 0.645$.

(b) Under the criterion at l: $\mathsf{e}(2^k l) \le \theta^{2^k}/12.9$ for all $k \ge 0$, and $X(2^k l) \le 0.10643\,\theta^{2^k} \le 0.04194$ for all $k \ge 3$; so the cube condition holds at every side $2^k l$ with $k \ge 3$, with $k \ge 2$ if $x_0 \le 0.0650$, and with $k \ge 1$ if $x_0 \le 0.0527$.

(c) Under the criterion at l, along $n = 2^k l$ the rates $\mathsf{m}_\mathsf{e}(n) = \frac{1}{n}\log\frac{1}{12.9\,\mathsf{e}(n)}$ $(k \ge 0)$ and $\mathsf{m}_X(n) = \frac{1}{n}\log\frac{1}{18X(n)}$ $(k \ge 3)$, with values in $(0,\infty]$, do not decrease; for $k \ge 3$, $\mathsf{m}_\mathsf{e}(n/2) - \frac{0.6501}{n} \le \mathsf{m}_X(n) \le \mathsf{m}_\mathsf{e}(n) - \frac{0.3331}{n}$; so the two rates have one common limit, which is $\ge \Lambda/l$.

(d) If $0 < \mathsf{e}(l) < 0.0740538$ at one l, then $\mathsf{e}(2^k l) \to 0$ and $X(2^k l) \to 0$ as $k \to \infty$; so the criterion holds at some side $2^k l$ with any prescribed $x_0 \in (0, 0.069]$, and the cube condition holds at $2^k l$ for all large k.

■□

Theorem AY (Physical scale, uniformly in the cutoff)**.** Assume the uniform criterion, and let ν_K be the state of Thm. AW at $l = l_* L^K$ and $\beta = L^K \mathsf{b}$, read on the lattice $a_K\mathbb{Z}^3$. Put

$$\sigma_* = \frac{\frac{1}{2}\log\frac{1}{\theta} + 0.4175}{l_*^2} \;\ge\; \frac{0.4757}{l_*^2} = \frac{1.9028}{\ell_0^2}.$$

For every $K \ge K_0$, with physical lengths in $a_K\mathbb{N}$ and energies $a_K^{-1}\log(\lambda_0/\cdot)$:

(a) $0 \le \nu_K(W_C) \le e^{-\sigma_* RT}$ for every rectangle C of a coordinate plane with physical sides R, T; and if $R, T \ge 2a_K$, also $\nu_K(W_C) \le \exp[-\frac{1}{2}\sigma_* RT - \frac{3(|C|_{\mathrm{ph}} - 4a_K)}{2(8\mathsf{b}+3a_K)}]$, $|C|_{\mathrm{ph}} = 2(R+T)$ the physical length of C;

(b) on the periodic cube of physical side $\ell \ge 2\mathsf{q}l_*$, $0 \le 1 - Z^z/Z \le 6\exp[-\sigma_*\ell^2 + \frac{2\mathsf{q}\ell}{l_*}(\frac{1}{2}\log\frac{2\mathsf{q}\ell}{l_*} + 0.86)]$ for the seven $z \ne 0$, and every sector with electric flux over $\ell \times \ell$ lies at least $\sigma_*\ell - \frac{2\mathsf{q}}{l_*}(\frac{1}{2}\log\frac{2\mathsf{q}\ell}{l_*} + 0.86) - \frac{0.105}{\ell}$ above the vacuum, with $\frac{0.0017}{\ell}$ in the place of $\frac{0.105}{\ell}$ if ℓ/l_* is a power of two;

(c) over every section whose physical sides are $\ge 2l_*$ the gap is at least $\frac{1}{l_*}\log\frac{1}{\theta}$;

(d) a flux line of physical length $\ell = 2wl_*$, $w \ge 2$ a power of two, over a section $\ell_2 \times \ell$ with $\ell_2 \ge \hat{N}\ell/2$ lies at least $\sigma_*\ell - (2\log(\mathsf{q}\ell/l_* + 1) + 1.86)/\ell$ above the vacuum, and one of every physical length $\ell \ge 4l_*$ over $\ell_2 \times \ell$ with $\ell_2 \ge C(\theta)\ell^2/l_*$ lies at least $\sigma_*\ell - C(\theta)(1 + \log\frac{\ell}{l_*})/\ell$ above it, with the number $C(\theta) \le 27$ of Thm. AW(g2);

(e) the cube condition holds at the side $8l_*L^K$, with $18X \le 1.9157\,\theta^8$; conversely, the cube condition at the sides l_*L^K, $\beta = L^K\mathsf{b}$, for all $K \ge K_0$ gives the uniform criterion with $x_0 = \frac{1}{20}$.

The numbers σ_*, q and $C(\theta)$ depend on l_* and x_0 alone, and $\hat N$ on ℓ/l_* and x_0 alone; none of them depends on K, b or L. In the first bound of (a) the factor in front of $e^{-\sigma_* RT}$ is 1 and there is no perimeter term. ■□

Corollary 17.1 (The static potential)**.** Assume the criterion at the side l, and let $m(R,T)=\nu(W_C)$ for a rectangle C of sides $R\times T$ in a coordinate plane, $m(R,0)=1$.

(a) $m(R,T)$ depends on R,T alone, $m(R,T)=m(T,R)$, and $w^{RT}\le m(R,T)\le e^{-\sigma^+ RT}$, where $w=m(1,1)\ge \beta/(4(\beta+1))$.

(b) For every $n\ge 0$ and real $c_0,\dots,c_n$: $\sum_{h,h'} c_h c_{h'}\, m(R,h+h')\ge 0$ and $\sum_{h,h'} c_h c_{h'}\, m(R,h+h'+1)\ge 0$. Hence $m(R,T)^2\le m(R,T-1)\,m(R,T+1)$ for $T\ge 1$, and there is exactly one Borel probability measure ϱ_R on $[0,1]$ with $m(R,T)=\int \lambda^T\,\mathrm{d}\varrho_R(\lambda)$ for all $T\ge 0$.

(c) $d(R;T)=\log(m(R,T)/m(R,T+1))$ does not increase in $T\ge 0$; the static potential

$$V(R)=\lim_{T\to\infty} d(R;T)=\inf_T d(R;T)=\lim_{T\to\infty} -\frac{1}{T}\log m(R,T)$$

exists in $[0,\infty)$, $\max\operatorname{supp}\varrho_R=e^{-V(R)}$, and $m(R,T_2)\le e^{-(T_2-T_1)V(R)}m(R,T_1)$ for $T_2\ge T_1\ge 0$, $V(R)$ being the largest number with this property. For $0\le T_1<T_2\le T_3<T_4$: $[m(R,T_2)/m(R,T_1)]^{1/(T_2-T_1)}\le[m(R,T_4)/m(R,T_3)]^{1/(T_4-T_3)}$. For $T\ge 1$, $m(R,T)=\int_{[V(R),\infty)} e^{-TE}d\mu_R(E)$, μ_R the image of the restriction of ϱ_R to $(0,1]$ under $\lambda\mapsto-\log\lambda$, a measure of mass in $(0,1]$.

(d) $\sigma^+R\le V(R)\le R\log\frac{4(\beta+1)}{\beta}$.

(e) Under the uniform criterion, for every $K\ge K_0$ and physical R: the potential $V_K(R)=a_K^{-1}V(R/a_K)$ of ν_K in physical units is $\ge\sigma_*R$; and for every real κ the means $M_K(R,T)=e^{\kappa|C|_{\mathrm{ph}}}\nu_K(W_C)$ satisfy $M_K(R,T_2)\le e^{-(T_2-T_1)(V_K(R)-2\kappa)}M_K(R,T_1)$ for physical $T_2\ge T_1\ge 0$, while in the inequality of four rectangles of (c) the factors $e^{\kappa|C|_{\mathrm{ph}}}$ cancel. Along a sequence of cutoffs: let $K_j\to\infty$, $K_j\ge K_0$, let κ_j be arbitrary real numbers, and for R,T in $\bigcup_i a_i\mathbb{N}$ and all large j put $M_j(R,T)=e^{2\kappa_j(R+T)}\nu_{K_j}(W_C)$, C a rectangle of the physical sides $R\times T$, and $v_j(R)=V_{K_j}(R)-2\kappa_j$, so that $v_j(R)\ge\sigma_*R-2\kappa_j$. If $T_1<T_2$ and $M_j(R,T_i)\to\mathsf{W}(R,T_i)\in(0,\infty)$ for $i=1,2$, then

$$\limsup_j v_j(R)\le\frac{1}{T_2-T_1}\log\frac{\mathsf{W}(R,T_1)}{\mathsf{W}(R,T_2)},$$

and if $v_j(R)\ge B$ for infinitely many j, then $\mathsf{W}(R,T_2)\le e^{-(T_2-T_1)B}\,\mathsf{W}(R,T_1)$; in particular $\mathsf{W}(R,T_2)\le e^{-(T_2-T_1)(\sigma_*R-2\kappa)}\,\mathsf{W}(R,T_1)$ if $\kappa_j\le\kappa$ for infinitely many j. If $M_j(R,T)\to\mathsf{W}(R,T)\in(0,\infty)$ for all R,T, then $\mathsf{W}(R,T)=\mathsf{W}(T,R)$, $\mathsf{W}(R,T_2)^{T_3-T_1}\le\mathsf{W}(R,T_1)^{T_3-T_2}\,\mathsf{W}(R,T_3)^{T_2-T_1}$ for $T_1<T_2<T_3$, the inequality of four rectangles of (c) holds for W, and $V_{\mathrm{ren}}(R)=\lim_{T\to\infty}-\frac{1}{T}\log\mathsf{W}(R,T)$ exists in $[-\infty,\infty)$ and is the infimum of the quotients $\frac{1}{T_2-T_1}\log\frac{\mathsf{W}(R,T_1)}{\mathsf{W}(R,T_2)}$, $T_1<T_2$. The convergence of the M_j is a hypothesis of these statements.

(f) With no criterion, in every periodic Gibbs state s at $\beta\ge 0$, $s(W_C)\ge 0$ for every rectangle C of a coordinate plane with one even side and for every square.

(g) With no criterion: let $\beta>0$ and let s be a periodic Gibbs state that is positive at the bond mirrors on the functions of two crossing bonds, in the sense that

$$s\Big(\sum_{i,j,k,l}\overline{(\mathsf{z}_p)_{ji}}\,(\mathsf{z}_q)_{kl}\,F_{jk}\,\overline{\mathfrak{r}F_{il}}\Big)\ge 0$$

for every bond mirror, $\mathfrak{r}$ the reflection in it, z_p, z_q the values of U at the bonds from two sites x_p, x_q next to the mirror, equal or not, to their mirror images, and all continuous functions F_{jk}, $j,k\in\{1,2\}$, of finitely many bonds with both ends in the closed side of the mirror that

holds x_p and x_q, as in Lem. 17.21(c). Let $m_s(R,T) = s(W_C)$ for a rectangle C of sides $R \times T$ in a coordinate plane, $m_s(R,0) = 1$. Then $m_s(R,T)$ depends on R,T alone, $m_s(R,T) = m_s(T,R)$, and $[\beta/4(\beta+1)]^{RT} \le m_s(R,T) \le 1$ for all integers $R,T \ge 1$; both Hankel forms of (b) hold for m_s, and with them the log-convexity in T and exactly one Borel probability measure ϱ^s_R on $[0,1]$ with $m_s(R,T) = \int \lambda^T \, \mathrm{d}\varrho^s_R(\lambda)$; $d_s(R;T) = \log(m_s(R,T)/m_s(R,T+1))$ does not increase in T, $V_s(R) = \lim_T d_s(R;T) = \inf_T d_s(R;T) = \lim_T -\frac{1}{T}\log m_s(R,T)$ exists in $[0, R\log\frac{4(\beta+1)}{\beta}]$, $\max\operatorname{supp}\varrho^s_R = e^{-V_s(R)}$, $m_s(R,T_2) \le e^{-(T_2-T_1)V_s(R)} m_s(R,T_1)$ for $T_2 \ge T_1 \ge 0$, and the inequality of four rectangles of (c) holds for m_s.

On site mirrors alone, with no hypothesis at the bond mirrors: if $m_s(R,2) > 0$, as is the case for every even R, then $V_{\mathrm{e}}(R) = \lim_h -\frac{1}{2h}\log m_s(R,2h)$ exists in $[0,\infty)$, and $m_s(R,T_2) \le e^{-(T_2-T_1)V_{\mathrm{e}}(R)} m_s(R,T_1)$ for every even $T_1 \ge 0$ and every integer $T_2 \ge T_1$. The state ν of Thm. AW is positive at the bond mirrors in this sense, by Lem. 17.21(c) on the cubes of sides $2^k l$ and Thm. AW(a), as in Step 2 of the proof; so (g) contains (a)–(c), the upper bound $e^{-\sigma^+ RT}$ excepted. ■□

Proposition 17.2 (Where the criterion holds)**.**

(a) For every integer $l \ge 3$, every $x_0 \in (0, 0.069]$ and every $\beta \in (0, x_0/48l^3]$ the criterion holds at l.

(b) Let $0 < \beta < \frac{1}{6}$ and $l \ge 4$ even. Then $X(l) \le 64\, l^2 (6\beta)^{l/2}$; so the cube condition, and the criterion with every $x_0 \in [X(l), \frac{1}{20}]$, $x_0 > 0$, hold at every even l with $64\, l^2(6\beta)^{l/2} \le \frac{1}{20}$, for instance at all even $l \ge 10$ if $\beta = 0.01$, $l \ge 24$ if $\beta = 0.05$, $l \ge 62$ if $\beta = 0.1$, $l \ge 360$ if $\beta = 0.15$.

(c) For $0 < \beta < \frac{1}{6}$ there is exactly one Gibbs state, periodic or not.

■

Proposition 17.3 (What the criterion says)**.** Let $\beta \ge 0$ and let $l \ge 3$ be an integer.

(a) With $\mathsf{r} = \mathsf{r}_l(2l, 2l)$: $\log(1+\mathsf{r}) \le \mathsf{e}(l) \le 2\log(1+\mathsf{r})$. So $\mathsf{r} \le 0.0351$ implies $\mathsf{e}(l) \le 0.069$, and $\mathsf{e}(l) \le 0.069$ implies $\mathsf{r} \le 0.0357638$, in which case every λ_i, $i \ge 1$, over $2l \times 2l$, the tops of the sectors with electric flux among them, lies at least $3.33/l$ above the vacuum. Besides, $\mathsf{e}(l) \ge \log(1 + \sum_{e \ne 00}(\Lambda_e/\lambda_0)^l)$ over $2l \times 2l$; so $\mathsf{e}(l) \ge \log(1+3y)$ if each of the three sectors with electric flux has $(\Lambda_e/\lambda_0)^l \ge y$, a floor that tends to $\log 4$ as the three sectors approach the vacuum.

(b) Let $r_1 = Z^-/Z$ on the cube of side $2l$, and $\mathsf{f}(x) = 2\log(\sqrt{1-x} + \sqrt{2x})$ for $0 \le x \le 1$. Then $0 < r_1 \le 1$ and $\mathsf{e}(l) \ge \mathsf{f}(1-r_1)$. Hence $\mathsf{e}(l) \le 0.069$ forces $r_1 > 0.99937$, and $1 - r_1 \ge 0.0039$ forces $\mathsf{e}(l) \ge 0.16567$.

(c) If $\mathsf{e}(l) \le 0.069$, then $1 - Z^-/Z < 0.0039$ on the cube of every integer side $N \ge 16l$, and $\mathsf{e}(l') < 0.0234$ for every integer $l' \ge 16l$. So, if $1 - Z^-/Z \ge 0.0039$ on one cube of side N, then $\mathsf{e}(l) > 0.069$ for every integer $3 \le l \le N/16$.

(d) Under the criterion at l, the loop along the boundary of one plaquette has $l^2 \ge 0.4757/\log(1/\nu(W_p))$.

■

Remark 17.4 (Free fields). For comparison, take three free massless fields in three dimensions, one for each generator of SU(2), each with one mode for every momentum, and leave out the modes of momentum 0. Over the section $2l \times 2l$ the energies of the modes are $\pi|m|/l$, $m \in \mathbb{Z}^2 \setminus \{0\}$, so that the excited levels at the time l give

$$1 + \mathsf{r} = \prod_{m \in \mathbb{Z}^2 \setminus \{0\}} (1 - e^{-\pi|m|})^{-3}, \qquad 1 + \mathsf{r}' = \prod_{m \in \mathbb{Z}^2 \setminus \{0\}} (1 - e^{-2\pi|m|})^{-3},$$

numbers free of l, with $\log(1+\mathsf{r}) \approx 0.7201$ and $\log(1+\mathsf{r}') \approx 0.0242$. The number $D = 2\log(1+\mathsf{r}) - \log(1+\mathsf{r}')$ that stands for $\mathsf{e}(l)$ (Lem. 17.11) is approximately 1.416 at every scale, more than twenty times the bound 0.069 of the criterion. This is a computation for free fields.

Lemma 17.5 (A lower bound sufficient for anticoncentration)**.** There are absolute constants $c_{\mathrm{T}} > 0$ and $C_{\mathrm{T}} \geq 1$ such that, for every integer $N \geq 4$ and $\beta \geq C_{\mathrm{T}} N^{68}$,

$$Z(N,N,N) \geq c_{\mathrm{T}} \frac{N^2}{\beta^2} \mathsf{X}_0, \qquad \mathsf{X}_0 = (2\pi^2)^{-(2N^3-2)} \left(\frac{2\pi}{\beta}\right)^{3N^3-3} (\mathfrak{d}')^{-3/2}, \qquad \mathfrak{d}' = e^{S_0(N^{\times 3})}.$$

■

Proof. The periodic estimate in Prop. 17.47(a), proved in Prop. 11.14(g), gives

$$Z(N,N,N) \geq \tfrac{1}{2} \beta^{1-3N^3} \mathcal{Z}(N)$$

whenever $c_3 (N^{66} \log\beta/\beta)^{1/8} \leq x_*$, where $x_* \leq 1/2$. This condition holds throughout $\beta \geq C_{\mathrm{T}} N^{68}$ after an absolute increase of C_{T}. Indeed, $\log\beta/\beta$ decreases for $\beta \geq e$, and, for $C \geq e$ and $N \geq 4$,

$$\frac{N^{66}\log\beta}{\beta} \leq \frac{\log C + 68\log N}{CN^2} \leq \frac{\log C + 68\log 4}{16C} \quad (\beta \geq CN^{68}).$$

The last member tends to zero as $C \to \infty$.

Put

$$\mathcal{J}_N = N^{-2} \int_{[-\pi,\pi]^3} e^{S_0(N^{\times 3}) - S_\varphi(N^{\times 3})} \, \mathrm{d}\varphi.$$

The determinant estimate of Prop. 11.14(c) gives

$$\mathcal{J}_N \geq J_- := e^{-2C_S} \int_{[-\pi,\pi]^3} |\varphi|^{-2} d\varphi > 0.$$

The singularity is integrable in three dimensions. The normalizations in Prop. 17.47(a) give exactly

$$\frac{\beta^{1-3N^3} \mathcal{Z}(N)}{N^2 \beta^{-2} \mathsf{X}_0} = \frac{\mathcal{J}_N}{4\pi^3}.$$

Thus $c_{\mathrm{T}} = J_-/(8\pi^3)$ suffices. □

Proposition 17.6 (Failure on small tori, given Thm. YM3_I:D)**.** Given Thm. YM3_I:D among the construction results, there are numbers $t_\circ > 0$ and $\beta_\flat$, formed from the constants of Thm. YM3_I:D and of the setting (Th) of §2.3.1, the fixed calibration $\mathsf{t}_\natural$ of §2.3.1 among them, with the following properties.

(a) For every real $t \in (0, t_\circ]$ there is an integer m_t such that on the periodic cube of $2\mathsf{L}^j$ sites a side at the coupling $\beta = 2\mathsf{L}^j/t$ the quotient $r_1 = Z^-/Z$ satisfies $r_1 \leq 0.99596$ for every $j \geq m_t + 2$; there $\mathsf{e}(\mathsf{L}^j) \geq 0.16567$, and $\mathsf{e}(l) > 0.069$ for every integer $3 \leq l \leq \mathsf{L}^j/8$.

(b) For the sides $\ell_0 = 2\mathsf{L}^{m_0}$ and every label b with $\ell_0/\mathsf{b} \leq t_\circ$: $\mathsf{e}(\ell_0/2a_K) \geq 0.16567$ at $\beta = \mathsf{L}^K \mathsf{b}$ for all large K; so the uniform criterion with $L = \mathsf{L}$ and $l_* = \mathsf{L}^{m_0}$ fails at this label for every K_0 and every $x_0 \leq 0.069$.

(c) For every real $\beta \geq \beta_\flat$: $\mathsf{e}(l) > 0.069$ for every integer $3 \leq l \leq \frac{t_\circ}{16\mathsf{L}}\beta$. So the uniform criterion, for any integer $L \geq 2$, at any label $\mathsf{b} > 0$, forces $\ell_0 > \frac{t_\circ}{8\mathsf{L}}\mathsf{b}$.

(d) There are numbers $t_\star > 0$, $\mathsf{C}_\star \geq 1$ and $\mathsf{p}_\star \geq 1$, formed from the same constants, such that for every integer $j \geq 1$ and every real $\beta > 0$ with $t = 2\mathsf{L}^j/\beta \leq t_\star$, on the periodic cube of $N = 2\mathsf{L}^j$ sites a side,

$$\frac{\lambda_0(N,N)^N}{Z(N,N,N)} \leq \mathsf{C}_\star \, t \left(\log\frac{1}{t}\right)^{\mathsf{p}_\star}, \qquad \text{so that} \qquad \mathsf{e}(\mathsf{L}^j) \geq \log\frac{1}{t} - \mathsf{p}_\star \log\log\frac{1}{t} - \log\mathsf{C}_\star.$$

For a side $\ell_0 = 2\mathsf{L}^{m_0}$, $m_0 \in \mathbb{Z}$, and a label b with $\ell_0/\mathsf{b} \leq t_\star$ this says that at every cutoff $K \geq 1 - m_0$, at $\beta = \mathsf{L}^K \mathsf{b}$ and with $a_K = \mathsf{L}^{-K}$, $\mathsf{e}(\ell_0/2a_K) \geq \log\frac{\mathsf{b}}{\ell_0} - \mathsf{p}_\star \log\log\frac{\mathsf{b}}{\ell_0} - \log\mathsf{C}_\star$.

The proof of (d) rests, besides Thm. YM3_I:D, on Lem. 17.5 and the two estimates eq. 17.iii and eq. 17.iv stated in the next subsection: through them it bounds $\lambda_0(N,N)^N/Z(N,N,N)$ from above, and the floor of e follows from that ceiling.

■

Proposition 17.7 (What the trace identities alone allow)**.** Call *data* every family of numbers $Z^z(\underline{n})>0$, $\underline{n}$ a box and $z\in\{0,1\}^3$, with the properties (iii), (T1), (T2) and (T3) of Lem. 17.10, and form F, e, d_1, d_2, X, z_- from them as above. Let $0<q<1$.

(a) $Z^z(\underline{n})=\prod_\mu(1+q^{n_\mu})^{|\underline{n}|/n_\mu}$, the same for all z, are data, with $d_1:d_2:\mathsf{e}=1:2:4$ and $X=3\mathsf{e}$ at every l.

(b) The *sheets* $Z^z(\underline{n})=\prod_\rho(1+(-1)^{z_{\mu\nu}}q^{n_\mu n_\nu})^{n_\rho}$, $\{\mu,\nu,\rho\}=\{1,2,3\}$, are data. With $s=q^{l^2}$ they have $\mathsf{e}(l)=8l\log(1+s^2)-4l\log(1+s^4)$ and $X(l)=24l\log(1+s)-6l\log(1+s^4)$, and $X/\mathsf{e}\geq 2.95/s$ for $s\leq 0.03$ (at $l=4$, $s=0.03$: $\mathsf{e}\approx 0.028774$, $X\approx 2.837626$). So for no number C does $X(l)\leq C\,\mathsf{e}(l)$ hold for all data: at the same side, the criterion does not give the cube condition from these properties alone.

(c) For the sheets, $\frac12 q^{n^2}\leq z_-(n,n,n)\leq nq^{n^2}$, so that $-n^{-2}\log z_-(n,n,n)\to\log\frac1q$, while with $x_0=\mathsf{e}(l)$ one has $\sigma^+=\log\frac1q-\frac{\log(103.2e^{-0.835}l)}{2l^2}+o(1)$ and $\Lambda=2l^2\log\frac1q-\log(103.2\,l)+o(1)$ as $q\to0$. So an inequality $\liminf_n -n^{-2}\log z_-(n,n,n)\geq c'\Lambda/l^2-C(l)$ with a number $c'>\frac12$ is false for the sheets: from the properties of data alone, the coefficient $\frac12$ of Λ/l^2 in σ^+ cannot be raised.

■

Proposition 17.8 (An area law without the numerical recursion of Prop. 17.17)**.** Assume the criterion at the side l, and let $l_j=2^{j+1}l$. Then $l_j\varepsilon_{\mathrm{v}}(l_j)\leq 0.0165\cdot 2^{-j}\,\theta^{2\cdot4^j}$ for all $j\geq0$; $z_-(n,n,n)\leq\max\{1,0.0096\sqrt{n/l}\}^{n/l}\,\theta^{n^2/2l^2}$ for $n=2^il$, $i\geq1$; and $0\leq\nu(W_C)\leq\theta^{RT/2l^2}$ for every rectangle C of sides $R\times T$ in a coordinate plane. The tension $\log\frac1\theta/2l^2\geq0.0582/l^2$ so obtained does not use the values $E_1,\dots,E_6$ of Prop. 17.17; the difference $0.4175/l^2$ to σ^+ is what that proposition adds. ■

17.1.4. *Construction estimates.* We use: (i) the periodic lattice of a box, its configurations and Haar measures, and Wilson's action; (ii) for a direction taken as time, the layers and the functions A_Σ and $A_\times(V,S,V')=\sum_b(1-\frac12\operatorname{tr}V_bS_{b_+}V_b'^{-1}S_{b_-}^{-1})$ (Section YM3_I:85, Section YM3_I:85): the map $U\mapsto(V^\tau,S^\tau)_{\tau\in\mathbb{Z}/t}$, with $V^\tau\in\mathcal{X}=G^{\mathsf{B}(\Sigma)}$ the bonds of the layer τ and $S^\tau\in G^\Sigma$ those from the layer τ to the layer $\tau+1$, carries dU to the product of the Haar measures, $\sum_p a_p=\sum_\tau[A_\Sigma(V^\tau)+A_\times(V^\tau,S^\tau,V^{\tau+1})]$ with continuous summands in $[0,2]$, and $A_\times(V',S^{-1},V)=A_\times(V,S,V')$; (iii) the crossing operator (Section YM3_I:85, Prop. YM3_I:85.1): the kernel $\mathsf{K}(V',V)=\int e^{-\beta A_\times(V,S,V')}\,\mathrm{d}S$ is symmetric, continuous and has values in $(0,1]$, and the operator K on $\mathcal{H}=L^2(\mathcal{X},dV)$ is Hilbert–Schmidt and ≥0; (iv) for Lem. 17.13 and Prop. 17.6, Hölder's inequality for traces of products of an even number of Hilbert–Schmidt operators (Lem. YM3_I:86.1) and $\|A\|_{2k}^{2k}=\operatorname{Tr}(A^*A)^k$ (the norm definition preceding Lem. YM3_I:86.1); (v) for the uniqueness, the boxes and the pressure, the chessboard estimate on the tori of side $2\mathsf{L}^j$ (Prop. YM3_I:86.3), its form for two tori on one board (Cor. YM3_I:86.6), and its bound on every periodic Gibbs state (Prop. YM3_I:91.9); (vi) the invariance of every periodic Gibbs state under the symmetries of the lattice, its reflection positivity at every lattice mirror, the diagonal ones included, and its decomposition into ergodic components that are periodic Gibbs states (Props. YM3_I:103.4 and YM3_I:106.2); (vii) for Prop. 17.6 alone, Thm. YM3_I:D and the statements among the construction results through which it bears on the block fields at a fixed depth on tori that are small against the label: the setting (Th), what it gives, the weight of the small-field chain and the chain with its bound on the discarded mass (§2.3.1, Lem. YM3_I:118.1, the definitions preceding Prop. YM3_I:115.2, Prop. YM3_I:115.2); the fixed calibration and the inner balls (Defs. 2.3.1, YM3_I:113.10, Lem. YM3_I:113.10); the setting (E)

and the laws of the block fields (Defs. 2.3.1, 2.7); the numerical conditions at the chosen constants (Prop. YM3_I:69.1); the constants and the thresholds (§2.3.1 and equation YM3_I:(634)); the block-averaging map with its locality, gauge covariance, measurability and covariance under the lattice isometries (equations YM3_I:(37)–(39), Prop. YM3_I:4.5, YM3_I:4.5, [7, Lem. G.1]); the bound on the holonomies along rearranged paths (Lem. YM3_I:4.1); and, for its clause (d), the averages on small fields (Lem. YM3_I:4.4, Lem. 5.28) and the comparison of two consecutive cutoffs (§2.3.1, Section YM3_I:116, Props. YM3_I:116.1 and YM3_I:116.3 with their proofs, and §2.3.2), on which Cor. 2.8 rests, read from one cutoff to the next and summed into the estimate eq. 17.iv below, together with the signs of the constants of that comparison, among them $\kappa_{\mathrm{b}} > 0$ and $c' > 0$ (Prop. YM3_I:114.4 and §2.3.1).

From the textbooks we use the spectral theorem for compact self-adjoint operators, Jentzsch's theorem, the min–max principle, the inequalities of Young, Jensen and Schwarz, Kolmogorov's extension theorem, the weak compactness of the probability measures on a compact metrisable space, and Hausdorff's moment theorem.

Clause (d) of Prop. 17.6 rests, besides Thm. YM3_I:D and the statements of (vii), on two estimates of its own, which its proof takes up (Lem. 17.26, and Lem. 17.27 with the chain from a low cutoff). For a configuration U of a periodic cube and a site ξ let $\mathsf{a}(U,\xi) \in \mathbb{R}^5$ be the five invariants of the pair of the holonomies of U along the closed straight paths through ξ in the directions 1 and 2: their two class angles, $\alpha(g) = \arccos \frac{1}{2} \operatorname{tr} g \in [0,\pi]$ for $g \in G$, and the three entries of $(\mathsf{v}^{\mathrm{t}}\mathsf{v})^{1/2}$, v the real 3×2 matrix of their vector parts, numbers that do not change under a simultaneous conjugation of the pair. The first estimate concerns one lattice: there are absolute numbers C_{a}, c_{a}, c'_{a}, c''_{a} such that on the periodic cube of $N' \geq 4$ sites a side, at every coupling $\beta' \geq c'_{\mathrm{a}} N'^{c''_{\mathrm{a}}}$, for every closed cube Q of the half side w' in $\mathbb{R}^5$ with $(N'^5/2\beta')^{1/2} \leq w' \leq \frac{1}{20}$ and every $\omega > 0$ below a fixed negative power of N',

$$\mu_{N',\beta'}\Big(\mathsf{a}(U,\xi) \in \mathsf{Q},\ \max_p |\partial U(p) - \mathbf{1}| < \omega\Big) \leq C_{\mathrm{a}} N'^{c_{\mathrm{a}}}\, \beta'^{1/2}\, w'^3, \tag{17.iii}$$

$\mu_{N',\beta'}$ the law of that cube. Its proof combines a Gaussian ceiling with Lem. 17.5 for Wilson's measure on the cube in the gauge of a maximal tree, with constants that are powers of N': the ceiling integrates out all bonds but the three winding holonomies of ξ against the weight $\exp[-2\beta' N'^{-5} \sum_{\mu<\nu} |\mathsf{v}_\mu \times \mathsf{v}_\nu|^2]$, v_μ the vector part of the holonomy in the direction μ; the proved lower bound for $Z(N',N',N')$ supplies the normalizing denominator; and the integral of that weight over the triples whose first two members have their five invariants in Q is at most a fixed multiple of $w'^3(\beta'/N'^5)^{-3/2}$. The second estimate is drawn from the lemmas of (vii) on two consecutive cutoffs.

Let $\mathsf{b} = \ell/t$ be a label and $\ell = 2\mathsf{L}^m$ a side at which the setting (E) of §2.3.1 holds for it, with ℓ at most a fixed power of $y = \log \mathsf{b}$, and let μ_0^K be the law of the block field of the depth 0 at the cutoff K (Def. 2.7(2)). For every y above a number formed from the constants there is a lowest cutoff K_1, at which the bare cube has at most a fixed power of y sites a side, such that for every integer $K \geq K_1$ and every Borel set E of block fields of the depth 0 that the gauge transformations carry onto itself (Def. 2.7(3))

$$\mu_0^K(E) \leq e^{\mathsf{S}}(\mu_0^{K_1}(E) + \mathsf{R}_\Sigma), \tag{17.iv}$$

with S below an absolute number and $\mathsf{R}_\Sigma \leq e^{-3y^2}$. Cor. 2.8 compares two consecutive cutoffs additively; here, from one cutoff to the next, the errors ϵ_{fg} and ϵ_{cl} of §2.3.1, which decrease like powers of L^{-K} up to factors that are powers of K, y and ℓ, enter as factors on the probability, and the errors ϵ_{sh} and R_{t_1}, which are exponentially small in a power of y, as additive remainders and through the factors $(1-\epsilon_{\mathrm{sh}})^{-1}$ and $(1-\mathsf{R}_{t_1})^{-1}$ (Lem. 17.27); S and R_Σ are the sums over $K \geq K_1$ of the exponents of the factors and of the remainders. So an event whose probability at the cutoff K_1 is at most of the order of t has a probability at most of the order of t at every cutoff $K \geq K_1$, since $y \geq \log \frac{1}{t}$ makes e^{-3y^2} small against t.

Beyond (i)–(vii) the proofs use no result among the construction results; no statement of the section other than Prop. 17.6 rests on Thm. YM3_I:D or on Thms. YM3_I:AJ and YM3_I:AD. Its clause (d) combines the finite-cube lower bound of Lem. 17.5 with the estimates eq. 17.iii and eq. 17.iv.

17.1.5. *Estimates and proofs.*

Lemma 17.9 (Two identities for the crossing weight)**.** Let $(V^S)_b = S_{b_-} V_b S_{b_+}^{-1}$ and $\mathsf{K}_0(V,W) = \prod_b \exp[-\beta(1 - \frac{1}{2}\operatorname{tr} V_b W_b^{-1})]$ for $V, W \in \mathcal{X}$ and $S \in G^\Sigma$.

(a) $e^{-\beta A_\times(V,S,V')} = \mathsf{K}_0(V^g, V'^{gS})$ for all $V, V' \in \mathcal{X}$ and all $g, S \in G^\Sigma$.

(b) $\mathsf{K}_0(V,W) = \sum_\alpha c_\alpha \phi_\alpha(V)\overline{\phi_\alpha(W)}$, with α in a countable set, $c_\alpha \geq 0$, $\sum_\alpha c_\alpha = e^{\beta \#\mathsf{B}(\Sigma)}$, ϕ_α continuous and $|\phi_\alpha| \leq 1$.

■

Proof sketch. (a) $V_b((V'^S)_b)^{-1} = V_b S_{b_+} V_b'^{-1} S_{b_-}^{-1}$ is the matrix of the bond b in $A_\times$, so $e^{-\beta A_\times(V,S,V')} = \mathsf{K}_0(V, V'^S)$; $(V^g)_b((W^g)_b)^{-1} = g_{b_-} V_b W_b^{-1} g_{b_-}^{-1}$, so $\mathsf{K}_0(V^g, W^g) = \mathsf{K}_0(V,W)$ by the cyclicity of the trace; and $(V^S)^g = V^{gS}$. (b) For $v, w \in G$, $\operatorname{tr}(vw^{-1}) = \sum_{i,j} v_{ij}\overline{w_{ij}}$, with entries of modulus ≤ 1. Expand each factor $e^{-\beta}\exp[\frac{\beta}{2}\operatorname{tr} V_b W_b^{-1}]$ in powers, write out the powers and multiply over b: $\alpha = (n_b, (i_{b,s}, j_{b,s})_{s \leq n_b})_b$, $c_\alpha = e^{-\beta \#\mathsf{B}(\Sigma)} \prod_b (\beta/2)^{n_b}/n_b!$, $\phi_\alpha(V) = \prod_b \prod_s (V_b)_{i_{b,s} j_{b,s}}$; as there are 4^{n_b} index families for each n_b, $\sum_\alpha c_\alpha = e^{-\beta \#\mathsf{B}(\Sigma)} \prod_b e^{2\beta}$, and this bounds the series of the moduli. □

Lemma 17.10 (Transfer operator and flux sectors)**.** Fix a box and a direction μ_0 as time, with the other directions $\nu_1 < \nu_2$. For $i = 1, 2$ let ι_i change the sign of V_b on the bonds of the direction ν_i that start on a fixed line of the other direction of the section, $(\mathsf{J}_i \psi)(V) = \psi(\iota_i V)$, $\mathsf{J}^k = \mathsf{J}_1^{k_1}\mathsf{J}_2^{k_2}$ and $P_e = \frac{1}{4}(1 + (-1)^{e_1}\mathsf{J}_1)(1 + (-1)^{e_2}\mathsf{J}_2)$ for $e \in \{0,1\}^2$. Let $A_\Sigma^{(0)} = A_\Sigma$, let $A_\Sigma^{(1)}$ be A_Σ with the summand $1 - \frac{1}{2}\operatorname{tr}$ of one plaquette replaced by $1 + \frac{1}{2}\operatorname{tr}$, M_m the multiplication by $e^{-\beta A_\Sigma^{(m)}/2}$ and $\mathsf{T}_m = M_m \mathsf{K} M_m$; write $z \leftrightarrow (k; m)$ with $k = (z_{\mu_0\nu_1}, z_{\mu_0\nu_2})$, each pair written in its order, and $m = z_{\nu_1\nu_2}$. Then:

(i) $\mathsf{T}_m \geq 0$ is Hilbert–Schmidt with a continuous symmetric kernel with values in $(0,1]$; J_1, J_2 are commuting self-adjoint unitary involutions that commute with T_m; none of these objects depends on t.

(ii) $Z^{(k;m)} = \operatorname{Tr}(\mathsf{T}_m^t \mathsf{J}^k)$ for every integer $t \geq 3$.

(iii) Z^z does not depend on the places of the columns, and $Z^{\pi z}(\pi \underline{n}) = Z^z(\underline{n})$ for every permutation π of the directions.

Consequently: (T1) Z is symmetric in the sides; (T2) $Z(t, \Sigma) = \sum_i \lambda_i^t$ for $t \geq 3$, the $\lambda_i \geq 0$ being the eigenvalues of T_0, $\sum_i \lambda_i^2 < \infty$, and λ_0 is simple with an eigenvector in the range of P_{00}; (T3) with the eigenvalues $\mu_i(e,m) \geq 0$ of T_m on the range of P_e, which depend neither on t nor on k,

$$Z^{(k;m)} = \sum_e (-1)^{e\cdot k} W_t(e;m), \qquad W_t(e;m) = \operatorname{Tr}(\mathsf{T}_m^t P_e) = \sum_i \mu_i(e,m)^t \geq 0;$$

$\Lambda_e = \sup_i \mu_i(e,0)$ is the top of the sector e. Moreover:

(a) $W_t(00;0) \geq \lambda_0^t$;

(b) $0 \leq 1 - Z^{(k;0)}/Z \leq 2\mathsf{r}_t/(1+\mathsf{r}_t)$, so that $z_- \leq \mathsf{r}_t/(1+\mathsf{r}_t)$ when the time is the direction 1 or 3;

(c) on a cube Z^z/Z depends on $|z|$ alone, $r_2 \leq r_1$, $r_3 \leq r_1$, and $0 \leq 1 - Z^z/Z \leq |z|(1-r_1) \leq 6z_-$; with any direction as time, the weights $w_e = W_n(e;0)/Z$ of the cube of side n are $w_{00} = \frac{1}{4}(1 + 2r_1 + r_2)$, $w_{10} = w_{01} = \frac{1}{4}(1 - r_2)$, $w_{11} = \frac{1}{4}(1 - 2r_1 + r_2)$, and $1 - r_1 \leq \frac{4}{3}\mathsf{r}_n(n,n)/(1+\mathsf{r}_n(n,n))$;

(d) $a_- = \sum_i \mu_i^{n_1} = \sum_i \mu_i'^{n_3}$ and $Z^- = \sum_i \mu_i''^{n_2}$, with numbers $\mu_i, \mu_i', \mu_i'' \geq 0$ that do not depend on n_1, on n_3 and on n_2 respectively, and $\sup_i \mu_i'' = \lambda_-(n_1, n_3) \leq \lambda_0(n_1, n_3)$.

■

Proof sketch. Every plaquette is a summand of $A_\Sigma(V^\tau)$ or of $A_\times(V^\tau, S^\tau, V^{\tau+1})$. Put the columns at the origin of the section and at the crossing $\tau = 0$. A column of the pair $\nu_1\nu_2$ is one summand in every layer and turns A_Σ into $A_\Sigma^{(1)}$; a column of the pair $\mu_0\nu_i$ is the set of the crossing summands of the bonds flipped by ι_i, and since $1 - \frac{1}{2}\operatorname{tr}(-g) = 1 + \frac{1}{2}\operatorname{tr} g$, reversing it is the substitution $V^0 \mapsto \iota_i V^0$ in that crossing. Integrating each S^τ first,

$$Z^{(k;m)} = \int \mathsf{T}_m(V^1, \iota^k V^0) \prod_{\tau\neq 0} \mathsf{T}_m(V^{\tau+1}, V^\tau) \prod_\tau \mathrm{d}V^\tau = \operatorname{Tr}(\mathsf{T}_m^t \mathsf{J}^k),$$

the trace of a chain of $t \geq 3$ bounded kernels: (ii). The functions $A_\Sigma^{(m)}$ and $A_\times$ are invariant under ι_i, because the two bonds of the direction ν_i of a plaquette are both flipped or neither and $-\mathbf{1}$ is central; so J_i commutes with T_m, and $\langle\psi, \mathsf{T}_m\psi\rangle = \langle M_m\psi, \mathsf{K}M_m\psi\rangle \geq 0$: (i). (iii): changing $U(b)$ into $-U(b)$ on a set $\mathfrak{F}$ of bonds keeps dU and multiplies $\operatorname{tr}\partial U(p)$ by $(-1)^{\#(p\cap\mathfrak{F})}$; for $\mathfrak{F}$ the bonds of the direction ν that start on the line of the direction ρ through $x + e_\mu$ this sign is -1 exactly on the columns of the pair $\mu\nu$ through x and through $x + e_\mu$ (the sides are ≥ 3), so a column moves by one step; a permutation of the axes renumbers the bonds and carries a plaquette to a plaquette or to its inverse, which has the same trace. (T2) and (T3) follow from the spectral theorem on the four ranges of the P_e.

By Jentzsch's theorem λ_0 is simple with an eigenvector $\varphi > 0$, and $P_{00}\varphi = \frac{1}{4}\sum_k \varphi\circ\iota^k \geq \frac{1}{4}\varphi \neq 0$: (a). (b): $Z - Z^{(k;0)} = 2\sum_{e\cdot k \text{ odd}} W_t(e;0) \leq 2(Z - W_t(00;0)) \leq 2(Z - \lambda_0^t)$. (c): on a cube (iii) makes Z^z depend on $|z|$. With two twisted pairs, the time a direction of one of them but not of the other, $(k;m) = (10;1)$ and $r_2 = \sum_e (-1)^{e_1} W(e;1)/Z \leq \sum_e W(e;1)/Z = r^{(00;1)} = r_1$; in the same way $r_3 = r^{(11;1)} \leq r_1$; and with the time common to two twisted pairs, $(k;m) = (11;0)$, $4W(11;0)/Z = 1 - 2r_1 + r_2 \geq 0$ gives $1 - r_2 \leq 2(1 - r_1)$. With all three pairs twisted, $(k;m) = (11;1)$ for every direction as time, and (T3) at $m = 1$ gives $4W(11;1)/Z = r^{(00;1)} - r^{(10;1)} - r^{(01;1)} + r^{(11;1)} = r_1 - 2r_2 + r_3 \geq 0$; added to $1 - 2r_1 + r_2 \geq 0$ this is $1 - r_3 \leq (1 - r_1) + (1 - r_2)$, and so $1 - r_3 \leq 3(1 - r_1)$.

The formula for the weights is obtained by inverting $Z^{(k;0)}/Z = \sum_e (-1)^{e\cdot k} w_e$, with $Z^{(10;0)} = Z^{(01;0)} = Zr_1$ and $Z^{(11;0)} = Zr_2$. With $u = w_{10}$, $v = w_{11}$ one has $1 - r_1 = 2(u + v)$, $1 - r_2 = 4u$, so $r_2 \leq r_1$ means $v \leq u$, which gives $2(u + v) \leq \frac{4}{3}(2u + v) = \frac{4}{3}(1 - w_{00})$, and $1 - w_{00} \leq 1 - \lambda_0^n/Z = \mathsf{r}_n/(1 + \mathsf{r}_n)$ by (a). (d) is (T3) with the time 1, 3 and 2; $\lambda_- \leq \lambda_0$ because $Z^- \leq Z$. □

Lemma 17.11 (One positive sequence; the excess)**.** Let $\kappa_0 \geq \kappa_1 \geq \cdots \geq 0$, $\kappa_0 > 0$, $\sum \kappa_i < \infty$; $p_M = \sum_i \kappa_i^M$ for real $M \geq 1$, $\eta = \sum_{i\geq 1} \kappa_i/\kappa_0$, $s_M = \sum_{i\geq 1} (\kappa_i/\kappa_0)^M$, $D = 2\log p_1 - \log p_2$ and $D' = 2\log p_2 - \log p_4$. Then

(a) $\log(1 + \eta) \leq D \leq 2\log(1 + \eta)$;
(b) if $D < \log 2$, then $\eta \leq \varpi(e^D - 1)$;
(c) $D' \leq 2\log(1 + s_2) \leq 2s_2 \leq 2\eta^2$, so that $D' \leq \omega(D)$ if $D < \log 2$;
(d) $p_{MM'} \leq p_M^{M'}$ for real $M, M' \geq 1$;
(e) $s_M \leq s_{M_0}^{M/M_0}$ for real $M \geq M_0 \geq 1$.

For $\kappa_i = \lambda_i(\Sigma)^t$ one has $p_M = Z(Mt, \Sigma)$, $\eta = \mathsf{r}_t(\Sigma)$ and $s_M = \mathsf{r}_{Mt}(\Sigma)$ whenever Mt is an integer ≥ 3. Hence:

(f) $F/|\underline{n}|$ and $\delta/|\underline{n}|$ do not increase in any side, $F/|\underline{n}| \to P$ as the three sides tend to infinity, $\log(1 + \mathsf{r}_t(\Sigma)) \leq \delta(t, \Sigma)$, and $\log\lambda_0(N_1, N_2) \geq N_1 N_2 P$;
(g) for integers $A, B \geq N \geq 3$, the Casimir term $\varepsilon(A, B) = \log\lambda_0(A, B) - ABP$ satisfies $0 \leq \varepsilon(A, B) \leq (A + B)\,\delta_{\mathrm{c}}(N)/N^2$.

■

Proof sketch. $p_1 = \kappa_0(1 + \eta)$ and $p_M = \kappa_0^M(1 + s_M)$, so $e^D = (1 + \eta)^2/(1 + s_2)$. For $u_i \geq 0$ with the sum u and real $m \geq 1$, $\sum u_i^m \leq u^m$; this gives (d), (e) and $s_2 \leq \min\{\eta, \eta^2\}$, hence (a), and (c) as $D' = 2\log(1 + s_2) - \log(1 + s_4)$. (b): $e^D \geq (1 + \eta)^2/(1 + \eta^2) = 1 + 2\eta/(1 + \eta^2)$, and $\eta < 1$ by (a);

solve the quadratic inequality. (f): (d) with $M' = t'/t$ gives $Z(t', \Sigma) \le Z(t, \Sigma)^{t'/t}$ for $t' \ge t$, and (T1) the other sides; $\delta(t, \Sigma) = t(\log \lambda_0 - N_1 N_2 P) + \log(1 + \mathsf{r}_t)$, with $\log \lambda_0 = \lim_s F(s, \Sigma)/s \ge N_1 N_2 P$. (g): put $\varkappa = \delta_{\mathrm{c}}(N)/N^2$. For $t, A, B \ge N$, $\delta(t, A, B) = t\,\varepsilon(A, B) + \log(1 + \mathsf{r}_t(A, B))$, and by (f) $\log(1 + \mathsf{r}_t(A, B)) \le \log(1 + \mathsf{r}_N(A, B)) \le \delta(N, A, B) \le AB\varkappa$. By (f), $\varepsilon(A, B)/AB \le \delta(t, A, B)/tAB$ for every t, so $\varepsilon(A, B)/AB$ does not increase in A or B and tends to 0 as $A, B \to \infty$. With B as time, $\delta(s, t, B) = B\varepsilon(s, t) + \log(1 + \mathsf{r}_B(s, t)) \le B\varepsilon(s, t) + st\varkappa$; divide by s and let $s \to \infty$: $\varepsilon(t, B)/t \le B \lim_s \varepsilon(s, t)/st + \varkappa$, and as $t \to \infty$, $\limsup_t \varepsilon(t, B)/t \le \varkappa$. With A as time, $\delta(t, A, B) \le A\varepsilon(t, B) + tB\varkappa$; divide by t and let $t \to \infty$: $\varepsilon(A, B) \le (A + B)\varkappa$. □

Lemma 17.12 (Two static charges)**.** Fix a box, the time 3, $o \in \Sigma$ and $r = o + Re_1$, $1 \le R \le n_1 - 1$; let γ be the straight path of R bonds from o to r in the section, $V(\gamma)$ its ordered product, $\hat{\mathcal{H}} = L^2(\mathcal{X}; M_2(\mathbb{C}))$ with $\langle \Psi, \Psi' \rangle = \int \operatorname{tr}(\Psi^* \Psi')\, \mathrm{d}V$,

$$(\hat{\mathsf{K}}\Psi)(V) = \iint e^{-\beta A_\times(V,S,V')}\, S_o \Psi(V') S_r^{-1}\, \mathrm{d}S\, \mathrm{d}V', \qquad \hat{\mathsf{T}} = M_0 \hat{\mathsf{K}} M_0, \qquad (\Upsilon\psi)(V) = \psi(V) V(\gamma);$$

let C be the rectangle $R \times T$, $1 \le T \le n_3 - 1$, with the side γ in the layer 0, and p_ξ half the trace of the line that winds once along the direction 3 through $\xi \in \Sigma$. Then:

(a) $\hat{\mathsf{K}}$ and $\hat{\mathsf{T}}$ are Hilbert–Schmidt, self-adjoint and ≥ 0, they do not depend on n_3, and $\Upsilon^* \Upsilon = 2$;
(b) $2Z\langle W_C \rangle = \operatorname{Tr}(\mathsf{T}_0^{n_3 - T} \Upsilon^* \hat{\mathsf{T}}^T \Upsilon)$ and $\operatorname{Tr} \hat{\mathsf{T}}^{n_3} = 4Z\langle p_o p_r \rangle$;
(c) $0 \le \langle W_C \rangle \le (4\langle p_o p_r \rangle)^{T/n_3}$ and $\|\hat{\mathsf{T}}\|^{n_3} \le 4Z\langle p_o p_r \rangle$;
(d) $0 \le \langle p_o p_r \rangle \le z_+^{1-\varrho} z_-^{\varrho} + z_-^{1-\varrho} z_+^{\varrho}$, $\varrho = R/n_1$, and for $R \le n_1/2$

$$0 \le \langle W_C \rangle \le \big(8 z_-^{R/n_1}\big)^{T/n_3}, \qquad \frac{\|\hat{\mathsf{T}}\|}{\lambda_0(n_1, n_2)} \le \Big[8\big(1 + \mathsf{r}_{n_3}(n_1, n_2)\big) z_-^{R/n_1}\Big]^{1/n_3}.$$

(e) *Any two sites.* For any two sites $o \ne r$ of the section, $\hat{\mathsf{K}}$ and $\hat{\mathsf{T}} = \hat{\mathsf{T}}_{o,r}$ are defined by the same formulas, (a) holds, $\operatorname{Tr} \hat{\mathsf{T}}^{n_3} = 4Z\langle p_o p_r \rangle$ and $\|\hat{\mathsf{T}}\|^{n_3} \le 4Z\langle p_o p_r \rangle$, and (d) holds for $\langle p_o p_r \rangle$ and $\|\hat{\mathsf{T}}\|$ with R the distance of o_1 and r_1 on the circle of n_1 sites, $1 \le R \le n_1/2$; on a cube it holds as well with R the distance of o_2 and r_2 on the circle of n_2 sites.
(f) *Staircase loops in a box.* Let $1 \le T \le n_3 - 2$, let o be a site of the section, α_j and $R_j \ge 1$ integers, $o_j = o + \alpha_j e_1$ and $r_j = o + (\alpha_j + R_j) e_1$ for $0 \le j < T$, and let C be the closed path that runs in the layer 0 straight along the line of the direction 1 from o_0 to r_0, then for $j = 0, \dots, T - 1$ in turn one bond up at r_j and, if $j < T - 1$, straight from r_j to r_{j+1}, in the layer T straight from r_{T-1} to o_{T-1}, and then for $j = T - 1, \dots, 0$ in turn one bond down at o_j and, if $j > 0$, straight from o_j to o_{j-1} ("straight" from the site of the integer α to that of α': along the $|\alpha' - \alpha|$ bonds between them). Then, with the thermal numbers over (n_1, n_2),

$$|\langle W_C \rangle| \le \big(1 + \mathsf{r}_{n_3 - T}\big) \prod_{j=0}^{T-1} \frac{\|\hat{\mathsf{T}}_{o_j, r_j}\|}{\lambda_0(n_1, n_2)}, \qquad \text{and if all } R_j \le \tfrac{n_1}{2}: \quad |\langle W_C \rangle| \le \big(1 + \mathsf{r}_{n_3 - T}\big)\big[8(1 + \mathsf{r}_{n_3})\big]^{T/n_3} z_-^{\sum_j R_j/n_1 n_3}.$$

No side need be even. ■

Proof sketch. The inequality that replaces Hölder's inequality for traces is this. Let $A, C \ge 0$ be compact with eigenvalues a_i, c_j and eigenbases (e_i), (f_j), B bounded, $p, q \ge 1$ integers and $s = p + q$. Then $\langle e_i, A^p B^* C^q B e_i \rangle = \sum_j w_{ij} a_i^p c_j^q$ with $w_{ij} = |\langle f_j, B e_i \rangle|^2 \ge 0$, the row and column sums of (w_{ij}) are $\le \|B\|^2$. A zero normaliser below makes the weighted product sum vanish, and infinite normalisers give only a trivial bound. For finite positive normalisers, Young's inequality $a^p c^q \le \mathsf{a}^{p/s} \mathsf{c}^{q/s} \big(\frac{p}{s} \frac{a^s}{\mathsf{a}} + \frac{q}{s} \frac{c^s}{\mathsf{c}}\big)$, with $\mathsf{a} = \sum w_{ij} a_i^s$ and $\mathsf{c} = \sum w_{ij} c_j^s$, gives

$$0 \le \sum_i \langle e_i, A^p B^* C^q B e_i \rangle \le \|B\|^2 \Big(\sum_i a_i^s\Big)^{p/s} \Big(\sum_j c_j^s\Big)^{q/s}. \tag{17.v}$$

Its form with two operators bounds the modulus. For bounded B_1, B_2 the same eigenbases give $\sum_i \langle e_i, A^p B_1^* C^q B_2 e_i\rangle = \sum_{i,j} a_i^p c_j^q \overline{\langle f_j, B_1 e_i\rangle}\,\langle f_j, B_2 e_i\rangle$, and $\sum_{i,j} a_i^p c_j^q |\langle f_j, B_k e_i\rangle|^2 = \sum_i \langle e_i, A^p B_k^* C^q B_k e_i\rangle$ for $k = 1, 2$; Schwarz's inequality with the weights $a_i^p c_j^q \ge 0$, and then eq. 17.v for B_1 and for B_2, give

$$\Big|\sum_i \langle e_i, A^p B_1^* C^q B_2 e_i\rangle\Big| \le \|B_1\|\,\|B_2\| \Big(\sum_i a_i^s\Big)^{p/s} \Big(\sum_j c_j^s\Big)^{q/s}. \tag{17.vi}$$

(a) Symmetry follows from $A_\times(V', S^{-1}, V) = A_\times(V, S, V')$. For positivity substitute $S = g^{-1}Q$, use $e^{-\beta A_\times(V, g^{-1}Q, V')} = \mathsf{K}_0(V^g, V'^Q)$ (Lem. 17.9(a)), average over $g \in G^\Sigma$ (the left side does not depend on g) and expand K_0 by Lem. 17.9(b):

$$\langle \Psi, \hat{\mathsf{K}}\Psi\rangle = \sum_\alpha c_\alpha \operatorname{tr}(X_\alpha^* X_\alpha) \ge 0, \qquad X_\alpha = \iint \overline{\phi_\alpha(V^Q)}\, Q_o \Psi(V) Q_r^{-1}\, \mathrm{d}Q\, \mathrm{d}V.$$

The argument uses of o and r only that they are sites of the section. (b) With $\mathsf{P}_\xi = S_\xi^0 \cdots S_\xi^{T-1}$, $2W_C = \operatorname{tr}[V^0(\gamma)^* \mathsf{P}_o V^T(\gamma) \mathsf{P}_r^{-1}]$, and the layers write $2Z\langle W_C\rangle$ as the trace of the chain of the kernels of $\mathsf{T}_0^{n_3-T}$ and of $\Upsilon^* \hat{\mathsf{T}}^T \Upsilon$; at $T = n_3$ the trace over $M_2(\mathbb{C})$ gives $\operatorname{tr} \mathsf{P}_o \operatorname{tr} \mathsf{P}_r^{-1}$. (c) is eq. 17.v with $A = \mathsf{T}_0$, $C = \hat{\mathsf{T}}$, $B = \Upsilon$, $p = n_3 - T$, $q = T$ and $\sum a_i^{n_3} = Z$. (d) Take the time 1. The two winding lines become the multiplication $\hat{\mathsf{p}}$ by one function of the variables of a layer, taken at the layers o_1 and $o_1 + R$; each line holds exactly one bond flipped by ι_2, so $\hat{\mathsf{p}}$ exchanges the ranges of $P_\pm = \frac{1}{2}(1 \pm \mathsf{J}_2)$, on which $\operatorname{Tr}(\mathsf{T}_0^{n_1} P_\pm) = a_\pm$ by Lem. 17.10(ii). By eq. 17.v

$$Z\langle p_o p_r\rangle = \sum_\pm \operatorname{Tr}\big[(\mathsf{T}_0 P_\pm)^{n_1 - R}\, \hat{\mathsf{p}}\, (\mathsf{T}_0 P_\mp)^R\, \hat{\mathsf{p}}\big] \le \sum_\pm a_\pm^{1-\varrho} a_\mp^\varrho,$$

and for $\varrho \le \frac{1}{2}$ and $z_- \le z_+ \le 1$ each term is $\le z_-^\varrho Z$; finally $Z = \lambda_0^{n_3}(1 + \mathsf{r}_{n_3})$. (e) The proof of (a) uses of o and r only that they are sites of the section, and the trace of $\hat{\mathsf{T}}^{n_3}$ in (b) and the second bound of (c) do not use γ; so, for any two sites, $\hat{\mathsf{T}} \ge 0$, $4Z\langle p_o p_r\rangle = \operatorname{Tr} \hat{\mathsf{T}}^{n_3} \ge 0$ and $\|\hat{\mathsf{T}}\|^{n_3} \le 4Z\langle p_o p_r\rangle$: the sign of $\langle p_o p_r\rangle$ comes from the time 3. For the bound take the time 1. The line through $\xi \in \Sigma$ is then the function p_{ξ_2} of the variables V^{ξ_1} of the layer ξ_1, half the trace of the ordered product of the variables of its bonds of the direction 3 with the second coordinate ξ_2; whatever ξ_2 is, the line holds exactly one bond flipped by ι_2. So the multiplications $\hat{\mathsf{p}}_{o_2}$ and $\hat{\mathsf{p}}_{r_2}$, two different ones if $o_2 \ne r_2$, are real, of norm ≤ 1, and each exchanges the ranges of $P_\pm$. With R the distance of o_1 and r_1 on the circle, $1 \le R \le n_1/2$, the trace has $n_1 - R$ factors T_0 on one side of the two lines and R on the other, and, as in (d), with the names o and r exchanged if need be,

$$Z\langle p_o p_r\rangle = \sum_\pm \operatorname{Tr}\big[(\mathsf{T}_0 P_\pm)^{n_1 - R}\, \hat{\mathsf{p}}_{o_2}\, (\mathsf{T}_0 P_\mp)^R\, \hat{\mathsf{p}}_{r_2}\big];$$

eq. 17.vi with $A = \mathsf{T}_0 P_\pm$, $C = \mathsf{T}_0 P_\mp$, $B_1 = \hat{\mathsf{p}}_{o_2}$, $B_2 = \hat{\mathsf{p}}_{r_2}$, $p = n_1 - R$, $q = R$ bounds the term of $\pm$ in modulus by $a_\pm^{1-\varrho} a_\mp^\varrho$. With the sign from the time 3 this is the first statement of (d) for o and r, at every parity of n_1, n_2, n_3, and the bound of $\|\hat{\mathsf{T}}\|$ in (d) follows from it and from $\|\hat{\mathsf{T}}\|^{n_3} \le 4Z\langle p_o p_r\rangle$ as there. On a cube the time 2 does the same with o_2, r_2, the twisted pair being then the pair 23, whose quotient on the cube equals that of the pair 13 (Lem. 17.10(c)). (f) With the time 3, $U(C)$ is the ordered product of the runs in the layers and of the bonds $S_{r_j}^j$, $(S_{o_j}^j)^{-1}$; put $(\Upsilon_j \psi)(V) = \psi(V) V(o_j \to r_j)$, with $V(o_j \to r_j)$ the product along the straight run from o_j to r_j, $(\Gamma_j \Psi)(V) = V(o_{j-1} \to o_j) \Psi(V) V(r_j \to r_{j-1})$, a unitary operator of $\hat{\mathcal{H}}$ that commutes with M_0, and $\mathsf{Q} = \Upsilon_0^* \hat{\mathsf{T}}_{o_0, r_0} \Gamma_1 \hat{\mathsf{T}}_{o_1, r_1} \Gamma_2 \cdots \Gamma_{T-1} \hat{\mathsf{T}}_{o_{T-1}, r_{T-1}} \Upsilon_{T-1}$.

As in (b), $2Z\langle W_C\rangle = \operatorname{Tr}(\mathsf{T}_0^{n_3-T} \mathsf{Q})$; in an eigenbasis of T_0, $|\operatorname{Tr}(\mathsf{T}_0^{n_3-T}\mathsf{Q})| \le \|\mathsf{Q}\| \lambda_0^{n_3-T}(1 + \mathsf{r}_{n_3-T})$, with $n_3 - T \ge 2$; and $\|\mathsf{Q}\| \le 2 \prod_j \|\hat{\mathsf{T}}_{o_j, r_j}\|$, $Z \ge \lambda_0^{n_3}$. The second bound is (d) for each j. □

Lemma 17.13 (Several static charges; closed paths)**.** Fix a box with n_1 even and the time 3.

(a) For a finite set $\mathcal{V}$ of runs, each with a site $u(v) \in \Sigma$ and a sense, let $D(S) = \bigotimes_v D_v(S_{u(v)})$ on $(\mathbb{C}^2)^{\otimes\mathcal{V}}$, with $D_v(g) = g$ for the sense up and $D_v(g) = \bar g$ for the sense down, $(\hat{\mathsf{K}}_D\Psi)(V) = \iint e^{-\beta A_\times(V,S,V')} D(S)\Psi(V')\,\mathrm{d}S\,\mathrm{d}V'$ and $\hat{\mathsf{T}}_D = M_0\hat{\mathsf{K}}_D M_0$. Then $\hat{\mathsf{T}}_D \ge 0$ and $\|\hat{\mathsf{T}}_D\|^{n_3} \le \operatorname{Tr}\hat{\mathsf{T}}_D^{n_3} = 2^{\#\mathcal{V}} Z\langle\prod_v p_{u(v)}\rangle$.

(b) Let $\#\mathcal{V}$ be even, m_τ the number of the $u(v)$ in the layer $\tau \in \{1,\dots,n_1\}$ of the direction 1, and ℓ the number of τ with $m_1 + \dots + m_\tau$ odd. If $\ell \le n_1/2$, then $|\langle\prod_v p_{u(v)}\rangle| \le 2z_-^{\ell/n_1}$.

(c) Let C be a closed lattice path in a cube of h layers, $h+1 \le \min_\mu n_\mu$, that runs bonds of the direction 3 in T gaps, $n_3 \ge T+2$; in the gap j let v_j be the number of these bonds and ℓ_j the number of integers α such that an odd number of them have first coordinate $\le \alpha$, and assume $\ell_j \le n_1/2$. Then, with r taken over the section (n_1, n_2),

$$|\langle W_C\rangle| \le 2^{c_3(C)-1}(1+\mathsf{r}_{n_3-T}) \prod_j \Big[2^{\mathsf{v}_j+1}(1+\mathsf{r}_{n_3}) z_-^{\ell_j/n_1}\Big]^{1/n_3}.$$

(d) Let D be a continuous unitary representation of G on $\mathbb{C}^d$ with $D(-\mathbf{1}) = -\mathbf{1}$, and $W_C^D = d^{-1}\operatorname{tr} D(U(C))$. Then (a)–(c) hold with $D_v = D$ for the sense up and $D_v = \overline{D}$ for the sense down, with $d^{-1}\operatorname{tr} D$ of the line that winds once along the direction 3 through ξ in the place of p_ξ, $d^{\#\mathcal{V}}$ in the place of $2^{\#\mathcal{V}}$, and W_C^D, $d^{c_3(C)-1}$, $2d^{\mathsf{v}_j}$ in the place of W_C, $2^{c_3(C)-1}$, 2^{v_j+1}. ■

Proof sketch. (a) As in Lem. 17.12(a), with $D(g^{-1}Q) = D(g)^{-1}D(Q)$; the trace of the n_3-th power gives $\prod_v \operatorname{tr} D_v(\mathsf{P}_{u(v)})$, and $\operatorname{tr}\bar g = \operatorname{tr} g$. (b) With the time 1, $Z\langle\prod_v p_{u(v)}\rangle = \operatorname{Tr}\prod_\tau(\mathsf{T}_0\hat{\mathsf{p}}^\tau)$, $\hat{\mathsf{p}}^\tau$ the multiplication by the product of the line functions of the layer τ. Each line holds one flipped bond, so $\hat{\mathsf{p}}^\tau$ maps the range of P_s to that of $P_{s(-1)^{m_\tau}}$; splitting the trace over $s = \pm$, the factor of the layer τ becomes $\mathsf{T}_0 P_{s_\tau}\hat{\mathsf{p}}^\tau$, with $s_\tau = -s$ for exactly ℓ layers. Hölder's inequality for the trace of the n_1 factors (Lem. YM3_I:86.1), and $\|\mathsf{C}\hat{\mathsf{p}}\|_{n_1}^{n_1} = \operatorname{Tr}(\mathsf{C}\hat{\mathsf{p}}^2\mathsf{C})^{n_1/2} \le \operatorname{Tr}\mathsf{C}^{n_1} = a_\pm$ for $\mathsf{C} = \mathsf{T}_0 P_\pm$ (by min–max, as $0 \le \mathsf{C}\hat{\mathsf{p}}^2\mathsf{C} \le \mathsf{C}^2$), bound the term of s by $a_s^{1-\ell/n_1} a_{-s}^{\ell/n_1}$. (c) Cut C into pieces in single layers and runs of the direction 3: $2W_C = \Gamma_0 D_0(S^0)\Gamma_1 \cdots D_{T-1}(S^{T-1})\Gamma_T$, where D_j is the tensor product over the runs of the gap j and Γ_j, a function of V^j, is the tensor product over the pieces of the layer j of unitary 2×2 matrices, of cups (linear forms on $\mathbb{C}^2\otimes\mathbb{C}^2$ with the entries of a matrix of G) and of caps (vectors with such entries).

Cups and caps have the norm $\sqrt{2}$ and occur at the changes from down to up and from up to down, $c_3(C)$ times each, so $\prod_j \sup_V \|\Gamma_j(V)\| = 2^{c_3(C)}$. As in Lem. 17.12(b), $2Z\langle W_C\rangle = \operatorname{Tr}(\mathsf{T}_0^{n_3-T}\mathsf{Q})$ with $\mathsf{Q} = \Gamma_0\hat{\mathsf{T}}_{D_0}\Gamma_1\cdots\hat{\mathsf{T}}_{D_{T-1}}\Gamma_T$; in an eigenbasis of T_0, $|\operatorname{Tr}(\mathsf{T}_0^{n_3-T}\mathsf{Q})| \le \|\mathsf{Q}\|\lambda_0^{n_3-T}(1+\mathsf{r}_{n_3-T})$, and (a), (b) bound $\|\hat{\mathsf{T}}_{D_j}\|^{n_3} \le 2^{\mathsf{v}_j+1}\lambda_0^{n_3}(1+\mathsf{r}_{n_3})z_-^{\ell_j/n_1}$; numbering the layers so that C lies in the layers $1,\dots,h$ makes the ℓ of (b) equal to ℓ_j. (d) The proofs of (a)–(c) use of the representation $g \mapsto g$ only that it is continuous and unitary, which gives the positivity of $\hat{\mathsf{T}}_D$ and pointwise unitary pieces in the layers, and that it changes its sign at $-\mathbf{1}$, which makes every line function odd under the flip and of modulus ≤ 1; a cup or a cap of D, a linear form or a vector with the entries of a matrix of $D(G)$, has the norm $\sqrt{d}$, and the trace over $(\mathbb{C}^d)^{\otimes\mathcal{V}}$ of the n_3-th power gives $d^{\#\mathcal{V}}Z$ times the mean of the product of the line functions. □

Lemma 17.14 (A floor at one length bounds the loops)**.** Let $\beta \ge 0$ and $L_1, L_2, L_3 \ge 3$ integers; take the first direction as time over the section (L_2, L_3), with its λ_0, r_s and Λ_-, and put $\phi = \log(\lambda_0/\Lambda_-) \in [0,\infty]$. Let C be a rectangle $R\times T$ of a $(1,3)$-plane with $1 \le R \le L_1 - 3$ and $1 \le T \le L_3 - 1$, and p_o, p_r the lines of Lem. 17.12 through its corners in one layer of the direction 3. Then

$$0 \le \langle W_C\rangle \le (4\langle p_o p_r\rangle)^{T/L_3}, \qquad \langle p_o p_r\rangle \le \frac{1+\mathsf{r}_{L_1-R}}{1+\mathsf{r}_{L_1}}\Big[e^{-\phi R} + z_-(L_1-R, L_2, L_3)\Big];$$

so, if $\phi > 0$, $\limsup_{L_1\to\infty} \langle W_C\rangle_{(L_1,L_2,L_3)} \le 4^{T/L_3} e^{-\phi R T/L_3}$. ■

Proof sketch. The first inequality is Lem. 17.12(c). With the time 1, as in the proof of Lem. 17.12(d), $Z\langle p_o p_r\rangle = \sum_\pm \operatorname{Tr}(\mathsf{T}_\pm^{L_1-R}\hat{\mathsf{p}}\,\mathsf{T}_\mp^{R}\hat{\mathsf{p}})$ with $\mathsf{T}_\pm = \mathsf{T}_0 P_\pm$ and $\|\hat{\mathsf{p}}\| \le 1$. The nonzero eigenvalues of T_- are those of the sectors 01 and 11, so $\|\mathsf{T}_-\| = \Lambda_-$, and $\|\mathsf{T}_+\| \le \lambda_0$. For $B \ge 0$ of trace class and $Y \ge 0$ bounded, $\operatorname{Tr}(BY) = \operatorname{Tr}(B^{1/2} Y B^{1/2}) \le \|Y\| \operatorname{Tr} B$. With $B = \mathsf{T}_+^{L_1-R}$ and $Y = \hat{\mathsf{p}}\mathsf{T}_-^R\hat{\mathsf{p}}$ the term of $+$ is $\le \Lambda_-^R \lambda_0^{L_1-R}(1+\mathsf{r}_{L_1-R})$; with $B = \mathsf{T}_-^{L_1-R}$ and $Y = \hat{\mathsf{p}}\mathsf{T}_+^R\hat{\mathsf{p}}$ the term of $-$ is $\le \lambda_0^R \operatorname{Tr}\mathsf{T}_-^{L_1-R} = \lambda_0^R a_-(L_1-R,L_2,L_3) = \lambda_0^{L_1}(1+\mathsf{r}_{L_1-R}) z_-(L_1-R,L_2,L_3)$. Divide by $Z = \lambda_0^{L_1}(1+\mathsf{r}_{L_1})$. As $L_1\to\infty$ the quotient of the thermal factors tends to 1, λ_0 being simple, and $z_-(s,L_2,L_3) \le \lambda_0^{-s}\operatorname{Tr}\mathsf{T}_-^s \le (\Lambda_-/\lambda_0)^{s-2}\lambda_0^{-2}\operatorname{Tr}\mathsf{T}_-^2 \to 0$ if $\phi > 0$. □

Lemma 17.15 (Flux weight and vortex line)**.**

(a) For integers $n_1' \ge n_1 \ge 3$, $n_3' \ge n_3 \ge 3$, $n_2 \ge 3$ and $\kappa = n_1' n_3'/(n_1 n_3)$, a real number,

$$a_-(n_1',n_2,n_3') \le a_-(\underline{n})^\kappa, \qquad z_-(n_1',n_2,n_3') \le \big[z_-(\underline{n})\, e^{\delta(\underline{n})}\big]^\kappa.$$

(b) For all integers $t, N, n \ge 3$, with $\varepsilon = \varepsilon_{\mathrm{v}}(t,N)$,

$$2z_-(t,n,N) \le n\varepsilon + \mathsf{r}_n(t,N), \qquad n\varepsilon \le \mathsf{r}_n(t,N) - \log(1-2z_-(t,2n,N)).$$

■

Proof sketch. (a) By Lem. 17.10(d), $a_- = \sum_i \mu_i^{n_1}$ with μ_i independent of n_1, so Lem. 17.11(d) with a real exponent gives $a_-(n_1',n_2,n_3) \le a_-(n_1,n_2,n_3)^{n_1'/n_1}$; the same holds in the third side, and $Z(n_1',n_2,n_3') \ge e^{\kappa|\underline{n}|P}$. (b) With the time along the column, $Z(t,n,N) = \lambda_0^n(1+\mathsf{r}_n)$ and $Z^-(t,n,N) = \sum_i \mu_i''^{\,n}$ with $\sup_i \mu_i'' = \lambda_0 e^{-\varepsilon}$; so $1-2z_- = Z^-/Z \ge e^{-n\varepsilon}/(1+\mathsf{r}_n) \ge 1-n\varepsilon-\mathsf{r}_n$. For the second inequality, which uses that the twisted spectrum is ≥ 0, $\sum \mu_i''^{\,2n} \le \lambda_-^n \sum \mu_i''^{\,n}$ gives $\lambda_-^n \ge Z^-(t,2n,N)/Z^-(t,n,N) \ge (1-2z_-(t,2n,N))\lambda_0^{2n}/(\lambda_0^n(1+\mathsf{r}_n))$. □

Proposition 17.16 (Recursion; excess and thermal numbers)**.** Let $\beta \ge 0$ and let $l \ge 3$ be an integer.

(a) With $\Sigma_1 = (l,l)$, $\Sigma_2 = (2l,l)$, $\Sigma_3 = (2l,2l)$ and $(d_1,d_2,d_3) = (d_1,d_2,\mathsf{e})$: $\log(1+\mathsf{r}_l(\Sigma_j)) \le d_j(l) \le 2\log(1+\mathsf{r}_l(\Sigma_j))$, and $X = 4d_1 + 2d_2 + \mathsf{e}$.

(b) If $Y_2(\mathsf{e}(l)) < \log 2$, then $d_1(2l) \le \omega(\mathsf{e}(l))$, $d_2(2l) \le \omega(Y_1(\mathsf{e}(l)))$, $\mathsf{e}(2l) \le \Psi(\mathsf{e}(l))$ and $X(2l) \le \Phi(\mathsf{e}(l))$.

(c) $\Psi(x) \le 12.9x^2$ and $\Phi(x) \le 19.89x^2$ for $0 < x \le 0.069$; $\Psi(x) \le 11.03x^2$ and $\Phi(x) \le 17.71x^2$ for $0 < x \le \frac{1}{20}$; $\Psi(x) < x$ for $0 < x < 0.0740538$.

(d) Under the criterion, for $n = 2^k l$, $k \ge 1$, and $x = \mathsf{e}(n/2) \le \theta^{n/2l}/12.9$:

$$\mathsf{r}_{n/2}(n,n) \le 0.51832\,x, \quad \mathsf{r}_{n/2}(2n,n) \le 1.09990\,x, \quad \mathsf{r}_{n/2}(2n,2n) \le 2.53905\,x;$$

$$\mathsf{r}_n(n,n) \le 0.001615\,\theta^{n/l},$$

$$\mathsf{r}_n(2n,n) \le 0.00732\,\theta^{n/l},$$

$\delta_{\mathrm{c}}(n) \le 0.01655\,\theta^{n/l}$, $d_1(n) \le 0.0032288\,\theta^{n/l}$, $d_2(n) \le 0.0145396\,\theta^{n/l}$; and $\delta_{\mathrm{c}}(N) < 0.1324\,\theta^{N/2l}$ for every integer $N \ge 2l$.

(e) Let $\tilde\omega(D) = 2\log(1+\varpi(e^D-1)^2) \le \omega(D)$, and let $\tilde Y_1, \tilde Y_2, \tilde\Psi, \tilde\Phi$ be Y_1, Y_2, Ψ, Φ with $\tilde\omega$ in the place of ω. Then (b) holds with $\tilde\omega$, $\tilde Y_1$, $\tilde\Psi$, $\tilde\Phi$. With $X_0 = 0.069$ and $X_{k+1} = \tilde\Psi(X_k)$, the iterates $X_1,\dots,X_5$ are 0.0604446, 0.0432902, 0.0195722, 0.0034309, 0.0000960 to the digits shown, the X_k decrease to 0, and $\bar\delta_j = \sum_{s\ge 0} 8^{-s-1}\tilde\Phi(X_{j-1+s})$ decreases in j, with $\bar\delta_4 \le 0.00073051$. If $\mathsf{e}(l) \le 0.069$, with no other hypothesis, then $\mathsf{e}(2^k l) \le X_k$ and $\delta_{\mathrm{c}}(2^j l) \le \bar\delta_j$ for all $k \ge 0$ and $j \ge 1$.

■

Proof sketch. (a) Double the sides of the cube one after the other: by (T1), X is the sum of $4[2F(l,l,l)-F(2l,l,l)]$, $2[2F(2l,l,l)-F(2l,2l,l)]$ and $2F(2l,2l,l)-F(2l,2l,2l)$, and each bracket is the D of Lem. 17.11 for $\kappa_i=\lambda_i(\Sigma_j)^l$. (b) Over $(2l,2l)$ with $\kappa_i=\lambda_i^l$: $D=\mathsf{e}(l)$ and $D'=d_1(2l)\le\omega(\mathsf{e})$. Doubling one side of the section at most doubles a defect, up to defects already bounded: by Lem. 17.11(d) with the time in the second direction, $F(l,4l,2l)\le 2F(l,2l,2l)$, so

$$2F(l,4l,2l)-F(2l,4l,2l)\le 2\mathsf{e}(l)+d_1(2l)\le Y_1(\mathsf{e}(l)),$$

and Lem. 17.11(c) over $(4l,2l)$ gives $d_2(2l)\le\omega(Y_1)$; in the same way $2F(l,4l,4l)-F(2l,4l,4l)\le Y_2$, and over $(4l,4l)$ one doubling of the time squares the defect: $\mathsf{e}(2l)\le\omega(Y_2)=\Psi$. Then (a) at $2l$. (c) $\varpi(x)/x$ and $(e^D-1)/D$ increase, so $\Psi(x)/x^2$ and $\Phi(x)/x^2$ do not decrease on $(0,0.0741]$; their values at 0.069 are 12.893528 and 19.881793, at $\frac{1}{20}$ they are 11.029686 and 17.709146, to the digits shown; $\Psi(x)/x$ increases; its positive fixed point lies in $(0.0740538,0.0740539)$, and $Y_2<\log 2$ throughout this interval. (d) Induction with (b), (c): $12.9\,\mathsf{e}(2^{k+1}l)\le(12.9\,\mathsf{e}(2^kl))^2$, so $\mathsf{e}(2^kl)\le\theta^{2^k}/12.9\le 0.069$ and $X(2^{k+1}l)\le\frac{19.89}{166.41}\theta^{2^{k+1}}\le 0.11953\,\theta^{2^{k+1}}$. At $l'=n/2$ the sections $(2l',2l')$, $(4l',2l')$, $(4l',4l')$ have at the time l' the defects x, $\le Y_1(x)$, $\le Y_2(x)$, and Lem. 17.11(b) with the monotone quotients at 0.069 gives the first three bounds. Then $\mathsf{r}_n=s_2\le\eta^2$ gives $\mathsf{r}_n(n,n)\le\frac12\omega(x)\le 0.268652\,x^2\le 0.001615\,\theta^{n/l}$, likewise $\mathsf{r}_n(2n,n)$, and $d_1(n)\le\omega(x)$, $d_2(n)\le\omega(Y_1(x))$. For the excess, the pressure cancels in $X(n)=8\delta_{\mathrm{c}}(n)-\delta_{\mathrm{c}}(2n)$, and Lem. 17.11(f) gives

$$\delta_{\mathrm{c}}(n)=\sum_{i\ge0}8^{-i-1}X(2^in)\le 0.11953\,\theta^{n/l}\sum_{i\ge0}8^{-i-1}\theta^{(2^i-1)n/l}\le 0.01655\,\theta^{n/l}.$$

For an integer N with $2^jl\le N<2^{j+1}l$, $j\ge1$, Lem. 17.11(f) gives $\delta_{\mathrm{c}}(N)\le 8\,\delta_{\mathrm{c}}(2^jl)\le 0.1324\,\theta^{2^j}<0.1324\,\theta^{N/2l}$. (e) By Lem. 17.11(b), (c), $D'\le 2\log(1+\eta^2)\le\tilde\omega(D)$, and the proof of (b) uses of ω only that it increases. The numbers $X_1,\dots,X_5$ and $\bar\delta_4$ are the values of the recursion $X_{k+1}=\tilde\Psi(X_k)$ from $X_0=0.069$ and of the series that defines $\bar\delta_4$; the X_k decrease to 0 because $\tilde\Psi\le\Psi$ and $\Psi(x)<x$ on $(0,0.0740538)$, and $\bar\delta_j$ decreases because $\tilde\Phi$ increases. If $\mathsf{e}(l)\le X_0$, the induction gives $\mathsf{e}(2^kl)\le X_k$, and $\delta_{\mathrm{c}}(2^jl)=\sum_{s\ge0}8^{-s-1}X(2^{j+s}l)\le\sum_s 8^{-s-1}\tilde\Phi(X_{j+s-1})=\bar\delta_j$. □

Proposition 17.17 (Vortex lines on tubes)**.** Assume the criterion; put $l_j=2^{j+1}l$ and $w=2^j$.

(a) $l'\varepsilon_{\mathrm{v}}(l')\le 0.01643\,\theta^{l'/l}$ for $l'=2^kl$, $k\ge1$.

(b) Let $l'=2^kl$, $k\ge1$, $l'\varepsilon_{\mathrm{v}}(l')\le e^{-E}$, $\hat N\ge2$ an integer, $y=\hat Ne^{-E}$, $\mathsf{t}=\theta^{l'/l}$, $\bar z_1=y+\frac12(0.001615\,\mathsf{t})^{2\hat N}$ and $\bar z_2=\bar z_1^4e^{8\hat N\cdot0.01655\,\mathsf{t}}<\frac12$. Then

$$2l'\varepsilon_{\mathrm{v}}(2l')\le\frac{2}{\hat N}\Big\{(0.001615\,\mathsf{t}^2)^{\hat N/2}+\frac{2\bar z_2}{1-2\bar z_2}\Big\}.$$

(c) $l_j\varepsilon_{\mathrm{v}}(l_j)\le e^{-\sigma^+l_j^2}$ for all $j\ge0$.

(d) For real $M\ge w\mathsf{q}$ with Ml_j an integer: $z_-(l_j,Ml_j,l_j)\le Me^{-\varsigma w^2}$ and $\delta(l_j,Ml_j,l_j)\le 0.01655\,M\theta^{l_j/l}$.

(e) Let $l'=l_j$ and let $N_3\ge l'$ and $n_2\ge\mathsf{q}l'^2/2l$ be integers. Over the section (n_2,N_3), with the first direction as time, the top Λ_- of the sectors odd under the flip of the side N_3 lies at least $\sigma^+N_3-\frac{N_3}{l'^2}\big[\log\frac{n_2}{l'}+0.01655\,\frac{n_2}{l'}\theta^{l'/l}\big]$ above the vacuum.

■

Proof sketch. (a) The second inequality of Lem. 17.15(b) at $t=N=n=l'$, with $z_-(l',2l',l')\le\mathsf{r}_{l'}(2l',l')\le 0.00732\,\mathsf{t}$ (Lem. 17.10(b), the time 1) and $\mathsf{r}_{l'}(l',l')\le 0.001615\,\mathsf{t}$ (Prop. 17.16(d)). (b) Three moves. The first inequality of Lem. 17.15(b) on the box $(l',2\hat Nl',l')$, with $\mathsf{r}_{2\hat Nl'}(l',l')\le\mathsf{r}_{l'}(l',l')^{2\hat N}$ (Lem. 17.11(e)), gives $z_-\le\bar z_1$. Lem. 17.15(a) with $\kappa=4$ passes to the box $(2l',2\hat Nl',2l')$, a fourth power at the cost $e^{4\delta}$, with $\delta(l',2\hat Nl',l')\le 2\hat N\delta_{\mathrm{c}}(l')$. The second inequality of Lem. 17.15(b) for the tube $2l'\times2l'$ at the time $\hat Nl'$, with $\mathsf{r}_{\hat Nl'}(2l',2l')\le\mathsf{r}_{2l'}(2l',2l')^{\hat N/2}$, returns to the vortex line.

(c) Take $\hat N_j = 4\cdot 3^j$ and write $\mathsf{t}_j = \theta^{l_j/l} = e^{-2^j\cdot 2\Lambda}$. For real E and $\mathsf{t}\in(0,1]$ let $\mathsf{H}_j(E,\mathsf{t})$ be the right member of (b) at $l'=l_j$ and $\hat N=\hat N_j$, formed with $y=\hat N_j e^{-E}$, $\bar z_1 = y+\frac12(0.001615\,\mathsf{t})^{2\hat N_j}$ and $\bar z_2 = \bar z_1^4 e^{8\hat N_j\cdot 0.01655\,\mathsf{t}}$, where $\bar z_2<\frac12$. Identically $\mathsf{H}_j = \frac{2}{\hat N_j}y^4 e^{8\hat N_j\cdot 0.01655\,\mathsf{t}}\mathsf{B}_j$, that is,

$$-\log\mathsf{H}_j(E,\mathsf{t}) = 4E - 3\log\hat N_j - 8\hat N_j\cdot 0.01655\,\mathsf{t} - \log(2\mathsf{B}_j),\qquad \mathsf{B}_j = \frac{(0.001615\,\mathsf{t}^2)^{\hat N_j/2}}{y^4\,e^{8\hat N_j\cdot 0.01655\,\mathsf{t}}} + \frac{2(\bar z_1/y)^4}{1-2\bar z_2}.$$

One value of θ serves all. Let $\Delta = 2\Lambda - 0.23284$, which is ≥ 0 as $2\log\frac{1}{0.8901}\ge 0.23284$, and $\mathring{\mathsf{t}}_j = e^{-2^j\cdot 0.23284}$, the value of t_j at $2\Lambda=0.23284$, so that $\mathsf{t}_j = \mathring{\mathsf{t}}_j e^{-2^j\Delta}$. Let $E_0=4.3414$, and let $E_1,E_2,\dots$ be numbers with $E_{j+1}\le -\log\mathsf{H}_j(E_j,\mathring{\mathsf{t}}_j)$, $\bar z_2<\frac12$ at $(E_j,\mathring{\mathsf{t}}_j)$. Then $l_j\varepsilon_{\rm v}(l_j)\le e^{-E_j-4^j\Delta}$ for all $j\ge 0$ and every $\theta\le 0.8901$. At $j=0$ this is (a) at $l'=2l$, as $0.01643\,\theta^2 = \exp[-\log\frac{1}{0.01643}-0.23284-\Delta]$ and $\log\frac{1}{0.01643}+0.23284\ge 4.3414$. From j to $j+1$ apply (b) with $E=E_j+4^j\Delta$ and $\mathsf{t}=\mathsf{t}_j$, and compare each number with its value at $(E_j,\mathring{\mathsf{t}}_j)$: y is that value times $e^{-4^j\Delta}$; $(0.001615\,\mathsf{t})^{2\hat N_j}$ is it times $e^{-2^{j+1}\hat N_j\Delta}\le e^{-4^j\Delta}$; so $\bar z_1$ is at most it times $e^{-4^j\Delta}$; as $e^{8\hat N_j\cdot 0.01655\,\mathsf{t}}$ increases in t, $\bar z_2$ is at most it times $e^{-4^{j+1}\Delta}$, and so is $\frac{2\bar z_2}{1-2\bar z_2}$, as $u\mapsto 1/(1-2u)$ increases; and $(0.001615\,\mathsf{t}^2)^{\hat N_j/2}$ is it times $e^{-2^j\hat N_j\Delta}\le e^{-4^{j+1}\Delta}$, as $\hat N_j\ge 4\cdot 2^j$.

So each of the two terms of the right member of (b) is at most its value at $(E_j,\mathring{\mathsf{t}}_j)$ times $e^{-4^{j+1}\Delta}$, and

$$l_{j+1}\varepsilon_{\rm v}(l_{j+1})\le \mathsf{H}_j(E_j+4^j\Delta,\mathsf{t}_j)\le \mathsf{H}_j(E_j,\mathring{\mathsf{t}}_j)\,e^{-4^{j+1}\Delta}\le e^{-E_{j+1}-4^{j+1}\Delta}.$$

Numerical bounds. The functions in the recursion are explicit and monotone on the intervals used above. Outward interval evaluation gives

x	$\Psi(x)/x^2$	$\Phi(x)/x^2$
0.069	$(12.89352831, 12.89352832)$	$(19.88179283, 19.88179284)$
0.05	$(11.02968611, 11.02968612)$	$(17.70914610, 17.70914611)$.

For the successive lower bounds $E_0,\dots,E_6$ below, the differences $-\log\mathsf{H}_j(E_j,\mathring{\mathsf{t}}_j)-E_{j+1}$ exceed, respectively,

$$9.7\cdot 10^{-5},\quad 5.1\cdot 10^{-5},\quad 3.8\cdot 10^{-6},\quad 6.4\cdot 10^{-5},\quad 3.5\cdot 10^{-5},\quad 7.6\cdot 10^{-5}.$$

In each evaluation $\bar z_2<1/2$. The geometric tail displayed below gives a lower bound greater than 1.909266. The sharper defect recursion likewise gives $\bar\delta_4<0.00073051$. These bounds justify the directions of rounding used in the argument.

The numbers at $2\Lambda=0.23284$. There B_j is a number close to 2, and one may take $E_1,\dots,E_6 =$ 11.3558, 35.5848, 128.3243, 495.6445, 1962.8155, 7829.1628, each at most $-\log\mathsf{H}_j(E_j,\mathring{\mathsf{t}}_j)$ at the one before. For $j\ge 6$ the losses $3\log\hat N_j + 8\hat N_j\cdot 0.01655\,\mathring{\mathsf{t}}_j + \log(2\mathsf{B}_j)$ are at most $3\log\hat N_j+\log 4.01$, so that $E_{j+1}=4E_j-3\log\hat N_j-\log 4.01$ may be taken, and this closed recursion gives

$$4^{-j}E_j\ge 4^{-6}E_6 - \sum_{i\ge 6}4^{-i-1}(3\log 4+3i\log 3+\log 4.01)\ge 1.909266.$$

So $4^{-j}E_j\ge 0.23284+1.67$ for every $j\ge 0$, hence $4^{-j}(E_j+4^j\Delta)\ge 2\Lambda+1.67$, and $l_j\varepsilon_{\rm v}(l_j)\le\exp[-4^j(2\Lambda+1.67)] = e^{-\sigma^+ l_j^2}$. (d) The first inequality of Lem. 17.15(b) with $n=Ml_j$, (c), and $\mathsf{r}_{Ml_j}(l_j,l_j)\le(0.001615\,\theta^{2w})^M\le e^{-2\Lambda Mw}\le e^{-\varsigma w^2}$, as $2\Lambda\mathsf{q}=\varsigma$, give $2z_-\le(M+1)e^{-\varsigma w^2}$; Lem. 17.11(f) gives $\delta\le M\delta_{\rm c}(l_j)$. (e) For every integer $t\ge l'$, by Lem. 17.10(d) and Lem. 17.15(a) at the real factors t/l' and N_3/l', $\Lambda_-^t\le a_-(t,n_2,N_3)\le a_-(l',n_2,l')^{tN_3/l'^2}$; so $\log\Lambda_-\le\frac{N_3}{l'^2}[F+\log z_-](l',n_2,l')$, while $\log\lambda_0(n_2,N_3)\ge n_2N_3P$. Subtracting, $\log(\lambda_0/\Lambda_-)\ge\frac{N_3}{l'^2}[-\log z_--\delta](l',n_2,l')$, and (d) with $M=n_2/l'\ge w\mathsf{q}$ bounds the bracket below by $\varsigma w^2-\log M-0.01655\,M\theta^{l'/l}$, with $\varsigma w^2=\sigma^+l'^2$. □

Proposition 17.18 (Slabs)**.** For integers $N, a, b, t \geq 3$ let $\mathsf{e}^{(N)}(t) = 2F(t, 2t, N) - F(2t, 2t, N)$, $d^{(N)}(t) = 2F(t, t, N) - F(2t, t, N)$, $P^{(N)} = \inf_{a,b} F(a, b, N)/ab$ and $\delta^{(N)}(a, b) = F(a, b, N) - abP^{(N)}$.

(a) For every $\beta \geq 0$: $0 \leq \delta^{(N)}(a, b) \leq \delta(a, b, N)$, $\delta^{(N)}(a, b)/ab$ does not increase in a or b, $\delta^{(N)}(a, a)/a^2 \to 0$, and $\log(1 + \mathsf{r}_a(b, N)) \leq \delta^{(N)}(a, b)$; if $Y_1(\mathsf{e}^{(N)}(t)) < \log 2$, then $d^{(N)}(2t) \leq \omega(\mathsf{e}^{(N)}(t))$ and $\mathsf{e}^{(N)}(2t) \leq \omega(Y_1(\mathsf{e}^{(N)}(t)))$.

Assume now the criterion.

(b) Let $n_0 = 2^k l \leq N < 2n_0$, $k \geq 1$, $\chi' = 0.3602\,\theta^{n_0/l}$ and $t_i = 2^i n_0$. Then $2.72\,\mathsf{e}^{(N)}(t_i) \leq \chi'^{2^i}$, $\delta^{(N)}(t_i, t_i) \leq 0.133\,\chi'^{2^i}$, $\delta^{(N)}(n_0, n_0) \leq 0.01655\,\frac{N}{n_0}\theta^{n_0/l}$, $\mathsf{r}_{t_i}(t_i, N) \leq 0.14\,\chi'^{2^i}$, and $\mathsf{r}_{t_i}(b, N) \leq 0.28\,\chi'^{2^i}$ for $t_i \leq b < 2t_i$.

(c) Let $N = 2^k l$, $k \geq 1$, $\chi = 0.03\,\theta^{N/l}$ and $t_i = 2^i N$. Then $2.06\,\mathsf{e}^{(N)}(t_i) \leq \chi^{2^i}$, $d^{(N)}(t_i) \leq 0.1202\,\chi^{2^i}$, $\mathsf{r}_{t_i}(t_i, N) \leq 0.0613\,\chi^{2^i}$, $\mathsf{r}_{t_i}(2t_i, N) \leq \chi^{2^i}$ and $\delta^{(N)}(t_i, t_i) \leq 0.1826\,\chi^{2^i}$. If moreover $N = 2wl$ with $w \geq 2$, and $\hat{N}$, g are as in Thm. AW(g1), then $t_i\varepsilon_{\mathrm{v}}(t_i, N) \leq \exp[-2^i(\sigma^+ N^2 - \mathsf{g})]$ for all $i \geq 0$.

■

Proof sketch. (a) The slab of thickness N is a datum in two dimensions: $(a, b) \mapsto F(a, b, N)$ is symmetric and has the trace formula in each variable, so Lem. 17.11 and the proof of Prop. 17.16(b) go over with one side of the section frozen; $P^{(N)} \geq NP$ gives $\delta^{(N)} \leq \delta(\cdot, \cdot, N)$. (b) The pressures cancel at the start: $\mathsf{e}^{(N)}(n_0) \leq 2\delta(n_0, 2n_0, N) \leq 4\frac{N}{n_0}\delta_{\mathrm{c}}(n_0) < 0.1324\,\theta^{n_0/l} \leq 0.1049$. On $(0, 0.1049]$, $\omega(Y_1(x)) \leq 2.72x^2$ and $\omega(x) \leq 0.5593x^2$, so $2.72\,\mathsf{e}^{(N)}(t_{i+1}) \leq (2.72\,\mathsf{e}^{(N)}(t_i))^2$ and $2.72\,\mathsf{e}^{(N)}(n_0) \leq \chi'$. Since $4F(t, t, N) - F(2t, 2t, N) = 2d^{(N)}(t) + \mathsf{e}^{(N)}(t) = 4\delta^{(N)}(t, t) - \delta^{(N)}(2t, 2t)$, and for $i \geq 1$, $2d^{(N)}(t_i) + \mathsf{e}^{(N)}(t_i) \leq (2 \cdot 0.5593 + 2.72)\,\mathsf{e}^{(N)}(t_{i-1})^2 \leq 0.518842\,\chi'^{2^i}$, summation with the weights 4^{-j-1} gives $\delta^{(N)}(t_i, t_i) \leq 0.13236\,\chi'^{2^i}$ for $i \geq 1$; at $i = 0$, $\delta^{(N)}(n_0, n_0) \leq \delta(n_0, n_0, N) \leq \frac{N}{n_0}\delta_{\mathrm{c}}(n_0) < 0.0331\,\theta^{n_0/l} \leq 0.0919\,\chi'$.

Finally $\log(1 + \mathsf{r}_{t_i}(b, N)) \leq \delta^{(N)}(t_i, b) \leq \frac{b}{t_i}\delta^{(N)}(t_i, t_i)$. (c) At the dyadic thickness the start is $\mathsf{e}^{(N)}(N) = d_2(N) \leq 0.0145396\,\theta^{N/l} \leq 0.01152$ and $d^{(N)}(N) = d_1(N) \leq 0.0032288\,\theta^{N/l}$; for $x \leq 0.0116$, $\omega(Y_1(x)) \leq 2.06x^2$, $\omega(x) \leq 0.5059x^2$ and $e^x - 1 \leq 1.006x$, and for $D \leq 0.00286$, $\varpi(e^D - 1) \leq 0.5008D$. So $2.06\,\mathsf{e}^{(N)}(t_i) \leq \chi^{2^i}$; $d^{(N)}(t_i) \leq 0.5059\,\mathsf{e}^{(N)}(t_{i-1})^2 \leq 0.1202\,\chi^{2^i}$; Lem. 17.11(b) over (t_i, N) gives $\mathsf{r}_{t_i}(t_i, N) \leq 0.5008\,d^{(N)}(t_i)$, and Lem. 17.11(a) over $(2t_i, N)$ gives $\mathsf{r}_{t_i}(2t_i, N) \leq e^{\mathsf{e}^{(N)}(t_i)} - 1$; the sum with the weights 4^{-j-1} gives the bound on $\delta^{(N)}$.

In the flat tubes $t \times N$ one doubling of the width squares $t\varepsilon_{\mathrm{v}}(t, N)$. At $i = 0$, Prop. 17.17(c) gives $N\varepsilon_{\mathrm{v}}(N, N) \leq e^{-E_0}$, $E_0 = \sigma^+ N^2$. From $t = t_i$ to $2t$, with $n = \hat{N}t$ and $y_i = \hat{N}e^{-E_i}$: the first inequality of Lem. 17.15(b) at the time $2n$, with $\mathsf{r}_{2n}(t, N) \leq \mathsf{r}_t(t, N)^{2\hat{N}} \leq e^{-4E_i}$, gives $z_-(t, 2n, N) \leq (1 + 10^{-7})y_i$; Lem. 17.15(a) with $\kappa = 2$ in the width squares it at the cost $2F(t, 2n, N) - F(2t, 2n, N) \leq 4\hat{N}\delta^{(N)}(t, t) \leq \xi_i := 0.732\,\hat{N}\chi^{2^i}$; and the second inequality of Lem. 17.15(b) for the tube $2t \times N$ at the time n gives

$$2t\,\varepsilon_{\mathrm{v}}(2t, N) \leq 4.01\,\hat{N}e^{-2E_i + \xi_i} =: e^{-E_{i+1}}.$$

As $\hat{N}\chi \leq 0.7936$, $\sum_i 2^{-i-1}\xi_i \leq 0.294$, and $2^{-i}E_i \geq \sigma^+ N^2 - \log\hat{N} - \log 4.01 - 0.294 \geq \sigma^+ N^2 - \mathsf{g}$. □

Proposition 17.19 (Flux lines of every integer length)**.** Assume the criterion; let $N \geq 4l$ be an integer, n_0, κ, τ, χ_0, E_0, $\hat{N}'$, h and g' as in Thm. AW(g2), $\mathsf{E} = \sigma^+ n_0^2$ and $t_i = 2^i n_0$. Then $6 \leq \hat{N}' < \mathsf{q}N/l + 2$, $\hat{N}' \leq 1.3453\,\mathsf{E}_0 + 2$, $\mathsf{h} \leq 0.4274\,\kappa + 0.0208$, and $t_i\varepsilon_{\mathrm{v}}(t_i, N) \leq \exp[-2^i(\mathsf{E}_0 - \mathsf{g}')]$ for all $i \geq 0$. ■

Proof sketch. Numbers. $\log\frac{1}{\chi_0} = -\log 0.3602 + 2w\Lambda \geq 1.48677$; the bounds on $\hat{N}'$ follow from $2\mathsf{E}_0/\log\frac{1}{\chi_0} < 2\kappa\mathsf{q}w = \mathsf{q}N/l$, from the fact that the quotient exceeds 4 at $w = 2$ and increases in w, and from $2/1.48677 \leq 1.3453$. As $\tau = \theta^{2w} \leq 0.8901^4$, the number $c_\tau = 0.01655\,\tau$ satisfies

$c_\tau \le 0.010389$, and $\mathsf{h} = c_\tau \hat N'$. With $4\mathsf{q}\cdot 0.01655\, we^{-2w\Lambda} \le 0.8548$ (as in the proof of Thm. AW(d)), $\mathsf{h} < 0.01655(2\kappa\mathsf{q}w+2)\tau \le 0.4274\kappa + 0.0208$. By the choice of $\hat N'$, $\chi_0^{\hat N'/2} \le e^{-\mathsf{E}_0}$. Here $\mathsf{E}_0 = \kappa\mathsf{E}$ and $\mathsf{E} = \sigma^+ n_0^2 = \varsigma w^2 \ge 4\cdot 1.90284 = 7.61136$. For $\kappa\in[1,2]$, $E \ge 7.6$ and $0 < c \le 0.052$ the functions

$$\gamma_c(\kappa, E) = \kappa\big[\log(1.3453\,\kappa E + 2) + c\,(1.3453\,\kappa E + 2) - E\big]$$

increase in c, are convex in κ and decrease in E. As $\log\hat N' \le \log(1.3453\,\kappa\mathsf{E}+2)$ and $\mathsf{h} \le c_\tau(1.3453\,\kappa\mathsf{E}+2)$,

$$\log\big[\hat N' e^{-\mathsf{E}+\mathsf{h}}\big]^\kappa \le \gamma_{0.010389}(\kappa,\mathsf{E}), \qquad \log\big[\hat N' e^{-\mathsf{E}+5\mathsf{h}}\big]^\kappa \le \gamma_{0.051945}(\kappa,\mathsf{E}), \qquad 0.051945 = 5\cdot 0.010389.$$

On $\kappa\in[1,2]$, $E \ge 7.61136$ each of the two functions is largest at $E = 7.61136$ and at $\kappa = 1$ or $\kappa = 2$, where $\gamma_{0.010389}$ has approximate values -4.97953 and -8.53047, and $\gamma_{0.051945}$ approximate values -4.47090 and -6.66219. So $\bar z_0 := [\hat N' e^{-\mathsf{E}+\mathsf{h}}]^\kappa \le e^{-4.97952} \le 0.00688$ and $6.1\,[\hat N' e^{-\mathsf{E}+5\mathsf{h}}]^\kappa \le 6.1\,e^{-4.47090} \le 0.0698$. *The start.* The first inequality of Lem. 17.15(b) for the tube $n_0\times n_0$ at the time $\hat N' n_0$, Prop. 17.17(c) and $\mathsf{r}_{\hat N' n_0}(n_0,n_0) \le \chi_0^{\hat N'} \le e^{-\mathsf{E}}$ give $z_-(n_0, \hat N' n_0, n_0) \le \hat N' e^{-\mathsf{E}}$; with $\delta(n_0, \hat N' n_0, n_0) \le \hat N' \delta_{\mathrm c}(n_0) \le \mathsf{h}$, Lem. 17.15(a) at the real factor κ in the third side gives $z_-(n_0, \hat N' n_0, N) \le \bar z_0$; and the second inequality of Lem. 17.15(b) for the tube $n_0\times N$ at the time $\hat N' n_0/2$, with $\mathsf{r}_{\hat N' n_0/2}(n_0,N) \le (0.14\chi_0)^{\hat N'/2} \le \bar z_0$ (Prop. 17.18(b)), gives $n_0\varepsilon_{\mathrm v}(n_0,N) \le \frac{6.1}{\hat N'}\bar z_0 = e^{-E_0'}$, $E_0' = \mathsf{E}_0 - (\kappa-1)\log\hat N' - \kappa\mathsf{h} - \log 6.1$.

The recursion. As in Prop. 17.18(c), with the slab of the integer thickness N of Prop. 17.18(b), one doubling of the width squares $t\varepsilon_{\mathrm v}(t,N)$: $E_{i+1}' = 2E_i' - \log\hat N' - \log 4.1 - \xi_i'$, with $\xi_0' = 4\kappa\mathsf{h}$ and $\xi_i' = 0.532\,\hat N'\chi_0^{2^i}$ for $i\ge 1$; the bound $6.1[\hat N' e^{-\mathsf{E}+5\mathsf{h}}]^\kappa \le 0.0698$ keeps $y_i = \hat N' e^{-E_i'}$ so small that the step closes at every i, and $\sum_i 2^{-i-1}\xi_i' \le (2\kappa+0.68)\mathsf{h}$. Hence $2^{-i}E_i' \ge E_0' - \log\hat N' - \log 4.1 - (2\kappa + 0.68)\mathsf{h} \ge \mathsf{E}_0 - \mathsf{g}'$, as $\log 6.1 + \log 4.1 \le 3.22$. More precisely, the unused positive tail of this same recurrence gives

$$\begin{aligned} E_i' &= 2^i\Big(E_0' - \log\hat N' - \log 4.1 - \sum_{j\ge 0} 2^{-j-1}\xi_j'\Big) + \log\hat N' + \log 4.1 + \sum_{j\ge i} 2^{i-j-1}\xi_j' \\ &\ge 2^i(\mathsf{E}_0 - \mathsf{g}') + \log\hat N' + \log 4.1 + \tfrac12\xi_i'. \end{aligned}$$

Thus subtracting $\log\hat N' + \xi_i'/4$ still leaves the floor $2^i(\mathsf{E}_0 - \mathsf{g}')$, also at $i = 0$. □

Proposition 17.20 (A local function in a long box)**.** Let $\beta \ge 0$, Σ a section, $h \ge 1$ and $t \ge h+2$ integers, $s = t - h - 1$, and A a bounded Borel function of the variables of h consecutive layers and of the crossings between them. There is a number $a_\infty(\Sigma, A)$, $|a_\infty| \le \sup|A|$, that depends neither on t nor on the position of the layers, with $|\langle A\rangle_{(t,\Sigma)} - a_\infty(\Sigma,A)| \le 2\sup|A|\,\mathsf{r}_s(\Sigma)$. As $\mathsf{r}_s(\Sigma)\to 0$, the laws of the boxes (t,Σ) converge, as $t\to\infty$, on the bounded Borel functions of finitely many layers: to the law of the infinite cylinder over Σ. ■

Proof sketch. Integrating the weights of the h layers and the $h+1$ crossings with A inserted gives a kernel $\hat A$ dominated by $\sup|A|$ times that of T_0^{h+1}, so $\|\hat A\| \le \sup|A|\lambda_0^{h+1}$, and $Z\langle A\rangle = \mathrm{Tr}(\mathsf{T}_0^s\hat A) = \sum_i \lambda_i^s\langle e_i, \hat A e_i\rangle$ in an eigenbasis. With $a_\infty = \lambda_0^{-h-1}\langle e_0, \hat A e_0\rangle$, which is determined because λ_0 is simple: $Z\langle A\rangle = \lambda_0^t(a_\infty + \vartheta\sup|A|\,\mathsf{r}_s)$ with $|\vartheta|\le 1$, and $Z = \lambda_0^t(1+\mathsf{r}_t)$. The thermal number tends to 0 by dominated convergence, λ_0 being simple and $\sum\lambda_i^2 < \infty$; the limits are consistent, and Kolmogorov's theorem gives the law of the cylinder. □

Lemma 17.21 (Mirrors of a box)**.** Fix a box and a direction μ as time; let $c\in\mathbb{Z}+\frac12$, and $\mathfrak{r}$ the reflection $x_\mu \mapsto 2c - x_\mu$ of the box.

(a) Let $\vartheta \ge 2$ be an integer with $2\vartheta \le n_\mu$, and A a bounded Borel function of the bonds with both ends in the ϑ layers below c. Then $\langle A\,\overline{\mathfrak{r}A}\rangle \ge 0$ and $|\langle A\rangle|^2 \le \langle A\,\overline{\mathfrak{r}A}\rangle$; n_μ may be odd. If $n_\mu = 2\vartheta$ and A' is another such function, $|\langle A\,\mathfrak{r}\overline{A'}\rangle|^2 \le \langle A\,\overline{\mathfrak{r}A}\rangle\langle A'\,\overline{\mathfrak{r}A'}\rangle$.

(b) Let $N = 2h \geq 4$, $c \in (\mathbb{Z} + \frac{1}{2})^3$, and H_ϵ, $\epsilon \in \{0,1\}^3$, functions of the cell $\mathsf{C}_h(c)$. On the cube (N,N,N), $|\langle \prod_\epsilon H_\epsilon^{[\epsilon]} \rangle| \leq \prod_\epsilon |||H_\epsilon|||_N$; so $|||\cdot|||_N$ is a seminorm, $|\langle A \rangle_{(N,N,N)}| \leq |||A|||_N \leq \sup |A|$, the mean of the product of the copies of A over $\epsilon \in E$ is at most $|||A|||_N^{\#E}$ in modulus for every $E \subset \{0,1\}^3$, and $|||A|||_N^8 \leq \langle |A|^8 \rangle_{(N,N,N)}$.

(c) Let n_μ be even and the mirror lie between the layers 0 and 1 of the direction μ; let x_p, x_q be two sites of the layer 1, equal or not, z_p, z_q the values of U at the bonds from x_p to $\mathfrak{r} x_p$ and from x_q to $\mathfrak{r} x_q$, and A_{jk}, $j,k \in \{1,2\}$, bounded Borel functions of the bonds with both ends in the layers $1, \dots, n_\mu/2$. Then

$$\Big\langle \sum_{i,j,k,l} \overline{(\mathsf{z}_p)_{ji}}\, (\mathsf{z}_q)_{kl}\, A_{jk}\, \overline{\mathfrak{r} A_{il}} \Big\rangle \geq 0.$$

■

Proof sketch. Let $\mathsf{T}' = \mathsf{K}^{1/2} M_0^2 \mathsf{K}^{1/2}$, which has the eigenvalues of T_0. For a function A of ϑ consecutive layers and the $\vartheta - 1$ crossings between them let S_A be the operator whose kernel, a function of the first and the last of these layers, is the integral of A against the weights of the ϑ layers and of the inner crossings over all other variables, and $\mathsf{Y}_A = \mathsf{K}^{1/2} \mathsf{S}_A \mathsf{K}^{1/2}$, a Hilbert–Schmidt operator; $\mathsf{Y}_1 = \mathsf{T}'^{\vartheta}$. Integrating the layers in turn as in Lem. 17.10, the mean of a product of such functions on consecutive slabs, with free layers between them, is the trace of the product of their operators and of powers of T'; and, the weights being invariant under $\mathfrak{r}$ because $A_\times(V', S^{-1}, V) = A_\times(V, S, V')$, the operator of $\overline{\mathfrak{r} A}$ on the mirrored slab is Y_A^*.

So $Z\langle A \rangle = \operatorname{Tr}(\mathsf{T}'^{n_\mu - \vartheta} \mathsf{Y}_A)$ and $Z\langle A\, \overline{\mathfrak{r} A'} \rangle = \operatorname{Tr}(\mathsf{T}'^{n_\mu - 2\vartheta} \mathsf{Y}_{A'}^* \mathsf{Y}_A)$. (a) Write $\operatorname{Tr}(\mathsf{T}'^{n_\mu - \vartheta} \mathsf{Y}_A) = \operatorname{Tr}(\mathsf{T}'^{n_\mu/2} \cdot \mathsf{Y}_A \mathsf{T}'^{v})$ with $v = \frac{1}{2}(n_\mu - 2\vartheta) \geq 0$, a real power of a positive operator; Schwarz's inequality for Hilbert–Schmidt operators gives $|Z\langle A \rangle|^2 \leq \operatorname{Tr} \mathsf{T}'^{n_\mu} \, \|\mathsf{Y}_A \mathsf{T}'^{v}\|_2^2 = Z \cdot Z\langle A\, \overline{\mathfrak{r} A} \rangle$, with $\|\mathsf{Y}_A \mathsf{T}'^{v}\|_2^2 = \operatorname{Tr}(\mathsf{T}'^{2v} \mathsf{Y}_A^* \mathsf{Y}_A) \geq 0$; at $n_\mu = 2\vartheta$, Schwarz's inequality for $\operatorname{Tr}(\mathsf{Y}_{A'}^* \mathsf{Y}_A)$ is the second statement. (b) The reflection $\mathfrak{r}_\mu$ of the cube fixes the two bond mirrors $x_\mu = c_\mu$ and $x_\mu = c_\mu + h$, and the half below the first of them is the slab of the cell.

Group the eight factors into the four with $\epsilon_\mu = 0$ and their four mirror images: the second statement of (a) gives $|\Lambda(H)|^2 \leq \Lambda(H^0)\Lambda(H^1)$ for $\Lambda(H) = \langle \prod_\epsilon H_\epsilon^{[\epsilon]} \rangle$, where H^j is the family with the index ϵ_μ set to j; three directions give the first bound, and the mean of the eight copies of one function is ≥ 0. Expanding $|||H + H'|||_N^8$ into 2^8 such means gives the triangle inequality. With $H_\epsilon = A$ for $\epsilon \in E$ and $H_\epsilon = 1$ otherwise one gets the bound for subsets; Hölder's inequality with eight exponents 8 and the invariance of the cube law under the $\mathfrak{r}_\mu$ give the last bound. (c) Take μ as time; the mirror also fixes the plane between the layers $n_\mu/2$ and $n_\mu/2 + 1$.

Integrating in each half the layers and crossings between its two outer layers produces from A_{jk} a function Φ_{jk} of $(V^1, V^{n_\mu/2})$, and from $\overline{\mathfrak{r} A_{il}}$, by the symmetry of the weights, $\overline{\Phi_{il}}$ at the mirrored layers 0 and $n_\mu/2 + 1$. The crossing between the layers 0 and 1 carries the two cut bonds, which enter exactly as in the operator $\hat{\mathsf{K}}$ of Lem. 17.12 with the charges at the sites of x_p and x_q: the function under the mean is $\operatorname{tr}[(\overline{\mathfrak{r} A})^{\mathrm{t}} \mathsf{z}_p^{-1} A\, \mathsf{z}_q]$ for the matrices $A = (A_{jk})$, $\overline{\mathfrak{r} A} = (\overline{\mathfrak{r} A_{il}})$. The crossing between $n_\mu/2$ and $n_\mu/2 + 1$ enters through K.

Hence Z times the mean equals $\langle \Phi, (\hat{\mathsf{K}} \otimes \mathsf{K}) \Phi \rangle \geq 0$, by Lem. 17.12(a), (e), whose proof uses of the two sites only that they lie in the section, and the positivity of K. □

Lemma 17.22 (Comparison of a functional with its dominant state)**.** Let $\mathcal{A}$ be a real vector space with an element 1, N a seminorm and g a linear functional on $\mathcal{A}$ such that, with $\mathsf{R}(x) = (1+x)^8 - 1 - 8x$,

$$\mathsf{N}(1 + tG)^8 \leq 1 + 8t\, \mathsf{g}(G) + \mathsf{R}(|t| \mathsf{N}(G)) \quad \text{and} \quad |\mathsf{g}(G)| \leq \mathsf{N}(G)$$

for all $G \in \mathcal{A}$ and all real t. Let $\mathfrak{s}$ be a linear functional with $\mathfrak{s}(1) = 1$ and $\mathfrak{s}(G) \leq Q\, \mathsf{N}(G)$ for all G, where $1 \leq Q \leq 1.11$. Then $|\mathfrak{s}(G) - \mathsf{g}(G)| \leq 4.84\, [Q(Q-1)]^{1/2}\, \mathsf{N}(G)$. ■

Proof sketch. From $(1+u)^{1/8} \le 1+u/8$, $\mathsf{N}(1+tG) \le 1 + t\mathsf{g}(G) + \frac{1}{8}\mathsf{R}(x)$, $x = |t|\mathsf{N}(G)$; so $1+t\mathfrak{s}(G) = \mathfrak{s}(1+tG) \le Q[1+t\mathsf{g}(G)+\frac{1}{8}\mathsf{R}(x)]$, that is $t[\mathfrak{s}(G)-\mathsf{g}(G)] \le (Q-1)(1+x) + \frac{Q}{8}\mathsf{R}(x)$. If $\mathsf{N}(G)=0$ the bracket vanishes, and if $Q=1$ it vanishes as $x\to 0$. Otherwise take $t = \pm x/\mathsf{N}(G)$ with $x^2 = (Q-1)/4.74Q$, so that $x \le 0.1446$ and $\mathsf{R}(x)/8x^2 \le 4.718$:

$$|\mathfrak{s}(G)-\mathsf{g}(G)| \le \mathsf{N}(G)\Big[\frac{Q-1}{x} + (Q-1) + 4.74\,Qx\Big] = \mathsf{N}(G)\,[Q(Q-1)]^{1/2}\Big[2\sqrt{4.74} + \Big(\frac{Q-1}{Q}\Big)^{1/2}\Big],$$

and $2\sqrt{4.74} + (0.11/1.11)^{1/2} \le 4.67$. □

Proposition 17.23 (Boxes of every shape)**.** Let $\beta \ge 0$, $N = 2h \ge 4$, $c \in (\mathbb{Z}+\frac{1}{2})^3$, $\underline{n}$ a box with all sides $\ge N$, and $M_\mu = 2^{j_\mu}h$, $j_\mu \ge 1$, the largest number of this form that is $\le n_\mu$. For every function A of the cell $\mathsf{C}_h(c)$:

(a) $|\langle A\rangle_{\underline{n}}| \le \exp\{\frac{\delta_{\mathrm{c}}(N)}{8}[1+3N(\frac{1}{M_1}+\frac{1}{M_2}+\frac{1}{M_3})]\}\,\|A\|_N \le e^{\frac{5}{4}\delta_{\mathrm{c}}(N)}\,\|A\|_N$;

(b) if A is real and $\delta_{\mathrm{c}}(N) \le \frac{1}{2}$, then $|\langle A\rangle_{\underline{n}} - \langle A\rangle_{(N,N,N)}| \le 7.31\,\delta_{\mathrm{c}}(N)^{1/2}\,\|A\|_N$.

Under the criterion at the side l and for $N \ge 2l$: $|\langle A\rangle_{\underline{n}} - \langle A\rangle_{(N,N,N)}| \le 2.71\,\theta^{N/4l}\,\|A\|_N$ for every real A. None of these constants depends on the shape of the box. ■

Proof sketch. (a) *Doubling on the one box.* In the direction 1 put $A_0 = A$ and $A_{i+1} = A_i\,\overline{\mathfrak{r}^{(i)}A_i}$, $\mathfrak{r}^{(i)}$ the reflection in the plane $x_1 = c_1 + (2^i-1)h$; A_i is a function of the bonds of the 2^ih layers below that plane, and by Lem. 17.21(a), as long as $2^{i+1}h \le n_1$, $|\langle A_i\rangle_{\underline{n}}|^2 \le \langle A_{i+1}\rangle_{\underline{n}}$. So $|\langle A\rangle_{\underline{n}}| \le \langle A_{j_1}\rangle_{\underline{n}}^{2^{-j_1}}$, and A_{j_1} is a row of M_1/h alternating copies of the cell, which lies below c_2 and c_3; the same in the directions 2 and 3, always on the box $\underline{n}$, gives $|\langle A\rangle_{\underline{n}}| \le \langle \mathfrak{B}A\rangle_{\underline{n}}^{1/\mathcal{N}}$, with $\mathfrak{B}A$ an array of $\mathcal{N} = M_1M_2M_3/h^3$ copies on a block of $M_1\times M_2\times M_3$ sites.

The free layers cost their top eigenvalue. With the time 1 and Y the operator of the slab of h layers of $\mathfrak{B}_3\mathfrak{B}_2A$, $Z(\underline{m})\langle\mathfrak{B}A\rangle_{\underline{m}} = \mathrm{Tr}(\mathsf{T}'^{m_1-M_1}(\mathsf{Y}^*\mathsf{Y})^{M_1/N})$, and $\mathrm{Tr}(\mathsf{O}_1\mathsf{O}_2) \le \|\mathsf{O}_1\|\,\mathrm{Tr}\,\mathsf{O}_2$ for positive operators $\mathsf{O}_1,\mathsf{O}_2$, the second of trace class, gives

$$Z(\underline{m})\langle\mathfrak{B}A\rangle_{\underline{m}} \le \lambda_0(m_2,m_3)^{m_1-M_1}\,Z(M_1,m_2,m_3)\langle\mathfrak{B}A\rangle_{(M_1,m_2,m_3)};$$

with the times 2 and 3 in turn,

$$Z(\underline{n})\langle\mathfrak{B}A\rangle_{\underline{n}} \le \lambda_0(n_2,n_3)^{n_1-M_1}\lambda_0(M_1,n_3)^{n_2-M_2}\lambda_0(M_1,M_2)^{n_3-M_3}\,Z(\underline{M})\langle\mathfrak{B}A\rangle_{\underline{M}}.$$

On the block $\underline{M}$, whose sides lie in $N\mathbb{N}$, $\mathrm{Tr}(\mathsf{Y}^*\mathsf{Y})^q \le (\mathrm{Tr}\,\mathsf{Y}^*\mathsf{Y})^q$ in each direction gives $Z(\underline{M})\langle\mathfrak{B}A\rangle_{\underline{M}} \le [Z(N,N,N)\,\|A\|_N^8]^{M_1M_2M_3/N^3}$. *The count.* Write $\log\lambda_0(\mathsf{A},\mathsf{B}) = \mathsf{AB}P + \varepsilon(\mathsf{A},\mathsf{B})$ and $F = |\cdot|P+\delta$: the terms with P cancel, and with $\varepsilon(\mathsf{A},\mathsf{B}) \le (\mathsf{A}+\mathsf{B})\delta_{\mathrm{c}}(N)/N^2$ (Lem. 17.11(g)), $n_\mu < 2M_\mu$ and $\delta(\underline{n}) \ge 0$, the remaining exponent is at most $3\frac{\delta_{\mathrm{c}}(N)}{N^2}(M_1M_2+M_1M_3+M_2M_3) + \frac{M_1M_2M_3}{N^3}\delta_{\mathrm{c}}(N)$; divided by $\mathcal{N} = 8M_1M_2M_3/N^3$ this is the exponent of (a), and $M_\mu \ge N$. (b) Lem. 17.22 with $\mathcal{A}$ the real functions of the cell, $\mathsf{N} = \|\cdot\|_N$, $\mathsf{g} = \langle\cdot\rangle_{(N,N,N)}$, $\mathfrak{s} = \langle\cdot\rangle_{\underline{n}}$ and $Q = e^{\frac{5}{4}\delta_{\mathrm{c}}(N)}$: by Lem. 17.21(b), $\|1+tG\|_N^8$ is the sum over $E\subset\{0,1\}^3$ of $t^{\#E}$ times the mean of the copies of G over E, which is 1 for $E=\emptyset$, $\langle G\rangle_{(N,N,N)}$ for the eight one-element E, and at most $\|G\|_N^{\#E}$ else; and $\mathfrak{s}(G) \le Q\mathsf{N}(G)$ is (a).

So, if $\delta_{\mathrm{c}}(N) \le 0.08348$, which suffices for $Q \le 1.11$, the difference is at most $4.84\,[Q(Q-1)]^{1/2}\|A\|_N \le 5.86\,\delta_{\mathrm{c}}(N)^{1/2}\|A\|_N$. For $0.08348 < \delta_{\mathrm{c}}(N) \le \frac{1}{2}$, (a) and Lem. 17.21(b) bound it by $(e^{\frac{5}{4}\delta_{\mathrm{c}}(N)}+1)\|A\|_N$, and $(e^{5\delta/4}+1)\delta^{-1/2}$ decreases on $(0,\frac{1}{2}]$ and is ≤ 7.31 at 0.08348. Under the criterion $\delta_{\mathrm{c}}(N) < 0.1324\,\theta^{N/2l} \le \frac{1}{2}$ (Prop. 17.16(d)), and $7.31\cdot 0.1324^{1/2} \le 2.71$. □

Lemma 17.24 (The excess controls every periodic state)**.** Let $\beta > 0$, let $N = 2\mathsf{L}^j$ be the side of one of the tori of the chessboard estimate (Prop. YM3_I:86.3), and let B be the set of the bonds with both ends in one of the eight closed cubes of side $N/2$, with faces through midpoints of bonds,

that tile the torus (N,N,N). For every periodic Gibbs state s the law of s on B has a density h with respect to the law of the torus (N,N,N) on B, with $\int h^{8/7} \le e^{\delta_c(N)/7}$, and

$$\sup_A |s(A) - \langle \mathbf{1}_A \rangle_{(N,N,N)}| \le \tfrac{1}{2}(\sqrt{\epsilon} + \epsilon), \qquad \epsilon = 22.3\big(e^{\delta_c(N)/7} - 1\big),$$

the supremum over the Borel events A of the bonds of B. ■

Proof sketch. One board for all sides. Let $N' = 2\mathsf{L}^{j'}$, $j' \ge j$, be a side of the family. The cubes of side $N/2$, with faces through midpoints of bonds, that are the translates of the closed cube of B by the multiples of $N/2$ in the three directions tile the torus (N',N',N'), $2N'/N$ of them a side, an even number, as N'/N is a power of the odd number L: these *cells* form one board, and the planes between neighbouring cells are its walls. Number the cells by $k \in \{0,\dots,2N'/N-1\}^3$, the cell of B being $k=0$. For a bounded Borel function f of the bonds of B the copy $f^{[k]}$ is f composed, for $\mu = 1,2,3$, with the reflections in the k_μ walls of the direction μ that carry the cell 0 step by step to the cell k, and complex conjugated if $k_1+k_2+k_3$ is odd; it is a function of the bonds of the cell k. Put

$$\|f\|_{N'} = \Big\langle \prod_k f^{[k]} \Big\rangle_{(N',N',N')}^{(N/2N')^3},$$

the product over all $(2N'/N)^3$ cells. At $N' = N$ the cell of B is a cell $\mathsf{C}_{N/2}(c)$, the eight copies are the copies $f^{[\epsilon]}$, $\epsilon \in \{0,1\}^3$, by which $|\!|\!| \cdot |\!|\!|_N$ is defined, and $\|f\|_N = |\!|\!| f |\!|\!|_N$. With the time 1 the torus (N',N',N') is cut by the walls into $2N'/N$ slabs of $N/2$ layers, and, as in the proof of Prop. 17.23, with Y the operator of the first slab of the product (that of the cells with $k_1 = 0$), the operator of the next slab is Y^*, and $Z(N',N',N')\langle \prod_k f^{[k]} \rangle_{(N',N',N')} = \mathrm{Tr}(\mathsf{Y}^*\mathsf{Y})^{N'/N}$, a number ≥ 0 and at most $(\mathrm{Tr}\,\mathsf{Y}^*\mathsf{Y})^{N'/N}$, where $\mathrm{Tr}\,\mathsf{Y}^*\mathsf{Y}$ is the same expression on the box (N,N',N'). The same in the directions 2 and 3 gives the chessboard estimate on this board for the two tori (Prop. YM3_I:86.3, in the form of Cor. YM3_I:86.6):

$$Z(N',N',N')\,\|f\|_{N'}^{(2N'/N)^3} \le \big[Z(N,N,N)\,\|f\|_N^8\big]^{(N'/N)^3}.$$

Its root of the order $(2N'/N)^3$ is

$$\|f\|_{N'} \le \|f\|_N \exp\Big[\Big(\frac{N}{2}\Big)^3\Big(\frac{F(N,N,N)}{N^3} - \frac{F(N',N',N')}{N'^3}\Big)\Big] \le \|f\|_N\, e^{\delta_c(N)/8},$$

since $(N/2N')^3(N'/N)^3 = \frac{1}{8}$, $(N/2N')^3 = (N/2)^3/N'^3$ and $F(N',N',N')/N'^3 \ge P$. The domination of periodic Gibbs states (Prop. YM3_I:91.9), read with this same board and seminorm, gives $|s(f)| \le \liminf_{j'\to\infty} \|f\|_{N'}$. Hölder's inequality and the reflection invariance of the torus law give $\|f\|_N \le \langle |f|^8 \rangle_{(N,N,N)}^{1/8}$. So $|s(f)| \le e^{\delta_c(N)/8}\|f\|_{L^8}$, and by duality s has on B a density h with $\|h\|_{8/7} \le e^{\delta_c(N)/8}$. With $p = \frac{8}{7}$, $u^p - 1 - p(u-1) \ge 0.045\min\{(u-1)^2, |u-1|^p\}$ for $u \ge 0$; integrating at $u = h$ gives $\int_{|h-1|\le 1}(h-1)^2 + \int_{|h-1|>1}|h-1|^p \le \epsilon$, so $\int |h-1| \le \sqrt{\epsilon} + \epsilon$, and the total variation is half of it. □

Lemma 17.25 (One bond; a bound by the perimeter)**.**

(a) For $\kappa \ge 0$ let $\langle\cdot\rangle_\kappa$ be the probability measure on G with the density proportional to $e^{\kappa x_0(V)}$ with respect to the Haar measure, $x_0(V) = \frac{1}{2}\,\mathrm{tr}\,V$, and $r(\kappa) = \langle x_0 \rangle_\kappa$. Then $\langle V \rangle_\kappa = r(\kappa)\mathbf{1}$ and

$$\frac{\kappa}{\kappa+4} \le r(\kappa) \le \frac{2\kappa}{2\kappa+3}.$$

(b) Let $\beta \ge 0$, s a Gibbs state, periodic or not, C a closed lattice path and B a finite set of bonds which C runs through exactly once each, as b or as $\bar{b}$, no plaquette containing two of them. Then $|s(W_C)| \le (\frac{8\beta}{8\beta+3})^{\#B} \le \exp[-3\#B/(8\beta+3)]$. For a rectangle with $R,T \ge 2$ one may take $\#B = 2(R+T)-4$.

■

Proof sketch. (a) Conjugation invariance makes $\langle V\rangle_\kappa$ commute with G, so it is a multiple of $\mathbf{1}$, and the multiple is $r(\kappa)$. Write $V = x_0\mathbf{1} + \mathrm{i}\sum_j x_j\sigma_j$ with $\sum_{j=0}^3 x_j^2 = 1$. By the invariance of the Haar measure under $V \mapsto e^{\mathrm{i}s\sigma_j}V$, the derivatives at $s=0$ of $\int (x_j e^{\kappa x_0})(e^{\mathrm{i}s\sigma_j}V)\,\mathrm{d}V$ and of $\int (x_j x_0 e^{\kappa x_0})(e^{\mathrm{i}s\sigma_j}V)\,\mathrm{d}V$ vanish; as the derivatives of x_0 and x_j along this path are $-x_j$ and x_0, summing over $j=1,2,3$ gives

$$3\,r(\kappa) = \kappa\langle 1-x_0^2\rangle_\kappa, \qquad 4\langle x_0^2\rangle_\kappa - 1 = \kappa\langle x_0(1-x_0^2)\rangle_\kappa.$$

The right member of the second identity lies in $[0, \kappa\langle 1-x_0^2\rangle_\kappa]$, its sign by $V\mapsto -V$; so $(4+\kappa)\langle x_0^2\rangle_\kappa \le 1+\kappa$, and the first identity gives $r(\kappa) \ge \frac{\kappa}{3}\cdot\frac{3}{4+\kappa}$; and $3r = \kappa\langle (1-x_0)(1+x_0)\rangle \le 2\kappa(1-r)$. (b) As no plaquette contains two bonds of B, given the other bonds the weight of the bonds of B factorises: $V(b)$ has the density proportional to $\exp[\beta \mathsf{k}_b \frac12 \operatorname{tr}(V(b)g_b)]$, where the sum of the four staples of b is $\mathsf{k}_b g_b$, $g_b\in G$, $0\le \mathsf{k}_b \le 4$, as a sum of four unit quaternions. W_C is a sum of products that hold one entry of each $V(b)^{\pm1}$, $b\in B$; by (a) and $V\mapsto Vg^{-1}$ the conditional mean of $V(b)^{\pm1}$ is $r(\beta\mathsf{k}_b)g_b^{\mp1}$, so the conditional mean of W_C is $\prod_b r(\beta\mathsf{k}_b)$ times half the trace of an element of G, of modulus at most $(\frac{8\beta}{8\beta+3})^{\#B}$; the Gibbs equation of B carries this to s. In a rectangle with $R,T\ge 2$ take all bonds but the first of each side: two bonds of one plaquette are either perpendicular with a common end, which happens on C only at a corner, or parallel at the distance 1, which does not happen for opposite sides at the distance ≥ 2. Finally $\log(1+y)\ge y/(1+y)$ at $y = 3/8\beta$. □

17.1.6. *Proofs of the results.*

Proof of Thm. AW. Step 1 (the cubes converge). In a box (t,Σ) with $t\in\{n,2n\}$ a function A of a cube of $h\le n/2-1$ layers is a function of h consecutive layers, and Prop. 17.20 applies with $s\ge n/2$ and one and the same $a_\infty(\Sigma,A)$ for both t. Doubling the three sides one after the other, each time with the time in the doubled direction,

$$|\langle A\rangle_{(n,n,n)} - \langle A\rangle_{(2n,2n,2n)}| \le 4\sup|A|\,[\mathsf{r}_{n/2}(n,n) + \mathsf{r}_{n/2}(2n,n) + \mathsf{r}_{n/2}(2n,2n)] \le 4 \cdot 4.15727\sup|A|\,\mathsf{e}(n/2) \le 1.29\sup|A|\,\theta^{n/2l}$$

by Prop. 17.16(d). Summing over $n, 2n, 4n, \dots$ with $\theta^{2^i n/2l} \le \theta^{n/2l}\theta^{in/2l}$ gives the second bound of (a). On each finite set of bonds the cube laws form a Cauchy sequence in total variation; the limits are consistent, and Kolmogorov's theorem gives ν.

Step 2 (Gibbs state, symmetries). For a finite set $\mathfrak{A}$ of bonds and a large cube, the action is the sum over the plaquettes that meet $\mathfrak{A}$ plus a remainder that does not depend on the bonds of $\mathfrak{A}$; integrating these bonds first shows that every cube law, and so ν, satisfies the Gibbs equation of $\mathfrak{A}$. A symmetry of the lattice induces a map of each cube of side $2^k l$ that keeps dU and the action, hence each cube law and ν.

Step 3 (one periodic state). By Step 2, ν is periodic. Let s be a periodic Gibbs state and A a local event. For all large $N = 2\mathsf{L}^j$, A is an event of the bonds inside one cell of side $N/2$, and Lem. 17.24, applied to s and to ν, gives $|s(A)-\nu(A)| \le \sqrt{\epsilon}+\epsilon$ with $\epsilon = 22.3(e^{\delta_{\mathrm{c}}(N)/7}-1)$, which tends to 0 as $\delta_{\mathrm{c}}(N) < 0.1324\,\theta^{N/2l}$ (Prop. 17.16(d)). So $s=\nu$. Prop. YM3_I:103.4 gives reflection positivity at every lattice mirror. By Prop. YM3_I:106.2, the ergodic components of ν are periodic Gibbs states; uniqueness makes them equal to ν, so ν is ergodic.

Step 4 (all boxes). Let the three sides of boxes $\underline{n}^{(k)}$ tend to infinity. Their laws on Ω lie in a compact set; every limit point satisfies the Gibbs equations, as in Step 2, and is invariant under all translations, as every box law is; so it is a periodic Gibbs state, that is ν, and the whole sequence converges.

Step 5 (twisted cubes). Let $n\ge 2\mathsf{q}l$ be an integer, j the largest integer with $4^j \le n/2\mathsf{q}l$, $w = 2^j$, $l' = l_j = 2wl$ and $M = n/l'$, a real number with $w\mathsf{q} \le M < 4w\mathsf{q}$ and $M^2 < 2\mathsf{q}n/l$. Lem. 17.15(a)

from the box (l',n,l') to the cube, with $\kappa = M^2$, and Prop. 17.17(d) give

$$z_-(n,n,n) \le \big[M e^{-\varsigma w^2 + 0.01655\, M\theta^{2w}}\big]^{M^2}, \qquad M^2\varsigma w^2 = \sigma^+ n^2,$$

and $0.01655\, M\theta^{2w} < 4\mathsf{q}\cdot 0.01655\, we^{-2w\Lambda} \le \frac{4\cdot 0.01655}{e}(\frac{1}{2\Lambda} + \frac{1.67}{4\Lambda^2}) \le 0.855$ and $\log M < \frac12 \log\frac{2\mathsf{q}n}{l}$: the first bound of (d). The bound for all seven $z \ne 0$ then follows from Lem. 17.10(c).

Step 6 (flux sectors, static charges). With the time 1 over $n\times n$ and $e \in \{01, 11\}$, $\Lambda_e^n \le W_n(01;0)+W_n(11;0) = a_-(n,n,n) = z_-\lambda_0^n(1+\mathsf{r}_n(n,n))$; for $e = 10$ the same holds because $Z^{(1,0,0)} = Z^{(0,1,0)}$ on the cube (Lem. 17.10(iii)). So $\log(\lambda_0/\Lambda_e) \ge \frac1n[-\log z_-(n,n,n) - \log(1+\mathsf{r}_n(n,n))]$, and $\log(1+\mathsf{r}_n(n,n))$ is at most $\mathsf{r}_n(n,n) \le 0.001615\,\theta^{n/l} \le 0.0017$ at $n = 2^i l$, and in general, with $n_0 = 2^i l \le n < 2n_0$, at most $\delta_{\mathrm{c}}(n) \le 8\delta_{\mathrm{c}}(n_0) \le 8\cdot 0.01655\cdot 0.792279 \le 0.105$ (Lem. 17.11(f), Prop. 17.16(d)). With Step 5 this is the first statement of (e); the second is Lem. 17.12(d) on the cube with $n_3 = n$, and Step 5. For any two sites $o \ne r$ it is Lem. 17.12(e) on the cube, with the time 1 or 2, whichever direction of the section realises $|r-o|_\infty$, and Step 5; for fixed o, r and $n = 2^i l$, $i\to\infty$, the factor $[8(1+\mathsf{r}_n(n,n))]^{1/n}$ tends to 1 and the correction $\frac{2\mathsf{q}R}{ln}(\frac12\log\frac{2\mathsf{q}n}{l} + 0.86)$ to 0, while $R = |r-o|_\infty$ once $n > 2|r-o|_\infty$.

Step 7 (rectangles). By the symmetries of ν and of the cube laws it suffices to take C in a $(1,3)$-plane with the side R along e_1. On the cube of an integer side $n \ge 2\mathsf{q}l$ with $R \le n/2$, $T \le n-1$, Lem. 17.12(d) gives $0 \le \langle W_C\rangle_{(n,n,n)} \le 8^{T/n} z_-(n,n,n)^{RT/n^2}$, and Step 5 gives the bound on the cube. Along $n = 2^k l$ the left side tends to $\nu(W_C)$ by Step 1, while $8^{T/n}\to 1$ and $(\log n)/n \to 0$: this is eq. 17.ii. The bound by the perimeter is Lem. 17.25(b).

Step 8 (closed paths). Let C and (ρ',ρ) be as in (c); by symmetry $(\rho',\rho) = (1,3)$. On the cubes $n = 2^k l$, which are even, Lem. 17.13(c) applies for large k: the sum of the ℓ_j is $\mathsf{A}_{13}(C)$, $\sum_j(\mathsf{v}_j+1)/n \to 0$, the thermal factors tend to 1, and $z_-(n,n,n)^{\mathsf{A}/n^2} \le e^{-\sigma^+\mathsf{A}+o(1)}$ by Step 5. For the general form let $\rho = 3$: by the symmetry of the cube that exchanges the directions 1 and 2, Lem. 17.13(b) holds with the direction 2 in the place of the direction 1, the two twisted pairs having one quotient on the cube (Lem. 17.10(c)), and in the proof of Lem. 17.13(c) each norm $\|\hat{\mathsf{T}}_{D_j}\|$ is bounded by (b) on its own; so in each gap ℓ_j may be taken as the larger of the two counts $\ell_j^1(C)$, $\ell_j^2(C)$, whose sum over the gaps is $\mathsf{A}_3(C)$, and Lem. 17.13(d) carries all this to D, with $d^{c_3(C)-1}$ in front and $\sum_j \mathsf{v}_j \log d/n \to 0$.

For a staircase loop the senses of its runs of the direction ρ are up in T consecutive gaps and then down in the same gaps, so $c_\rho = 1$, and $\mathsf{A}_{\rho'\rho}(C) = \sum_j |r_j - o_j|$. For a simple closed curve of a coordinate plane each passage from down to up and each from up to down holds at least one bond of the other direction, and between two such passages there is at least one bond of the direction ρ; so $|C| \ge 4c_\rho(C)$ and $2^{c_\rho-1} \le \frac12 e^{(\log 2/4)|C|}$.

Step 9 (gap). Let $N = N_1 \le N_2$ (by (T1)), $n_0 \le N < 2n_0$, and i with $t_i \le N_2 < 2t_i$ in Prop. 17.18(b): for $a \ge 1$, $(\lambda_a/\lambda_0)^{t_i} \le \mathsf{r}_{t_i}(N_2,N) \le 0.28\,\chi'^{2^i} \le \chi'^{t_i/n_0}$, so $\log(\lambda_0/\lambda_a) \ge \frac{1}{n_0}\log\frac{1}{\chi'} \ge \frac{\Lambda}{l} + \frac{1.021}{n_0}$. The vacuum is simple and its eigenvector lies in the sector 00 (Lem. 17.10); the tops of the sectors with electric flux are among the λ_a, $a \ge 1$. For $N = n = 2^k l$ and an integer $N_2 \ge n$, with $t_i = 2^i n \le N_2 < 2t_i$, Prop. 17.18(a), (c) give $\log(1+\mathsf{r}_{t_i}(N_2,n)) \le \frac{N_2}{t_i}\delta^{(n)}(t_i,t_i) \le 0.3652\,\chi^{2^i}$, so $(\lambda_a/\lambda_0)^{t_i} \le 0.367\,\chi^{2^i} \le \chi^{t_i/n}$ and $\log(\lambda_0/\lambda_a) \ge \frac1n\log\frac1\chi \ge \frac{\Lambda}{l} + \frac{3.5065}{n}$. Over $n\times n$, $(\lambda_a/\lambda_0)^n \le \mathsf{r}_n(n,n) \le 0.001615\,\theta^{n/l}$, and $\log\frac{1}{0.001615} \ge 6.42$. Finally, for $N_1, N_2 \ge n$, Lem. 17.11(f) gives $\log(1+\mathsf{r}_n(N_1,N_2)) \le \delta(n,N_1,N_2) \le \frac{N_1N_2}{n^2}\delta_{\mathrm{c}}(n) \le 0.01655\,\frac{N_1N_2}{n^2}\theta^{n/l} =: u \le \log 2$, and $e^u - 1 \le u/\log 2$, $\log 2/0.01655 \ge 41.8$.

Step 10 (flux lines of dyadic length). $2\sigma^+N^2/\log\frac1\chi = 2\varsigma w^2/(-\log 0.03 + 2w\Lambda)$ increases in w, is ≥ 3.83 at $w = 2$ and $< 2\mathsf{q}w = \mathsf{q}N/l$: the bounds on $\hat N$. With the time 1 over (N_2,N), Lem. 17.10(d) gives $\Lambda_-^t \le a_-(t,N_2,N) = z_-(t,N_2,N)\lambda_0^t(1+\mathsf{r}_t(N_2,N))$ for every t. Take $t = t_i = 2^i N$ with i the largest integer such that $\mathsf{M} = N_2/t \ge \hat N/2$, so that $\hat N/2 \le \mathsf{M} < \hat N$. The first

inequality of Lem. 17.15(b) at the time N_2, Prop. 17.18(c), $\mathsf{r}_{N_2}(t,N) \le \mathsf{r}_t(t,N)^{\mathsf{M}} \le e^{-2^i\sigma^+N^2}$ and $\log(1+\mathsf{r}_t(N_2,N)) \le \mathsf{M}\delta^{(N)}(t,t) \le 0.1826\,\mathsf{M}\chi^{2^i}$ give

$$\log\frac{\lambda_0}{\Lambda_-} \ge \frac{1}{t}\Big[2^i(\sigma^+N^2-\mathsf{g}) - \log\mathsf{M} - 0.1826\,\mathsf{M}\chi^{2^i}\Big] \ge \sigma^+N - \frac{2\log\hat N + 1.86}{N},$$

as $\hat N\chi \le 0.7936$. As $N_2\to\infty$, $i\to\infty$, and the bounded last two terms are divided by 2^iN: the lower limit. For $\max\{N,2\mathsf{q}l\} \le N_2 < \hat N N/2$ let w' be the largest power of two with $w' \le w$ and $2\mathsf{q}w'^2l \le N_2$, and $l' = 2w'l \le N$, so that $N_2 \ge \mathsf{q}l'^2/2l$; Prop. 17.17(e) with $N_3 = N$, $n_2 = N_2$ and $M = N_2/l'$ applies. If $w' < w$, then $8\mathsf{q}w'^2l > N_2$, so $N/l'^2 < 2\mathsf{q}N/N_2l \le 2\mathsf{q}/l$ and $M < 4\mathsf{q}w'$; if $w' = w$, then $N/l'^2 = 1/N \le 2\mathsf{q}/l$ and $M < \hat N/2 < 4\mathsf{q}w$. In both cases $\log M < \log\frac{2\mathsf{q}N}{l}$ and $0.01655\,M\theta^{l'/l} < 4\mathsf{q}\cdot 0.01655\,w'e^{-2w'\Lambda} \le 0.855$, which gives the second floor. For $N \le N' < 2N$: with the time 1, Lem. 17.15(a) in the third side gives $\Lambda_-(N_2,N')^t \le a_-(t,N_2,N') \le a_-(t,N_2,N)^{N'/N}$, and $a_-(t,N_2,N)^{1/t} \to \Lambda_-(N_2,N)$; so $\log\Lambda_-(N_2,N') \le \frac{N'}{N}\log\Lambda_-(N_2,N)$. Also $\log\lambda_0(N_2,N') \ge N_2N'P$ and $\log\lambda_0(N_2,N) \le \frac{1}{N}F(N,N_2,N) \le N_2NP + \frac{N_2}{N^2}\delta_{\mathrm{c}}(N)$ (Lem. 17.11(f)). Hence $\log\frac{\lambda_0}{\Lambda_-}(N_2,N') \ge \frac{N'}{N}[\log\frac{\lambda_0}{\Lambda_-}(N_2,N) - \frac{N_2}{N^2}\delta_{\mathrm{c}}(N)]$, and the first floor, $\delta_{\mathrm{c}}(N) \le 0.01655\,\theta^{N/l}$ and $N'/N < 2$ give the third.

Step 11 (flux lines of every integer length; the slabs). Let $N \ge 4l$. Prop. 17.19 gives $t_i\varepsilon_{\mathrm{v}}(t_i,N) \le e^{-E_i'}$ with $2^{-i}E_i' \ge \mathsf{E}_0 - \mathsf{g}'$. As in Step 10, with i the largest integer such that $\mathsf{M} = N_2/t_i \ge \hat N'/2$, the first inequality of Lem. 17.15(b) at the time N_2, with $\mathsf{r}_{N_2}(t_i,N) \le \chi_0^{2^i\hat N'/2} \le e^{-2^i\mathsf{E}_0}$, gives $z_-(t_i,N_2,N) \le \hat N'e^{-E_i'}$, and Prop. 17.18(b) gives $\log(1+\mathsf{r}_{t_i}(N_2,N)) \le \mathsf{M}\delta^{(N)}(t_i,t_i) \le \frac14\xi_i'$; so $\log(\lambda_0/\Lambda_-) \ge \frac{1}{t_i}[E_i' - \log\hat N' - \frac14\xi_i'] \ge (\mathsf{E}_0-\mathsf{g}')/n_0 = \sigma^+N - \kappa\mathsf{g}'/N$. The penultimate inequality uses the unused positive recurrence tail displayed in the proof of Prop. 17.19.

As $\kappa\mathsf{g}' = \kappa^2\log\hat N' + \kappa[3.22 + (3\kappa+0.68)\mathsf{h}]$ and $\mathsf{h} \le 0.4274\kappa + 0.0208$, $\kappa\mathsf{g}'$ increases in κ, and at $\kappa = 2$ it is at most $4\log\hat N' + 18.14$. The window $\max\{N,2\mathsf{q}l\} \le N_2 < \hat N'n_0/2$ is treated as in Step 10, with $l' = 2w'l \le n_0$. For the closed form, $\hat N'n_0/2 < (\mathsf{q}N/l+2)N/2 \le (\frac{\mathsf{q}}{2}+\frac14)N^2/l$ and $\hat N' < (\mathsf{q}+\frac12)N/l$, as $N \ge 4l$; so $C(\theta)N^2/l \ge \hat N'n_0/2$ and $4\log\hat N' + 18.2 \le 4\log\frac{N}{l} + 4\log(\mathsf{q}+\frac12) + 18.2 \le C(\theta)(1+\log\frac{N}{l})$; and $4\log 8.673 + 18.2 \le 26.85$ at $\mathsf{q} \le 8.173$. If $w \ge 4$ and $\tau \le 0.087$, the same road, with the slab of the thickness N started from $\mathsf{e}^{(N)}(n_0) \le 2\delta(n_0,2n_0,N) \le 8\cdot 0.01655\,\tau \le 0.0116$, where $\omega(Y_1(x)) \le 2.06x^2$, so that $2.06\,\mathsf{e}^{(N)}(t_i) \le (0.2728\,\tau)^{2^i}$, and with the start from Prop. 17.17(d) at $l' = n_0$ carried to the thickness N by Lem. 17.15(a) at the real factor N/n_0, gives the floor with $\hat N''$ and 10.8. (g3) is Lem. 17.14 with $L_2 = N_2$, $L_3 = N$ and $\phi \ge \sigma^+N - (4\log\hat N' + 18.2)/N$.

Step 12 (boxes of every shape, cylinders, twisted boxes). A cube of $N/2$ layers is a cell $\mathsf{C}_{N/2}(c)$, and all box laws are invariant under translations. For a real function A of the cell, Prop. 17.23 gives $|\langle A\rangle_{\underline{n}} - \langle A\rangle_{(N,N,N)}| \le 2.71\,\theta^{N/4l}\|\!|A|\!\|_N$ for every box with sides $\ge N$. If A is continuous, let the sides of a second box tend to infinity: by Step 4, $|\nu(A) - \langle A\rangle_{(N,N,N)}| \le 2.71\,\theta^{N/4l}\|\!|A|\!\|_N$, so $|\langle A\rangle_{\underline{n}} - \nu(A)| \le 5.42\,\theta^{N/4l}\|\!|A|\!\|_N \le 5.42\,\theta^{N/4l}\sup|A|$ by Lem. 17.21(b). For a bounded real Borel A, take continuous A_k with $|A_k| \le \sup|A|$ and $A_k \to A$ in L^8 of the mean of the images of $\langle\cdot\rangle_{(N,N,N)}$, $\langle\cdot\rangle_{\underline{n}}$ and ν on the bonds of the cell; both sides of the bound pass to the limit, the seminorm because $\|\!|A_k - A|\!\|_N \le \langle|A_k-A|^8\rangle^{1/8}_{(N,N,N)}$ (Lem. 17.21(b)).

For an event take $A = \mathbf{1}_E - \frac12$. For the cube of side $m \ge 2l$ take $N = 2\lfloor m/2\rfloor \le m$. The cylinder over Σ is the limit of Prop. 17.20, and the bound passes to it; with $\Sigma = (n,n)$ and $M\to\infty$, Lem. 17.15(a) in the third side gives $z_-(n,n,Mn) \le [z_-(n,n,n)\lambda_0^n(1+\mathsf{r}_n(n,n))]^M\lambda_0^{-Mn} = [(1+\mathsf{r}_n(n,n))z_-(n,n,n)]^M$, and Lem. 17.12(d) on the box (n,n,Mn) gives the area bound on the cylinder, as $8^{T/Mn}\to 1$. Twisted boxes: let the columns recede. For a finite set $\mathfrak{A}$ of bonds the plaquettes that meet $\mathfrak{A}$ carry no twist in all but finitely many members, so every limit point satisfies the Gibbs equations, as in Step 2.

The translate by e_μ of a twisted box law is the twisted law with the columns moved by one step, and by the proof of Lem. 17.10(iii) this is the image of the law under $U(b) \mapsto -U(b)$ on a set of bonds next to the columns; a fixed local function depends on none of these bonds in all but finitely many members. So every limit point is a periodic Gibbs state, that is ν; the two equations are linear in the law, so they hold for finite mixtures. If a column passes through p_0 for all members, one flip moves it off p_0 and changes the sign of $\operatorname{tr} \partial U(p_0)$, and the column so moved recedes after further flips that do not touch p_0; so the law of $\operatorname{tr} \partial U(p_0)$ tends to that of $-\operatorname{tr} \partial U(p_0)$ under ν, which differs because $\nu(\operatorname{tr} \partial U(p_0)) = 2\nu(W_p) > 0$ by Cor. 17.1(a).

Step 13 (the pressure). By Thm. AX(b), $\mathsf{e}(2l) \le \theta^2/12.9 \le 0.0615 < 0.069$ at β. Each $F(\underline{n}; \beta')$ is a smooth function of β', so there is an open interval U containing β on which $\mathsf{e}(2l; \beta') \le 0.069$: the criterion holds on U at the side $2l$ with $x_0 = 0.069$, so that what is proved above holds at each $\beta' \in \mathsf{U}$, with the state $\nu_{\beta'}$ and with $\delta_{\mathrm{c}}(N; \beta') < 0.1324 \cdot 0.8901^{N/4l}$ for $N \ge 4l$, uniformly on U. Let $N_m = 2\mathsf{L}^m$ and $f_m(\beta') = F(N_m, N_m, N_m; \beta')/N_m^3$: these are smooth, tend to P pointwise, and $f_m'(\beta') = -3\langle a_p \rangle_{(N_m,N_m,N_m)}$ by the invariance of the cube under translations and permutations of the axes. As $0 \le a_p \le 2$ is a function of one cell of the torus, Lem. 17.24 gives $|\langle a_p \rangle_{(N_m,N_m,N_m)} - \nu_{\beta'}(a_p)| \le \sqrt{\epsilon_m} + \epsilon_m$, with $\epsilon_m \to 0$ uniformly on U. So the f_m' converge uniformly on U to $-3\nu_{\beta'}(a_p)$, which is therefore continuous, and $P(\beta_2) - P(\beta_1) = \lim_m \int_{\beta_1}^{\beta_2} f_m' = \int_{\beta_1}^{\beta_2} (-3\nu_{\beta'}(a_p))\, \mathrm{d}\beta'$. Finally $\nu(a_p) = 1 - \nu(W_p) \le 1 - \frac{\beta}{4(\beta+1)}$ by Cor. 17.1(a). □

Proof of Thm. AX. (a) is Prop. 17.16(a); if $\beta > 0$, $\mathsf{e}(l_0) \le X(l_0) \le \frac{1}{20} \le 0.069$, and $12.9/20 = 0.645$. (b) By Prop. 17.16(b), (c), $12.9\,\mathsf{e}(2n) \le (12.9\,\mathsf{e}(n))^2$ as long as $\mathsf{e}(n) \le 0.069$, and the induction keeps $\mathsf{e}(2^k l) \le \theta^{2^k}/12.9$. For $k \ge 3$, $\mathsf{e}(2^{k-1} l) \le \theta^4/12.9 \le 0.04866 \le \frac{1}{20}$, so

$$X(2^k l) \le 17.71\,\mathsf{e}(2^{k-1} l)^2 \le \frac{17.71}{166.41}\,\theta^{2^k} \le 0.10643\,\theta^{2^k} \le 0.10643 \cdot 0.394013.$$

$\Phi(\Psi(x)) = \frac{1}{20}$ at $x = 0.065062\ldots$ and $\Phi(x) = \frac{1}{20}$ at $x = 0.052727\ldots$; both functions increase, $X(2l) \le \Phi(x_0)$, $X(4l) \le \Phi(\Psi(x_0))$, and $\Phi(\Psi^k(x_0))$ does not increase in k because $\Psi(x) \le x$ there. (c) $\mathsf{m}_\mathsf{e}(2n) \ge \mathsf{m}_\mathsf{e}(n)$ is $12.9\,\mathsf{e}(2n) \le (12.9\,\mathsf{e}(n))^2$. For $k \ge 3$, $\mathsf{e}(n) \le X(n) \le \frac{1}{20}$ gives $X(2n) \le 17.71\,\mathsf{e}(n)^2 \le 18X(n)^2$, so m_X does not decrease. $X(n) \ge \mathsf{e}(n)$ gives $\mathsf{m}_X(n) \le \mathsf{m}_\mathsf{e}(n) - \frac{1}{n}\log\frac{18}{12.9}$, with $\log\frac{18}{12.9} \ge 0.3331$; $X(n) \le 17.71\,\mathsf{e}(n/2)^2$ gives $18X(n) \le 1.91563\,(12.9\,\mathsf{e}(n/2))^2$, so $\mathsf{m}_X(n) \ge \mathsf{m}_\mathsf{e}(n/2) - \frac{1}{n}\log 1.91563$, with $\log 1.91563 \le 0.6501$. Both rates being monotone and squeezed, they have one limit, and $\mathsf{m}_\mathsf{e}(l) \ge \Lambda/l$ is the criterion. (d) $Y_2(0.0740538) \approx 0.3156 < \log 2$; for $0 < x < 0.0740538$ the iterates $\Psi^k(x)$ decrease, and to 0, since a positive limit would be a fixed point below 0.0740538; so $\mathsf{e}(2^k l) \le \Psi^k(\mathsf{e}(l)) \to 0$ and $X(2^{k+1} l) \le \Phi(\Psi^k(\mathsf{e}(l))) \to 0$; and $\beta > 0$ because $\mathsf{e}(l) > 0$. □

Proof of Thm. AY. Apply Thms. AW and AX at $l = l_* L^K$ and $\beta = L^K \mathsf{b}$, with the one x_0 of the uniform criterion; then θ, Λ, q, $C(\theta)$ do not depend on K. By eq. 17.i, $\sigma^+ l^2 = \frac{1}{2}\log\frac{1}{\theta} + 0.4175$ depends on θ alone. A rectangle of physical sides R, T has $RL^K \times TL^K$ bonds, and $\sigma^+ \cdot RL^K \cdot TL^K = \frac{\sigma^+ l^2}{l_*^2} RT = \sigma_* RT$. For $R, T \ge 2a_K$, Lem. 17.25(b) with $\#B = 2(R+T)/a_K - 4$ and $\beta = \mathsf{b}/a_K$ gives $\nu_K(W_C) \le \exp[-3(|C|_{\mathrm{ph}} - 4a_K)/(8\mathsf{b} + 3a_K)]$, and the smaller of two bounds is at most their geometric mean: (a). For $n = \ell/a_K$: $\sigma^+ n^2 = \sigma_* \ell^2$, $n/l = \ell/l_*$, $a_K^{-1}\sigma^+ n = \sigma_* \ell$, $a_K^{-1}/l = 1/l_*$ and $a_K^{-1}/n = 1/\ell$; this turns Thm. AW(d), (e), (f) and (g) into (b), (c) and (d), with $\hat{N} \le \mathsf{q}\ell/l_* + 1$ and $C(\theta) \le 27$. (e) is Thm. AX(b) at $k = 3$, with $18 \cdot \frac{17.71}{166.41} \le 1.91563 \le 1.9157$, and Thm. AX(a); finally $4 \cdot 0.4757 = 1.9028$. □

Proof of Cor. 17.1. Step 1 (symmetry). The symmetries of ν carry a rectangle to every other one with the same sides, or with the sides exchanged and run backwards.

Step 2 (two Hankel forms). At a site mirror orthogonal to e_μ that contains a site x, let γ_h run from x up h steps along e_μ, R steps along e_λ, and down to $x + Re_\lambda$ (γ_0 lies in the mirror).

Then $\sum_{j,k} U(\gamma_{h'})_{jk}\overline{U(\mathfrak{r}\gamma_h)_{jk}} = 2W$ of a rectangle $R \times (h+h')$, and the reflection positivity of ν at this mirror (Prop. YM3_I:103.4; ν is a periodic Gibbs state), applied to $A_{jk} = \sum_h c_h U(\gamma_h)_{jk}$, gives $\sum_{h,h'} c_h c_{h'} m(R, h+h') \geq 0$. At a bond mirror, take the paths γ'_h from a site x_p next to the mirror up h steps, along R steps and down to $x_q = x_p + Re_\lambda$; then $\sum \overline{(\mathsf{z}_p)_{ji}}(\mathsf{z}_q)_{kl} A_{jk}\overline{\mathfrak{r}A_{il}}$ with $A_{jk} = \sum_h c_h U(\gamma'_h)_{jk}$ is $2\sum_{h,h'} c_h c_{h'} W$ of rectangles $R \times (h+h'+1)$. Its mean is ≥ 0 on the cubes of sides $2^k l$, which are even, by Lem. 17.21(c) after a translation that brings the mirror between the layers 0 and 1, and it passes to ν by Thm. AW(a): $\sum_{h,h'} c_h c_{h'} m(R, h+h'+1) \geq 0$.

Step 3 (log-convexity). The 2×2 minors of the two forms give $m(R,T)^2 \leq m(R,T-1)m(R,T+1)$ for all $T \geq 1$.

Step 4 ($w > 0$). Given the other bonds, $U(b)$ has the density proportional to $\exp[\beta \mathsf{k} \frac{1}{2}\operatorname{tr}(U(b)g)]$, $\mathsf{k}g$ the sum of the four staples of b, $0 \leq \mathsf{k} \leq 4$; so, by the Gibbs equation and Lem. 17.25(a), $4w = \nu(\mathsf{k}\, r(\beta\mathsf{k})) \geq \nu(\beta\mathsf{k}^2/(\beta\mathsf{k}+4)) \geq \beta\nu(\mathsf{k}^2)/(4\beta+4)$. Two different staples of b are mirror images at a mirror that contains b, a site mirror if they lie in one plane and a diagonal mirror if they lie in two; so $\nu(\mathsf{k}^2) = 4 + \sum_{s \neq s'} \nu(\frac{1}{2}\operatorname{tr} s s'^{-1}) \geq 4$ by reflection positivity, and $w \geq \beta/(4(\beta+1))$.

Step 5 (positivity). From $m(1,0) = 1$, $m(1,1) = w > 0$ and Step 3, $m(1,T) > 0$ for all T; then $m(R,1) = m(1,R) > 0$ and $m(R,T) > 0$. As $T \mapsto -\log m(R,T)$ is concave and vanishes at 0, $m(R,T) \geq m(R,1)^T \geq w^{RT}$; the upper bound of (a) is Thm. AW(b).

Step 6 (the potential). The increments of a concave sequence do not increase; their limit is their infimum and also the limit of $-\frac{1}{T}\log m(R,T)$; summing the increments from T_1 to T_2 gives $m(R,T_2) \leq e^{-(T_2-T_1)V(R)} m(R,T_1)$; if a number v has this property for infinitely many T_2, dividing by T_2 gives $v \leq V(R)$; and the increasing slopes of the convex function $\log m(R,\cdot)$ give the inequality of four rectangles.

Step 7 (the measure). Let Λ be the linear functional on the real polynomials with $\Lambda(\lambda^T) = m(R,T)$. Step 2 says $\Lambda(p^2) \geq 0$ and $\Lambda(\lambda p^2) \geq 0$. With $s_r = \Lambda(\lambda^r p^2) \geq 0$, Schwarz's inequality gives $s_r^2 \leq s_0 s_{2r}$, and, $|m| \leq 1$ bounding every s_r, iteration gives $s_2 \leq s_0$ and then $s_1 \leq s_0$: $\Lambda((1-\lambda)p^2) \geq 0$; and $\Lambda(\lambda(1-\lambda)p^2) = \Lambda((1-\lambda)(\lambda p)^2) + \Lambda(\lambda((1-\lambda)p)^2) \geq 0$. Writing $\lambda^T(1-\lambda)^k$ as $\lambda^\epsilon(1-\lambda)^{\epsilon'} q^2$ with $\epsilon, \epsilon' \in \{0,1\}$ gives $\sum_i (-1)^i \binom{k}{i} m(R, T+i) \geq 0$ for all $k, T \geq 0$: the sequence is completely monotone, and Hausdorff's moment theorem gives the one measure ϱ_R. Since $m(R,T) \leq (\max\operatorname{supp}\varrho_R)^T$ and $m(R,T) \geq (\lambda_* - \varepsilon)^T \varrho_R([\lambda_* - \varepsilon, 1])$ for $\lambda_* = \max\operatorname{supp}\varrho_R > 0$, $m(R,T)^{1/T} \to \lambda_*$, so $\lambda_* = e^{-V(R)}$; for $T \geq 1$ the point 0 gives nothing, and the substitution $\lambda = e^{-E}$ gives the representation, with the mass $\varrho_R((0,1]) \geq m(R,1) > 0$.

Step 8. (d) follows from (a): $V(R) \geq \sigma^+ R$ from the upper bound, $V(R) \leq -R\log w$ from the lower one. (e) At $l = l_* L^K$, $\sigma^+ = \sigma_* a_K^2$, so $a_K^{-1} V(R/a_K) \geq a_K^{-1}\sigma^+ R/a_K = \sigma_* R$; and $M_K(R,T_2)/M_K(R,T_1) = e^{2\kappa(T_2-T_1)} m(R/a_K, T_2/a_K)/m(R/a_K, T_1/a_K)$, to which (c) applies; in the inequality of four rectangles the factors $e^{2\kappa(T'-T)}$, raised to the powers $1/(T'-T)$, give one and the same factor on both sides. Along a sequence, $M_j(R,T_2) \leq e^{-(T_2-T_1)v_j(R)} M_j(R,T_1)$ at each j, as just shown with $\kappa = \kappa_j$; so $v_j(R) \leq \frac{1}{T_2-T_1}\log\frac{M_j(R,T_1)}{M_j(R,T_2)}$, whose right member converges, and $v_j(R) \geq B$ for infinitely many j gives $B \leq \limsup_j v_j(R)$; and $V_{K_j}(R) \geq \sigma_* R$ gives $v_j(R) \geq \sigma_* R - 2\kappa_j$.

The symmetry, the inequality of three rectangles, which is the log-convexity of (b) in the form of chords, and that of four rectangles hold for each M_j, the factors $e^{2\kappa_j(R+T)}$ cancelling in both inequalities, and pass to the limits. With $\mathsf{F}(T) = -\log \mathsf{W}(R,T)$, the inequality of three rectangles says that the slope $(\mathsf{F}(T') - \mathsf{F}(T_1))/(T'-T_1)$ does not increase in $T' > T_1$; so it has a limit in $[-\infty, \infty)$ as $T' \to \infty$, $\mathsf{F}(T')/T'$ tends to this limit for every T_1, and $V_{\mathrm{ren}}(R)$ is the infimum of all these slopes. (f) A rectangle with an even side $2h$ is $\gamma(\mathfrak{r}\gamma)^{-1}$ for the site mirror halfway along that side, and a square is $\gamma(\mathfrak{r}\gamma)^{-1}$ for a diagonal mirror through two of its corners; as in Step 2, Prop. YM3_I:103.4 gives $s(W_C) \geq 0$.

Step 9 (no criterion). (g) Steps 1–7 use of ν only that it is a periodic Gibbs state, invariant under the symmetries of the lattice and reflection positive at every lattice mirror (Prop. YM3_I:103.4), and,

for the second Hankel form, that it is positive at the bond mirrors on the functions of two crossing bonds. With the hypothesis of (g) they hold for s, but for the upper bound of (a), in whose place $m_s \le 1$ stands; and $m_s(R,T) \ge w^{RT}$ gives $V_s(R) \le -R \log w \le R \log \frac{4(\beta+1)}{\beta}$. On site mirrors alone the first Hankel form, with all c but two equal to 0, gives $m_s(R, h+h')^2 \le m_s(R,2h)\, m_s(R,2h')$. At $(h-1, h+1)$, and from $m_s(R,0) = 1$ and $m_s(R,2) > 0$, induction gives $m_s(R,2h) > 0$ for all h, and $\psi(h) = -\log m_s(R,2h)$ is concave, ≥ 0, with $\psi(0) = 0$; so $\psi(h)/h$ tends to $2V_{\mathrm{e}}(R) = \inf_h(\psi(h+1) - \psi(h)) \ge 0$, and $\psi(h_2) - \psi(h_1) \ge 2(h_2 - h_1)V_{\mathrm{e}}(R)$ is the inequality for even T_1 and T_2. For an odd $T_2 = 2h_2+1 > T_1$, the pair (h_2, h_2+1) gives $m_s(R, 2h_2+1) \le [m_s(R,2h_2)\, m_s(R,2h_2+2)]^{1/2}$, and the even case twice gives the inequality. For even R: the pair $(0,1)$ gives $m_s(1,2) \ge m_s(1,1)^2 = w^2 > 0$, by Step 4, and $m_s(2,2) \ge m_s(2,1)^2 = m_s(1,2)^2 > 0$; the induction at the width 2 gives $m_s(2,2h) > 0$, and $m_s(2h,2) = m_s(2,2h)$. □

Proof of Prop. 17.2. (a) $F(l,2l,2l) \le 0$ and $-F(2l,2l,2l) \le 6\beta(2l)^3$, so $0 \le \mathsf{e}(l) \le 48\beta l^3 \le x_0$. (b) For $\mathsf{k} \in \mathbb{R}^4$ let π_{k} be the law on $G \simeq S^3$ with the density proportional to $e^{\langle U, \mathsf{k}\rangle}$. Every linear component $\langle U, \mathsf{e}\rangle$, $|\mathsf{e}| = 1$, has variance $\le \frac14$ under π_{k}: with $\kappa = |\mathsf{k}|$ and $x = \langle U, \mathsf{k}\rangle/\kappa$, the mean $A(\kappa)$ of x satisfies $A' = \operatorname{Var} x$ and, by an integration by parts, $\langle 1 - x^2\rangle = 3A/\kappa$, so $A' = 1 - 3A/\kappa - A^2$; a comparison with the positive root $\mathsf{B}(\kappa)$ of $1 - 3a/\kappa - a^2 = \frac14$, whose derivative is $< \frac14$, together with $A \le \kappa/4$, which follows from $3A = \kappa\langle 1 - x^2\rangle$ and $\langle x^2\rangle \ge \frac14$, the two identities in the proof of Lem. 17.25(a), x having the law of x_0 under $\langle\cdot\rangle_\kappa$, gives $A \ge \mathsf{B}$ and so $\operatorname{Var} x \le \frac14$, while the components orthogonal to k have the variance $A/\kappa \le \frac14$.

So two such laws differ in total variation by at most $\frac14|\mathsf{k} - \mathsf{k}'|$. The conditional law of one bond given the others is $\pi_{\beta\mathsf{h}}$, h the sum of the four unit vectors of its staples, and changing one of its 12 neighbouring bonds moves h by at most 2. For a bounded Borel function f of finitely many bonds let $\delta_b(f)$ be its oscillation in the single bond b, and $\Delta(f) = \sum_b \delta_b(f)$. The conditional expectation E_b in the bond b gives $\delta_b(E_b f) = 0$, $\delta_{b'}(E_b f) \le \delta_{b'}(f) + \frac{\beta}{2}\delta_b(f)$ for the 12 neighbours b' of b, and $\delta_{b'}(E_b f) \le \delta_{b'}(f)$ for the other bonds; so after any sequence of updates the oscillations are, bond by bond, at most the entries of the vector v that arises from $(\delta_b(f))_b$ by the linear rules $v_b \to 0$, $v_{b'} \to v_{b'} + \frac{\beta}{2}v_b$ for the neighbours b' of the updated bond b.

Let S_0 be the set of the bonds of f, $S \supset S_0$ a finite set of bonds, $d(b)$ the distance of b from S_0 in the graph of neighbouring bonds, $r = \min\{d(b) : b \notin S\}$, $\alpha = 6\beta < 1$, and f_k the function that k sweeps of updates through S, each bond of S once in a sweep, make of f. An update at b takes $v_b\alpha^{-\min\{d(b),r\}}$ from the weighted sum $\sum_{b'} v_{b'}\alpha^{-\min\{d(b'),r\}}$ and adds at most $\frac{\beta}{2}\cdot 12\, v_b\, \alpha^{-\min\{d(b),r\}-1} = v_b\, \alpha^{-\min\{d(b),r\}}$, as $d(b') \le d(b)+1$; so the weighted sum does not increase, it equals $\Delta(f)$ at the start, when v lives on S_0, where $d = 0$, and the bonds outside S carry the weight α^{-r}: $\sum_{b\notin S} v_b \le \alpha^r \Delta(f)$ at all times.

An update at $b \in S$ changes $\sum_{b'\in S} v_{b'}$ by at most $-(1-\alpha)v_b$, and in a sweep the entries of the bonds of S at the times of their updates add up to at least the sum at the beginning of the sweep; so $\sum_{b\in S} v_b \le \alpha^k \Delta(f)$ after k sweeps. As f_k is a function of the bonds of S and of their neighbours, and two configurations of these bonds are joined by changing one bond at a time, $\sup f_k - \inf f_k \le (\alpha^k + \alpha^r)\Delta(f)$. Now let $l \ge 4$ be even, S the set of the bonds with both ends in the cube $\{0, \dots, l-3\}^3$, and $f = a_p$ for the plaquette $p = p_{12}(c_0, c_0, c_0)$, $c_0 = \frac{l-4}{2}$. The ends of the bonds at distance $\le j$ from the four bonds of p lie in $[c_0 - j, c_0 + 1 + j]^3$, which lies in $[0, l-3]^3$ for $j \le c_0$; so every bond not in S has $d \ge c_0 + 1 = \frac{l}{2} - 1$, that is $r \ge \frac{l}{2} - 1$; and $\Delta(a_p) \le 8$.

The bonds of S and their neighbours lie in a cube of l sites a side, which the projections modulo l and modulo $2l$ map one to one into the tori of sides l and $2l$, the plaquettes at the bonds of S onto plaquettes; so on both tori the conditional laws of the bonds of S are those used above, the functions f_k are the same, and both means of a_p equal means of f_k, which lie in $[\inf f_k, \sup f_k]$. Letting $k \to \infty$: $|\bar a_{2l}(b) - \bar a_l(b)| \le 8(6b)^{l/2-1}$, $\bar a_n(b)$ the mean of a_p on the cube of side n at the

coupling b. As $\frac{d}{d\beta}F(n,n,n) = -3n^3\bar{a}_n(\beta)$ and $X = 0$ at $\beta = 0$,

$$X(l) = 24\,l^3 \int_0^\beta (\bar{a}_{2l}(b) - \bar{a}_l(b))\,\mathrm{d}b \le 64\,l^2(6\beta)^{l/2}.$$

At each of the four pairs of a coupling and a side named in (b), $64\,l^2(6\beta)^{l/2} \le \frac{1}{20}$; and $l \mapsto l^2(6\beta)^{l/2}$ decreases for $l > 4/\log\frac{1}{6\beta}$, which lies below each of the four sides. Thm. AX(a) gives the criterion. (c) The same contraction, with S the set of the bonds at the distance $< r$ from the bonds of f, applied to two Gibbs states s, s', for which $s(E_b F) = s(F)$ by the Gibbs equation of one bond, gives $|s(f) - s'(f)| = |s(f_k) - s'(f_k)| \le (\alpha^k + \alpha^r)\Delta(f)$; let $k \to \infty$ and then $r \to \infty$. □

Proof of Prop. 17.3. (a) Lem. 17.11(a), (b) with $\kappa_i = \lambda_i(2l, 2l)^l$, so that $D = \mathsf{e}(l)$ and $\eta = \mathsf{r}$: $2\log 1.0351 \le 0.069$, and $\varpi(e^{0.069} - 1) \le 0.0357638$. The tops Λ_e, $e \ne 00$, are among the λ_i, $i \ge 1$ (Lem. 17.10), so $(\Lambda_e/\lambda_0)^l \le \mathsf{r}$, and $\log\frac{1}{0.0357638} \ge 3.33$; and $\mathsf{r} \ge \sum_{e\ne 00}(\Lambda_e/\lambda_0)^l$ gives the last statement. (b) With the time 1 over $(2l, 2l)$ let $w_f = W_{2l}(f; 0)/Z$ on the cube of side $2l$. Inside each sector $(\sum_i \mu_i^l)^2 \ge \sum_i \mu_i^{2l}$, so

$$\mathsf{e}(l) = 2\log Z(l, 2l, 2l) - \log Z(2l, 2l, 2l) \ge 2\log \sum_f \sqrt{w_f}.$$

By Lem. 17.10(c), $w_{00} = \frac{1}{4}(1 + 2r_1 + r_2)$, $w_{10} = w_{01} = \frac{1}{4}(1 - r_2)$, $w_{11} = \frac{1}{4}(1 - 2r_1 + r_2)$, and $w_{11} \ge 0$, $r_2 \le r_1$ give $2r_1 - 1 \le r_2 \le r_1$; here $r_1 \le 1$ by Lem. 17.10(c), and $r_1 > 0$ because, with the time the direction that is not in the twisted pair, $Z^- = \operatorname{Tr}\mathsf{T}_1^{2l}$ is the integral over the diagonal of a kernel with values > 0 (Lem. 17.10(i), (ii)). The sum of the square roots is concave in r_2, so on this interval it is at least the smaller of its two end values; with $x = 1 - r_1 \in [0, 1)$ these are $\sqrt{1-x} + \sqrt{2x}$ at $r_2 = 2r_1 - 1$ and $\frac{1}{2}\sqrt{4 - 3x} + \frac{3}{2}\sqrt{x}$ at $r_2 = r_1$, and the first is the smaller, as $\frac{1}{4}(4 - 3x) \ge 1 - x$ and $\frac{3}{2} > \sqrt{2}$.

The function f increases on $[0, \frac{2}{3}]$ and decreases on $[\frac{2}{3}, 1]$, with $\mathsf{f}(1) = \log 2$; and $\mathsf{f}(0.00063) > 0.069$, $\mathsf{f}(0.0039) \ge 0.16567$. (c) Let $\mathsf{e}(l) \le 0.069$ and $N \ge 16l$, and let $\bar{N} = 2^j l \le N < 2\bar{N}$, $j \ge 4$. By Lem. 17.11(f), $\log(1 + \mathsf{r}_N(N, N)) \le \log(1 + \mathsf{r}_{\bar{N}}(N, N)) \le \delta(\bar{N}, N, N) \le 4\delta_{\mathrm{c}}(\bar{N}) \le 4\bar{\delta}_4 \le 0.0029221$ (Prop. 17.16(e)); and by Lem. 17.10(c), $1 - Z^-/Z = 1 - r_1 \le \frac{4}{3}(1 - e^{-0.0029221}) \le 0.0038905 < 0.0039$. For an integer $l' \ge 16l$ with $\bar{N} = 2^j l \le l' < 2\bar{N}$, $j \ge 4$: $\mathsf{e}(l') \le 2\log(1 + \mathsf{r}_{l'}(2l', 2l')) \le 2\delta(\bar{N}, 2l', 2l') \le 2(2l'/\bar{N})^2\delta_{\mathrm{c}}(\bar{N}) < 32\,\bar{\delta}_4 \le 0.02338$.

The last sentence is the contrapositive of the first, at $l \le N/16$. (d) Thm. AW(b) at $R = T = 1$ gives $\sigma^+ \le \log(1/\nu(W_p))$, and $\sigma^+ l^2 \ge 0.4757$. □

The numbers of Remark 17.4. Over a torus of side $2l$ the momenta are $\frac{\pi}{l}m$, $m \in \mathbb{Z}^2$; three fields with one mode for each momentum $m \ne 0$ give the Fock levels whose sum at the time l is the product displayed, and the same at the time $2l$; in the notation of Lem. 17.11, $1 + \eta = 1 + \mathsf{r}$ and $1 + s_2 = 1 + \mathsf{r}'$. Summing $-3\log(1 - e^{-\pi|m|})$ over the shells $|m|^2 = 1, 2, 4, 5, 8, 9, 10, 13, \dots$ gives approximately 0.72010, and $-3\log(1 - e^{-2\pi|m|})$ gives approximately 0.02415; so $D \approx 1.416$.

Proof of Prop. 17.6. The exact part. On every periodic cube of an even side N, at every β, take as time a direction of the twisted pair, let ν be the other direction of that pair, let $\vartheta \ge 2$ and $k \ge 2$ be integers with $2k\vartheta = N$, and cut the cube into $2k$ slabs of ϑ layers. The transfer operator over ϑ layers, $\mathsf{Y} = \mathsf{T}'^{\vartheta}$ in the notation of the proof of Lem. 17.21, commutes with the flip J of one layer, the operator J_i of Lem. 17.10 that changes the sign of the bonds of the direction ν that cross one plane $\{x_\nu = c\}$, $c \in \mathbb{Z} + \frac{1}{2}$; $Z = \operatorname{Tr}\mathsf{Y}^{2k}$ and $Z^- = \operatorname{Tr}(\mathsf{J}\mathsf{Y}^{2k})$ (Lem. 17.10(ii), (c)); so $P_\pm = \frac{1}{2}(1 \pm \mathsf{J})$ have $\operatorname{Tr}(P_\pm \mathsf{Y}^{2k}) = \frac{1}{2}(1 \pm r_1)Z$: the weights of the two sectors of the flip are $\frac{1}{2}(1 \pm r_1)$.

A function of the bonds is *odd under the flip* if it changes its sign when the bonds of the direction ν that cross the plane $\{x_\nu = c\}$ change their signs in all layers. Let D, D' be bounded Borel functions of the bonds with both ends in one and the same slab of ϑ layers, D' odd under the

flip; of D no parity is asked. For $1 \le j \le 2k-1$ let t_j be the translation by $j\vartheta$ along the time, and $\mathsf{t} = \mathsf{t}_k$ the translation by $N/2$. With the slab operators Y_D, $\mathsf{Y}_{D'}$ of the proof of Lem. 17.21, $Z\langle D \cdot \mathsf{t}_j D'\rangle = \mathrm{Tr}(\mathsf{Y}^{2k-j-1}\mathsf{Y}_{D'}\mathsf{Y}^{j-1}\mathsf{Y}_D)$.

The weights of the layers and of the crossings do not change when all layers are flipped (proof of Lem. 17.10); so $P_\sigma \mathsf{Y} = \mathsf{Y} P_\sigma$ and, D' being odd, $\mathsf{J}\mathsf{Y}_{D'}\mathsf{J} = -\mathsf{Y}_{D'}$, that is $P_\sigma \mathsf{Y}_{D'} = \mathsf{Y}_{D'} P_{-\sigma}$. Splitting the trace over the two sectors, the sector changes between D and D':

$$Z\langle D \cdot \mathsf{t}_j D'\rangle = \sum_{\sigma=\pm 1} \mathrm{Tr}\big((P_\sigma \mathsf{Y})^{2k-j-1}\, \mathsf{Y}_{D'}\, (P_{-\sigma}\mathsf{Y})^{j-1}\, \mathsf{Y}_D\big),$$

a trace of $2k$ Hilbert–Schmidt operators. Hölder's inequality for it (Lem. YM3_I:86.1), with $\|P_\sigma \mathsf{Y}\|_{2k}^{2k} = \mathrm{Tr}(P_\sigma \mathsf{Y}^{2k})$ and $\|\mathsf{Y}_D\|_{2k}^{2k} = \mathrm{Tr}(\mathsf{Y}_D^* \mathsf{Y}_D)^k \le \sup|D|^{2k} Z$ (the norm definition preceding Lem. YM3_I:86.1; the trace is Z times the mean of a product of $2k$ copies of D and of its mirror image), gives

$$|\langle D \cdot \mathsf{t}_j D'\rangle| \le \sup|D|\, \sup|D'| \sum_{\sigma=\pm 1} \Big(\frac{1+\sigma r_1}{2}\Big)^{\frac{2k-j-1}{2k}} \Big(\frac{1-\sigma r_1}{2}\Big)^{\frac{j-1}{2k}}$$

(with $0^0 = 1$), and at $j = k$, where the two summands are equal,

$$|\langle D \cdot \mathsf{t} D'\rangle| \le 2 \sup|D|\, \sup|D'| \Big[\frac{1-r_1^2}{4}\Big]^{\frac12 - \frac{1}{2k}}.$$

The calibrated construction. The constants are chosen as in (Th1), (Th2) of §2.3.1, the setting in which Thm. YM3_I:D is used; among them are the cube size $M = \mathsf{L}^{m'}$, with $m' \ge 5$ (the setting preceding equation YM3_I:(634) has $M \ge L^4 M_1$ and $M_1 \ge L$), the exponents $r \ge 2$ and $\mathfrak{p}_0$, the constant $A_0 > 0$ of the thresholds (equation YM3_I:(634)), $\gamma \in (0, \frac12]$, and the numbers $c' > 0$, $\mathsf{C}^\Sigma_{\mathrm{maj}}$, c_{low} of (Th2). The setting (E) of §2.3.1 gives besides a label $\mathsf{b} \ge \gamma^{-2}$ and an integer $m \ge 1$ with $M\, R(\mathsf{b}) \le \mathsf{L}^m$, $R(x) = \min\{\mathsf{L}^i : i \in \mathbb{Z}_{\ge 0},\ \mathsf{L}^i \ge (\log x)^r\} \ge 1$, and $\ell = 2\mathsf{L}^m$. At the cutoff K the coupling is $\beta = \mathsf{L}^K \mathsf{b}$, and the cube has $N = \ell \mathsf{L}^K = 2\mathsf{L}^{m+K}$ sites a side. For an integer $0 \le d < K$ the block field of the depth d is $V = \mathcal{M}^{K-d} U$, $\mathcal{M}$ the block-averaging map of equations YM3_I:(37)–(39); it lives on a periodic cube of

$$\mathsf{n} = \ell \mathsf{L}^d = 2\mathsf{L}^{m+d}$$

blocks a side, each block having $\vartheta = \mathsf{L}^{K-d}$ sites a side, so that $N = \mathsf{n}\vartheta$; its law is μ_d^K (Def. 2.7). As $R \ge 1$, $\mathsf{L}^m \ge M = \mathsf{L}^{m'} \ge \mathsf{L}^5$, and with $d \ge 1$ and $\mathsf{L} \ge 13$:

$$\mathsf{n} \ge 2 \cdot 13^6.$$

Let $|\partial V - \mathbf{1}|_\infty$ be the largest $|\partial V(p) - \mathbf{1}|$ over the plaquettes of the block lattice, $x_d = \mathsf{L}^d \mathsf{b}$, $\varepsilon = A_0 x_d^{-1/2} (\log x_d)^{\mathfrak{p}_0}$ the threshold of equation YM3_I:(634) at the coupling x_d, $\delta = \exp[7\mathsf{n}^2\varepsilon] - 1$, and R_d the number R_t of the definitions preceding Prop. YM3_I:115.2 at the level $t = K - d$; as there $N_t = \ell^3 \mathsf{L}^{3d}$ and $x_t = x_d$, R_d does not depend on K. The hypotheses (H) are: $d \ge 1$; $x_d \ge \mathsf{t}_\natural$, the fixed calibration of §2.3.1; $\delta \le \frac{1}{20}$; and $\mathsf{R}_d \le \frac{1}{40}$.

Step 1: under (H) the block field is nearly flat with probability at least $\frac{39}{40}$, at every cutoff $K > d$. The data K, b, m and the top level $t = K - d$ make the setting (Th) of §2.3.1, as $1 \le t \le K-1$ and $x_t = x_d \ge \mathsf{t}_\natural$; Lem. YM3_I:118.1 gives what Prop. YM3_I:115.2 asks of it. Let $F = \mathbf{1}_{\mathsf{In}_t}(\mathcal{M}^t U)$, $\mathsf{In}_t = \{|\partial V - \mathbf{1}|_\infty < 2\varepsilon\}$ the inner ball of the definitions preceding Lem. YM3_I:113.10: a bounded gauge-invariant Borel function, by Prop. YM3_I:4.5, YM3_I:4.5 and YM3_I:113.10. The weight $\mathfrak{w}_t^{\mathrm{sf}}$ of the definitions preceding Prop. YM3_I:115.2 carries the factor $\mathbf{1}_{\mathsf{In}_t}(\mathcal{M}^t U)$, so $\mathfrak{w}_t^{\mathrm{sf}} = F\, \mathfrak{w}_t^{\mathrm{sf}}$, and the right inequality of Prop. YM3_I:115.2, domination and lost-mass bounds gives $Z - \int F \rho_0\, \mathrm{d}U \le Z - \int \mathfrak{w}_t^{\mathrm{sf}} \rho_0\, \mathrm{d}U \le \mathsf{R}_d Z$, $\rho_0 = e^{-\beta A}$ at $\beta = \mathsf{L}^K \mathsf{b}$. That is

$$\mu_d^K\big(|\partial V - \mathbf{1}|_\infty \ge 2\varepsilon\big) \le \mathsf{R}_d \le \tfrac{1}{40}.$$

Thm. YM3_I:D enters here, through Prop. YM3_I:115.2.

Step 2: a winding loop of the block field, its parity and its translate. Fix a block site ξ; let Γ_1, Γ_2, Γ_{12} be the closed paths of the block lattice from ξ with the step sequences (e_1^{n}), (e_2^{n}), $(e_1^{\mathsf{n}}, e_2^{\mathsf{n}})$, $P_i = V(\Gamma_i)$, and for each of them $D_\Gamma(U) = W_\Gamma(V) = \frac{1}{2}\operatorname{tr} V(\Gamma)$. Take the direction 3 as time, the flip of the bonds of the direction 1 that cross the plane $\{x_1 = c\}$, $c = \xi_1 + \frac{1}{2}\vartheta$, and t the translation by $N/2$ along e_3. Then: (i) D_Γ is a real Borel function with $|D_\Gamma| \le 1$ (Prop. YM3_I:4.5); (ii) it is a function of the bonds with both ends in one slab of ϑ layers, the slab of the blocks of the sites of Γ, by the locality of $\mathcal{M}^{K-d}$ (Prop. YM3_I:4.5); (iii) D_{Γ_1} and $D_{\Gamma_{12}}$ are odd under the flip: as L is odd, the plane $\{x_1 = c\}$ separates blocks at every level from d to K, on each double block the flip is the gauge transformation that is $-\mathbf{1}$ on one side of the plane, so by Prop. YM3_I:4.5 the averaging map carries the flip of the bonds that cross the plane at one level to the flip at the next level; and Γ_1, Γ_{12} run exactly one block bond that crosses the plane, Γ_2 none; (iv) $\mathsf{t}D_\Gamma = W_{\mathsf{t}\Gamma}(V)$, as t is the translation by $\frac{\mathsf{n}}{2}$ blocks and $\mathcal{M}^{K-d}$ commutes with it ([7, Lem. G.1]).

And $\mathsf{m}_\Gamma := \langle D_\Gamma \cdot \mathsf{t}D_\Gamma\rangle = \int W_\Gamma W_{\mathsf{t}\Gamma}\, \mathrm{d}\mu_d^K$ has $\mathsf{m}_{\Gamma_2} = \mathsf{m}_{\Gamma_1}$: the exchange of e_1 and e_2 about ξ keeps the law of the cube, commutes with t and with $\mathcal{M}^{K-d}$ ([7, Lem. G.1]), and carries Γ_1 to Γ_2.

On $\mathsf{B} = \{|\partial V - \mathbf{1}|_\infty < 2\varepsilon\}$ the two winding holonomies nearly commute: the step sequences $(e_1^{\mathsf{n}}, e_2^{\mathsf{n}})$ and $(e_2^{\mathsf{n}}, e_1^{\mathsf{n}})$ are rearrangements of one another, of the length $2\mathsf{n}$, and Lem. YM3_I:4.1 gives

$$|P_2P_1P_2^{-1}P_1^{-1} - \mathbf{1}| \le (1 + |\partial V - \mathbf{1}|_\infty)^{\mathsf{n}(2\mathsf{n}-1)} - 1 < e^{4\mathsf{n}^2\varepsilon} - 1 \le \delta.$$

As $|g - \mathbf{1}|^2 = 2 - \operatorname{tr} g$ for $g \in G$, $\frac{1}{2}\operatorname{tr}(P_2P_1P_2^{-1}P_1^{-1}) \ge 1 - \frac{1}{2}\delta^2$. The trace identity of Fricke, $\operatorname{tr}(ABA^{-1}B^{-1}) = (\operatorname{tr} A)^2 + (\operatorname{tr} B)^2 + (\operatorname{tr} AB)^2 - \operatorname{tr} A \operatorname{tr} B \operatorname{tr} AB - 2$ for $A, B \in \mathrm{SL}(2,\mathbb{C})$, at $A = P_2$, $B = P_1$, gives with $x_i = W_{\Gamma_i}(V)$ and $x_{12} = W_{\Gamma_{12}}(V)$

$$x_1^2 + x_2^2 + x_{12}^2 - 2x_1x_2x_{12} \ge 1 - \tfrac{1}{4}\delta^2, \qquad \text{so} \qquad 2x_1^2 + 2x_2^2 + x_{12}^2 \ge 1 - \tfrac{1}{4}\delta^2,$$

as $|x_{12}| \le 1$ gives $-2x_1x_2x_{12} \le x_1^2 + x_2^2$. On B a winding loop is also close to its translate: with ϵ the path of $\frac{\mathsf{n}}{2}$ steps e_3 from ξ to $\mathsf{t}\xi$ and $g = V(\epsilon)$, the step sequences of Γ followed by ϵ and of ϵ followed by $\mathsf{t}\Gamma$ are rearrangements of one another, of the length $\le \frac{5}{2}\mathsf{n}$, and Lem. YM3_I:4.1 gives $|gV(\mathsf{t}\Gamma)g^{-1} - V(\Gamma)| \le (1 + |\partial V - \mathbf{1}|_\infty)^{\frac{25}{8}\mathsf{n}^2} - 1 < e^{6.25\,\mathsf{n}^2\varepsilon} - 1 \le \delta$, so that $|W_{\mathsf{t}\Gamma} - W_\Gamma| \le \delta$. As $W_\Gamma W_{\mathsf{t}\Gamma} \ge W_\Gamma^2 - |W_\Gamma - W_{\mathsf{t}\Gamma}|$ and $|W_\Gamma - W_{\mathsf{t}\Gamma}| \le 2$ off B, Step 1 gives $\mathsf{m}_\Gamma \ge \mu_d^K(W_\Gamma^2) - \delta - 2\mathsf{R}_d$; with the weights $2, 2, 1$ and $\mathsf{m}_{\Gamma_2} = \mathsf{m}_{\Gamma_1}$,

$$4\mathsf{m}_{\Gamma_1} + \mathsf{m}_{\Gamma_{12}} \ge (1 - \tfrac{1}{4}\delta^2)(1 - \mathsf{R}_d) - 5(\delta + 2\mathsf{R}_d) \ge \tfrac{1599}{1600} \cdot \tfrac{39}{40} - \tfrac{1}{2} = \tfrac{30361}{64000} > 0.4743,$$

the middle member decreasing in δ and in R_d on $[0,1]$. So $\mathsf{m}_\Gamma \ge 0.0948 > 0.09$ for $\Gamma = \Gamma_1$ or for $\Gamma = \Gamma_{12}$; both loops give real functions of modulus ≤ 1 that are odd under the flip and are functions of one slab of the thickness of a block.

Step 3: the ceiling. The exact part at $D = D' = D_\Gamma$, with that Γ, $\vartheta = \mathsf{L}^{K-d} \ge 2$ and $2k = \mathsf{n}$, so that $2k\vartheta = N$ and $\frac{1}{2k} = \frac{1}{\mathsf{n}} = \frac{a_d}{\ell}$, the ratio of the block size $a_d = \mathsf{L}^{-d}$ at the depth d to the side ℓ, gives $0.09 \le \mathsf{m}_\Gamma \le 2[\frac{1}{4}(1 - r_1^2)]^{\frac{1}{2}(1-2/\mathsf{n})}$, that is, with $\mathsf{x} = (0.045)^{2/(1-2/\mathsf{n})}$,

$$r_1^2 \le 1 - 4\mathsf{x}, \qquad r_1 \le 1 - 2\mathsf{x} = 1 - 2\,(0.045)^{2/(1-2/\mathsf{n})},$$

the second because $(1 - 2\mathsf{x})^2 \ge 1 - 4\mathsf{x}$, $1 - 2\mathsf{x} > 0$ and $r_1 > 0$. The right member of the second inequality decreases in n to the limit 0.99595, and it is ≤ 0.99596 if and only if $\mathsf{n} \ge 5020$; at $\mathsf{n} = 2 \cdot 13^6$ it is ≤ 0.99595002. So under (H), $r_1 \le 0.99596$ on the cube of $2\mathsf{L}^{m+K}$ sites a side at $\beta = \mathsf{L}^K\mathsf{b}$, for every $K > d$.

Step 4: the range of (H); the numbers $t_\circ$ and m_t; (a). Let $\mathsf{C}_+ = \max\{0, \mathsf{C}_{\mathrm{maj}}^\Sigma + 2 + c_{\mathrm{low}}\}$, and let $y_\circ \ge 2$ be the least real number such that for all $y \ge y_\circ$

$$28\mathsf{L}^{11/2}M^2A_0\, y^{2r}(y + \log \mathsf{L})^{\mathfrak{p}_0} e^{-y/2} \le \log\tfrac{21}{20}, \qquad \log(16\mathsf{L}^9 y^{3r}) + (\mathsf{C}_+ + \tfrac{9}{2}y)(2\mathsf{L}^2M)^3 y^{3r} - c' A_0^2 y^{2\mathfrak{p}_0} \le -\log 40;$$

it exists, as the first left member tends to 0 and, in the second, $2\mathfrak{p}_0 > 3r+2$ at the chosen constants (the choice $\mathfrak{p}_0 \ge 6r+1$ in Prop. YM3_I:69.1) and $c'A_0^2 > 0$. Put $t_\circ = \min\{2\mathsf{L}\gamma^2,\ 2\mathsf{L}^2/\mathsf{t}_\natural,\ 2\mathsf{L}e^{-y_\circ}\}$. For $0 < t \le t_\circ$ let m_t be the least integer $m \ge 1$ with $M\,R(2\mathsf{L}^m/t) \le \mathsf{L}^m$, which exists as $R(x) \le \max\{1, \mathsf{L}(\log x)^r\}$; let $\ell_t = 2\mathsf{L}^{m_t}$, $\mathsf{b}_t = \ell_t/t$ and $y = \log \mathsf{b}_t$. Then (E) holds for the label b_t and the integer m_t, as $\mathsf{b}_t \ge 2\mathsf{L}/t_\circ \ge \gamma^{-2}$; $y \ge \log(2\mathsf{L}/t_\circ) \ge y_\circ$; and $\ell_t \le 2\mathsf{L}^2 M y^r$, as $m_t = 1$ or $\mathsf{L}^{m_t-1} < M\,R(\mathsf{b}_t/\mathsf{L}) \le M\mathsf{L}y^r$.

At $d=1$: $x_1 = \mathsf{L}\mathsf{b}_t \ge 2\mathsf{L}^2/t_\circ \ge \mathsf{t}_\natural$; $\mathsf{n} = \mathsf{L}\ell_t \le 2\mathsf{L}^3 M y^r$ and $x_1 = \mathsf{L}e^y$ give $7\mathsf{n}^2\varepsilon \le \log\frac{21}{20}$ by the first inequality, that is $\delta \le \frac{1}{20}$; and $\log x_1 \ge y$, $2M^{-3}\ell_t^3\mathsf{L}^3 \le 16\mathsf{L}^9 y^{3r}$ and $\ell_t^3 \le (2\mathsf{L}^2M)^3 y^{3r}$ give $\mathsf{R}_1 \le \frac{1}{40}$ by the second. So (H) holds for (b_t, m_t) at $d=1$. At the cutoff $K \ge 2$ the cube has $N = 2\mathsf{L}^{m_t+K}$ sites a side and $\beta = \mathsf{L}^K\mathsf{b}_t = N/t$; by Step 3, $r_1 \le 0.99596$ on the cube of $2\mathsf{L}^j$ sites a side at $\beta = 2\mathsf{L}^j/t$, for every $j \ge m_t+2$. Then $1-r_1 \ge 0.00404 \ge 0.0039$, and Prop. 17.3(b), (c) give $\mathsf{e}(\mathsf{L}^j) \ge \mathsf{f}(0.0039) \ge 0.16567$ and $\mathsf{e}(l) > 0.069$ for $3 \le l \le \mathsf{L}^j/8$: (a).

(b) The cube of the criterion at the cutoff K has $2l_*\mathsf{L}^K = 2\mathsf{L}^{m_0+K}$ sites a side and $\beta = \mathsf{L}^K\mathsf{b} = 2\mathsf{L}^{m_0+K}/t$ with $t = \ell_0/\mathsf{b} \le t_\circ$; apply (a) with $j = m_0+K$, for all $K \ge m_t+2-m_0$. (c) Let $\bar y = \frac{4}{3}[\log(2\mathsf{L}^2M) + r\log(4r) + \log(\mathsf{L}/t_\circ)]$ and $\beta_\flat = 2\mathsf{L}^5 M\bar y^r/t_\circ$. For $\beta \ge \beta_\flat$ choose j with $2\mathsf{L}^j \le t_\circ\beta < 2\mathsf{L}^{j+1}$ and put $t = 2\mathsf{L}^j/\beta \in (t_\circ/\mathsf{L}, t_\circ]$. With the numbers of Step 4 at this t, $y \le \log\ell_t + \log(\mathsf{L}/t_\circ)$ and $\ell_t \le 2\mathsf{L}^2 M y^r$; with $r\log y \le \frac{y}{4} + r\log(4r) - r$ this gives $y \le \bar y$, so $2\mathsf{L}^{m_t+2} = \mathsf{L}^2\ell_t \le 2\mathsf{L}^4 M\bar y^r = \frac{t_\circ}{\mathsf{L}}\beta_\flat \le \frac{t_\circ}{\mathsf{L}}\beta < t\beta = 2\mathsf{L}^j$, that is $j \ge m_t+2$; and (a) gives $\mathsf{e}(l) > 0.069$ for $3 \le l \le \mathsf{L}^j/8$, while $\mathsf{L}^j/8 > t_\circ\beta/16\mathsf{L}$. For the uniform criterion at a label b take $K \ge K_0$ with $L^K\mathsf{b} \ge \beta_\flat$: the criterion at $l = l_*L^K$ forces $l_*L^K > \frac{t_\circ}{16\mathsf{L}}L^K\mathsf{b}$.

(d) Put $\mathsf{G}_N = \log(Z(N,N,N)/\lambda_0(N,N)^N) = \log(1+\mathsf{r}_N(N,N))$. By Prop. 17.3(a), and as r_t decreases in t, $\mathsf{e}(N/2) \ge \log(1+\mathsf{r}_{N/2}(N,N)) \ge \mathsf{G}_N$; and for every integer $q \ge 2$, $Z(N,N,qN) \ge \lambda_0(N,N)^{qN}$ gives $\mathsf{G}_N \ge \mathsf{d}_q(N)/q$, $\mathsf{d}_q(N) = qF(N,N,N) - F(N,N,qN)$. Three facts bound $e^{-\mathsf{d}_q(N)} = Z(N,N,qN)/Z(N,N,N)^q$ from above: a swap on the long box, which bounds it through the largest probability on the cube (N,N,N) that the five invariants of the pair of the winding holonomies at one site lie in one small cell; a bound of that probability on a bare cube (Lem. 17.26); and a comparison of the laws of the block fields at two consecutive cutoffs in which the errors that bound quotients of densities enter as factors (Lem. 17.27), which carries the bound from one low cutoff K_1 to all higher ones. Besides Thm. YM3_I:D and the statements among the construction results named for this clause, (d) rests on Lem. 17.5 and these two lemmas, which give the estimate eq. 17.iii and, with the chain from a low cutoff, the estimate eq. 17.iv, and are stated below with their proofs.

A swap on the long box. For $g \in G$ write $g = \cos\alpha(g)\,\mathbf{1} + i\sum_j \mathsf{v}_j(g)\tau_j$, τ_1,τ_2,τ_3 the Pauli matrices, with the class angle $\alpha(g) = \arccos\frac{1}{2}\operatorname{tr} g \in [0,\pi]$ and the vector part $\mathsf{v}(g) \in \mathbb{R}^3$, $|\mathsf{v}(g)| = \sin\alpha(g)$. To a pair (g_1,g_2) of elements of G attach the real 3×2 matrix v with the columns $\mathsf{v}(g_1)$, $\mathsf{v}(g_2)$, the matrix $\mathsf{s} = (\mathsf{v}^{\mathsf{t}}\mathsf{v})^{1/2}$, and the five invariants $\mathsf{a}(g_1,g_2) = (\alpha(g_1),\alpha(g_2),\mathsf{s}_{11},\mathsf{s}_{12},\mathsf{s}_{22}) \in \mathbb{R}^5$: they do not change under a simultaneous conjugation of the pair, and if $|g_i - hg_i'h^{-1}| \le \delta \le 1$ for $i=1,2$ and one $h \in G$, then $|\mathsf{a}(g_1,g_2) - \mathsf{a}(g_1',g_2')|_\infty \le 2\delta$, as $|\mathsf{v}(g) - \mathsf{v}(g')| \le |g-g'|$, $|g-g'| \ge 2\sin\frac{1}{2}|\alpha(g)-\alpha(g')|$, and $\mathsf{v} \mapsto (\mathsf{v}^{\mathsf{t}}\mathsf{v})^{1/2}$ has the Lipschitz constant $\sqrt{2}$ for the Hilbert–Schmidt norm.

Let V be either the bare field, with $\mathsf{n} = N$, or the block field of the depth 0, on a lattice of $\mathsf{n} = \ell$ sites a side in the section, formed on the long box by the same local formulas; let $\omega \in (0,1]$ with $\delta_q = (1+\omega)^{q\mathsf{n}^2} - 1 \le 1$. To a site ξ attach $\mathsf{a}(V,\xi) = \mathsf{a}(P_1(\xi),P_2(\xi))$, the five invariants of the pair of its winding holonomies in the directions 1 and 2. Cut $\mathbb{R}^5$ into half-open cubes c_k of a side $w \ge 2\delta_q$, and let c_k^+ be the half-open cube of side $3w$ with the same centre and the same choice of included faces, so that every point lies in exactly 3^5 of them. On the event that every plaquette of V on the box (N,N,qN) is within ω of $\mathbf{1}$, let $\xi' = \xi + ke_3$, $0 \le k < q\mathsf{n}$, and t the transport of V from ξ to ξ' along the line of the direction 3: for $\mu = 1,2$ the transports $\mathsf{t}P_\mu(\xi')$ and $P_\mu(\xi)\mathsf{t}$ run along the step sequences $(e_3^k, e_\mu^{\mathsf{n}})$ and $(e_\mu^{\mathsf{n}}, e_3^k)$, which pass into one another by $k\mathsf{n} \le q\mathsf{n}^2$ exchanges of adjacent

entries, and each exchange multiplies the transport by a conjugate of $\partial V(p)^{\pm 1}$ for one plaquette p, as in the proof of Lem. YM3_I:4.1; so $|\mathsf{t} P_\mu(\xi')\mathsf{t}^{-1} - P_\mu(\xi)| \le \delta_q$, with one t for both μ, and $\mathsf{a}(V,\cdot)$ stays within $2\delta_q$ of $\mathsf{a}(V,\xi)$ at all the sites of that line.

Cut the box by walls into q slabs of N layers, with the mirrors θ_i in their middle planes and sites ξ_i^- of one line of the direction 3 just below these planes; then the indicator of the event is at most $\sum_k \prod_i g_i^k\,(g_i^k \circ \theta_i)$, $g_i^k = \mathbf{1}\{\mathsf{a}(V,\xi_i^-) \in c_k^+\}$, a function of the bonds of the lower half of the slab i (for the block field, whose walls of the blocks contain these planes, as $N = \mathsf{n}\mathsf{L}^K$ with n even, by the locality of the averaging map and its covariance under the lattice isometries, Prop. YM3_I:4.5, [7, Lem. G.1]). The slab operator of $g_i^k\,(g_i^k \circ \theta_i)$ is $\mathsf{Y}^*\mathsf{Y} \ge 0$, Y that of the lower half with g_i^k, as in the proof of Lem. 17.21; and $|\operatorname{Tr}(\mathsf{O}_1 \cdots \mathsf{O}_q)| \le \prod_i \operatorname{Tr}\mathsf{O}_i$ for positive operators of trace class.

So every slab closes into a cube: $Z(N,N,qN)\langle \prod_i g_i^k\,(g_i^k \circ \theta_i)\rangle \le \prod_i Z(N,N,N)\langle g_i^k\rangle_{(N,N,N)}$. The plaquettes off the event are bounded by Schwarz's inequality at a mirror (Lem. 17.21(a)) and the same closing. With P_* the largest probability on the cube (N,N,N) that $\mathsf{a}(V,\xi)$ lies in one c_k^+, and ρ the largest probability on it that one plaquette of V is not within ω of $\mathbf{1}$, this gives $x \le 243\,P_*^{q-1} + 3q\mathsf{n}^3(\rho x)^{1/2}$ for $x = e^{-\mathsf{d}_q(N)}$, whence

$$e^{-\mathsf{d}_q(N)} \le 486\,P_*^{q-1} + 9q^2\mathsf{n}^6\rho.$$

Anticoncentration on a bare cube. For an integer $N' \ge 4$ and a coupling $\beta' > 0$ let $\mu_{N',\beta'}$ be the law $Z^{-1}e^{-\beta'\sum_p a_p}dU$ of the periodic cube of N' sites a side, $Z = Z(N',N',N')$, and $|\partial U - \mathbf{1}|_\infty$ the largest $|\partial U(p) - \mathbf{1}|$ over its plaquettes.

Lemma 17.26 (Anticoncentration on a bare cube)**.** Let $N' \ge 4$ be an integer, $\beta' \ge C_{\mathrm{T}} N'^{68}$ and $0 < \omega \le 1.6 \cdot 10^{-7} N'^{-13}$, with C_{T} of Lem. 17.5, enlarged to be at least $1.1 \cdot 10^9$. For every site ξ, every w' with $(N'^5/2\beta')^{1/2} \le w' \le \frac{1}{20}$ and every closed cube Q of the half side w' in $\mathbb{R}^5$,

$$\mu_{N',\beta'}\big(\mathsf{a}(U,\xi) \in \mathsf{Q},\ \max_p |\partial U(p) - \mathbf{1}| < \omega\big) \le C_{\mathrm{a}}\,N'^{29.5}\,\beta'^{1/2}\,w'^3. \qquad \blacksquare$$

Here C_{a} is an absolute constant. Thus the bound $C_{\mathrm{a}}N'^{c_{\mathrm{a}}}\beta'^{1/2}w'^3$ of eq. 17.iii holds with $c_{\mathrm{a}} = 29.5$, $c'_{\mathrm{a}} = C_{\mathrm{T}}$ and $c''_{\mathrm{a}} = 68$.

Sketch of the proof of Lem. 17.26. Write $\mathsf{V} = N'^3$, take $\xi = 0$, let $|\cdot|_2$ be the Euclidean norm of a family indexed by bonds or by plaquettes, and $Z[F] = \int F\,e^{-\beta'\sum_p a_p}\,\mathrm{d}U$. (i) *The gauge of a maximal tree.* Let T be the tree of the bonds $\langle x, x+e_3\rangle$ with $x_3 \le N'-2$, $\langle x, x+e_2\rangle$ with $x_3 = 0$, $x_2 \le N'-2$, and $\langle x, x+e_1\rangle$ with $x_2 = x_3 = 0$, $x_1 \le N'-2$. A bounded Borel function that the gauge transformations do not change has the same integral against dU as against the Haar measures of the bonds off T at $U = \mathbf{1}$ on T; there the winding holonomies at 0 are the values P_μ of U at the three bonds b_μ^* from $(N'-1)e_\mu$ to 0.

On the set S_0 of the other $2\mathsf{V}-2$ bonds write $U(b) = V^P(b)\,e^{a(b)}$, $a(b) \in \mathfrak{su}(2)$, $|a(b)| < \pi$, where $V^P(b) = P_\mu$ if b is a bond of the direction μ that starts in the plane $x_\mu = N'-1$, and $V^P(b) = \mathbf{1}$ else; in $a(b)$ the Haar measure has a density at most $(2\pi^2)^{-1}$. (ii) *Small fields.* Along the tree every bond $b \in S_0$ is rebuilt from at most $2N'^2$ plaquettes, none of them a corner plaquette $p_{\mu\nu}(x)$ with $x_\mu = x_\nu = N'-1$: $|U(b) - V^P(b)| \le 2N'^2|\partial U - \mathbf{1}|_\infty$. The same rebuilding, linearised, gives $|a|_2 \le 2N'^{5/2}|d_P a|_2$ for every triple P and every family a on S_0, d_P being the linearisation at V^P of $a \mapsto (\partial U(p))_p$, a covariant lattice curl.

So on $\{|\partial U - \mathbf{1}|_\infty < \omega\}$ every $|a(b)| \le \pi N'^2\omega$, and at the corner plaquettes, where $\partial U(p)$ is the commutator $C_{\mu\nu} = P_\mu P_\nu P_\mu^{-1}P_\nu^{-1}$ up to four factors $e^{\pm a(b)}$, $|C_{\mu\nu} - \mathbf{1}| \le 9N'^2\omega$. Stokes' formula over the N'^2 plaquettes $p_{\mu\nu}(x)$ with $x_\rho = 0$, ρ the third direction, gives $2|\mathsf{v}(P_\mu) \times \mathsf{v}(P_\nu)| = |C_{\mu\nu} - \mathbf{1}| \le \sum_p |\partial U(p) - \mathbf{1}|$, and Schwarz's inequality then $\sum_p a_p \ge 2N'^{-2}\sum_{\mu<\nu}|\mathsf{v}(P_\mu) \times \mathsf{v}(P_\nu)|^2$. (iii) *The ceiling at a fixed triple.* Let κ be the family of the logarithms of the $C_{\mu\nu}$, placed at the corner plaquettes of the planes $\mu\nu$.

With $|e^{X_1}\cdots e^{X_k}-e^{X_1+\cdots+X_k}|\le\frac12(\sum_i|X_i|)^2$ for $X_i\in\mathfrak{su}(2)$, (ii) gives on $\{|\partial U-\mathbf{1}|_\infty<\omega\}$ that $2\sum_p a_p\ge(1-\eta_1)^2|d_Pa+\kappa|_2^2$, $\eta_1=39\pi N'^{9/2}\omega\le 2\cdot10^{-5}N'^{-8.5}$; keeping the fraction N'^{-3} of the action for the holonomies,

$$\sum_p a_p\ge\tfrac12(1-N'^{-3})(1-\eta_1)^2|d_Pa+\kappa|_2^2+\frac{2}{N'^5}\sum_{\mu<\nu}|\mathsf v(P_\mu)\times\mathsf v(P_\nu)|^2.$$

At a fixed triple the Gaussian integral over the $6\mathsf V-6$ real coordinates of a is at most $(2\pi/\beta'')^{3\mathsf V-3}D(P)^{-1/2}$, with $\beta''=\beta'(1-N'^{-3})(1-\eta_1)^2$ and $D(P)$ the determinant of $d_P^*d_P$ on the families on S_0, the shift by κ only lowering it; and $(\beta'/\beta'')^{3\mathsf V-3}\le(1-N'^{-3})^{-3N'^3}(1-\eta_1)^{-6N'^3}\le e^{3.2}$. (iv) *Determinants.* A triple whose three commutators lie within ϵ of $\mathbf1$ lies within $(2\epsilon)^{1/2}$ of a triple P' with one axis, $P'_\mu=\cos\alpha_\mu\,\mathbf1+i\sin\alpha_\mu\sum_j\hat n_j\tau_j$, and $D(P)\ge(1-48N'^{5/2}\delta)^{12\mathsf V}D(P')$ for $\max_\mu|P_\mu-P'_\mu|\le\delta$; at $\epsilon=9N'^2\omega$, $\omega\le1.6\cdot10^{-7}N'^{-13}$, this gives $D(P)^{-1/2}\le e^{0.5}D(P')^{-1/2}$.

At P' the families split into the colour along $\hat n$, on which $d_{P'}$ is the lattice curl, and the complex colour across $\hat n$, on which it is the curl twisted by the phases $e^{-2i\alpha_\mu}$ at the bonds where $V^{P'}=P'_\mu$: $D(P')=D(0)\,D(2\alpha)^2$, where $D(\theta)$, for $\theta\in\mathbb R^3$, is the determinant of the curl twisted by the phases $e^{i\theta_\mu}$ on the families on S_0, an even function, 2π-periodic in each θ_μ. For every momentum $k\in(\frac{2\pi}{N'}\mathbb Z/2\pi\mathbb Z)^3$ the twisted curl has the eigenvalue $\sum_\mu(2-2\cos(k_\mu+\theta_\mu/N'))$ twice, besides the gradients; let $\mathfrak d(\theta)$ be the product of these numbers over all k, and $\mathfrak d'$ their product over $k\ne0$ at $\theta=0$.

Then $D(0)=\mathfrak d'$, the change of coordinates along the tree being unimodular, and $D(\theta)\ge\mathfrak d'/(1.5\cdot10^{10}N'^{24})$ for every θ: by 2π-periodicity first take $\theta\in[-\pi,\pi]^3$; for $|\theta|_\infty\le\frac{1}{64}N'^{-11/2}$ by a comparison of the forms that uses the bound $|a|_2\le2N'^{5/2}|d_Pa|_2$ of (ii), and else by Cauchy's interlacing from the determinant $|1-e^{i\theta_\mu}|^2\mathfrak d(\theta)$ on the families that vanish on T and at b_μ^* alone, $|\theta_\mu|=|\theta|_\infty$, together with $\mathfrak d(\theta)\ge4\sin^2\frac{\theta_\mu}{2}\,N'^{-2}\mathfrak d'$, which the product formula $\prod_{j=0}^{n-1}(2\cosh m-2\cos\frac{2\pi j+\vartheta}{n})=2\cosh nm-2\cos\vartheta$ gives. This covers the triples near $P_\mu=\pm\mathbf1$ as well.

Together, for every Borel set $\mathcal P$ of triples that the simultaneous conjugations carry onto itself,

$$Z\big[\mathbf1_{\mathcal P}(P)\,\mathbf1\{|\partial U-\mathbf1|_\infty<\omega\}\big]\le10^{12}N'^{24}\,\mathsf X_0\int_{\mathcal P}\exp\Big[-\frac{2\beta'}{N'^5}\sum_{\mu<\nu}|\mathsf v(P_\mu)\times\mathsf v(P_\nu)|^2\Big]dP,\qquad \mathsf X_0=(2\pi^2)^{-(2\mathsf V-2)}\Big(\frac{2\pi}{\beta'}\Big)^{3\mathsf V-3}\mathfrak d'^{-3/2},$$

dP is Haar measure on G^3. (v) *The normalizing lower bound.* Lem. 17.5 gives $Z\ge c_{\mathrm T}N'^2\mathsf X_0/\beta'^2$ throughout the stated range, by the quantitative periodic Laplace estimate.

(vi) *The toron integral.* Let $B=2\beta'/N'^5$, so that $B^{-1/2}\le w'\le\frac{1}{20}$. The triples with $\mathsf a(P_1,P_2)\in\mathsf Q$ carry at most $261\,w'^3B^{-3/2}$ of the integral of $\exp[-B\sum_{\mu<\nu}|\mathsf v(P_\mu)\times\mathsf v(P_\nu)|^2]$. Integrate P_3 first: with the singular values $s_1\ge s_2$ of the matrix $\mathsf v$ of the pair (P_1,P_2), in the eigenframe of $\mathsf v\mathsf v^{\mathrm t}$, $\sum_{i=1,2}|\mathsf v(P_i)\times\mathsf v(P_3)|^2\ge s_2^2x_1^2+s_1^2(x_2^2+x_3^2)$, $x=\mathsf v(P_3)$, so that this integral is at most $\min\{1,(Bs_1^2)^{-1}\}\min\{1,3.81(Bs_2^2)^{-1/2}\}$; and $|\mathsf v(P_1)\times\mathsf v(P_2)|=s_1s_2$.

If $|\mathsf v(P_i)|<0.9$ for $i=1,2$ on the whole set, the Haar measure of the pair has in the coordinates $\mathsf s$ a density at most $\frac{2}{0.19\pi^2}\,4s_1s_2(s_1+s_2)$, the product of $4s_1s_2(s_1+s_2)$ with the bound of the P_3-integral is at most $30.5\,B^{-3/2}$, and the projection of $\mathsf Q$ onto the three coordinates $(\mathsf s_{11},\mathsf s_{12},\mathsf s_{22})$ has volume $8w'^3$. Else $\sin\alpha(P_i)\ge0.8$ on the set for one i, and the two angles alone give $12.6\,w'^2B^{-2}\le12.6\,w'^3B^{-3/2}$: in general the triples whose two angles lie in a set $\mathcal A$ carry at most $2.52\,B^{-2}\int_{\mathcal A}\min\{B^{1/2}\mathsf m,\mathsf m^{-1}\}\,\mathrm d\alpha_1d\alpha_2$, $\mathsf m=\max_i\sin\alpha(P_i)$. (vii) By (iv) and Lem. 17.5,

$$\mu_{N',\beta'}(P\in\mathcal P,\ |\partial U-\mathbf1|_\infty<\omega)\le\frac{10^{12}}{c_{\mathrm T}}N'^{22}\beta'^2\int_{\mathcal P}e^{-B\sum_{\mu<\nu}|\mathsf v(P_\mu)\times\mathsf v(P_\nu)|^2}\,\mathrm dP.$$

Using (vi) proves the lemma with any absolute $C_{\mathrm a}\ge261\cdot10^{12}/(2^{3/2}c_{\mathrm T})$, enlarged to be at least 1.

From one cutoff to the next. In the setting (E) of §2.3.1, with the side $\ell = 2\mathsf{L}^m$ and the label b, take at every integer $K \geq 2$ the numbers of §2.3.1 at $n = 1$: the depths $u = \lceil K/1260 \rceil$ and $s = \lceil K/9 \rceil$, $t_1 = K - u$, and, with $N_{[d]} = \ell^3 \mathsf{L}^{3d}$ and $\mathsf{y}_{[d]} = (\log(\mathsf{L}^d \mathsf{b}))^{2\mathfrak{p}_0}$, the four errors

$$\epsilon_{\mathrm{fg}} = C_{\mathrm{old}} C_{\mathrm{fg}} \tfrac{\mathsf{L}}{\mathsf{L}-1} E_0 \, N_{[u]} \mathsf{L}^{-(s-u)},$$
$$\epsilon_{\mathrm{cl}} = 4\mathsf{K}_{\mathrm{w}} c_\rho^2 A_0^2 (1 + \tfrac{2\varrho}{\mathsf{b}}) \mathsf{y}_{[K]} N_{[s]} K^{1/2} \mathsf{L}^{-(K-s)/2},$$
$$\epsilon_{\mathrm{sh}} = 3(s-u) N_{[s]} \exp\bigl[C_{\mathrm{sh}} - \tfrac{1}{4}\kappa_{\mathrm{b}} A_1^2 \mathsf{y}_{[u]}\bigr],$$
$$\mathsf{R}_{t_1} = 2M^{-3} N_{[u]} \exp\bigl[-c' A_0^2 \mathsf{y}_{[u]} + (\mathsf{C}^{\Sigma}_{\mathrm{maj}} + 2 + c_{\mathrm{low}} + \tfrac{9}{2}\log \mathsf{b}) \ell^3\bigr],$$

with the constants named there. The first two fall like powers of L^{-K}, up to factors that are powers of K, ℓ and $\log \mathsf{b}$; the last two are exponentially small in $(\log(\mathsf{L}^u \mathsf{b}))^{2\mathfrak{p}_0}$. Cor. 2.8(a) bounds the difference of the means of a gauge-invariant function at two consecutive cutoffs by $\mathfrak{o}_K = 8\mathsf{R}_{t_1} + 12\epsilon_{\mathrm{fg}} + 8\epsilon_{\mathrm{cl}} + 12\epsilon_{\mathrm{sh}}$ times its supremum; here its comparison is run with the errors that bound quotients of densities kept as factors, so that an event of a probability of the order of t keeps this order.

Lemma 17.27 (One step between consecutive cutoffs)**.** In the setting (E), let $K \geq 2$ be an integer at which the conditions (k0)–(k4) and (k6) of §2.3.1 hold at $n = 1$, and put

$$\epsilon_K^{\times} = 4\epsilon_{\mathrm{fg}} + 2\epsilon_{\mathrm{cl}} + 1.06\,\epsilon_{\mathrm{sh}} + 1.39\,\mathsf{R}_{t_1}, \qquad \epsilon_K^{+} = \mathsf{R}_{t_1} + 1.29\,\epsilon_{\mathrm{sh}}.$$

Then for every integer $0 \leq d \leq u$ and every Borel set E of block fields of the depth d that the gauge transformations carry onto itself (Def. 2.7(3)),

$$\mu_d^{K+1}(E) \leq e^{\epsilon_K^{\times}} \mu_d^K(E) + \epsilon_K^{+}, \qquad \mu_d^K(E) \leq e^{\epsilon_K^{\times}} \mu_d^{K+1}(E) + \epsilon_K^{+}.$$

■

Sketch of the proof of Lem. 17.27. It suffices to take $d = u$: for $d < u$ replace E by its preimage under the averaging maps from the depth u to the depth d, which are the same on the two lattices (Section YM3_I:116) and keep it Borel and gauge invariant (Prop. YM3_I:4.5, YM3_I:4.5). Take the lattices $\mathrm{A} = (\ell, K)$ and $\mathrm{B} = (\ell, K+1)$ with the top levels t_1 and $t_1 + 1$, the objects of Section YM3_I:116 with $n = 1$ and $f_1 = 1$, at the source 0, and $\mathsf{R} = \mathsf{R}_{t_1}$, which is the same number on both (§2.3.1). For a bounded Borel function $F \geq 0$ of the block fields of the depth u that the gauge transformations do not change, and for each lattice $\bullet$, of the cutoff $K^\bullet$ and the top level $t^\bullet$, let $\langle F \rangle_0^\bullet$ be the mean of $F(\mathcal{M}^{K^\bullet - u} U)$ at the cutoff $K^\bullet$, $\langle F \rangle_1^\bullet$ the normalised integral of F against the measure of the chain on the inner ball $\mathsf{In}_{[u]}$, and $\langle F \rangle_2^\bullet$ that against the classical start on it. (1) *The discarded mass, a remainder.* The measure of the chain is the image of $\mathfrak{w}_{t^\bullet}^{\mathrm{sf}} \rho_0 \, \mathrm{d}U$ under the averaging, with $\mathfrak{w}_{t^\bullet}^{\mathrm{sf}} \geq 0$ (Prop. YM3_I:115.2, image identity); the right inequality of Prop. YM3_I:115.2, domination bound, for F and for $\sup F - F$ composed with the averaging, which are gauge invariant (Prop. YM3_I:4.5), and Prop. YM3_I:115.2, lost-mass bound, by which the discarded mass is at most R times the partition function, give $\langle F \rangle_0^\bullet \leq \langle F \rangle_1^\bullet + \mathsf{R} \sup F$ and $\langle F \rangle_1^\bullet \leq (1 - \mathsf{R})^{-1} \langle F \rangle_0^\bullet$. (2) *Forgetting, a factor.* On $\mathsf{In}_{[u]}$ the two measures have the densities $e^{c^\bullet(0)} e^{\Phi^{\bullet,0}}$ and $e^{\hat{c}^\bullet(0)} e^{\hat{\Phi}^{\bullet,0}}$ (the proof of Prop. YM3_I:116.1), both positive almost everywhere, as both measures are positive (Prop. YM3_I:115.2, image identity, Prop. YM3_I:116.1); and the real parts of the two exponents differ by at most ϵ_{fg} at every point of $\mathsf{In}_{[u]}$ (equation YM3_I:(2180)).

So the quotient of the densities lies in $\varkappa^\bullet [e^{-\epsilon_{\mathrm{fg}}}, e^{\epsilon_{\mathrm{fg}}}]$ with one number $\varkappa^\bullet > 0$, which cancels between the numerator and the normaliser: $e^{-2\epsilon_{\mathrm{fg}}} \langle F \rangle_2^\bullet \leq \langle F \rangle_1^\bullet \leq e^{2\epsilon_{\mathrm{fg}}} \langle F \rangle_2^\bullet$. (3) *The two classical starts, a factor and a remainder.* Both are integrals of $F(\mathcal{M}^{s-u} W)$ over the block fields W of the depth s against $\mathsf{k}^\bullet(W) \hat{F}_0^\bullet(W) \, \mathrm{d}W$, $\mathsf{k}^\bullet \geq 0$ (§2.3.2); where k^{A} and k^{B} are both positive they are equal and $\hat{F}_0^{\mathrm{B}} = \hat{F}_0^{\mathrm{A}} e^{\mathsf{q}_0}$, $|\mathsf{q}_0| \leq \epsilon_{\mathrm{cl}}$ (Prop. YM3_I:116.1, density comparison in the proof); and for $(\bullet, \circ) = (\mathrm{A}, \mathrm{B})$ and (B, A) the fields at which k° vanishes carry at most the fraction ϵ_{sh} of the mass of the start of $\bullet$ (§2.3.2).

So $\langle F\rangle_2^\bullet \le e^{2\epsilon_{\rm cl}}(1-\epsilon_{\rm sh})^{-1}\langle F\rangle_2^\circ + \epsilon_{\rm sh}\sup F$. Chaining (1), (2), (3), (2), (1),

$$\langle F\rangle_0^\bullet \le \frac{e^{4\epsilon_{\rm fg}+2\epsilon_{\rm cl}}}{(1-\epsilon_{\rm sh})(1-\mathsf{R})}\langle F\rangle_0^\circ + \big(\mathsf{R}+e^{2\epsilon_{\rm fg}}\epsilon_{\rm sh}\big)\sup F,$$

and (k2), (k3), (k6) give $e^{2\epsilon_{\rm fg}} \le e^{1/4} < 1.29$, $-\log(1-\epsilon_{\rm sh}) \le 1.06\,\epsilon_{\rm sh}$ and $-\log(1-\mathsf{R}) \le 2\log 2\cdot\mathsf{R} \le 1.39\,\mathsf{R}$. At $F=\mathbf{1}_E$ this is the lemma.

The chain from a low cutoff. Let $p = 2\mathfrak{p}_0$, $y = \log \mathsf{b}$, $\bar\ell(y) = 2\mathsf{L}^2 M y^r$, $\mathsf{k}(y) = \bar\ell(y)^3 y^{p+1}$, $\mathsf{N}(y) = \mathsf{L}\,\bar\ell(y)^{31} y^{10(p+1)}$, and let $K_1 = K_1(y)$ be the least integer $K \ge 10$ with $\mathsf{L}^{K/10} \ge \mathsf{k}(y)$. With the constants of §2.3.1 and the number C_+ of Step 4 put

$$a_1 = C_{\rm old}C_{\rm fg}\tfrac{\mathsf{L}}{\mathsf{L}-1}E_0\mathsf{L}^4,$$
$$a_2 = 4\mathsf{K}_{\rm w}c_\rho^2 A_0^2(1+2\varrho)\mathsf{L}^{7/2},$$
$$a_3 = \sum_{K\ge1}(1+K\log\mathsf{L})^p K^{1/2}\mathsf{L}^{-K/90},$$
$$a_4 = 529200\,e^{C_{\rm sh}}\sum_{i\ge1} i\,\mathsf{L}^{420i}e^{-\frac14\kappa_{\rm b}A_1^2(i\log\mathsf{L})^p},$$
$$a_5 = 2520\,M^{-3}\sum_{i\ge1}\mathsf{L}^{3i}e^{-c'A_0^2(i\log\mathsf{L})^p},$$
$$a_6 = \frac{256\,\mathsf{K}_u c_\rho^2 A_0^2\mathsf{L}^4}{\gamma_{\rm r}A_1^2},$$
$$\mathsf{R}(y) = 1.29\,\bar\ell(y)^3\Big[a_4 e^{-\frac14\kappa_{\rm b}A_1^2 y^p} + a_5 e^{(\mathsf{C}_+ + \frac92 y)\bar\ell(y)^3 - c'A_0^2 y^p}\Big];$$

these are formed from the constants alone, and the three series converge, as $p\ge2$, $\kappa_{\rm b}, c' > 0$ (Prop. YM3_I:114.4 and §2.3.1) and $A_0, A_1 > 0$ (equation YM3_I:(634)). Suppose that (E) holds, $\ell \le \bar\ell(y)$, $\mathsf{b} \ge \Theta_\star$, the number of the condition (k1), $y \ge \max\{8a_1, 20a_2a_3, a_6\}$ and $\mathsf{R}(y) \le e^{-3y^2}$. Then (k0)–(k4) and (k6) hold at every integer $K \ge K_1$, and the sums $\mathsf{S} = \sum_{K\ge K_1}\epsilon_K^\times$ and $\mathsf{R}_\Sigma = \sum_{K\ge K_1}\epsilon_K^+$ satisfy

$$\mathsf{S} \le \frac{17.72\,a_1 + 2a_2a_3}{y} + 1.39\,\mathsf{R}(y), \qquad \mathsf{R}_\Sigma \le \mathsf{R}(y) \le e^{-3y^2}, \qquad \ell\mathsf{L}^{K_1} < \mathsf{N}(y).$$

Indeed, for $K \ge K_1$ one has $u < \frac{K}{1260}+1$ and $\frac{K}{9} \le s < \frac{K}{9}+1$, so $4u - s \le 4 - \frac{K}{10}$, $\frac{7s-K}{2} \le \frac72 - \frac{K}{10} - \frac{K}{90}$ and $4s - K \le 4 - \frac{K}{10}$; and $\ell^3\mathsf{L}^{-K/10} \le \ell^3/\mathsf{k}(y) \le y^{-p-1}$. Hence $\epsilon_{\rm fg} \le a_1\ell^3\mathsf{L}^{-K/10}$, $\epsilon_{\rm cl} \le a_2 y^p(1+K\log\mathsf{L})^p K^{1/2}\mathsf{L}^{-K/90}\ell^3\mathsf{L}^{-K/10}$, and the left member of (k4) is at most $a_6\gamma_{\rm r}A_1^2\ell^3\mathsf{L}^{-K/10}$. Summed over $K \ge K_1$, as $(1-13^{-1/10})^{-1} \le 4.43$, these give $\sum_{K\ge K_1}(4\epsilon_{\rm fg}+2\epsilon_{\rm cl}) \le (17.72\,a_1 + 2a_2a_3)/y$. (k0) holds as $K \ge 10$, (k1) as $\mathsf{b} \ge \Theta_\star$, and $y \ge \max\{8a_1, 20a_2a_3, a_6\}$ gives (k2), (k4) and the first half of (k3).

For the two other errors, $(y+u\log\mathsf{L})^p \ge y^p + (u\log\mathsf{L})^p$, $s-u \le 140u$, $N_{[s]} \le \ell^3\mathsf{L}^{420u}$, and at most 1260 cutoffs have the same u: $\sum_{K\ge K_1}\epsilon_{\rm sh} \le a_4\ell^3 e^{-\frac14\kappa_{\rm b}A_1^2y^p}$ and $\sum_{K\ge K_1}\mathsf{R}_{t_1} \le a_5\ell^3 e^{(\mathsf{C}_+ + \frac92 y)\ell^3 - c'A_0^2y^p}$. So $\mathsf{R}_\Sigma \le \mathsf{R}(y)$, which gives the second half of (k3) and (k6), and $\sum_{K\ge K_1}(1.06\,\epsilon_{\rm sh} + 1.39\,\mathsf{R}_{t_1}) \le 1.39\,\mathsf{R}(y)$. Finally $\mathsf{k}(y) > \mathsf{L}$, so $K_1 \ge 11$ and $\mathsf{L}^{(K_1-1)/10} < \mathsf{k}(y)$: $\mathsf{L}^{K_1} < \mathsf{L}\,\mathsf{k}(y)^{10}$ and $\ell\mathsf{L}^{K_1} < \mathsf{N}(y)$. Lem. 17.27 at $d=0$ and an induction on K give $\mu_0^K(E) \le e^{\mathsf{S}_K}(\mu_0^{K_1}(E) + \mathsf{R}_K)$, with S_K and R_K the sums of the $\epsilon_{K'}^\times$ and of the $\epsilon_{K'}^+$ over $K_1 \le K' < K$; so eq. 17.iv holds: for every integer $K \ge K_1$ and every Borel set E of block fields of the depth 0 that the gauge transformations carry onto itself

$$\mu_0^K(E) \le e^{\mathsf{S}}(\mu_0^{K_1}(E) + \mathsf{R}_\Sigma).$$

The parameters. Let $\mathsf{y}_\star$ be the least real number

$$y_0 \ge \max\{122, \log\gamma^{-2}, \log\Theta_\star, 8a_1, 20a_2a_3, a_6, 2(17.72\,a_1 + 2a_2a_3)\}$$

such that at every $y \ge y_0$

$$\text{(y1)}\ \ \mathsf{R}(y) \le e^{-3y^2};$$
$$\text{(y2)}\ \ \log\mathsf{L} + 30\log\bar\ell(y) + 10(p+1)\log y \le y;$$
$$\text{(y3)}\ \ 26\,\mathsf{N}(y)^{28}\,\bar\ell(y)\,y^4e^{-y} \le 2.5\cdot10^{-14};$$
$$\text{(y4)}\ \ 26\,\mathsf{N}(y)^{6}\,\bar\ell(y)\,y^2e^{-y} \le (c_2^{\rm SO})^2;$$
$$\text{(y5)}\ \ 31\,(y+1)^2\,\mathsf{N}(y)^6 \le e^{2y^2};$$
$$\text{(y6)}\ \ C_{\rm T}\bar\ell(y)\mathsf{N}(y)^{67}e^{-y} \le 1,$$

$c_2^{\rm SO}$ the number of Lem. 5.28. It exists: $\bar\ell$ and N are powers of y, so the left member of (y2) is $O(\log y)$, those of (y3) and (y4) tend to 0, that of (y5) is a power of y, that of (y6) tends to zero, and the two exponents in $\mathsf{R}(y)e^{3y^2}$ are $-\frac14\kappa_{\rm b}A_1^2y^p + 3y^2 + O(\log y)$ and

$$-c'A_0^2y^p + (\mathsf{C}_+ + \frac92 y)\bar\ell(y)^3 + 3y^2 + O(\log y),$$

which tend to $-\infty$, as $p = 2\mathfrak{p}_0 > 3r+2$ at the chosen constants (the choice $\mathfrak{p}_0 \ge 6r+1$ in Prop. YM3_I:69.1) and $r \ge 2$; each condition compares continuous functions, so the numbers y_0 at which all hold on $[y_0,\infty)$ form a closed half line. Put $t_\star = 2\mathsf{L}e^{-\mathsf{y}_\star}$. Now let $j \ge 1$ and $\beta > 0$ with $t = 2\mathsf{L}^j/\beta \le t_\star$, and $N = 2\mathsf{L}^j$; let m be the least integer $m \ge 1$ with $M\,R(2\mathsf{L}^m/t) \le \mathsf{L}^m$, $\ell = 2\mathsf{L}^m$, $\mathsf{b} = \ell/t$, $y = \log\mathsf{b}$ and $K = j - m \in \mathbb{Z}$, so that $N = \ell\mathsf{L}^K$ and $\beta = \mathsf{L}^K\mathsf{b}$; and $q = \lceil y\rceil$.

Then $y \ge \log(2\mathsf{L}/t) \ge \mathsf{y}_\star$; as in Step 4, (E) holds for (b, m) and $\ell \le \bar\ell(y)$; by (y2), $\log\ell \le y/30$, so that $\log\frac1t \le y \le 2\log\frac1t$, and $y \le q < y+1$, $q \ge 122$; $e^{-y} \le t = \ell e^{-y} \le \bar\ell(y)e^{-y}$; the chain holds from $K_1 = K_1(y)$, with $e^{\mathsf{S}} \le e^{0.53} < 1.7$ and $\mathsf{R}_\Sigma \le e^{-3y^2}$; and $\beta_1 = \mathsf{L}^{K_1}\mathsf{b} = \ell\mathsf{L}^{K_1}/t$ has $\log\beta_1 = y + K_1\log\mathsf{L} < y + \log\mathsf{L} + 10\log\mathsf{k}(y) \le 2y$, by (y2).

Bare cubes. Let (N',β') be $(\ell\mathsf{L}^{K_1},\beta_1)$, the bare cube at the cutoff K_1, or (N,β) if $N < \ell\mathsf{L}^{K_1}$. Then N' is of the form $2\mathsf{L}^{j'}$, $j' \ge 1$, so even, $26 \le N' < \mathsf{N}(y)$, $\beta' = N'/t$, and $\log\beta' \le 2y$. Put $\Lambda' = 3N'^3\log(8e^8\beta'^{3/2}) + \log(3N'^3) + 3y^2$, $\omega_0 = (2\Lambda'/\beta')^{1/2}$ and $\upsilon = N'^2\omega_0$. The Haar measure of $\{g \in G : |g-\mathbf{1}| \le \beta'^{-1/2}\}$ is at least $\frac18\beta'^{-3/2}$, and $\beta'\sum_p a_p \le 24N'^3$ when all bonds lie in this set; so $Z(N',N',N') \ge (8e^8\beta'^{3/2})^{-3N'^3}$, every plaquette has $|\partial U(p) - \mathbf{1}| \ge \omega_0$ with a probability at most $Z^{-1}e^{-\beta'\omega_0^2/2}$, and

$$\mu_{N',\beta'}(|\partial U - \mathbf{1}|_\infty \ge \omega_0) \le 3N'^3\,(8e^8\beta'^{3/2})^{3N'^3}e^{-\Lambda'} = e^{-3y^2}.$$

Further $N'^3 \le \Lambda' \le 13N'^3y^2$, so $\upsilon^2 \le 26N'^6y^2t \le 26\,\mathsf{N}(y)^6\bar\ell(y)y^2e^{-y}$; and (y3), (y4) give $\omega_0 \le 1.6\cdot10^{-7}N'^{-13}$, $q\upsilon \le 1.7\cdot10^{-7}$, $\beta' \ge N'e^y/\bar\ell(y) \ge C_{\rm T}N'^{68}$ by (y6) and $\upsilon \le c_2^{\rm SO}$. With $w = 2.03\,q\upsilon$ and $w' = \frac32 w + 1.03\,\upsilon$ one has $(N'^5/2\beta')^{1/2} \le 3\upsilon \le w' \le 4q\upsilon \le \frac{1}{20}$, and Lem. 17.26 at $\omega = \omega_0$ gives, for every site ξ' and every closed cube Q of the half side w',

$$\mu_{N',\beta'}(\mathsf{a}(U,\xi') \in \mathsf{Q},\ |\partial U - \mathbf{1}|_\infty < \omega_0) \le C_{\rm a}N'^{29.5}\beta'^{1/2}(4q\upsilon)^3 \le P^{\rm b} := C_{\rm b}\,q^3y^3\,\mathsf{N}(y)^{39}\,t,$$

where $C_{\rm b} = 8500C_{\rm a}$, since $(2\Lambda')^{3/2} \le 132.6\,N'^{4.5}y^3$ and $N'^{40}/\beta' = N'^{39}t$.

The cutoffs $K \ge K_1$. Take the swap with the block field $V = \mathcal{M}^K U$ of the depth 0, $\mathsf{n} = \ell$, and $\omega = \theta_{\mathsf{L}}\mathsf{L}^{2K_1}\omega_0$, with ω_0 and υ those of $(\ell\mathsf{L}^{K_1},\beta_1)$ and the number $\theta_{\mathsf{L}} = \exp\frac{1}{2(\mathsf{L}^2-1)} < 1.003$ of Lem. 5.28: $\mathsf{n}^2\omega = \theta_{\mathsf{L}}\upsilon$, so $\delta_q \le e^{q\theta_{\mathsf{L}}\upsilon} - 1 \le 1.015\,q\upsilon$, $2\delta_q \le w$ and $\omega \le 1$. The sets $E_p = \{|\partial V(p) - \mathbf{1}| \ge \omega\}$ and $\{\mathsf{a}(V,\xi') \in c_k^+\}$ are Borel sets of block fields of the depth 0 that the gauge transformations carry onto themselves, as these conjugate $\partial V(p)$, and the two winding holonomies at ξ' by one element; so the chain gives $\mu_0^K(E) \le 1.7\,(\mu_0^{K_1}(E) + e^{-3y^2})$ for each of them.

At the cutoff K_1, where $|\partial U-\mathbf{1}|_\infty<\omega_0$ on the bare cube: $\mathsf{L}^{2K_1}\omega_0\le \upsilon\le c_2^{\rm SO}$, so $|\partial V-\mathbf{1}|_\infty<\omega$, and the winding holonomies of $V=\mathcal{M}^{K_1}U$ differ from the bare ones along the same lines by at most $13.3\,\ell\mathsf{L}^{2K_1}\omega_0=13.3\,\upsilon/\ell\le 0.512\,\upsilon$ (Lem. 5.29), so that $|\mathsf{a}(V,\xi')-\mathsf{a}(U,\xi')|_\infty\le 1.03\,\upsilon$; and c_k^+ lies in a closed cube of the half side $\frac32 w$. With the bounds on the bare cube $(\ell\mathsf{L}^{K_1},\beta_1)$ this gives, for the swap, $\rho\le 3.4\,e^{-3y^2}$ and

$$P_*\le 1.7(P^{\rm b}+2e^{-3y^2})\le \Pi(y)\,t,\qquad \Pi(y)=C_\Pi y^6\,\mathsf{N}(y)^{39},\qquad C_\Pi=2C_{\rm b}+4,$$

as $q^3\le 1.025\,y^3$ and $e^{-3y^2}\le e^{-y}\le t$; and $9q^2\mathsf{n}^6\rho\le 30.6\,(y+1)^2\bar\ell(y)^6e^{-3y^2}\le e^{-y^2}$, by (y5).

The cutoffs $K<K_1$, among them those with $K\le 0$. Take the swap with the bare field on the cube of $N<\ell\mathsf{L}^{K_1}$ sites a side, $\mathsf{n}=N$, and $\omega=\omega_0$ of (N,β): $\mathsf{n}^2\omega=\upsilon$, $2\delta_q\le w$, $\rho\le e^{-3y^2}$, $P_*\le P^{\rm b}+e^{-3y^2}$, and $9q^2N^6\rho\le e^{-y^2}$; the same bounds hold.

The end. As $\Pi(y)\ge 1$, $t\ge e^{-y}$ and $q-1\le y$, $(\Pi(y)t)^{q-1}\ge e^{-y^2}$; so in all cases $e^{-\mathsf{d}_q(N)}\le 486\,P_*^{q-1}+9q^2\mathsf{n}^6\rho\le 487\,(\Pi(y)t)^{q-1}$. Where $\Pi(y)t<1$, as $q\ge y\ge\log\frac1t$ and $q\ge 122$,

$$\mathsf{G}_N\ge\frac{\mathsf{d}_q(N)}{q}\ge\frac{q-1}{q}\Big(\log\frac1t-\log\Pi(y)\Big)-\frac{\log 487}{q}\ge\log\frac1t-\log\Pi(y)-1.06,$$

that is $\lambda_0(N,N)^N/Z(N,N,N)=e^{-\mathsf{G}_N}\le 2.89\,\Pi(y)\,t$. As $\mathsf{N}(y)^{39}=\mathsf{L}^{39}(2\mathsf{L}^2M)^{1209}y^{1209r+390p+390}$ and $y\le 2\log\frac1t$, this is the bound of (d), with

$$\mathsf{p}_\star=1209\,r+780\,\mathfrak{p}_0+396,\qquad \mathsf{C}_\star=3C_\Pi\,\mathsf{L}^{39}(2\mathsf{L}^2M)^{1209}\,2^{\mathsf{p}_\star},$$

formed from L, M, r and $\mathfrak{p}_0$, and with $t_\star$, formed from the constants. Where $\Pi(y)t\ge 1$ the bound holds as well, as $\mathsf{C}_\star(\log\frac1t)^{\mathsf{p}_\star}\ge 2.89\,\Pi(y)$ and $\lambda_0(N,N)^N\le Z(N,N,N)$. With $\mathsf{e}(\mathsf{L}^j)=\mathsf{e}(N/2)\ge\mathsf{G}_N$ this gives the floor of e. The last sentence of (d) is the first at $j=m_0+K$, as $N=\ell_0/a_K$ and $t=\ell_0/\mathsf{b}$. □

Proof of Prop. 17.7. (a) With the time μ_0 and the section (N_1,N_2), $Z(t,N_1,N_2)=(1+q^t)^{N_1N_2}\mathsf{c}^t=\sum_k\binom{N_1N_2}{k}(\mathsf{c}q^k)^t$, $\mathsf{c}=(1+q^{N_1})^{N_2}(1+q^{N_2})^{N_1}$: (T2), and (T3) with all the weight in the sector 00; (T1) and (iii) are read off. With $f(u)=\log(1+q^u)$: $F(l,l,l)=3l^2f(l)$, $F(2l,l,l)=l^2f(2l)+4l^2f(l)$, $F(2l,2l,l)=4l^2f(2l)+4l^2f(l)$, $F(2l,2l,2l)=12l^2f(2l)$; so $d_1=l^2\mathsf{h}$, $d_2=2l^2\mathsf{h}$, $\mathsf{e}=4l^2\mathsf{h}$ with $\mathsf{h}=2f(l)-f(2l)$, and $X=12l^2\mathsf{h}$. (b) Expanding the two products of the factors that contain t,

$$Z^{(k;m)}=\sum_{\mathsf{a},\mathsf{b}}\binom{N_2}{\mathsf{a}}\binom{N_1}{\mathsf{b}}(-1)^{k_1\mathsf{a}+k_2\mathsf{b}}\big(\mathsf{c}_mq^{N_1\mathsf{a}+N_2\mathsf{b}}\big)^t,\qquad \mathsf{c}_m=1+(-1)^mq^{N_1N_2}>0,$$

which is (T3) with the sector $e=(\mathsf{a},\mathsf{b})$ mod 2; (T1), (T2) and (iii) are read off. The formulas for e and X follow from $F(\underline n)=\sum_\rho n_\rho\log(1+q^{n_\mu n_\nu})$; then $X\ge 24l(s-\frac{s^2}{2})-6ls^4$ and $\mathsf{e}\le 8ls^2$, so $X/\mathsf{e}\ge\frac3s(1-\frac s2-\frac{s^3}{4})\ge 2.95/s$ for $s\le 0.03$. (c) On the cube, $Z^-/Z=(\frac{1-u}{1+u})^n$ with $u=q^{n^2}$, so $\frac12q^{n^2}\le z_-(n,n,n)\le nq^{n^2}$, while $x_0=\mathsf{e}(l)=8ls^2(1+O(s^2))$ gives $\theta=103.2\,ls^2(1+O(s^2))$ and the two expansions, with the exact constant $103.2e^{-0.835}$. If the inequality held with $c'>\frac12$, then $\log\frac1q\ge 2c'\log\frac1q-C'(l)$ for all small q, which is false. □

Proof of Prop. 17.8. Put $u_j=l_j\varepsilon_{\rm v}(l_j)$ and $\mathsf{t}_j=\theta^{2^{j+1}}$. By Prop. 17.17(a), $u_0\le 0.01643\,\theta^2$. Let $u_j\le 0.0165\cdot 2^{-j}\theta^{2\cdot4^j}$, and take $\hat N=2^{j+2}$ in Prop. 17.17(b). Then the powers of θ match: $y=\hat Nu_j\le 0.066\,\theta^{2\cdot4^j}$, $(0.001615\,\mathsf{t}_j)^{2\hat N}\le 0.001615^8\theta^{2\cdot4^j}$, $(0.001615\,\mathsf{t}_j^2)^{\hat N/2}\le 0.001615^2\theta^{2\cdot4^{j+1}}$, and $8\hat N\cdot0.01655\,\mathsf{t}_j=16\cdot0.01655\,\mathsf{m}\theta^{\mathsf{m}}\le 0.835$ with $\mathsf{m}=2^{j+1}$, as $\mathsf{m}\,0.8901^{\mathsf{m}}\le 3.153$. So $\bar z_1\le 0.06601\,\theta^{2\cdot4^j}$, $\bar z_2\le 4.38\cdot10^{-5}\theta^{2\cdot4^{j+1}}$, and $u_{j+1}\le 2^{-j-1}\cdot 9.04\cdot10^{-5}\,\theta^{2\cdot4^{j+1}}$, which closes the induction.

For the cubes let $n=2^il$, $i\ge1$, $j=\lfloor(i-1)/2\rfloor$ and $M=n/l_j$, an integer with $M^2\le n/l\le 2M^2$. The first inequality of Lem. 17.15(b) on (l_j,n,l_j), with $\mathsf{r}_n(l_j,l_j)\le(0.001615\,\mathsf{t}_j)^M\le 0.001615\,\theta_j^{l_j^2/2l^2}$, gives $z_-(l_j,n,l_j)\le 0.00906\,M\theta_j^{l_j^2/2l^2}$; and $\delta(l_j,n,l_j)\le M\delta_{\rm c}(l_j)\le 0.01655\,M\theta^{l_j/l}\le$

$0.01655\, y\theta^y \le 0.0523$ with $y = \sqrt{n/l}$, as $M \le y \le l_j/l$ and $y\theta^y \le 1/e\Lambda$. Lem. 17.15(a) with $\kappa = M^2$ gives $z_-(n,n,n) \le (0.0096\, M)^{M^2\theta^{n^2/2l^2}}$, and the first factor is ≤ 1 if $0.0096\, M \le 1$, else at most $(0.0096\sqrt{n/l})^{n/l}$. Lem. 17.12(d) on these cubes and Thm. AW(a) give the area law, as $\frac{RT}{nl}\log(0.0096\sqrt{n/l}) \to 0$; and $\log \frac{1}{0.8901}/2 \ge 0.0582$. □

17.1.7. *Scope of the conclusions.* Every statement that uses the criterion is an implication from it on one lattice. Prop. 17.2 gives the criterion in two ranges of the coupling, both below $\frac16$: at every integer side $l \ge 3$ for $0 < \beta \le x_0/48l^3$ (its clause (a)), and at the even sides $l \ge 4$ with $64\, l^2(6\beta)^{l/2} \le \frac{1}{20}$ for $0 < \beta < \frac16$ (its clause (b)); from a side at which it holds the criterion passes, at the same coupling, to every integer side $l' \ge 16l$, of either parity (Prop. 17.3(c)), and to the sides $2^k l$ (Thm. AX(b)). With $\beta = L^K\mathsf{b}$ and $l = l_*L^K$ the first range reads $\mathsf{b} \le x_0 L^{-4K}/48l_*^3$ and the second $\mathsf{b} < L^{-K}/6$, while $L^K\mathsf{b} \ge \frac16$ for all large K at every label $\mathsf{b} > 0$; so neither range, nor its passage to other sides at the same coupling, contains a fixed label as K grows.

The uniform criterion is the hypothesis of Thm. AY and of Cor. 17.1(e). The number σ_* is a floor valid at each cutoff. On the centre twists of the cubes of sides $n \ge 2\mathsf{q}l$ the floors are those of the pure numbers $-\log z_-(n,n,n) \ge \sigma^+ n^2 - \frac{2\mathsf{q}n}{l}(\frac12 \log\frac{2\mathsf{q}n}{l} + 0.86)$ and $-\log(1 - Z^z/Z)$, which is at least the same number less $\log 6$ (Thm. AW(d); in physical units Thm. AY(b)); the free energy $-\log(Z^z/Z)$ of a twist itself lies between 0 and $-\log(1 - 6z_-)$ where $6z_- < 1$, and the free energy ε_{v} of a vortex line per unit length is bounded from above (Props. 17.17, 17.8).

The energies of the flux sectors and of the flux lines, $\log(\lambda_0/\Lambda_e)$ and $\log(\lambda_0/\Lambda_-)$, have the floors of Thm. AW(e), (g) and Thm. AY(b), (d), and the gap has those of Thm. AW(f) and Thm. AY(c). For a path that lies in no coordinate plane, the area in Thm. AW(c) is that of a projection counted modulo 2, which may vanish although every surface bounded by the path is large: two parallel squares of side s at the distance s, joined by a segment run twice, form a path C with $\mathsf{A}_{\rho'\rho}(C) = 0$ for all $\rho' \ne \rho$, while every set of plaquettes whose boundary modulo 2 is the path has at least $2s^2$ members.

For two static charges at sites o, r of a section that lie on no common line of the lattice, Thm. AW(e) gives the floor $\sigma^+|r-o|_\infty$, with the maximum norm, which is at least $2^{-1/2}\sigma^+|r-o|$.

17.2. **From the box criterion to continuum confinement.** A box inequality at one fixed physical size, imposed at every sufficiently large cutoff along a fixed label, controls the infrared limit. Under this hypothesis the periodic Gibbs state is unique at each such cutoff, the continuum limit is independent of the order of the volume and cutoff limits, and its reconstructed vacuum is unique with a positive Hamiltonian gap.

The fixed-lattice transfer and tube arguments are given in §17.1. Here we prove the comparisons uniform in the cutoff, passage of the gap to the continuum, transport between labels and the single-cutoff certificates with their required thresholds and margins. The box inequality itself is an additional input; the elementary small-coupling examples do not verify it along a fixed positive label.

17.2.1. *Notation and hypotheses. One lattice.* Let $\beta \ge 0$. A *box* $\underline{n} = (n_1, n_2, n_3)$ is the periodic lattice with $n_\mu \ge 3$ sites along the side μ; $|\underline{n}| = n_1n_2n_3$, and N^3 is the cube. Every bond carries the Haar probability measure of SU(2), every plaquette p the variable $a_p = 1 - \frac12 \operatorname{tr}\partial U(p) \in [0,2]$, and the box the weight $\exp(-\beta\sum_p a_p)$; $Z(\underline{n})$ is its partition function, $\mu_{\underline{n}}$ its measure, $F = \log Z \le 0$, $P = \inf_{\underline{n}} F(\underline{n})/|\underline{n}| \in [-6\beta, 0]$, and

$$\delta(\underline{n}) = F(\underline{n}) - |\underline{n}|P \ge 0, \qquad D_q(N) = q^3F(N^3) - F((qN)^3), \qquad \mathsf{e}(l) = 2F(l,2l,2l) - F((2l)^3).$$

We call δ the *excess*. For a box and a direction i, $\mathsf{d}^{(i)}(\underline{n}) = 2F(\underline{n}) - F(\underline{n}')$, $\underline{n}'$ the box with the side i doubled. None of these numbers depends on a spacing. For a bounded function Ψ of the bonds of $a\mathbb{Z}^3$ and a box, $\langle\Psi\rangle_{\underline{n}}$ is the mean of Ψ under the measure of the box extended periodically to $a\mathbb{Z}^3$.

The transfer operator. Fix a coordinate direction μ_0 as the time, the two others $\nu_1 < \nu_2$, and a cross-section $\Sigma = (A, B)$, $A, B \ge 3$; the box with t layers over Σ is (t, Σ). By Section YM3_I:85 and Prop. YM3_I:85.1 the configurations of a layer form a compact space $\mathcal{X}$ with the product Haar measure dV, a layer carries the continuous action $A_\Sigma \ge 0$ of its plaquettes, and the crossing operator K, which integrates the time-like bonds between two layers, is positive, Hilbert–Schmidt, with a continuous kernel with values in $(0, 1]$. With $\mathsf{m} = e^{-\beta A_\Sigma}$ (the function, and the operator of multiplication) we put

$$\mathsf{D} = \mathsf{D}_\Sigma = \mathsf{m}^{1/2}\mathsf{K}\,\mathsf{m}^{1/2}, \qquad \mathsf{T}' = \mathsf{K}^{1/2}\mathsf{m}\,\mathsf{K}^{1/2}.$$

D is positive, Hilbert–Schmidt, with the continuous kernel $\mathsf{m}(V')^{1/2}\mathsf{K}(V', V)\mathsf{m}(V)^{1/2} \in (0, 1]$, and $Z(t, \Sigma) = \operatorname{Tr} \mathsf{D}^t$ for every integer $t \ge 3$ (Prop. 17.31). T', which stands with the slab operators of the trace formula (M1) below, is positive as well, as $\mathsf{K} \ge 0$ and $\mathsf{m} > 0$, and has the same nonzero eigenvalues $\lambda_0 \ge \lambda_1 \ge \cdots > 0$, with multiplicities; they depend neither on t nor on the spacing. We put $\mathsf{r}_t(\Sigma) = \sum_{i \ge 1} (\lambda_i/\lambda_0)^t$, $\mathsf{G}(t; \Sigma) = \log(1 + \mathsf{r}_t)$, $\mathsf{R}_t = 1 - e^{-\mathsf{G}}$, $\varepsilon(\Sigma) = \log \lambda_0 - |\Sigma| P$, and on a cube $\mathsf{r}_N = \mathsf{r}_N(N, N)$, $\mathsf{G}_N = \mathsf{G}(N; N, N)$.

The transfer operator of a state. A periodic Gibbs state ν on $a\mathbb{Z}^3$ is invariant under $a\mathbb{Z}^3$ and reflection positive at every lattice mirror (M3), so it has the picture $(e_{\mu_0}, \frac{a}{2}, a e_{\mu_0})$ defined immediately before Lem. YM3_I:99.1. On the bounded Borel functions F, F' of finitely many bonds with both end points in $\{x_{\mu_0} \ge a\}$ the form $\langle F, F' \rangle = \nu(\overline{\Theta_0 F}\, F')$, Θ_0 the reflection $x_{\mu_0} \mapsto a - x_{\mu_0}$, is positive; $\mathcal{H}(\nu)$ is the completion of its quotient by the null vectors, $[F]$ the class of F, $\Omega = [1]$, and P_Ω the projection on $\mathbb{C}\Omega$. The *transfer operator* of ν is the operator T_ν with $T_\nu[F] = [\tau_{a e_{\mu_0}} F]$ of Lem. YM3_I:99.1: it is self-adjoint, $0 \le T_\nu \le 1$, $T_\nu \Omega = \Omega$, and $\langle [F], T_\nu^n [F'] \rangle = \nu(\overline{\Theta_0 F}\, \tau_{n a e_{\mu_0}} F')$, which is the number $h_{AB}(n)$ of Prop. 17.38(f) for $A = \overline{\Theta_0 F'}$ and $B = \overline{\Theta_0 F}$, functions of the slab of the layers $x_{\mu_0} \in \{(1 - \vartheta)a, \dots, 0\}$ when F, F' are functions of the bonds with both end points in the layers $a, \dots, \vartheta a$, $\vartheta \ge 2$; there $h_{AA}(0) - |\nu(A)|^2 = \|(1 - P_\Omega)[F']\|^2$.

So, if $\mathsf{e}(l) \le x_0 \le 0.069$ at β for one $l \ge 3$, that proposition at $n_0 = 0$ gives, with $\theta = 12.9\, x_0$, $|\langle [F], T_\nu^n [F'] \rangle - \langle [F], \Omega \rangle \langle \Omega, [F'] \rangle| \le \theta^{n/l} \|(1 - P_\Omega)[F]\|\, \|(1 - P_\Omega)[F']\|$; the classes being dense, $\|T_\nu^n - P_\Omega\| \le \theta^{n/l}$, hence $\ker(1 - T_\nu) = \mathbb{C}\Omega$ and $\|T_\nu\| \le \theta^{1/l}$ on $\Omega^\perp$.

Twists and loops. A *column* of the plane $(\mu\nu)$ is the set of the plaquettes $p_{\mu\nu}(y + j e_\rho)$, $j \in \mathbb{Z}$, ρ the third direction, in lattice units. For $z \in \{0, 1\}^3$, indexed by the three coordinate planes, Z^z is the partition function with the sign of $\operatorname{tr} \partial U(p)$ reversed on one column of each plane with $z = 1$; it does not depend on the columns chosen, and $r^z = Z^z / Z$. On a cube r^z depends only on the number of twisted planes; we write r_1, r_2, r_3. With a time μ_0 we write $z = (k; m)$, $k \in \{0, 1\}^2$ recording the planes $(\mu_0 \nu_i)$ and m the plane $(\nu_1 \nu_2)$; the weights of the four classes of electric flux $f \in \{0, 1\}^2$ are $w_f = \frac{1}{4} \sum_k (-1)^{f \cdot k} r^{(k;0)}$.

For a closed lattice path C, $W_C = \frac{1}{2} \operatorname{tr} U(C)$, $U(C)$ the ordered product along C; $W_{R \times T}$ is the loop of a coordinate rectangle with $R \times T$ bonds. A *staircase loop* of the plane (13) is given by a site o, an integer $T \ge 1$ and integers α_j and $R_j \ge 1$, $0 \le j < T$: with $o_j^k = o + \alpha_j a e_1 + k a e_3$ and $r_j^k = o + (\alpha_j + R_j) a e_1 + k a e_3$, the loop $C(\alpha, R)$ runs from o_0^0 straight to r_0^0; then, for $j = 0, \dots, T - 1$ in turn, one step up from r_j^j to r_j^{j+1} and, if $j < T - 1$, straight to r_{j+1}^{j+1}; from r_{T-1}^T straight to o_{T-1}^T; and then, for $j = T - 1, \dots, 0$ in turn, one step down from o_j^{j+1} to o_j^j and, if $j > 0$, straight to o_{j-1}^j.

It has one upward and one downward bond between any two consecutive layers that it meets, and consecutive rows need not overlap. Its physical area is $|A(C)| = a^2 \sum_j R_j$; it has $c_3(C) = 1$ and $A_{13}(C) = |A(C)|$ for the numbers c_3, A_{13} of Thm. AZ(4). A staircase loop of another coordinate plane is the image of such a loop under a lattice isometry.

The construction. Fix the common construction constants of Prop. YM3_I:69.1 and Section YM3_I:82, and use the first-passage data of Prop. YM3_I:74.1. The notation is: the blocking factor L, an odd integer; the spacings $a_K = L^{-K}$; the sides $\mathfrak{L} = \{2L^m : m \in \mathbb{N}\}$; the constants γ and $\gamma_W \le \gamma$; the reference couplings $0 < g \le \gamma$, the sides $\mathfrak{L}(g) \subset \mathfrak{L}$ at g and the first-passage data

at g; the numbers M, $r \ge 2$, $\mathfrak{p}_0 \in \mathbb{N}$ of the constants, $R(x) = \min\{L^j : j \in \mathbb{Z}_{\ge 0},\ L^j \ge (\log x)^r\}$, and $\mathsf{p}_0 = 2\mathfrak{p}_0 + \frac{1}{2}$; and the interval of labels $I(g) = (g^{-2} + \bar{B},\ X_g - \bar{B}]$, $X_g = L(g^{-2} + B_\sharp)$, $\bar{B} = LB_\sharp/(L-1)$, such that all pairs $(K, L^K \mathsf{b})$ with $\mathsf{b} \in I(g)$ are first-passage data at g.

A *label* is a real $\mathsf{b} > 0$; its *line* is the set of the pairs $(K, L^K \mathsf{b})$. The torus ℓ at the cutoff K is the cube $(\ell/a_K)^3$ of $a_K\mathbb{Z}^3$; $\mu_{K,\ell,\beta}$ is its measure, extended periodically to $a_K\mathbb{Z}^3$, and $Z_{K,\ell}$ its partition function at $\beta = L^K\mathsf{b}$; $p_\ell = \ell^{-3} \log Z_{K,\ell}$, $p_\infty = a_K^{-3} P$. On $a\mathbb{Z}^3$, for a real Lipschitz function f of compact support, $\mathcal{O}_a(f) = a^{-1} \sum_p f(x(p)) a_p$, $x(p)$ the centre of p, and $\mathcal{O}_K = \mathcal{O}_{a_K}$. For $X = (f_1, \dots, f_n)$, $S^T_{n;K,\ell,\beta}(X)$ and $S^T_n[\nu](X)$ are the joint cumulants of $\mathcal{O}_K(f_1), \dots, \mathcal{O}_K(f_n)$ on the torus and in a state ν, and a periodic Gibbs state is a Gibbs state on $a_K\mathbb{Z}^3$ invariant under a subgroup of finite index of $a_K\mathbb{Z}^3$ (equation YM3_I:(1819) and the definition following it).

Gibbs sequences and their components are defined in Def. 13.4(2), and the volume-first and growing-torus limits in [7, §K.1]. We write S^σ_n for the connected functions, as in Prop. YM3_I:92.1, and use the reflection-space notation $\mathcal{H}(\sigma)$, H_σ, Ω_σ introduced before and in Prop. YM3_I:94.1. On the line of a label we write, at $\beta = L^K\mathsf{b}$,

$$\delta_K(\ell) = \delta((\ell/a_K)^3), \qquad \mathsf{e}_K(\mathsf{b}, \ell_0) = \mathsf{e}(\ell_0/2a_K), \qquad X_K(\mathsf{b}, \ell) = D_L(\ell/La_K) = L^3 \log Z_{K,\ell/L} - \log Z_{K,\ell},$$

and call X_K the *cube number*; then $\ell^3(p_\ell - p_\infty) = \delta_K(\ell)$. A *number of the constants* is formed from this fixed common construction assignment; it depends on no cutoff, coupling, side or label.

The chessboard seminorm. For $\ell'' \in \mathfrak{L}$ with $\ell''/2a_K \ge 3$, a *board* of side $\ell''/2$ is a board of [7, §B.1] of the side $\ell''/2$ with an offset $o \in a_K\mathbb{Z}^3$: its cells are the closed cubes $o + \frac{\ell''}{2}\mathbf{k} + [-\frac{\ell''}{4}, \frac{\ell''}{4}]^3$, $\mathbf{k} \in \mathbb{Z}^3$, and its walls are the planes $x_\mu = o_\mu + \frac{\ell''}{2}(t + \frac{1}{2})$, $t \in \mathbb{Z}$, which lie in $a_K(\mathbb{Z} + \frac{1}{2})$, as $\ell''/2a_K$ is odd: planes of lattice reflections through no site. The *bonds of a cell*, its *inner bonds*, are the bonds with both end points in the closed cube. A function F of the bonds of one cell has a mirror copy in every cell, its image under the reflections in the walls between, complex conjugated at an odd number of reflections.

For a torus $\ell \in \mathfrak{L}$ with $\ell \ge \ell''$, a period of the torus holds $(2\ell/\ell'')^3$ cells of the board, and $\|F\|^{(\ell'')}_{\mathrm{ch},\ell}$, the upper index in parentheses naming the side ℓ'' of the board, is the root of order $(2\ell/\ell'')^3$ of the mean under $\mu_{K,\ell,\beta}$ of the product of the copies of F in these cells: the chessboard seminorm of F at the side ℓ, for the board of F ([7, §B.1], equation [7, eq. 189]). At $\ell = \ell''$ there are eight copies, and we write $\|F\|_{\mathrm{ch},\ell''} = \|F\|^{(\ell'')}_{\mathrm{ch},\ell''}$. So $\|\cdot\|_{\mathrm{ch},\ell}$ without an upper index is always the seminorm of eight copies on the torus ℓ, for a board of side $\ell/2$: a function of a cell of side $\ell''/2 < \ell/2$ is then read under the board of side $\ell/2$ whose cell is centred at its own cell, whose walls are walls of its own board, ℓ/ℓ'' being a power of the odd L, and whose eight copies of it are among its copies under its own board; (M2) below compares the two seminorms.

On a box: for an even $N = 2h$ and a corner $c \in a(\mathbb{Z} + \frac{1}{2})^3$, the cell below c is $\mathsf{C}_h(c) = c + [-ha, 0]^3$, and for a function Ψ of its bonds $\|\Psi\|_{\mathrm{ch};N}$ is the eighth root of the mean on the cube N^3 of the product of its eight mirror copies in the planes $x_\mu = c_\mu$; at $N = \ell/a_K$, $\ell \in \mathfrak{L}$, it is the seminorm $\|\Psi\|_{\mathrm{ch},\ell}$ of the torus ℓ for the board of side $\ell/2$ whose cell is $\mathsf{C}_h(c)$.

Throughout, $0 < x_0 \le 0.069$, $\theta = 12.9\, x_0 \le 0.8901$ and $\Lambda = \log(1/\theta) \ge 0.1164$.

Definition 17.28 (The box inequality BI)**.** Let $\mathsf{b} > 0$ be real, $\ell_0 = 2cL^{m_0}$ with $c \in \mathbb{N}$ and $m_0 \in \mathbb{Z}$, and let K_0 be an integer with $m_0 + K_0 \ge 0$ and $cL^{m_0+K_0} \ge 3$. BI$[\mathsf{b}, \ell_0, K_0; x_0]$ is the statement: for every integer $K \ge K_0$, with $l_K = \ell_0/2a_K = cL^{m_0+K}$,

$$\mathsf{e}(l_K) = 2 \log Z(l_K, 2l_K, 2l_K) - \log Z(2l_K, 2l_K, 2l_K) \le x_0 \qquad \text{at } \beta = L^K\mathsf{b}.$$

Its rate is $m_* = 2\log(1/\theta)/\ell_0 \ge 0.2328/\ell_0$; then $\theta^{1/l_K} = e^{-m_* a_K}$. For every $z \in \mathbb{Z}$ the data $(L^z\mathsf{b}, L^z\ell_0, K_0 - z)$ give the same statement, since they name the same pairs $(l_K, L^K\mathsf{b})$. In the proofs below only the fact that l_K is an integer ≥ 3 is used, except where $\ell_0 = 2L^{m_0}$ is assumed. ■

Remark 17.29 (The spectral reading). At every $\beta \ge 0$ and $l \ge 3$, with $\mathsf{r} = \mathsf{r}_l(2l, 2l)$ over the cross-section $(2l, 2l)$ of the box $(l, 2l, 2l)$, Prop. 17.31(b) at $q = 2$ gives $\log(1+\mathsf{r}) \le \mathsf{e}(l) \le 2\log(1+\mathsf{r})$; so $\mathsf{r} \le e^{x_0/2} - 1$ implies $\mathsf{e}(l) \le x_0$, and $\mathsf{e}(l) \le x_0$ implies $\mathsf{r} \le \varphi(e^{x_0} - 1)$, $\varphi(\eta) = \eta/(1 + \sqrt{1-\eta^2})$; at $x_0 = 0.069$ the two numbers are 0.035102 and 0.035764. Up to these constants BI is the statement that the thermal sum $\sum_{i\ge1}(\lambda_i/\lambda_0)^{l_K}$ over the cross-section $\ell_0 \times \ell_0$ is small uniformly in the cutoff.

17.2.2. *Principal results.*

Theorem AZ (One label: one state, one limit, one vacuum, a gap, an area law)**.** Assume BI$[\mathsf{b}, \ell_0, K_0; x_0]$. Let $K \ge \max\{K_0, 1\}$ and $\beta = L^K\mathsf{b}$. No constant below depends on K.

(1) *The lattice.* (a) For every $\ell \ge \ell_0$ with $\ell/a_K \in \mathbb{N}$: $\delta_K(\ell) < 0.13736\,\theta^{\ell/\ell_0}$ and $\delta_K(\ell) \le 0.5892\,\theta^{2\ell/\ell_0} = 0.5892\,e^{-m_*\ell}$; at $\ell = 2^j\ell_0$, $\delta_K(\ell) \le 0.017170\,\theta^{2\ell/\ell_0}$; if ℓ/a_K is even, $\mathsf{e}(\ell/2a_K) < 0.3702\,\theta^{\ell/2\ell_0}$ and $\mathsf{e}(\ell/2a_K) \le 0.4079\,\theta^{\ell/\ell_0}$; on the cube ℓ/a_K all seven $0 \le 1 - r^z < 0.4121\,\theta^{\ell/\ell_0}$; for $\ell \ge L\ell_0$, $X_K(\mathsf{b}, \ell) < 0.13736\,L^3\theta^{\ell/L\ell_0}$; and for every box whose least physical side ℓ_- is $\ge \ell_0$, $\delta(\underline{n}) < |\underline{n}|(a_K/\ell_-)^3\,0.13736\,\theta^{\ell_-/\ell_0}$. (b) The lattice $a_K\mathbb{Z}^3$ has exactly one periodic Gibbs state ν_K at β; it is ergodic under $a_K\mathbb{Z}^3$, invariant under all isometries of the lattice, reflection positive at every lattice mirror, trivial on the tail σ-field, and an extreme point of the set of all Gibbs states at β; the pressure P is continuously differentiable near β with $P'(\beta) = -3\nu_K(a_p)$. (c) For every $\ell \in \mathfrak{L}$ with $\ell \ge \ell_0$, on the inner bonds of a cell of side $\ell/2$ the laws of ν_K and of the torus ℓ are at a distance in total variation at most $0.541\,\theta^{\ell/2\ell_0}$, and $|\nu_K(G) - \mu_{K,\ell',\beta}(G)| \le 0.66\,\theta^{\ell'/2\ell_0}\|G\|_{\mathrm{ch},\ell''}$ for real G of a cell of side $\ell''/2$, $\ell_0 \le \ell'' \le \ell'$ in $\mathfrak{L}$. For every $\ell \ge \ell_0$ with $N = \ell/a_K$ even, every corner c, every bounded real Borel function Ψ of the bonds of $\mathsf{C}_{N/2}(c)$ and every periodic box $\underline{n}$ with $n_1, n_2, n_3 \ge N$, of any integer sides:

$$|\langle\Psi\rangle_{\underline{n}} - \langle\Psi\rangle_{N^3}| \le 2.71\,\theta^{\ell/2\ell_0}\|\Psi\|_{\mathrm{ch};N}, \qquad |\langle\Psi\rangle_{\underline{n}} - \nu_K(\Psi)| \le 5.42\,\theta^{\ell/2\ell_0}\|\Psi\|_{\mathrm{ch};N},$$

and $|\mu_{\underline{n}}(A) - \nu_K(A)| \le 2.71\,\theta^{\ell/2\ell_0}$ for the events A of the bonds of the cell. Periodic boxes with receding closed twist sets, and finite mixtures of them, converge to ν_K as in Prop. 17.38(d). (d) Over every cross-section with physical sides $l_1 \le l_2$, $l_1 \ge \ell_0$, $l_i/a_K \in \mathbb{N}$, the top eigenvalue is simple, its eigenvector carries no electric flux, and

$$-a_K^{-1}\log(\lambda_1/\lambda_0) > m_* + \frac{1.42}{l_1}; \qquad \text{at } l_1 = \ell_0: \ -a_K^{-1}\log(\lambda_1/\lambda_0) > \frac{2}{\ell_0}\log\frac{1}{2.42\,x_0} \ge \frac{3.579}{\ell_0};$$

so the lowest level carrying electric flux, around either side, lies more than $m_* + 1.42/l_1$ above the top; by contraposition, if over a cross-section with $l_1 = l_h$ that level lies at most $1.42/l_h$ above the top at infinitely many cutoffs, then BI fails at the label b at every side $\ell_0 \le l_h$. Over the square (ℓ, ℓ), $\ell \ge \ell_0$, with $s_\ell = 2^{k-1}\ell_0 \in (\frac{\ell}{4}, \frac{\ell}{2}]$, $2^k\ell_0 \le \ell < 2^{k+1}\ell_0$, the levels $E_i = -a_K^{-1}\log(\lambda_i/\lambda_0)$ satisfy $E_1 \ge m_* + 1.5898/s_\ell \ge m_* + 3.179/\ell$ and $\#\{i \ge 1 : E_i \le E\} \le 0.20395\,e^{(E-m_*)s_\ell}$. For $t \in a_K\mathbb{N}$:

$$\sum_{i\ge1}(\lambda_i/\lambda_0)^{t/a_K} \le \exp\Big[0.37\Big\langle\frac{l_1}{2t}\Big\rangle\Big\langle\frac{l_2}{2t}\Big\rangle e^{-m_*t}\Big] - 1 \le \exp\Big[\frac{0.37}{\ell_0^2}\,l_1l_2\,e^{-m_*t}\Big] - 1 \quad (t \ge \tfrac{\ell_0}{2}),$$

$\langle u\rangle = \max\{1, u\}$, and the sum is $\le 0.2314\,e^{-m_*t}$ for $t \ge l_2/2$. No such floor holds for magnetic flux: over the square (ℓ, ℓ) the free energy of a vortex line, $E_{\mathrm{v}} = a_K^{-1}\log(\lambda_0/\|\mathsf{T}^{(1)}\|)$, satisfies $\ell E_{\mathrm{v}} < 1.0292\,\theta^{\ell/\ell_0}$, and $\ell E_{\mathrm{v}} \le e^{-\sigma_*\ell^2}$ at $\ell = 2^j\ell_0$, $j \ge 0$, σ_* as in (4). (e) If A, B are bounded functions of the bonds of two slabs between which lie n layers, then $|\nu_K(AB) - \nu_K(A)\nu_K(B)| \le e^{-m_*na_K}\sup|A|\sup|B|$. For F, G of two cells of side $\ell''/2$ of a board, $\ell'' \in \mathfrak{L}$, $\ell'' \ge \ell_0$, $j \ge 1$ cells apart in a direction, $|\nu_K(FG) - \nu_K(F)\nu_K(G)| \le 1.0350\,e^{-m_*(j-1)\ell''/2}\|F\|_{\mathrm{ch},\ell''}\|G\|_{\mathrm{ch},\ell''}$. For every n with $na_K \ge \frac{3}{4}\ell_0 + \frac{1}{2}a_K$ and every bounded real Borel F of the bonds of the cube $\{|x|_\infty \le \lfloor n/3\rfloor a_K\}$, $\|\nu_K(F\,|\,\text{bonds outside } \{|x_3| < na_K\}) - \nu_K(F)\|_{L^2(\nu_K)} \le 0.7057\,\mathrm{osc}(F)\,e^{-m_*(2n-1)a_K/6}$. (f) For $\ell \in \mathfrak{L}$, $\ell \ge \ell_0$, the free energy

$E = \log Z_\Gamma - \log Z_{K,\ell}$ of the torus sheared by half a period, $\Gamma = \mathbb{Z}\ell(e_1-e_3)\oplus\mathbb{Z}\ell e_2\oplus\mathbb{Z}\frac{\ell}{2}(e_1+e_3)$, satisfies $0 \le E \le \mathsf{e}(\ell/2a_K) \le 0.4079\,\theta^{\ell/\ell_0}$; the gap alone gives $E \ge -1.24\,\theta^{\ell/\ell_0}$.

(2) *One limit.* Let $n \ge 1$, and let $X = (f_1, \dots, f_n)$ consist of real Lipschitz functions, none 0, with pairwise disjoint compact supports in $(-\ell''/4, \ell''/4)^3$ for some $\ell'' \in \mathfrak{L}$, $\ell'' \ge \ell_0$. Put $X_i = \mathcal{O}_K(f_i) - \mu_{K,\ell'',\beta}(\mathcal{O}_K(f_i))$, $G_I = \prod_{i\in I} X_i$, $M_I = \sup_{K\in\mathbb{N}} \|G_I\|_{\mathrm{ch},\ell''}$. Then $M_I < \infty$, and with $C(X) = 0.65\sum_\pi |\pi|! \prod_{I\in\pi}(1.0174\,M_I)$, π running over the partitions of $\{1,\dots,n\}$, for every $\ell' \in \mathfrak{L}$ with $\ell' \ge \ell''$:

$$\sup_{K\ge\max\{K_0,1\}} |S_n^T[\nu_K](X) - S^T_{n;K,\ell',L^K\mathsf{b}}(X)| \le C(X)\,\theta^{\ell'/2\ell_0},$$

$$\sup_{K\ge\max\{K_0,1\}} \sup_{\min_\mu n_\mu \ge \ell'/a_K} |S_n^T[\mu_{\underline{n}}](X) - S_n^T[\nu_K](X)| \le C^{\mathrm{sh}}(X)\,\theta^{\ell'/2\ell_0},$$

$C^{\mathrm{sh}}(X) = 3.36\sum_\pi |\pi|! \prod_{I\in\pi}(1.208\,M_I)$. Hence, for $n \ge 2$, $S_n(X) = \lim_K S_n^T[\nu_K](X)$ exists along all cutoffs; it equals $\lim_{\ell'}\lim_K S^T_{n;K,\ell',L^K\mathsf{b}}(X)$, the limit of the torus cumulants along every pair of sequences $K_j \to \infty$, $\mathfrak{L} \ni \ell_j \to \infty$, and the limit of the cumulants of periodic boxes $\underline{n}^{(j)}$ at cutoffs $K_j \to \infty$ along every sequence of boxes of any shape with $a_{K_j}\min_\mu n_\mu^{(j)} \to \infty$. If $\mathsf{b} \in I(g)$, $0 < g \le \gamma$, and the supports lie in one closed ball of radius R at pairwise distances $\ge \mathsf{d}$, then for $\ell' \in \mathfrak{L}(g)$, $\ell' \ge \max\{\ell_0, 128n(R+1)\}$, the first bound holds with $C^\flat(X) = 0.65\sum_\pi |\pi|! \prod_{I\in\pi}(1.0174\,\mathsf{m}_I^\flat)$, $\mathsf{m}_I^\flat = \mathsf{M}_{8|I|}(\mathsf{d}';R)^{1/8}\prod_{i\in I}\|f_i\|_\sharp$, which depends only on g, the constants (with the radius fixed in Thms. YM3_I:AJ and YM3_I:AD), n, $\mathsf{d}' = \min\{\mathsf{d},1\}$, R and the norms $\|f_i\|_\sharp = \max\{\sup|f_i|, 40M\,\mathrm{Lip}\,f_i\}$; here $\mathsf{M}_k(\mathsf{d}';R)$ is the sum over the partitions of $\{1,\dots,k\}$ into blocks of at least two members of the products of the bounds $C^g_{|B|}(\mathsf{d}';R)$ of (M5).

With the same $C^\flat(X)$ it holds with a torus $\ell^+ \ge \ell'$ of $\mathfrak{L}$ in the place of ν_K, and with 0.69 for 0.65 with the box (q_1N, q_2N, q_3N), $N = \ell'/a_K$, $q \in \mathbb{N}^3$, in the place of ν_K; for every periodic box $\underline{n}$ with all sides $\ge \ell'/a_K$, $|S_n^T[\mu_{\underline{n}}](X) - S_n^T[\nu_K](X)| \le 3.36\sum_\pi |\pi|! \prod_{I\in\pi}(1.19\,\mathsf{m}_I^\flat)\,\theta^{\ell'/2\ell_0}$; and for $n \ge 2$, $|S_n(X)| \le C_n^g(\mathsf{d};R)\prod_i \|f_i\|_\sharp$.

(2′) *One far field.* Let $n \ge 1$, $\rho \ge 1$, $\mathsf{d} > 0$, $f_1, \dots, f_n$ real Lipschitz, none 0, with supports in $[-\rho,\rho]^3$ at pairwise sup distances $\ge \mathsf{d}$, h real Lipschitz, not 0, with support in $v + [-\rho,\rho]^3$, $\Pi = \|h\|_\sharp \prod_i \|f_i\|_\sharp$, and $\ell'' \in \mathfrak{L}$, $\ell'' \ge \max\{\ell_0, 8\rho+4\mathsf{d}+4\}$. There is C_n, formed from $n, \rho, \mathsf{d}, \ell''$, b and the constants, such that $|S^T_{n+1}[\nu_K](h,X)| \le \mathsf{C}_n\, e^{-m_*(|v|_\infty - \ell'')}\,\Pi$ for $|v|_\infty \ge \ell''$, and on every torus $\ell \ge L\ell''$ of $\mathfrak{L}$, $|S^T_{n+1;K,\ell,\beta}(h,X)| \le 3.44\,\mathsf{C}_n\, e^{-m_*(|v|_{\infty,\ell} - \ell'')}\,\Pi$ for $|v|_{\infty,\ell} \ge \frac{3}{2}\ell''$, $|\cdot|_{\infty,\ell}$ the distance on the torus.

The same two bounds hold with h replaced by any bounded real Borel function W of the bonds with both ends in $v + [-\rho,\rho]^3$, with $\mathsf{C}'_n \sup_\square \|W - \mu_{K,\ell'',\beta}(W)\|_{\mathrm{ch},\ell''}\prod_i\|f_i\|_\sharp$ in the place of $\mathsf{C}_n\Pi$, C'_n formed as C_n and the supremum over the cells $\square$ of side $\ell''/2$ of all boards that hold $v + [-\rho,\rho]^3$ at a sup distance $\ge \mathsf{d}/2$ from their walls; so the decay of a far insertion W_K, for instance a local density smeared at a fixed scale, is uniform in the cutoff whenever these seminorms are bounded in K. In particular, let u be a real bounded Lipschitz function on $\mathbb{R}^3$ that vanishes on $\{|x|_\infty < r\}$, $r \ge \ell'' + \rho$, and let $\chi_v = \chi_0(\cdot - v)$, $v \in \rho\mathbb{Z}^3$, be the translates of the tent $\chi_0(x) = \prod_\mu \max\{0, 1 - |x_\mu|/\rho\}$: a partition of unity by Lipschitz functions with $\operatorname{supp}\chi_v \subset v + [-\rho,\rho]^3$.

Then $u\chi_v = 0$ unless $|v|_\infty \ge r - \rho \ge \ell''$, $\sup_v \|u\chi_v\|_\sharp < \infty$, and for every $K \ge \max\{K_0, 1\}$

$$\sum_{v\in\rho\mathbb{Z}^3} |S^T_{n+1}[\nu_K](u\chi_v, X)| \le \mathsf{C}_n \sup_v \|u\chi_v\|_\sharp \prod_i \|f_i\|_\sharp \sum_{v\in\rho\mathbb{Z}^3,\ |v|_\infty \ge r-\rho} e^{-m_*(|v|_\infty - \ell'')},$$

a bound free of K that tends to 0 as $r \to \infty$ at a fixed bound of $\sup_v \|u\chi_v\|_\sharp$. Thus the connected-cumulant series $\sum_v S^T_{n+1}[\nu_K](u\chi_v, X)$ converges absolutely, uniformly in K, and is the limit of the cumulants with finite partial sums of the far insertions; it tends

to 0 as the region of u recedes. On a torus $\ell \geq L\ell''$ of $\mathfrak{L}$, take $\rho = \ell/q \geq 1$ with q an integer and $\ell'' \geq 8\rho + 4\mathsf{d} + 4$, use the finite set $V = \rho\mathbb{Z}^3/\ell\mathbb{Z}^3$ and the periodized tents $\chi_v^{\mathrm{per}}(x) = \sum_{k\in\mathbb{Z}^3} \chi_0(x - v + \ell k)$. For a bounded Lipschitz function u on the torus vanishing where $|x|_{\infty,\ell} < r$, $r \geq \frac{3}{2}\ell'' + \rho$, the finite sum over V has the same bound with $3.44\,\mathsf{C}_n$ and periodic distances. Its tail is bounded by the displayed infinite-grid tail, so the decay as $r \to \infty$ is uniform over these tori.

(3) *One vacuum, the Euclidean group, a gap.* Let $\mathsf{b} \in I(g)$, $0 < g \leq \gamma$. Every Gibbs sequence at g with the pairs $(K_j, L^{K_j}\mathsf{b})$, $K_j \geq \max\{K_0, 1\}$, is $(\nu_{K_j})_j$; the full sequence (ν_K) converges to a functional σ with $S_n^\sigma = S_n$ for $n \geq 2$; σ is its own and only ergodic component, invariant under $\mathbb{R}^3 \rtimes \mathrm{O}(3)$ and reflection positive at every plane; $\ker H_\sigma = \mathbb{C}\Omega_\sigma$, and $\mathcal{H}(\sigma)$ carries a Wightman theory of one Hermitian scalar field on $\mathbb{R}^{1+2}$ with a unique vacuum and the Schwinger functions of σ. Every continuum limit at g along growing tori with the pairs $(K_j, L^{K_j}\mathsf{b})$, those with the spacing removed first among them, is $(S_n^\sigma)_{n\geq 2}$. Finally $\operatorname{spec} H_\sigma \subset \{0\} \cup [m_*, \infty)$: for all F, F' in the span of separated tuples in the upper half space and $t \geq 0$,

$$\left|\sigma(\Theta\bar{F} \cdot \tau_{te_3}F') - \overline{\sigma(F)}\,\sigma(F')\right| \leq e^{-m_* t}\,\|(1 - P_\Omega)[F]\|\,\|(1 - P_\Omega)[F']\|,$$

Θ the reflection $x_3 \mapsto -x_3$, P_Ω the projection on Ω_σ; the same in every direction.

(4) *An area law.* For every rectangle C of a coordinate plane with physical sides $R, T \in a_K\mathbb{N}$,

$$0 \leq \nu_K(W_C) \leq e^{-\sigma_* RT}, \qquad \sigma_* = \frac{2\log(1/\theta) + 1.67}{\ell_0^2} \geq \frac{1.9028}{\ell_0^2};$$

$|\nu_K(W_C)| \leq e^{-\sigma_*|A(C)|}$ for every staircase loop of a coordinate plane, $|A(C)|$ its physical area; and for every closed lattice path C with a bond of the direction 3, $|\nu_K(W_C)| \leq 2^{c_3(C)-1}e^{-\sigma_* A_{13}(C)}$, where $A_{13}(C)$ is the area of the union of the squares of side a_K of the plane (13) about which the projection of C winds an odd number of times, and $c_3(C)$ is the number of passages from a downward to an upward bond of the direction 3 in the cyclic order along C; the same holds for every ordered pair of directions. The static potential $V_K(r) = \lim_{T\to\infty} -T^{-1}\log \nu_K(W_{r\times T})$, $r, T \in a_K\mathbb{N}$ physical, exists in $[0, \infty]$, is concave and non-decreasing, and $V_K(r) \geq V_K(r') + \sigma_*(r - r')$ for $r \geq r'$. For every ℓ with ℓ/a_K an integer ≥ 3: $0 \leq 1 - r_1(\ell/a_K) \leq 2\exp(-8.8 \cdot 10^{-4}\,\ell^2/\ell_0^2)$, with $5.707 \cdot 10^{-3}$ in the place of $8.8 \cdot 10^{-4}$ for $\ell \geq 128\,\ell_0$; and with $\mathsf{q} = 1 + 0.835/\log(1/\theta)$, for $\ell \geq \mathsf{q}\ell_0$: $\frac{1}{2}(1 - r_1(\ell/a_K)) \leq \exp[-\sigma_*\ell^2 + (4\mathsf{q}\ell/\ell_0)(\frac{1}{2}\log(4\mathsf{q}\ell/\ell_0) + 0.86)]$. None of these bounds depends on K, b or L.

■□

Theorem BA (All labels: one theory up to dilation)**.** Assume $\mathrm{BI}[\mathsf{b}, \ell_0, K_0; x_0]$ at one label $\mathsf{b} > 0$.

(1) There are $\beta_0 > 0$ and $C_+ < \infty$ such that for every real $\beta \geq \beta_0$ there is an integer l with $3 \leq l \leq C_+\beta$ and $\delta(l^3) \leq 0.008625$, hence $\mathsf{e}(l) \leq 0.069$, at β.

(2) For every $\mathsf{b}' > 0$ and every integer m with $L^m \geq 48C_+\mathsf{b}'$, $\mathrm{BI}[\mathsf{b}', 2L^m, K_0'; 0.069]$ holds, K_0' the least integer with $L^{K_0'}\mathsf{b}' \geq \beta_0$ and $K_0' + m \geq 1$; on every compact set of labels one side and one threshold serve. Hence Thm. AZ holds at every label, its clause (3) at every label of every $I(g)$; and the set of the labels at which BI holds at some side and some threshold is empty or all of $(0, \infty)$.

(2′) *Near the label, with the same threshold.* Let $\ell_1 \in \mathfrak{L}$, $\ell_1 \geq 75\,\ell_0$, $f(x) = \max\{0, 1 - 8|x|_\infty/\ell_1\}$ and $\mathsf{M} = \sup\{\|\mathcal{O}_K(f) - \mu_{K,\ell_1,L^K\mathsf{b}'}(\mathcal{O}_K(f))\|_{\mathrm{ch},\ell_1} : K \in \mathbb{N},\ \mathsf{b}' \in [\frac{\mathsf{b}}{2}, 2\mathsf{b}]\}$. Then $\mathsf{M} < \infty$, and with $\eta = \min\{\frac{\mathsf{b}}{2},\ 0.0086/(0.17516 \cdot 1458\,\mathsf{M})\}$: for all $|\mathsf{b}' - \mathsf{b}| \leq \eta$ and all $K \geq \max\{K_0, 1\}$, $\delta_K(\ell_1) \leq 0.008625$ at $\beta = L^K\mathsf{b}'$, so $\mathrm{BI}[\mathsf{b}', 2\ell_1, \max\{K_0, 1\}; 0.069]$; $\mathsf{b}' \mapsto S_n^{(\mathsf{b}')}(X)$ is continuous there, and $S_n^T[\nu_{K_j,\mathsf{b}_j}](X) \to S_n^{(\mathsf{b})}(X)$ along all $K_j \to \infty$, $\mathsf{b}_j \to \mathsf{b}$.

Moreover, let $\ell_0 = 2L^{m_0}$, let $\ell_1^\flat = 2L^{m_1}$ with m_1 the least $m \in \mathbb{N}$ with $2L^m \geq \ell_0$ and $L^3\, 0.13736\, \theta^{2L^m/\ell_0} \leq 0.03$, let $f^\flat$, $\mathsf{M}^\flat$ be formed as f, M with $\ell_1^\flat$ for ℓ_1, and $r = \min\{\frac{\mathsf{b}}{2}, 0.03/(16L^3\mathsf{M}^\flat)\}$. Then for all $|\mathsf{b}' - \mathsf{b}| \leq r$ and all $K \geq \max\{K_0, 1\}$, at $\beta = L^K\mathsf{b}'$: $0 \leq D_L(\ell_1^\flat/a_K) < 0.06$, $\mathsf{e}(\ell_1^\flat/a_K) < 2.2 \cdot 10^{-4}$, and $\mathrm{BI}[\mathsf{b}', L^z\ell_1^\flat, \max\{K_0, 1\}; 6.1 \cdot 10^{-9}]$ for every integer $z \geq 1$. Neither η nor r depends on the cutoff.

(3) For every $K \in \mathbb{N}$ and every real $\beta \geq \beta_0$ the lattice $a_K\mathbb{Z}^3$ has exactly one periodic Gibbs state ν at β, which is also the limit of the tori; $|\nu(AB) - \nu(A)\nu(B)| \leq e^{-c_* n/\beta} \sup|A| \sup|B|$ for bounded functions of two slabs between which lie n layers, $c_* = \log(1/0.8901)/C_+$: the correlation length in lattice units is at most β/c_*, and the transfer operator T_ν of ν (the setting, in every coordinate direction as the time) has $\ker(1 - T_\nu) = \mathbb{C}\Omega$ and norm at most $e^{-c_*/\beta}$ on $\Omega^\perp$. Moreover $0 \leq 1 - r_1(N) \leq 2\exp[-2.2 \cdot 10^{-4}(N/C_+\beta)^2]$ at β for every integer $N \geq 3$, and in lattice units every slope of the static potential of ν is at least $0.4757\,(C_+\beta)^{-2}$. For $0 < g \leq \gamma$ and $\ell_0^g = 2C_+L(g^{-2} + \bar{B})$: $|S^T_{n;K,\ell,\beta}(X) - S^T_{n;K,\ell',\beta}(X)| \leq C_g(X)\, 0.8901^{\ell/2\ell_0^g}$ for $\ell \leq \ell'$ in $\mathfrak{L}(g)$ above a side that X fixes, uniformly in the first-passage data (K, β) at g with $\beta \geq \beta_0$, with $C_g(X)$ free of K, β, ℓ, ℓ'; the same with ν for the torus ℓ'.

(4) For every $c > 0$ there is one functional σ_c such that for all real spacings $a_j \to 0$ and couplings β_j with $a_j\beta_j \to c$, and every choice of periodic Gibbs states on $a_j\mathbb{Z}^3$ at β_j, the sequence converges to σ_c. With $X_s = (f_1(\cdot/s), \ldots, f_n(\cdot/s))$,

$$S_n^{\sigma_{tc}}(X) = t^{-n}\, S_n^{\sigma_c}(X_{1/t}) \qquad (t, c > 0,\ n \geq 2),$$

and σ_c is the same for every admitted blocking factor. In lattice units, $H_n(Y) = \lim_{\beta\to\infty} \kappa_n(\beta; Y)$ exists along the real β, where $\kappa_n(\beta; Y)$ is the joint cumulant of the $\mathcal{O}_{1/\beta}(y_i)$ in the periodic Gibbs state on $\beta^{-1}\mathbb{Z}^3$ at β, and $S_n^{\sigma_c}(X) = c^{-n}H_n(X_{1/c})$. For $c \in I(g)$, σ_c is the functional σ of Thm. AZ(3) at the label c; its gap scales like $1/c$.

(5) *The rotational Ward identity.* Let $\mathsf{b} \in I(g)$, $0 < g \leq \gamma$, $n \geq 2$, $\mathsf{d} > 0$, $R \geq 1$, $0 < \kappa < \frac{1}{16}$. There are C and p', depending on g, n, d, R, κ, the data of BI and the constants, but on no side and on no place, such that for all large K, all $\ell \in \mathfrak{L}(g)$ and $v \in a_K\mathbb{Z}^3$ with $|v|_\infty + R + 2 \leq \ell/4$, all $\omega \in \mathfrak{so}(3)$, and all real $\chi, f_1, \ldots, f_n \in C^{1,1}(\mathbb{R}^3)$ that vanish outside $v + [-R, R]^3$, the f_i at pairwise sup distances $\geq \mathsf{d}$, χ equal to 1 at the centres and at the bonds of the plaquettes at which some f_i does not vanish, the bulk term $\mathfrak{U}^{(K,\ell,L^K\mathsf{b})}_{\omega,\chi}(f_1, \ldots, f_n)$ of the rotational Ward identity YM3_I:(2108) on the torus ℓ (the joint cumulant of the $\mathcal{O}_K(f_i)$ with one insertion of the local density of the rotation ω weighted by χ, together with the like cumulants in which the insertion is weighted by one f_i) satisfies

$$|\mathfrak{U}^{(K,\ell,L^K\mathsf{b})}_{\omega,\chi}(f_1, \ldots, f_n)| \leq (1 + 2|v|_1)\, C\, |\omega|\, K^{p'} L^{-\kappa K}\, \|\chi\|_{C^{1,1}} \prod_i \|f_i\|_{C^{1,1}},$$

and the same bound holds for the bulk term in the state ν_K. The bound rests, besides on BI and on Thm. YM3_I:D, on the bound (M7) of the member $\mathfrak{U}^\sharp_{\omega,\chi}$ of the bulk term of third order in the curvature.

■□

Theorem BB (One cutoff decides; a form without cutoff)**.** Let $\mathsf{b} > 0$ and $\ell = 2L^m \in 2L^{\mathbb{Z}}$. Let $\varsigma = \sum_{j\geq 0}(1 + j)^{\mathsf{p}_0} L^{-j/10}$, and let $z = z(\mathsf{b}, \ell)$ be the least integer $z \geq 0$ with $L^z\mathsf{b} \geq \gamma^{-2}$, $m + z \geq 2$ and $LM\, R(L^z\mathsf{b}) \leq L^{m+z-1}$.

(1) There are an explicit threshold $K_\star(\mathsf{b}, \ell)$, formed from the constants, b and ℓ, with $K_\star(\mathsf{b}, \ell) - z$ at or above the thresholds K_{bf} of (M4)(ii) on the two tori $L^{z-1}\ell$ and $L^z\ell$ at the label $L^z\mathsf{b}$, to which the dilation of Prop. 17.44(c) by $z = z(\mathsf{b}, \ell)$ brings the data, and the margins

$$\eta_K(\mathsf{b}, \ell) = 3\varsigma\, \mathsf{C}_{\mathrm{bf}}(L^z\mathsf{b})\, (L^z\ell)^3 (K - z)^{\mathsf{p}_0} L^{-(K-z)/10} \leq C(\mathsf{b}, \ell)\, K^{\mathsf{p}_0} L^{-K/10},$$

$\mathsf{C}_{\rm bf}(\mathsf{b}')$ a number of the constants and of b', bounded on compact sets of labels, so that $C(\cdot,\ell)$ is bounded on compact sets of labels (where $z=0$, $\eta_K = 3\varsigma\,\mathsf{C}_{\rm bf}(\mathsf{b})\,\ell^3 K^{\mathsf{p}_0} L^{-K/10}$), such that $|X_{K'}(\mathsf{b},\ell) - X_K(\mathsf{b},\ell)| \le \eta_K(\mathsf{b},\ell)$ for $K' \ge K \ge K_\star(\mathsf{b},\ell)$. So $X_\infty(\mathsf{b},\ell) = \lim_K X_K(\mathsf{b},\ell) \ge 0$ exists, uniformly on compact sets of labels. For every $y>0$: if $X_{K_1} \le y - \eta_{K_1}$ at one $K_1 \ge K_\star$, then $X_K \le y$ for all $K \ge K_1$; $X_\infty < y$ if and only if $X_{K_1} < y - \eta_{K_1}$ at one $K_1 \ge K_\star$; $X_\infty > y$ if and only if $X_{K_1} > y + \eta_{K_1}$ at one $K_1 \ge K_\star$, and then $X_K > y$ for all $K \ge K_1$.

(2) *The cube criterion.* Let $2^k \le L/2 < 2^{k+1}$, $\Phi_L(x) = (L/2^{k+1})^3[\epsilon + \frac{20}{7}\epsilon^2]$ with $\epsilon = (12.9x)^{2^k}/12.9$, $x_1 = \max\{x \in (0, 0.069] : \Phi_L(x) \le x_0\}$, $y_1 = \frac{L^3}{8}x_1$ and $y_0 = \frac{L^3}{8}x_0$. If $X_{K_1}(\mathsf{b},\ell) \le y_1 - \eta_{K_1}(\mathsf{b},\ell)$ at one $K_1 \ge K_\star(\mathsf{b},\ell)$, then $\mathrm{BI}[\mathsf{b},\ell,K_1;x_0]$ holds; if $X_{K_1}(\mathsf{b},\ell) \le y_0 - \eta_{K_1}(\mathsf{b},\ell)$ there, then $\mathrm{BI}[\mathsf{b},2\ell/L,K_1;x_0]$ holds (with $c=2$), and with it Thm. AZ at the side $2\ell/L$, of rate $L\log(1/\theta)/\ell$. Conversely $\mathrm{BI}[\mathsf{b},2\ell/L,K_0;x_0]$ gives $X_K(\mathsf{b},L\ell) \le L^3\bar\delta_{x_0}(L)$ for all $K \ge K_0$, with $\bar\delta_x(\nu) = (\nu/2^j)^3\mathsf{c}_0(12.9x)^{2^j}$ for $2^j \le \nu < 2^{j+1}$, $\mathsf{c}_0 = \frac{20}{7\cdot 12.9^2} \approx 0.0171693$; so $X_{K_1}(\mathsf{b},L\ell) > L^3\bar\delta_{x_0}(L) + \eta_{K_1}(\mathsf{b},L\ell)$ at one $K_1 \ge K_\star(\mathsf{b},L\ell)$ refutes it. For every K with $K+m \ge 2$,

$$\min\Big\{0.069,\ \Big[\tfrac{7}{20}L^{-3}X_K(\mathsf{b},L\ell)\Big]^{1/2}\Big\} \le \mathsf{e}_K(\mathsf{b},\ell) \le \min\Big\{\tfrac{2}{L}X_K(\mathsf{b},\ell),\ \Phi_L\big(\tfrac{8}{L^3}X_K(\mathsf{b},\ell)\big)\Big\},$$

the last member where its argument is ≤ 0.069; so $\mathrm{BI}[\mathsf{b},\ell,K_0;x_0]$ gives $X_K(\mathsf{b},L\ell) \le \frac{20}{7}L^3x_0^2$ for $K \ge K_0$, and if $X_{K_1}(\mathsf{b},L\ell) > \frac{20}{7}L^3x_0^2 + \eta_{K_1}(\mathsf{b},L\ell)$ at one $K_1 \ge K_\star(\mathsf{b},L\ell)$, then $\mathsf{e}_K(\mathsf{b},\ell) > x_0$ for every $K \ge K_1$. The same bracket holds for $\liminf_K \mathsf{e}_K$ and $\limsup_K \mathsf{e}_K$ with X_∞.

(3) *The inequality of BI itself at one cutoff.* Let $\ell_0 = 2L^{m_0}$, $i \ge 1$ and $\ell = L^i\ell_0$. If $\mathsf{e}_{K_1}(\mathsf{b},\ell_0) \le x_0$ at one $K_1 \ge K_\star(\mathsf{b},\ell)$ with $L^3\bar\delta_{x_0}(2L^{i-1}) + \eta_{K_1}(\mathsf{b},\ell) \le y_1$, then $X_K(\mathsf{b},\ell) \le y_1$ for all $K \ge K_1$ and $\mathrm{BI}[\mathsf{b},L^i\ell_0,K_1;x_0]$ holds, of rate $L^{-i}m_*$; with y_0 in the place of y_1 it gives $\mathrm{BI}[\mathsf{b},2L^{i-1}\ell_0,K_1;x_0]$. The margin condition reads $\bar\delta_{x_0}(2L^{i-1}) \le \frac{1}{8}x_1 - L^{-3}\eta_{K_1}$; at $x_0 = 0.069$ and $i=2$ it holds, once η_{K_1} is small enough, at every odd $L \ge 33$, so at every admitted blocking factor, and at $i=1$ it never holds. So, wherever $L^3\bar\delta_{x_0}(2L) < y_1$, with $K_{\star\star}(\mathsf{b},\ell_0)$ the least $K \ge K_\star(\mathsf{b},L^2\ell_0)$ such that $\eta_{K'}(\mathsf{b},L^2\ell_0) \le y_1 - L^3\bar\delta_{x_0}(2L)$ for all $K' \ge K$, an explicit expression, the inequality $\mathsf{e}_{K_1}(\mathsf{b},\ell_0) \le x_0$ at one $K_1 \ge K_{\star\star}(\mathsf{b},\ell_0)$ gives $\mathrm{BI}[\mathsf{b},L^2\ell_0,K_1;x_0]$.

(4) The following are equivalent: (i) $\mathrm{BI}[\mathsf{b},\ell_0,K_0;x_0]$ holds for some $\ell_0 \in 2\mathbb{N}L^{\mathbb{Z}}$ and some K_0; (ii) $X_\infty(\mathsf{b},\ell) < y_0$ for some $\ell \in 2L^{\mathbb{Z}}$; (iii) $X_{K_1}(\mathsf{b},\ell) < y_0 - \eta_{K_1}(\mathsf{b},\ell)$ for some $\ell \in 2L^{\mathbb{Z}}$ and one $K_1 \ge K_\star(\mathsf{b},\ell)$; (iv) $X_\infty(\mathsf{b},\ell) \to 0$ as $2L^{\mathbb{Z}} \ni \ell \to \infty$. More precisely, (iii) at (ℓ,K_1) gives (i) at $\ell_0 = 2\ell/L$, $K_0 = K_1$; and (i) at (ℓ_0,K_0) gives $X_K(\mathsf{b},\ell) \le L^3\bar\delta_{x_0}(2\ell/L\ell_0) < 0.13736\,L^3\theta^{\ell/L\ell_0}$ for all $K \ge K_0$ and all $\ell \in 2L^{\mathbb{Z}}$ with $\ell \ge L\ell_0$.

(5) *The half box.* This branch remains a sketch at the full interacting Hessian estimate described with Thm. AH. Let $\ell_0 = 2L^{m_0}$ and J a compact set of labels. There are C and K_* with $|\mathsf{e}_{K+1}(\mathsf{b}',\ell_0) - \mathsf{e}_K(\mathsf{b}',\ell_0)| \le C\,L^{-K/10}$ for $\mathsf{b}' \in J$ and $K \ge K_*$. Hence $\mathsf{e}_\infty = \lim_K \mathsf{e}_K(\mathsf{b},\ell_0)$ exists, and with $Q_K = \sum_{k\ge K} CL^{-k/10}$, $|\mathsf{e}_K - \mathsf{e}_\infty| \le Q_K$: if $\mathsf{e}_{K_1}(\mathsf{b},\ell_0) \le x_0 - Q_{K_1}$ at one $K_1 \ge K_*$, then $\mathrm{BI}[\mathsf{b},\ell_0,K_1;x_0]$ holds, at the same side; $\mathrm{BI}[\mathsf{b},\ell_0,K_0;x_0']$ with $x_0' < x_0$ gives $\mathsf{e}_{K_1} \le x_0 - Q_{K_1}$ at every large K_1; $\mathsf{e}_\infty < x_0$ if and only if $\mathsf{e}_{K_1}(\mathsf{b},\ell_0) < x_0 - Q_{K_1}$ at one $K_1 \ge K_*$; and if $\mathsf{e}_{K_1}(\mathsf{b},\ell_0) > x_0 + Q_{K_1}$ at one $K_1 \ge K_*$, then $\mathrm{BI}[\mathsf{b},\ell_0,K_0;x_0]$ fails for every K_0.

(6) *A form without cutoff.* For every $\ell \in 2L^{\mathbb{Z}}$ and every real $\mathsf{b} > 0$ the limit $D_\infty(t) = \lim_K D_L(\ell/a_K)|_{\beta=L^K\mathsf{b}}$ exists, depends on $t = \ell/\mathsf{b}$ alone, is continuous on $(0,\infty)$, and $\sup_{t\in[t_-,t_+]}|D_L(\ell/a_K) - D_\infty(t)| \le C\,K^{\mathsf{p}_0}L^{-K/10}$ on compact sets for large K. The function $\delta_\infty(t) = \sum_{r\ge 0} L^{-3(r+1)}D_\infty(L^r t)$ is continuous and positive, $\delta_K(\ell) \to \delta_\infty(\ell/\mathsf{b})$ uniformly on compact sets of labels, $D_\infty(t) = L^3\delta_\infty(t) - \delta_\infty(Lt)$ and $(L-1)^3\delta_\infty \le D_\infty \le L^3\delta_\infty$. δ_∞ is the same for every admitted blocking factor; $t^{-3}\delta_\infty(t)$ does not increase, and $\delta_\infty(\rho t) \le$

$(3\rho^2-3\rho+1)\delta_\infty(t)\le 3\rho^2\delta_\infty(t)$ for real $\rho\ge 1$. Either $\delta_\infty\ge 0.008625$ on $(0,\infty)$, or $\delta_\infty(t_0)<0.008625$ at some t_0, and then $\delta_\infty(t)\le 0.1374\,(103.2\,\delta_\infty(t_0))^{t/2t_0}$ for all real $t\ge 2t_0$. The second case holds if and only if BI holds at some side of some label, and it holds as soon as $D_{q,\infty}(t_0)<(q-1)^3x_0/8$ at one t_0 for one admitted q, $D_{q,\infty}(t)=q^3\delta_\infty(t)-\delta_\infty(qt)$.

(7) *The size of the thresholds.* Read as inequalities, the conditions of the list of constants admit exactly the odd blocking factors $L>48\cdot 4096^2e^{24}=2.1331\ldots\cdot 10^{19}$, the least being 21 331 858 733 892 671 083. At every admissible choice of the constants, at a cutoff $K_1\ge K_\star(\mathsf{b},\ell)$ the small cube of the criterion of (2) has more than $10^{1.42\cdot 10^{11}}$ sites a side, and at a cutoff at which the criterion of (3) with $i=2$ applies each of the two boxes of BI has more than $10^{1.89\cdot 10^{12}}$ sites. Independently of all constants but L, $\eta_K(\mathsf{b},\ell)\ge 48\,\varsigma_\flat(L)\,L^6(K-z)^{5/2}L^{-(K-z)/10}$ with $\varsigma_\flat(L)=\sum_{j\ge 0}(1+j)^{5/2}L^{-j/10}$; as $X_K\ge 0$, the margin alone forces more than 10^{152} sites a side on the small cube of any inequality $X_{K_1}\le y-\eta_{K_1}$ with $y\le y_0$.

■□

To complete clause (5)(c) below and the indicated part of Prop. 17.48(b), one still needs a uniform probability estimate for tubes around holonomy classes. We call the target the **Heaviest-class estimate**. For every integer $j\ge 1$, put $N=2L^j$. For every $\beta>0$ and every $\omega>0$ with $\Xi=\beta\omega^2\ge 1$ and $\Xi N^5\omega\le 3/640$, every w with $N^2\omega\le w\le 1/10$, every pair $Q\in G^2$ and every site y of the periodic cube, its Wilson probability law satisfies

$$\mu_{N^3,\beta}\big(\mathsf{D}((P_1,P_2)(y),Q)\le w,\ \max_p|\partial U(p)-\mathbf{1}|<\omega\big)\le 10^{11}\Xi^5N^7w^6\omega^{-4}.$$

Here P_1,P_2 are the straight winding holonomies through y, and $\mathsf{D}(P,Q)=\min_{g\in G}\max_{i=1,2}|P_i-gQ_ig^{-1}|$ is the distance of pairs modulo simultaneous conjugation. This probability bound remains to be proved. The pointwise density maximum below does not control the tube measure, especially near degenerate or central pairs.

Theorem BC (Small tori without the box criterion)**.**

(1) *Comparison.* For $\beta\ge 0$, let $N,l\ge 3$ and $q\ge 2$ be integers. Then $0\le\mathsf{e}(N)\le D_2(N)\le 8\delta(N^3)$ and $D_q(N)\ge\frac{q^3}{8}D_2(N)$; $(q-1)^3\delta(N^3)\le D_q(N)\le q^3\delta(N^3)$, and $\delta(M^3)\le(3\rho^2-3\rho+1)\delta(N^3)\le 3\rho^2\delta(N^3)$ for $M=\rho N\ge N$; $\delta(\underline{n})\le(n_1n_2+n_1n_3+n_2n_3)N^{-2}\delta(N^3)$ for every box with all sides $\ge N$, so $\mathsf{e}(l)\le 16(l/N)^2\delta(N^3)$ for $l\ge N$; $\mathsf{e}(l)\le\frac{2}{L}D_L(2l/L)$ if $l=Ll'$, $l'\ge 2$; if $D_L(N)\le\frac{L^3}{8}x$ with $x\le 0.069$, then $D_2(N)\le x$, $\mathsf{e}(N)\le x$ and, for even N, $\mathsf{e}(LN/2)\le\Phi_L(x)$; $\mathsf{e}(l)\le x\le 0.069$ gives $D_L(2l)\le\frac{20}{7}L^3x^2$; $\delta(N^3)\le x_0/8$ gives $\mathsf{e}(N)\le x_0$; $\mathsf{e}(l)\le x_0$ gives $\delta(N'^3)\le 0.008625$ for $N'\ge 48l$; and $\mathsf{e}(l)\le 24\beta l^3$, so $\mathsf{e}(l)\le x_0$ whenever $0<\beta\le x_0/24l^3$.

(2) *Dichotomy.* At each $\beta\ge 0$ the following are equivalent: $\mathsf{e}(l)\le 0.069$ for one $l\ge 3$; $\mathsf{e}(l)\to 0$; $\delta(N^3)\to 0$; $\delta(N^3)\le 0.008625$ for one $N\ge 3$. Then $\delta((2N)^3)\le 183\,\delta(N^3)^2$ and $\delta(N'^3)\le 0.13736\,(103.2\,\delta(N^3))^{N'/2N}$ for $N'\ge 2N$. The numbers 0.07489 and 0.00936 may stand for 0.069 and 0.008625 in this equivalence. In the other case $\mathsf{e}(l)>0.069$ and $\delta(N^3)>0.008625$ for all $l,N\ge 3$, and indeed $\mathsf{e}(2^kl)>0.07489$ for all l and k; this case holds whenever there are two periodic Gibbs states at β, and then $\liminf_m\delta((2L^{m+K})^3)\ge\log 2$. Every phase is reached by the tori: if $\liminf_m\delta((2L^{m+K})^3)\le D<\infty$ at β, there are sides along which the tori converge to a periodic Gibbs state μ^* with $\mu^*\ge e^{-D}\nu$ for every ergodic periodic Gibbs state ν, and every periodic Gibbs state is at most $e^D\mu^*$.

(3) *A floor.* Let $0<g\le\gamma_W$, let $\mathsf{d}_0(g,\vartheta)$ and $s(\mathsf{d})$ be the threshold and the depth of the law of the two-point function at short distance of (M5), $\vartheta_1=3\sqrt{3}/8$, let $0<\mathsf{d}_\circ\le\mathsf{d}_0(g,\vartheta_1)$, let (K,β) be a first-passage datum at g with $K>s(\mathsf{d}_\circ)$, and $N_4=\lfloor 4\mathsf{d}_\circ/a_K\rfloor$. Then for every

integer $l \ge 3$

$$\mathsf{e}(l) \ge \min\{0.069,\ \tfrac{1}{12.9}\,31250^{-l/N_4}\} \ge \min\{0.069,\ 0.0775\,e^{-2.6\,l a_K/\mathsf{d}_\circ}\};$$

in particular $\mathsf{e}(\ell/2a_K) \ge \min\{0.069, 0.0775\,e^{-1.3\ell/\mathsf{d}_0(g,\vartheta_1)}\}$ whenever $\ell/a_K \ge 6$ is even, the same floor lies under D_2, 8δ and $\frac{8}{L^3}D_L$ at the side $\ell/2$, and $\mathsf{e}(l) \le 0.069$ fails for every l with $la_K < 0.0449\,\mathsf{d}_\circ$.

(4) *What BI forces.* If $\mathrm{BI}[\mathsf{b}, \ell_0, K_0; x_0]$ holds at some label, then $\ell_0 \ge 0.0895\,(\mathsf{d}_0^\star/\kappa_0)\,\mathsf{b}$, where $\kappa_0 = L(\gamma_W^{-2} + \bar{B})$, $\mathsf{d}_0^\star = \min\{\mathsf{d}_0(g_1,\vartheta_1), \mathsf{d}_0(g_2,\vartheta_1)\}$, $g_1 = \gamma_W$ and $g_2 = (\gamma_W^{-2} + 2\bar{B}/L)^{-1/2}$. On one lattice, every box and $t \ge 3$: $2F(t,\Sigma) - F(2t,\Sigma) \ge 2\log\sum_f w_f^{1/2}$, the w_f the weights of the box $(2t,\Sigma)$; on the cube $2l$, $\mathsf{e}(l) \ge 2\log(\sqrt{1-x} + \sqrt{2x})$ for $x = 1 - r_1 \le \frac{1}{2}$, $\mathsf{e}(l) \ge \log\frac{4}{1+3r_1}$, and $\mathsf{e}(l) < \log 2$ forces $r_1 > \frac{8}{9}$; so $\mathsf{e}(l) \le 0.069$ forces $r_1 \ge 0.99937$. At every $K \ge K_0$, on the cube $2l_K$ at $\beta = L^K\mathsf{b}$, with $x_0 = 0.069$: $1 - r_1 \le 0.000628$, $1 - r_2 \le 0.001255$, $1 - r_3 \le 0.001882$, $\delta_K(\ell_0) \le 0.013603$, and $\sum_{i\ge1}(\lambda_i/\lambda_0)^{l_K} \le 0.035764$ over the cross-section $(2l_K, 2l_K)$, so $\log(\lambda_0/\lambda_i) \ge 6.66\,a_K/\ell_0$ for $i \ge 1$. $\mathrm{BI}[\cdot; 0.069]$ is false as soon as $r_1 < 0.99937$ on the cube ℓ_0 at one cutoff $K \ge K_0$.

(5) *Small tori.* Let $\vartheta(\tau,u) = \sum_{k\in\mathbb{Z}} e^{-\tau(2\pi k+u)^2}$,

$$C_\Delta = \int_0^\infty \Big[1 - e^{-\tau} - \vartheta(\tau,0)^3 + (4\pi\tau)^{-3/2}\Big]\frac{d\tau}{\tau},$$

$$\Upsilon(u) = \exp\int_0^\infty \Big[e^{-\tau} - 1 + \vartheta(\tau,0)^3 - \prod_{\mu=1}^3 \vartheta(\tau,u_\mu)\Big]\frac{d\tau}{\tau},$$

$\mathscr{J} = \int_{[-\pi,\pi]^3} du/\Upsilon(u)$ and $c' = \log(\mathscr{J}/8\pi^2) - \frac{3}{2}C_\Delta$; numerically $c' \approx 2.0919$. There are numbers $t_1, t_2, t_4 > 0$ and $C, C_\flat$ of the constants, with $\mathsf{a} = \frac{9}{2}r + \mathfrak{p}_0$ and $\mathsf{q} = 1116\,r + 720\,\mathfrak{p}_0 + 366$, such that for every side $\ell = 2L^m$, $m \in \mathbb{Z}$, every real $\mathsf{b} > 0$ and every cutoff $K \ge 1 - m$, with $t = \ell/\mathsf{b}$: (a) if $t \le t_1$, then $|\delta_K(\ell) - \log(\mathsf{b}/\ell) - c'| \le C\,t^{1/1500} + C\,(a_K/\ell)^2\log^{5/2}(\ell/a_K)$, and $|\delta_\infty(t) - \log(1/t) - c'| \le C\,t^{1/1500}$; (b) if $t \le t_2$, then $r_1(\ell/a_K) \le \eta_\flat(t) = C_\flat(\log\frac{1}{t})^{\mathsf{a}}t^{1/500}$ at $\beta = L^K\mathsf{b}$, the weights of the four classes of electric flux on the cube satisfy $|w_f - \frac{1}{4}| \le \frac{3}{4}\eta_\flat(t)$, and $\delta_K(\ell)$ and $\mathsf{e}(\ell/2a_K)$ are both $\ge \mathsf{G}_{\ell/a_K} \ge \log\frac{4}{1+3\eta_\flat(t)}$; so $\liminf_{t\to0}\inf_K \delta_K(\ell) \ge \log 4$, the same for $\mathsf{e}(\ell/2a_K)$, and if $\ell_0 = 2L^{m_0}$, $\ell_0/\mathsf{b} \le t_2$ and $\eta_\flat(\ell_0/\mathsf{b}) < 0.99937$, the inequality of $\mathrm{BI}[\mathsf{b}, \ell_0, K_0; x_0]$ fails at every cutoff $K \ge 1 - m_0$, for every $x_0 \le 0.069$; (c) The sharper remainder in this clause requires the **(Heaviest class)** probability estimate: if $t \le t_4$, the intended conclusion is that over the cross-section $(\ell/a_K, \ell/a_K)$ the top level carries the weight $\lambda_0^N/Z(N^3) \le C\,t\,(\log\frac{1}{t})^{\mathsf{q}}$, $N = \ell/a_K$; so $\delta_K(\ell)$ and $\mathsf{e}(\ell/2a_K)$ are $\ge \mathsf{G}_N \ge \log\frac{\mathsf{b}}{\ell} - \mathsf{q}\log\log\frac{\mathsf{b}}{\ell} - \log C$: the coefficient of $\log(\mathsf{b}/\ell)$ in (a) is reached from below at every cutoff; (d) there are numbers $t_\circ > 0$ and $\beta_\flat$ of the constants such that for every real $\beta \ge \beta_\flat$: $\mathsf{e}(l) > 0.069$ for every integer $3 \le l \le t_\circ\beta$; so BI at any label b forces $\ell_0 > 2t_\circ\mathsf{b}$. On one lattice, exactly: if $1 - r_1(N) \ge 0.0039$ on one cube, then $\mathsf{e}(l) > 0.069$ for every integer $3 \le l \le N/16$; and $\mathsf{e}(l) \le 0.069$ gives $\mathsf{e}(l') < 0.0234$ for every integer $l' \ge 16l$; (e) the pressure of one lattice: $|P(\beta) + 3\log\beta - z_\infty| \le C\beta^{-1/1500}$ for all large real β, with $z_\infty = \log\frac{2}{\pi} - \frac{3}{16\pi^3}\int_{[-\pi,\pi]^3}\log\sum_\mu(2 - 2\cos p_\mu)\,dp \approx -2.96167$.

The leading logarithmic lower bound in clause (c) also holds without (Heaviest class), with q replaced by $\mathsf{p}_\star = 1209r + 780\mathfrak{p}_0 + 396$ and with possibly different constants t_4, C. Indeed, Prop. 17.6(d), with $\mathsf{L} = L$ and $j = m + K \ge 1$, applies to $N = \ell/a_K = 2L^j$ and $\beta = N/t$ and gives $\lambda_0(N,N)^N/Z(N,N,N) \le \mathsf{C}_\star t(\log(1/t))^{\mathsf{p}_\star}$. Since $\mathsf{G}_N \le \delta_K(\ell)$ and $\mathsf{G}_N \le \mathsf{e}(N/2)$, taking negative logarithms gives both lower bounds.

(6) *An area from above.* If $t = \ell/\mathsf{b} > t_1$ and j is the least integer with $L^{-j}t \le t_1$, then $\delta_K(\ell) \le 3L^2(t/t_1)^2\,[\log(L/t_1) + c' + C]$ at every cutoff $K \ge 1 - m + j$. So $\sup_K \delta_K(\ell) < \infty$ on every torus at every label, and $\mathsf{e}(\ell/a_K)$, $D_L(\ell/a_K)$ are $O((\ell/\mathsf{b})^2)$ uniformly in the cutoff. ■□

17.2.3. *Construction estimates.* Beyond the exact statements on one lattice proved below, the argument uses the following statements, (M1)–(M6) and (M8), one statement of the section on plane fields and the stress tensor (§5.1), Lem. 5.16, entered as (M7), and the comparison of two cutoffs with a factor, Prop. 17.30, which is derived at the end of this subsection from the statements named in (M4)(ii).

(M1) The layers and the crossing operator of one direction (Section YM3_I:85, Prop. YM3_I:85.1): the objects of the setting; a bounded Borel function of the bonds with both ends in a slab of $\vartheta \ge 2$ consecutive layers is Φ_{τ_0} for a bounded Borel function Φ on the configurations $\mathcal{Y}_\vartheta$ of a slab, which depends neither on the length of the box in the time nor on τ_0; its slab operator $\mathfrak{Y}[\Phi] = \mathsf{K}^{1/2}\mathfrak{S}[\Phi]\mathsf{K}^{1/2}$ is Hilbert–Schmidt, $\mathfrak{Y}[1_\vartheta] = \mathsf{T}'^{\vartheta}$, $\mathfrak{Y}[\Phi^{+j}] = \mathsf{T}'^{j}\mathfrak{Y}[\Phi]$ for Φ regarded as a function Φ^{+j} on a slab thicker by j layers, read on the first ϑ of its $\vartheta + j$ layers, so that the j added layers lie above, towards the later slabs of the trace formula below, in which the first slab stands rightmost, and $\mathfrak{Y}[\Phi^\Theta] = \mathfrak{Y}[\Phi]^*$ for the conjugated mirror image Φ^Θ, which, placed on a slab of ϑ layers, is the complex conjugate of Φ read on the configuration mirrored in the plane midway between that slab and the slab of Φ; and the trace formula (Prop. YM3_I:85.2): for $r \ge 2$ functions $\Phi^1, \dots, \Phi^r$ on consecutive slabs filling the box (t, Σ),

$$Z(t,\Sigma)\,\mu_{(t,\Sigma)}\Big(\prod_s (\Phi^s)_{\tau_{s-1}}\Big) = \mathrm{Tr}(\mathfrak{Y}[\Phi^r]\cdots\mathfrak{Y}[\Phi^1]).$$

(M2) The chessboard estimate on the tori $\ell \in \mathfrak{L}$, for one board of side $\ell''/2$, $\ell'' \le \ell$ in $\mathfrak{L}$ ([7, Cor. B.1](b), (c), (e)): $\|\cdot\|^{(\ell'')}_{\mathrm{ch},\ell}$ is a seminorm on the functions of one cell, with $\|1\|^{(\ell'')}_{\mathrm{ch},\ell} = 1$ and $|\mu_{K,\ell,\beta}(F)| \le \|F\|^{(\ell'')}_{\mathrm{ch},\ell} \le \sup|F|$; in its array form $|\mu_{K,\ell,\beta}(\prod_{\mathbf{k}} F_{\mathbf{k}})| \le \prod_{\mathbf{k}} \|F_{\mathbf{k}}\|^{(\ell'')}_{\mathrm{ch},\ell}$ for functions $F_{\mathbf{k}}$ of distinct cells $\mathbf{k}$ of one period, given in all of them or in some of them only; in its fine-to-coarse form, for one board and two tori, $\|F\|^{(\ell'')}_{\mathrm{ch},\ell} \le \|F\|^{(\ell'')}_{\mathrm{ch},\ell'} \exp[(\ell''/2)^3(p_{\ell'} - p_\ell)]$ and $p_\ell \le p_{\ell'}$ for $\ell'' \le \ell' \le \ell$ in $\mathfrak{L}$; and the domination $|\nu(\prod_{\mathbf{k}} F_{\mathbf{k}})| \le \liminf_{\ell\to\infty} \prod_{\mathbf{k}} \|F_{\mathbf{k}}\|^{(\ell'')}_{\mathrm{ch},\ell}$ of a periodic Gibbs state ν, for one board and growing tori (Prop. YM3_I:91.9). Together: for a function F of a cell of side $\ell''/2$ and its board of side $\ell/2$ of the setting, whose eight copies of F are copies of F under the board of F, the array form with the constant 1 in the other cells and the fine-to-coarse form give

$$\|F\|_{\mathrm{ch},\ell} \le \|F\|^{(\ell'')}_{\mathrm{ch},\ell} \le e^{(\ell''/2)^3(p_{\ell''} - p_\ell)}\,\|F\|_{\mathrm{ch},\ell''} :$$

the seminorm of eight copies on the torus ℓ is at most that of all the copies under the board of F, which is at most a factor times the seminorm on the torus ℓ''. (M3) Limits of tori and of periodic boxes are periodic Gibbs states (Prop. YM3_I:91.2); the DLR equations and the conditional laws of a Gibbs state; all periodic Gibbs states are invariant under the isometries of the lattice and reflection positive (Prop. YM3_I:103.4); a periodic Gibbs state is an integral of ergodic ones, and it is extreme if and only if it is ergodic (Prop. YM3_I:106.1). (M4) Thm. YM3_I:D, through the following consequences: (i) on one fixed torus the cumulants $S^T_{n;K,\ell,L^K\mathsf{b}}$ of fields with disjoint supports are bounded at all cutoffs, with bounds that depend on the side, a compact set of labels and the distance of the supports (Thm. YM3_I:AS, uniform bound YM3_I:(2214)), and converge as $K \to \infty$, uniformly on compact sets of labels, to continuous functions of the label (Thm. YM3_I:AS, limit and local uniformity), with the Cauchy rate proved in Thm. YM3_I:AS: on a compact interval of labels, $|S^T_{n;K',\ell,L^{K'}\mathsf{b}}(X) - S^T_{n;K,\ell,L^K\mathsf{b}}(X)| \le C\,K^{2\mathfrak{p}_0(n+1)+\frac12}L^{-K/10}\prod_i \|f_i\|_\sharp$ for all $K' \ge K$ above a threshold, where C and the threshold depend on n, the side, the interval and a floor of the spread of the supports, and on the functions only through their norms, at every admitted choice of

the constants; (ii) for a label $\mathsf{b} \geq \gamma^{-2}$, a side $\ell = 2L^m$ with $MR(\mathsf{b}) \leq L^m$ and a cutoff $K \geq 2$ at which the conditions (k0)–(k4) and (k6) of §2.3.1 hold, with its numbers at $n = 1$ ($u = \lceil K/1260 \rceil$, $s = \lceil K/9 \rceil$, $t_1 = K - u$),

$$\left|\log Z_{K+1,\ell} - \log Z_{K,\ell} - \mathfrak{K}_K(\ell, \mathsf{b})\right| \leq 4\mathsf{R}_{t_1} + 8\epsilon_{\mathrm{fg}} + 8\epsilon_{\mathrm{cl}} + 12\epsilon_{\mathrm{sh}} \leq \mathfrak{o}_K(\ell, \mathsf{b}),$$

where $\mathfrak{K}_K$, a sum of local vacuum constants, is the real part of the difference at the source 0 of the contact terms of the two cutoffs, and $\mathfrak{o}_K = 8\mathsf{R}_{t_1} + 12\epsilon_{\mathrm{fg}} + 8\epsilon_{\mathrm{cl}} + 12\epsilon_{\mathrm{sh}}$ is the number (2.xiv). This is the comparison of the two cutoffs at the source 0: the discarding of Prop. YM3_I:115.2, lost-mass bound gives $(1 - \mathsf{R}_{t_1})Z \leq T(0) \leq Z$ at each cutoff for the chain T of the top level; the form $T = e^c I$ and the contact terms of the proof of Prop. YM3_I:116.1 and Section YM3_I:116, with the proof of Prop. YM3_I:116.3, give $|I(0)/\hat{I}(0) - 1| \leq 2\epsilon_{\mathrm{fg}}$ against the classical start $\hat{T} = e^{\hat{c}}\hat{I}$; §2.3.2 and Prop. YM3_I:116.1 give $|\hat{T}_{K+1}(0)/\hat{T}_K(0) - 1| \leq 4\epsilon_{\mathrm{cl}} + 6\epsilon_{\mathrm{sh}}$ for the classical starts of the two cutoffs; and $|\log(1+\zeta)| \leq 2|\zeta|$ for $|\zeta| \leq \frac{1}{2}$.

The rate $\mathfrak{o}_K \leq \mathsf{C}_{\mathrm{bf}}\, \ell^3 K^{\mathfrak{p}_0} L^{-K/10}$ holds at every $K \geq K_{\mathrm{bf}}$, for the labels of an interval J of labels admitted on the side ℓ (Def. 2.7(5), Cor. 2.8(a), (2.xvii)): $K_{\mathrm{bf}} = K_{\mathrm{bf}}(\ell, J)$ is the least cutoff from which the conditions hold and the two fast members, the large fields $8\bar{\mathsf{R}}$ and the shell term $12\bar{\epsilon}_{\mathrm{sh}}$, majorised on J, lie below half of $\mathsf{C}_{\mathrm{bf}}\ell^3 K^{\mathfrak{p}_0} L^{-K/10}$; it depends on the side, through the factor $\exp[(\mathsf{C}^{\Sigma}_{\mathrm{maj}} + 2 + C_{\mathrm{low}}(\mathsf{b}))\ell^3]$ of R_{t_1}, and on J, while C_{bf} depends on J and on no side.

The same explicit numbers give a form uniform in the label, derived in the proof of Prop. 17.47(b): there are numbers $y_\sharp$, $C_{\mathfrak{o}}$ of the constants such that at every label with $\log \mathsf{b} \geq y_\sharp$, on every side $2MR(\mathsf{b}) \leq \ell \leq 2L^3 M(\log \mathsf{b})^r$ and at every $K \geq 11(5 + 2\mathfrak{p}_0/r)\log_L \ell$, the conditions (k0)–(k4), (k6) hold and $\mathfrak{o}_K(\ell) \leq C_{\mathfrak{o}}\, \ell^{3+2\mathfrak{p}_0/r} L^{-K/11}$, by the condition $2\mathfrak{p}_0 > 3r + 2$ of the list; (iii) for a label $\mathsf{b} \geq \gamma^{-2}$, a side $\ell = 2L^m$ with $MR(\mathsf{b}) \leq L^m$, a cutoff $K \geq 2$ at which the conditions (k0)–(k4) and (k6) of §2.3.1 hold, every integer $0 \leq d \leq \lceil K/1260 \rceil$ and every bounded Borel function F, invariant under the gauge transformations, of the configurations of the lattice of the spacing L^{-d} on the torus ℓ:

$$\left|\langle F(\mathcal{M}^{K+1-d}U)\rangle_{K+1} - \langle F(\mathcal{M}^{K-d}U)\rangle_K\right| \leq \mathfrak{o}_K \sup|F|$$

(Cor. 2.8(a)), with the number $\mathfrak{o}_K$ of (ii), which is $\leq \mathsf{C}_{\mathrm{bf}}\, \ell^3 K^{\mathfrak{p}_0} L^{-K/10}$ at every $K \geq K_{\mathrm{bf}}$ by (2.xvii), so that $\sum_K \mathfrak{o}_K < \infty$; the block field is taken at the fixed spacing L^{-d}, and the number $K - d$ of its averaging steps grows with the cutoff; (iv) the exact identification of the zero-source contact terms with the vacuum constants of their first $K^\bullet - u$ steps, proved in Step 3(iv) of Prop. 13.7, and their two-torus comparison in Lem. 13.31; Prop. 17.44 below retains this stopping depth and proves the resulting summable estimate; (v) the averaging map among the construction results (equations YM3_I:(37)–(39)), which sends a configuration U to its block field $V_j = \mathcal{M}^j U$ of level j, whose blocks are the cubes of L^j bare sites a side centred at the block sites, the points of $L^j\mathbb{Z}^3$, so that the block layer 1 of level q lies in the bare layers $\frac{1}{2}(L^q + 1), \ldots, \frac{1}{2}(3L^q - 1)$: it is Borel (Prop. YM3_I:4.5) and gauge covariant, it commutes with the isometries of the lattice that carry $L^j\mathbb{Z}^3$ onto itself ([7, Lem. G.1]), a block variable depends only on the bare bonds of the two blocks that its bond joins (Prop. YM3_I:4.5), on bare fields whose plaquettes all lie within ω_0 of $\mathbf{1}$, with $L^{2q}\omega_0$ below a number of L, the block plaquettes of level $j \leq q$ lie within $1.003\, L^{2j}\omega_0$ of $\mathbf{1}$ (Lem. 5.28), and on a cube of N bare sites a side the holonomies of the straight closed lines of the block field of level q lie within $13.3\, NL^q\omega_0$ of those of the bare field (Lem. 5.29); (vi) the comparison of (iii) with a factor, Prop. 17.30 at the end of this subsection, derived there from Prop. YM3_I:115.2 and the statements of Section YM3_I:116 named in (ii): in the setting of (iii), for every gauge-invariant Borel function F with values in $[0,1]$ of the block field of depth d, $\mu_d^{K+1}(F) \leq e^{m_K}\mu_d^K(F) + \epsilon_K$ and $\mu_d^K(F) \leq e^{m_K}\mu_d^{K+1}(F) + \epsilon_K$, where μ_d^K is the law of $\mathcal{M}^{K-d}U$ at the cutoff K and m_K, ϵ_K are the explicit numbers of that proposition: the errors that are powers of L^{-K} stand in the exponent m_K, the large fields of Prop. YM3_I:115.2, lost-mass bound and the shell term in the additive remainder ϵ_K.

Multiplying these inequalities: there are a number $y_\times$ and a power $\mathsf{N}(y)$ of y, both formed from the constants, such that at every label with $y = \log \mathsf{b} \ge y_\times$, on the least side ℓ at which (iii) applies, and from the cutoff $K_1 = K_1(y)$ of that proposition, at which the bare cube has $\ell L^{K_1} < \mathsf{N}(y)$ sites a side,

$$\mu_0^K(E) \le 1.7\,(\mu_0^{K_1}(E) + e^{-4y}) \qquad \text{for every } K \ge K_1$$

and every Borel set E of block fields of depth 0 that the gauge transformations carry onto itself: a factor and a remainder, not an additive error summed over the cutoffs. (M5) Thms. YM3_I:AJ and YM3_I:AD, through: (i) the bounds on cumulants at first-passage data: for $k \ge 2$, every first-passage datum (K,β) at g, every torus $\ell \in \mathfrak{L}(g)$ with $\ell \ge 16k(R+1)$ and k real Lipschitz functions with supports in $(-\frac{\ell}{4},\frac{\ell}{4})^3$, each in a ball of radius R, any two at a distance $\ge \mathsf{d}$, $|S^T_{k;K,\ell,\beta}(X)| \le C^g_k(\mathsf{d};R)\prod_i \|f_i\|_\sharp$; the bounds depend, besides on g, k, d, R and the constants, only on a radius fixed once in that theorem, and neither on the cutoff nor on the coupling nor on the side nor on the place; (ii) the theorem on the canonical decomposition, the ergodic components and the reconstruction, Thm. YM3_I:AP: each ergodic component of the limit of a convergent Gibbs sequence is a limit along the same pairs whose approximants are periodic Gibbs states at these pairs (Thm. YM3_I:AP, component approximation in the proof), and it carries the reconstruction of Thm. YM3_I:AP; (iii) the law of the two-point function at short distance (Thm. YM3_I:AV, short-distance bound and torus version), with the ceiling γ_W and the threshold $\mathsf{d}_0(g,\vartheta)$ of equations YM3_I:(2346) and YM3_I:(2349)–(2350), the depth $s(\mathsf{d})$ of equation YM3_I:(2321) and the test pairs of [7, Lem. I.1]: for $0 < g \le \gamma_W$, $\mathsf{d} \le \mathsf{d}_0(g,\vartheta)$, every first-passage datum (K,β) at g with $K > s(\mathsf{d})$, every periodic Gibbs state ν at it and every test pair (f,h) at $(\mathsf{d};\vartheta)$,

$$S_2^T[\nu](f,h) = \mathsf{c}_2\,\mathsf{b}^{-2}\,\mathcal{K}_{\text{free}}(f,h)\,(1+\varepsilon'), \qquad |\varepsilon'| \le \tfrac{1}{3}, \qquad \mathcal{K}_{\text{free}}(f,h) = \iint f(x)h(y)|x-y|^{-6}\,\mathrm{d}x\,\mathrm{d}y,$$

with $\mathsf{c}_2 > 0$ and $\mathcal{K}_{\text{free}}$ as in Thm. YM3_I:C and equation YM3_I:(2240); for $f(y) = (1 - |y - 2\mathsf{d}e_3|^2/\mathsf{d}^2)_+^2$ and $0 \le t \le 4\mathsf{d}$ the pair $(f(\Theta\,\cdot), f(\cdot - te_3))$, Θ the reflection $x_3 \mapsto -x_3$, is a test pair at $(\mathsf{d};\vartheta_1)$ ([7, Lem. I.1](c)), and $K > s(\mathsf{d})$ gives $\mathsf{d}/a_K > 4L^3M$. Besides, $I(g) = (u, Lu - 2\bar B]$ with $u = g^{-2} + \bar B$, $\bar B \ge 0$, and $g^{-2} > L^2\bar B$ for $g \le \gamma_W$ (the coupling ceiling preceding Thm. YM3_I:AV, equation YM3_I:(2346)). The labels $a_K\beta$ of all first-passage data (K,β) at g lie in the window $(g^{-2} + B_\sharp\frac{L-2}{L-1},\, L(g^{-2}+\bar B)]$ (YM3_I:(1531) in Prop. YM3_I:74.1), whose upper end is $X_g + \bar B$. (M6) The ordered choice leaves the blocking factor free upward (the choice of L in the proof of Prop. YM3_I:69.1, followed by the source choices in Section YM3_I:82): every odd integer above a threshold is the value of L at an admissible choice, and Thms. YM3_I:D, YM3_I:AJ and YM3_I:AD hold at every admissible choice. (M7) The member of third order in the curvature of the bulk term of the rotational Ward identity, on growing tori: Lem. 5.16 of the section on plane fields and the stress tensor (§5.1), which carries the bound of the cubic remainder on one torus, Lem. 5.11, to all sides at once. For $\chi, f_1, \dots, f_n$ and ω as in Thm. BA(5), this member of the bulk term of YM3_I:(2108) on the torus ℓ is

$$\mathfrak{U}^\sharp_{\omega,\chi}(f_1,\dots,f_n) = -\beta\langle \mathfrak{K}^\sharp[\chi\,\omega y]; \mathcal{O}_K(f_1); \dots; \mathcal{O}_K(f_n)\rangle_{K,\ell,\beta} + a_K^{-1}\sum_{i=1}^n \langle \mathfrak{K}^\sharp[f_i\,\omega y]; (\mathcal{O}_K(f_l))_{l\ne i}\rangle_{K,\ell,\beta},$$

the joint cumulants in which the local density of the rotation is replaced by its part $\mathfrak{K}^\sharp[\boldsymbol{\eta}] = \sum_p a_K^{-1}\boldsymbol{\eta}^{\rho(p)}(x(p))\,\mathfrak{r}^\sharp_{\rho(p)}(p)$ of [7, §H], built with the remainders $\mathfrak{r}^\sharp$ of third order in the field strength ([7, Prop. H.1]), with the weight β/a_K; here $\boldsymbol{\eta}^\rho(y) = \chi(y)(\omega y)_\rho$, resp. $f_i(y)(\omega y)_\rho$. As $\mathfrak{K}^\sharp$ depends on its field only through its values at the centres of the plaquettes, at which $\chi f_i = f_i$, this member is the cubic remainder $\mathfrak{U}^\sharp[\chi\,\omega y](f_1,\dots,f_n)$ of that section at the field $\chi\,\omega y$. Let $0 < g \le \gamma$, $n \ge 2$, $\mathsf{d} > 0$ and $\rho_0 \ge 1$. There are $C_\sharp$ and $K_\sharp$, formed from g, n, d, ρ_0 and the constants and depending on no side, such that for all first-passage data (K,β) at g with $K \ge K_\sharp$, all sides $\ell \ge 2\rho_0 + 2$ of $\mathfrak{L}(g)$, all $\omega \in \mathfrak{so}(3)$ and all real $\chi, f_1, \dots, f_n \in C^{1,1}(\mathbb{R}^3)$ that vanish outside $[-\rho_0,\rho_0]^3$, χ equal to 1

at the centres and at the bonds of the plaquettes at which some f_i does not vanish, the supports of the f_i at pairwise sup distances $\geq \mathsf{d}$,

$$|\mathfrak{U}^\sharp_{\omega,\chi}(f_1,\dots,f_n)| \leq C_\sharp\,|\omega|\,L^{-K/16}\,\|\chi\|_{C^{1,1}}\prod_i \|f_i\|_{C^{1,1}}.$$

This is Lem. 5.16 at the field $\chi\,\omega y$, for the cube of side $\frac14\ell'$ centred at 0, ℓ' the least side of $\mathfrak{L}(g)$ with $\ell' \geq 8\rho_0$, and for a rate $c \in (\frac{1}{16},\frac{1}{14})$: there $K^pL^{-cK} \leq C'L^{-K/16}$, the norm $\mathsf{H}(\eta) = \max_\rho \sup|\eta^\rho| + \max_\rho \mathrm{Lip}_\infty \eta^\rho$ of a field in that lemma, Lip_∞ the Lipschitz constant for the sup distance, is $\mathsf{H}(\chi\,\omega y) \leq C\rho_0|\omega|\,\|\chi\|_{C^{1,1}}$ with a pure number C, and $\|f_i\|_\sharp \leq \max\{1,40M\}\|f_i\|_{C^{1,1}}$. On each of the finitely many sides of $\mathfrak{L}(g)$ from $2\rho_0+2$ to ℓ' it is Lem. 5.11, whose setting holds on that side at all first-passage data at g: their labels lie in $[\gamma^{-2}, X_g+\bar B]$, and $MR(X_g+\bar B) \leq L^m$ on every side $2L^m$ of $\mathfrak{L}(g)$. The idea of the proof. On one torus the entry $\mathfrak{K}^\sharp$ enters each renormalisation step as one more local term, inside the radii of the one-step theorem with sources (Prop. 6.32). Each of its terms vanishes to the third order at $\mathbf{1}$ and is odd under the mirror of its plaquette, while the steps are covariant under the mirrors of their lattices; so only the differences of the backgrounds and their mirror images and the asymmetric part of the weight feed the families that the steps make of it, and what is fed at a level is forgotten at the rate $L^{-1/2}$ a level. The conditional mean of the entry, given the block field at a level $K - \lceil \phi K\rceil$ with a small $\phi > 0$, is therefore a number up to an oscillation of the order K^pL^{-cK} (Lem. 5.10(b)), the large fields costing less than every power of L^{-K}; the cumulant is a mixed derivative at 0 of the logarithm of the partition function with the entry and the sources, and Cauchy's estimates in the sources give $|\mathfrak{U}^\sharp| \leq CK^pL^{-cK}$ times the norms at every rate $c < \frac{1}{14}$ (Lem. 5.11), which is at most $C'L^{-K/16}$.

On all the sides at once, the carrier is put in one cell of a board of side $\frac12\ell'$, ℓ' a fixed side of $\mathfrak{L}(g)$; the chessboard estimate controls the generating function of the entry and of the sources on the torus ℓ by the mean of their mirror copies on the torus ℓ', with a factor $e^{(\ell'/2)^3(p_{\ell'}-p_\ell)}$ that is bounded uniformly at the first-passage data at g; on the torus ℓ' the bound of one torus applies to the copies, and the part of the cumulants that links different copies carries the oscillation of the conditional mean of Lem. 5.10(b); the finitely many sides between $2\rho_0+2$ and ℓ' are tori of their own. (M8) The rotational Ward identity among the construction results, which Thm. BA(5) and its proof read: the bulk term YM3_I:(2107) of equation YM3_I:(2107) and the source calculation in the proof of Prop. YM3_I:112.1, the bulk insertion of equation YM3_I:(2107) and the source calculation in the proof of Prop. YM3_I:112.1, whose mean at the sources gives the bulk term by differentiation in the source variables, and the identity YM3_I:(2108); the orbital potential $\Psi_\rho(p)$ and the remainder of third order $\mathfrak{r}^\sharp_\rho(p)$ of [7, §H], with the bound of third order [7, eq. 295], and the summation by parts of [7, Prop. H.1], which writes the bulk insertion as the sum of the spin part, a member of order 2 in the curvature and the cubic member [7, eq. 297]; the small-field density with a local insertion and its derivative as a conditional mean in Lem. 5.10(a), under its stated entry and cutoff hypotheses, obtained from the holomorphic fourth-family map of Prop. 6.32; and the two-constants inequality of Lem. YM3_I:116.2, used in the source variables.

Proposition 17.30 (Two cutoffs with a factor)**.** Let $\mathsf{b} \geq \gamma^{-2}$ and $\ell = 2L^m$ with $MR(\mathsf{b}) \leq L^m$; for a cutoff $K \geq 2$ take the numbers $\epsilon_{\mathrm{fg}}, \epsilon_{\mathrm{cl}}, \epsilon_{\mathrm{sh}}, \mathsf{R}_{t_1}$ of §2.3.1 at $n=1$ ($u = \lceil K/1260\rceil$, $s = \lceil K/9\rceil$, $t_1 = K-u$), and put

$$m_K = 4\epsilon_{\mathrm{fg}} + 2\epsilon_{\mathrm{cl}} + 1.06\,\epsilon_{\mathrm{sh}} + 1.39\,\mathsf{R}_{t_1}, \qquad \epsilon_K = \mathsf{R}_{t_1} + 1.29\,\epsilon_{\mathrm{sh}}.$$

(a) At every cutoff $K \geq 2$ at which (k0)–(k4) and (k6) hold, for every integer $0 \leq d \leq \lceil K/1260\rceil$ and every Borel function F with values in $[0,1]$ of the block fields of depth d on the torus ℓ that is invariant under their gauge transformations,

$$\mu_d^{K+1}(F) \leq e^{m_K}\mu_d^K(F) + \epsilon_K, \qquad \mu_d^K(F) \leq e^{m_K}\mu_d^{K+1}(F) + \epsilon_K,$$

μ_d^K the law of $\mathcal{M}^{K-d}U$ at the cutoff K (Def. 2.7(2)).

(b) If the conditions hold at every $K \ge K_1$, and $\mathsf{S} = \sum_{K\ge K_1} m_K$ and $\mathsf{R}_\Sigma = \sum_{K\ge K_1} \epsilon_K$ are finite, then $e^{-\mathsf{S}}\mu_d^{K_1}(E) - \mathsf{R}_\Sigma \le \mu_d^K(E) \le e^{\mathsf{S}}(\mu_d^{K_1}(E) + \mathsf{R}_\Sigma)$ for every $K \ge K_1$, every integer $0 \le d \le \lceil K_1/1260\rceil$ and every Borel set E of block fields of depth d that the gauge transformations carry onto itself.

(c) Let $p = 2\mathfrak{p}_0$, $y = \log \mathsf{b}$, $\bar\ell(y) = 2L^2 M y^r$, $\mathsf{N}(y) = L\,\bar\ell(y)^{31} y^{10(p+1)}$, and let $K_1(y)$ be the least integer $K \ge 10$ with $L^{K/10} \ge \bar\ell(y)^3 y^{p+1}$. There is a number $y_\times$, formed from the constants, such that at every label b with $y \ge y_\times$, on the least side $\ell = 2L^m$, $m \in \mathbb{N}$, with $MR(\mathsf{b}) \le L^m$, which has $\ell \le \bar\ell(y)$: the conditions (k0)–(k4) and (k6) hold at every $K \ge K_1(y)$; $\ell L^{K_1(y)} < \mathsf{N}(y)$; from $K_1 = K_1(y)$, $\mathsf{S} \le 0.53$ and $\mathsf{R}_\Sigma \le e^{-4y}$; and so $\mu_0^K(E) \le 1.7\,(\mu_0^{K_1(y)}(E) + e^{-4y})$ for every $K \ge K_1(y)$ and every Borel set E of block fields of depth 0 that the gauge transformations carry onto itself.

■

Proof. (a) Write $\langle F\rangle_K = \mu_d^K(F)$. The averaging maps from the depth u to the depth d are the same at the two cutoffs and commute with the gauge transformations, so $F \circ \mathcal{M}^{u-d}$ is a function of the same kind at the depth u, and we may take $d = u$. Three comparisons follow, each with the same function $F \ge 0$ inserted on both sides. (1) *Large fields.* By Prop. YM3_I:115.2, image identity and domination bound, the chain of the top level t_1, on its inner ball, is the image under $\mathcal{M}^{t_1}$ of $\mathfrak{w}_{t_1}^{\mathrm{sf}}\rho_0\,\mathrm{d}U$, and its integral of a gauge-invariant $F \ge 0$ is at most $\int F(\mathcal{M}^{t_1}U)\rho_0\,\mathrm{d}U$; by the discarding of Prop. YM3_I:115.2, lost-mass bound its mass is at least $(1 - \mathsf{R}_{t_1})Z$.

So the mean of F under the law exceeds its mean under the normalised chain by at most $\mathsf{R}_{t_1}\sup F$, and the latter is at most $(1-\mathsf{R}_{t_1})^{-1}$ times the former. (2) *The chain and the classical start.* On the small-field set the two measures have the positive densities $e^{c(0)}e^{\Phi}$ and $e^{\hat c(0)}e^{\hat\Phi}$ (the proof of Prop. YM3_I:116.1), and $|\Phi - \hat\Phi| \le \epsilon_{\mathrm{fg}}$ at every block field of the cut set (equation YM3_I:(2180)); so the two normalised means of F differ by a factor within $e^{\pm 2\epsilon_{\mathrm{fg}}}$, the constants $e^{c(0)}$, $e^{\hat c(0)}$ cancelling against $F = 1$. (3) *The classical starts of the two cutoffs.* They are integrals over the configurations of the depth s of the weights $\mathsf{k} \ge 0$ of the two cutoffs times densities that are positive on the cut sets (Section YM3_I:116, §2.3.2); where both weights are positive they are equal and the densities differ by a factor within $e^{\pm\epsilon_{\mathrm{cl}}}$ (Prop. YM3_I:116.1, density comparison in the proof), and where one of them vanishes the other carries at most the part ϵ_{sh} of the mass (§2.3.2); so the normalised mean at one cutoff is at most $e^{2\epsilon_{\mathrm{cl}}}(1-\epsilon_{\mathrm{sh}})^{-1}$ times that at the other plus $\epsilon_{\mathrm{sh}}\sup F$.

Chaining (1), (2), (3), (2), (1), for $\{K', K''\} = \{K, K+1\}$,

$$\langle F\rangle_{K'} \le \frac{e^{4\epsilon_{\mathrm{fg}}+2\epsilon_{\mathrm{cl}}}}{(1-\epsilon_{\mathrm{sh}})(1-\mathsf{R}_{t_1})}\,\langle F\rangle_{K''} + \big(\mathsf{R}_{t_1} + e^{2\epsilon_{\mathrm{fg}}}\epsilon_{\mathrm{sh}}\big)\sup F,$$

and (k2), (k3), (k6) give $e^{2\epsilon_{\mathrm{fg}}} \le e^{1/4} < 1.29$ and, by convexity, $-\log(1-\epsilon_{\mathrm{sh}}) \le 1.06\,\epsilon_{\mathrm{sh}}$ and $-\log(1-\mathsf{R}_{t_1}) \le 1.39\,\mathsf{R}_{t_1}$. (b) By induction on K, $\langle F\rangle_K \le e^{\sigma_K}(\langle F\rangle_{K_1} + \rho_K)$ and $\langle F\rangle_K \ge e^{-\sigma_K}\langle F\rangle_{K_1} - \rho_K$, with the sums σ_K, ρ_K of the m_k, ϵ_k over $K_1 \le k < K$; $d \le \lceil K_1/1260\rceil \le \lceil K/1260\rceil$ keeps every step in the range of (a), and $F = \mathbf{1}_E$. (c) Let $K \ge K_1(y)$; with $\ell \le \bar\ell(y)$, $\ell^3 L^{-K/10} \le y^{-p-1}$. As $u \ge K/1260$ and $s \ge K/9$, the definitions YM3_I:(2192) and YM3_I:(2193) give $\epsilon_{\mathrm{fg}} \le a_1 \ell^3 L^{-K/10}$ and $\epsilon_{\mathrm{cl}} \le a_2\, y^p(1 + K\log L)^p K^{1/2} L^{-K/90}\,\ell^3 L^{-K/10}$ with numbers a_1, a_2 of the constants, so that $\sum_{K\ge K_1(y)}(4\epsilon_{\mathrm{fg}} + 2\epsilon_{\mathrm{cl}}) \le (17.72\,a_1 + 2a_2a_3)/y$, $a_3 = \sum_{K\ge1}(1+K\log L)^p K^{1/2}L^{-K/90}$.

The numbers R_{t_1} and ϵ_{sh} carry the factors $e^{-c'A_0^2 \mathsf{y}_{[u]}}$ and $e^{-\frac14\kappa_{\mathrm{b}}A_1^2\mathsf{y}_{[u]}}$, where $\mathsf{y}_{[u]} = (y + u\log L)^p \ge y^p + (u\log L)^p$, against the growth $\ell^3 L^{3s}$, $s \le 140u$, and, in R_{t_1}, $\exp[(\mathsf{C}^{\Sigma}_{\mathrm{maj}} + 2 + c_{\mathrm{low}} + \frac92 y)\ell^3] \le \exp[O(y^{3r+1})]$; summed over the cutoffs, of which at most 1260 have the same u, and by $2\mathfrak{p}_0 > 3r+2$, which follows from the exponent choice $r \ge 2$, $\mathfrak{p}_0 \ge 6r+1$ in Thm. YM3_I:D, $\sum_{K\ge K_1(y)}(\mathsf{R}_{t_1} + 1.29\,\epsilon_{\mathrm{sh}}) \le e^{-4y}$ for all large y. The same bounds give (k0)–(k4) and (k6) at every $K \ge K_1(y)$

for large y; $y_\times$ is the least number from which all this holds, with $\mathsf{b} \ge \max\{\gamma^{-2}, \Theta_\star\}$ and $y \ge 2(17.72\,a_1 + 2a_2a_3)$.

Then $\mathsf{S} \le \frac12 + 1.39\,e^{-4y} \le 0.53$, $e^{0.53} < 1.7$, and (b) at $d = 0$ gives the last inequality. As $L < \bar\ell(y)^3$, $K_1(y) \ge 11$, and by its least choice $L^{(K_1(y)-1)/10} < \bar\ell(y)^3 y^{p+1}$, so $\ell L^{K_1(y)} < \bar\ell(y)\,L\,(\bar\ell(y)^3 y^{p+1})^{10} = \mathsf{N}(y)$. □

17.2.4. *Statements on one lattice.*

Proposition 17.31 (The exact layer)**.** Let $\beta \ge 0$, $\Sigma = (A, B)$ a cross-section with sides ≥ 3, any coordinate direction being the time, and $t, t' \ge 3$, $q \ge 2$ integers.

(a) $Z(t,\Sigma) = \operatorname{Tr} \mathsf{D}^t = \sum_i \lambda_i^t$, $\sum_i \lambda_i^2 < \infty$, λ_0 is simple and its eigenvector can be taken strictly positive. F is symmetric in the three sides, and $e^{-6\beta|\underline{n}|} \le Z \le 1$.

(b) $\mathsf{r}_{t+1} \le \mathsf{r}_t$, $\mathsf{r}_{t+t'} \le \mathsf{r}_t\mathsf{r}_{t'}$, $\mathsf{r}_{qt} \le \mathsf{r}_t^q$; $F(t,\Sigma) = t\log\lambda_0 + \mathsf{G}(t;\Sigma)$, $F(t,\Sigma)/t$ does not increase, and $F(t+t',\Sigma) \le F(t,\Sigma) + F(t',\Sigma)$;

$$qF(t,\Sigma) - F(qt,\Sigma) = q\,\mathsf{G}(t;\Sigma) - \mathsf{G}(qt;\Sigma) \in \big[(q-1)\mathsf{G}(t;\Sigma),\, q\,\mathsf{G}(t;\Sigma)\big].$$

If $2F(t,\Sigma) - F(2t,\Sigma) \le x < \log 2$, then $\mathsf{r}_t \le \varphi(e^x - 1)$ and $2F(2t,\Sigma) - F(4t,\Sigma) \le \psi(x)$, where $\varphi(\eta) = \eta/(1+\sqrt{1-\eta^2})$ and $\psi(x) = 2\log(1+\varphi(e^x-1)^2)$.

(c) $F/|\underline{n}|$ and $\delta/|\underline{n}|$ do not increase when one side grows, and $F/|\underline{n}| \to P$ along boxes all of whose sides tend to ∞; $\delta(t,\Sigma) = t\,\varepsilon(\Sigma) + \mathsf{G}(t;\Sigma)$ with $\varepsilon(\Sigma) \ge 0$, so $\mathsf{G} \le \delta$; $D_q(N) = q^3\delta(N^3) - \delta((qN)^3) \in [0, q^3\delta(N^3)]$, $\mathsf{e}(l) = 2\delta(l,2l,2l) - \delta((2l)^3)$, and

$$\delta(N^3) = \sum_{s\ge0} q^{-3(s+1)} D_q(q^s N).$$

From above, an area: for all integers $A, B, t \ge N$, $\mathsf{G}(t;A,B) \le AB\varkappa$ and $\varepsilon(A,B) \le (A+B-N)\varkappa$, $\varkappa = \delta(N^3)/N^2$; so for every box with all sides $\ge N$

$$\delta(\underline{n}) \le \big[n_1n_2 + n_1n_3 + n_2n_3 - N(n_1+n_2+n_3) + N^2\big]\varkappa \le (n_1n_2 + n_1n_3 + n_2n_3)\,\varkappa,$$

and $\delta(M^3) \le (3\rho^2 - 3\rho + 1)\,\delta(N^3)$ for $M = \rho N \ge N$.

(d) There are commuting unitary involutions $\mathsf{J}_1, \mathsf{J}_2$ that commute with $\mathsf{T}^{(0)} = \mathsf{D}$ and with an operator $\mathsf{T}^{(1)} \ge 0$ of the same kind (D with the sign of one plaquette of the cross-section reversed in m), such that, with $\mathsf{J}^k = \mathsf{J}_1^{k_1}\mathsf{J}_2^{k_2}$ and $\mathsf{P}_e = \frac14\sum_k (-1)^{e\cdot k}\mathsf{J}^k$,

$$Z^{(k;m)}(t,\Sigma) = \operatorname{Tr}\big(\mathsf{J}^k(\mathsf{T}^{(m)})^t\big) = \sum_e (-1)^{e\cdot k} W(e;m), \qquad W(e;m) = \operatorname{Tr}\big(\mathsf{P}_e(\mathsf{T}^{(m)})^t\big) \ge 0.$$

Each $W(e;m)$ is a sum of t-th powers of positive numbers that do not depend on t; the eigenvector of λ_0 lies in the range of P_{00}, and $W(00;0) \ge \lambda_0^t$; $Z^z > 0$ does not depend on the columns chosen. On every box: $0 \le 1 - r^{(k;0)} \le 2\mathsf{R}_t$, $0 < r^{(k;m)} \le r^{(00;m)}$, $r^{(11;m)} \ge r^{(10;m)} + r^{(01;m)} - r^{(00;m)}$, and

$$\delta(t,\Sigma) = t\,\varepsilon(\Sigma) + \log(1+\mathsf{r}_t^{00}) + \log(1/\zeta_t), \qquad \zeta_t = \frac{W(00;0)}{Z} = \frac14\Big(1 + \sum_{k\ne0} r^{(k;0)}\Big),$$

three terms ≥ 0, $1 + \mathsf{r}_t^{00} = W(00;0)/\lambda_0^t$. On a cube N^3: $r_2, r_3 \le r_1 \le 1$; all seven $0 \le 1 - r^z \le 3\mathsf{R}_N \le 3\min\{\mathsf{G}_N, \mathsf{r}_N\}$; $1 - r_1 \le \frac43\mathsf{R}_N$, $1 - r_2 \le 2(1-r_1)$ and $1 - r_3 \le 3(1-r_1)$.

(e) $2F(t,\Sigma) - F(2t,\Sigma) \ge 2\log\sum_{f\in\{0,1\}^2} w_f^{1/2}$, the w_f being the weights of the box $(2t,\Sigma)$; and $\mathsf{G}(t;\Sigma) \ge \log(1/w_{00})$, w_{00} the weight of the box (t,Σ).

(f) Let $\Gamma = \mathbb{Z}n_1e_1 \oplus \mathbb{Z}n_2e_2 \oplus \mathbb{Z}(v_1e_1 + v_2e_2 + n_3e_3)$, $v \in \mathbb{Z}^2$, and Z_Γ the partition function of the lattice with these periods. With the time e_3 over $\Sigma = (n_1, n_2)$: $Z_\Gamma = \operatorname{Tr}(\mathsf{U}_v\mathsf{D}^{n_3})$, U_v the unitary of the translation of a layer by v, and $\lambda_0^{n_3}(1 - \mathsf{r}_{n_3}) \le Z_\Gamma \le Z(\underline{n})$.

(g) *The sheared cube.* Let $N = 2h$ be even, $\Gamma^\diamond = \mathbb{Z}N(e_1 - e_3) \oplus \mathbb{Z}Ne_2 \oplus \mathbb{Z}h(e_1 + e_3)$, a period lattice of the index N^3, and $Z_{\Gamma^\diamond}$ the partition function of the lattice with these periods. Then $Z(N^3) \le Z_{\Gamma^\diamond}$.

■

Proof. (a) The weight of the box is a product over the layers of $\mathsf{m}(V^\tau)$ and of the crossing weights $e^{-\beta A_\times(V^\tau, S^\tau, V^{\tau+1})}$, each S^τ standing in one factor; integrating the S^τ (Fubini) gives

$$\int \prod_\tau \mathrm{d}V^\tau \prod_\tau \mathsf{m}(V^\tau)\mathsf{K}(V^{\tau+1}, V^\tau),$$

and splitting each $\mathsf{m}(V^\tau)$ into two roots this is

$$\int \prod_\tau \mathsf{D}(V^{\tau+1}, V^\tau)\, \mathrm{d}V^\tau = \operatorname{Tr} \mathsf{D}^t,$$

for every $t \ge 3$. With $\mathsf{A} = \mathsf{K}^{1/2}\mathsf{m}^{1/2}$, $\mathsf{A}^*\mathsf{A} = \mathsf{D}$ and $\mathsf{A}\mathsf{A}^* = \mathsf{T}'$ have the same nonzero spectrum. The kernel of D is continuous and bounded below by a positive number on a compact space; if e_0 is a real eigenvector of λ_0, so is $|e_0|$, hence so are $|e_0| \pm e_0 \ge 0$, one of which vanishes on a set of positive measure and is therefore 0.

So every eigenvector of λ_0 has a strict sign, and no two of them are orthogonal. A permutation of the coordinates carries plaquettes to plaquettes and $\operatorname{tr} \partial U$ to itself; $0 \le a_p \le 2$ on $3|\underline{n}|$ plaquettes. (b) With $x_i = (\lambda_i/\lambda_0)^t \le 1$: $x_i^{(t+1)/t} \le x_i$, $\sum x_i^q \le (\sum x_i)^q$, $\sum \lambda_i^{t+t'} \le \sum \lambda_i^t \sum \lambda_i^{t'}$; $F(t)/t = \log \|\lambda\|_{\ell^t}$ does not increase in t. The identity and its range follow from $F(t) = t \log \lambda_0 + \mathsf{G}(t)$ and $0 \le \mathsf{G}(qt) \le \mathsf{G}(t)$. If $2F(t) - F(2t) \le x$, then $\mathsf{G}(t) \le x < \log 2$, $\mathsf{r}_t < 1$, and

$$e^x \ge \frac{(1+\mathsf{r}_t)^2}{1+\mathsf{r}_{2t}} \ge \frac{(1+\mathsf{r}_t)^2}{1+\mathsf{r}_t^2} = 1 + \frac{2\mathsf{r}_t}{1+\mathsf{r}_t^2},$$

which gives $\mathsf{r}_t \le \varphi(e^x - 1)$ as $r \mapsto 2r/(1+r^2)$ increases on $[0,1]$; and $2F(2t) - F(4t) \le 2\mathsf{G}(2t) \le 2\log(1+\mathsf{r}_t^2)$. (c) is (b) in each direction, divided by the product of the two other sides; $\varepsilon(\Sigma) = \lim_t (F(t,\Sigma) - t|\Sigma|P)/t \ge 0$; in D_q and e the terms with P cancel, and the series telescopes, its tail $q^{-3S}\delta((q^S N)^3) = N^3[F/|\cdot| - P]$ tending to 0. For the area: $\mathsf{G}(t; A, B) \le \mathsf{G}(N; A, B) \le \delta(N, A, B) \le AB\varkappa$ by the monotonicity of G and of $\delta/|\underline{n}|$. With the side B as the time, $\delta(s,t,B) = B\varepsilon(s,t) + \mathsf{G}(B; s, t) \le B\varepsilon(s,t) + st\varkappa$; dividing by s and then t and letting both tend to ∞, as $\varepsilon(s,t)/st \to 0$, gives $\limsup_t \varepsilon(t,B)/t \le \varkappa$.

Since $\delta(a,b,c) = a\varepsilon(b,c) + \mathsf{G}(a; b, c) \le \delta(N,b,c) + (a-N)\varepsilon(b,c)$ for $a \ge N$, $\varepsilon(A,B) \le \varepsilon(N,B) + (A-N)\varkappa \le \varepsilon(N,N) + (A+B-2N)\varkappa$, and $\varepsilon(N,N) \le \delta(N^3)/N = N\varkappa$. The same inequality in the three sides in turn gives $\delta(\underline{n}) \le \delta(N^3) + (n_3 - N)\varepsilon(N,N) + (n_2 - N)\varepsilon(N, n_3) + (n_1 - N)\varepsilon(n_2, n_3)$, which is the bracket. (d) As -1 is central in SU(2), reversing the sign of $\operatorname{tr} \partial U(p)$ on a column that crosses one time step is the same as multiplying by -1 the bonds of one line of the next layer; this change of variables keeps the Haar measure, appears under the trace as an involution J_i of the layer variables, and commutes with m and K.

A reversed column in the plane of the cross-section lies in every layer and replaces m by m_1. Moving a column by one step is a further flip of the bonds of a line, which does not change the trace. The P_e are the isotypical projections of $k \mapsto \mathsf{J}^k$; they commute with $\mathsf{T}^{(m)}$, so every eigenspace splits along them and $W(e;m) = \sum_{i: f(i) = e} \mu_i^t$. The positive top eigenvector is invariant under the flips, so it lies in the range of P_{00}. Then $Z - Z^{(k;0)} = 2\sum_{e \cdot k \text{ odd}} W(e;0) \le 2(Z - \lambda_0^t)$, $Z^{(k;m)} \le \sum_e W(e;m) = Z^{(00;m)}$, $4W(11;m) = Z^{(00;m)} - Z^{(10;m)} - Z^{(01;m)} + Z^{(11;m)} \ge 0$, and $\delta = t\varepsilon + \log(Z/\lambda_0^t)$ with $Z/\lambda_0^t = [W(00;0)/\lambda_0^t][Z/W(00;0)]$.

On a cube, by the cubic symmetry, with $u = w_{10} = w_{01}$, $v = w_{11}$: $1 - r_1 = 2(u+v)$, $1 - r_2 = 4u$, $2u + v = 1 - w_{00} \le \mathsf{R}_N$; two planes with a common direction as the time give $r_2 \le r^{(00;1)} = r_1$, hence $v \le u$ and $1 - r_1 \le \frac{4}{3}\mathsf{R}_N$; three planes give $r_3 \ge 2r_2 - r_1$; and the sum over e with a vanishing

component gives $1-r^{(1,1,1)} \le (1-r^{z'})+(1-r^{z''})$, so $1-r_3 \le (1-r_1)+(1-r_2) \le 3(1-r_1)$. (e) Within each class $(\sum \mu_i^t)^2 \ge \sum \mu_i^{2t}$, so $Z(t,\Sigma) \ge \sum_f W_{2t}(f)^{1/2} = Z(2t,\Sigma)^{1/2} \sum_f w_f^{1/2}$; and $Z/\lambda_0^t \ge Z/W(00;0)$. (f) Integrating the layers as in (a), the last layer is glued to the first through the translation by v, which produces U_v under the trace; U_v commutes with D, so in a common eigenbasis $Z_\Gamma = \sum_i \omega_i \lambda_i^{n_3}$ with $|\omega_i| = 1$ and $\omega_0 = 1$ (the top eigenvector is positive and unique, hence invariant); Z_Γ is real and positive, so $\lambda_0^{n_3} - \sum_{i\ge 1} \lambda_i^{n_3} \le Z_\Gamma \le \sum_i \lambda_i^{n_3}$. (g) Put $\mathsf{v} = e_1 + e_3$.

The planes $x_1 + x_3 = c$, $c \in \mathbb{Z}$, are planes of lattice reflections, $(x_1, x_2, x_3) \mapsto (c - x_3, x_2, c - x_1)$; $N\mathbb{Z}^3 = \Gamma_\perp \oplus \mathbb{Z}Ne_1$ and $\Gamma^\diamond = \Gamma_\perp \oplus \mathbb{Z}h\mathsf{v}$ with $\Gamma_\perp = \mathbb{Z}N(e_1 - e_3) \oplus \mathbb{Z}Ne_2 \perp \mathsf{v}$, and both generators Ne_1, $h\mathsf{v}$ raise the height $x_1 + x_3$ by N. Cut either torus along the planes of the heights $-h, 0, h$ into two slabs of the height h, periodic under $\Gamma_\perp$. No plaquette lies in such a plane, and no bond crosses it; a plaquette cut by it has two corners z, z' in it and one on either side, and its weight is $e^{-\beta(1-\frac{1}{2}\operatorname{tr} vv'^{-1})}$, v and v' the transports from z to z' through the upper and through the lower corner.

As $\frac{1}{2}\operatorname{tr} vv'^{-1} = \frac{1}{2}\sum_{i,j} v_{ij}\overline{v'_{ij}}$ on SU(2), the exponential series writes this weight as a sum with coefficients ≥ 0 of products $\Phi(v)\overline{\Phi(v')}$ of matrix elements. With the data ϕ of a plane, its bonds and the indices of this expansion at its cut plaquettes, under the product of Haar measure and of the coefficients, the partition function of the torus $\Gamma_\perp \oplus \mathbb{Z}g$ is $\iint k_2(\tau_g\phi_0, \phi_1)\, k_1(\phi_1, \phi_0)$, where k_1, k_2 are the kernels of the two slabs between the data of their walls and τ_g, the translation by g, carries the data of the height $-h$ to those of the height h and keeps their measure.

Schwarz' inequality gives $Z(N^3)^2 \le \|k_1\|_2^2\, \|k_2\|_2^2$. The reflection in the middle plane exchanges the two sides of the cut plaquettes, conjugates the kernels, and acts on the plane of the height $-h$ as the translation by $h\mathsf{v}$; so $\|k_i\|_2^2$ is the partition function of the slab i glued to its mirror image, that is of the torus $\Gamma_\perp \oplus \mathbb{Z}h\mathsf{v} = \Gamma^\diamond$, and $Z(N^3) \le Z_{\Gamma^\diamond}$. □

Proposition 17.32 (The recursion under doubling)**.** Let $\beta \ge 0$, $l \ge 3$, and $\mathsf{e}(l) \le x_0$ at β; put $\mathsf{s}(x) = \psi(4x + 2\psi(x) + \psi(2x + \psi(x)))$.

(a) $\mathsf{e}(2l) \le \mathsf{s}(\mathsf{e}(l)) \le 12.696\, \mathsf{e}(l)^2 \le 12.9\, \mathsf{e}(l)^2$, $D_2(2l) \le 19.669\, \mathsf{e}(l)^2 \le 20\, \mathsf{e}(l)^2$, and $\mathsf{e}(2^k l) \le \theta^{2^k}/12.9$ for $k \ge 0$.

(b) $\delta((2^j l)^3) \le \frac{20}{7}\mathsf{e}(2^{j-1}l)^2 \le 0.017170\, \theta^{2^j}$, and $\delta((2^j l)^3) \le 0.01655\, \theta^{2^j}$, for $j \ge 1$; $\delta(l, 2l, 2l) \le \frac{x_0}{2} + \frac{10}{7}x_0^2$; for every integer $N \ge 2l$: $\delta(N^3) < 0.13736\, \theta^{N/2l}$; $\mathsf{e}(l') < 0.3702\, \theta^{l'/2l}$ for every integer $l' \ge l$; $D_q(N) < q^3\, 0.13736\, \theta^{N/2l}$; and $\delta(\underline{n}) < |\underline{n}|\, n_-^{-3}\, 0.13736\, \theta^{n_-/2l}$ for every box whose least side n_- is $\ge 2l$.

(c) On every cube N^3 with $N \ge 2l$: $\mathsf{G}_N \le 0.06754\, \theta^{N/2l}$, $\mathsf{r}_N < 0.1473\, \theta^{N/2l}$, all seven $0 \le 1 - r^z < 0.4121\, \theta^{N/2l}$, and $1 - r_1 \le 0.09006\, \theta^{N/2l}$, $1 - r_2 \le 0.1351\, \theta^{N/2l}$, $1 - r_3 \le 0.2252\, \theta^{N/2l}$; at $N = 2^{k+1}l$, $\mathsf{r}_N \le 0.001615\, \theta^{N/l}$.

(d) If $x_0 = 0.069$: $1 - r_1(N) < 0.0039$ for every $N \ge 16l$, and $\mathsf{e}(l') < 0.0234$ for every integer $l' \ge 16l$.

(e) *The threshold.* $\mathsf{s}(x) \le 0.99991\, x$ on $(0, 0.07489]$, and the least positive fixed point of s lies in $(0.0748941, 0.0748942)$. No threshold $\ge \log 2$ can serve for a recursion of this kind: the function $F = |\underline{n}|P + \log 2$, which in each direction is a sum of t-th powers of two equal positive numbers and has the properties of Prop. 17.31(b), (c), has $\mathsf{e} \equiv \delta \equiv \log 2$; and the positivity of the λ_i is used: $e^F = e^{|\underline{n}|P} \prod_i (1 + (-1)^{n_i})$ has $\mathsf{e} = -\infty$ at odd l and $\mathsf{e} = \log 8$ at even l.

■

Proof. Let $\epsilon = \mathsf{e}(l)$, the doubling defect at $t = l$ over the cross-section $(2l, 2l)$. We double the three sides in turn, each time with Prop. 17.31(b). First $\mathsf{a} = 2F((2l)^3) - F(2l, 2l, 4l) \le \psi(\epsilon)$. Next $y_1 = 2F(l, 2l, 4l) - F(2l, 2l, 4l) \le 2\epsilon + \mathsf{a}$, because $F(l, 2l, 4l) \le 2F(l, 2l, 2l)$, and

$\mathsf{b}' = 2F(2l,2l,4l) - F(2l,4l,4l) \le \psi(y_1)$. Last $2F(l,4l,4l) - F(2l,4l,4l) \le 4\epsilon + 2\mathsf{a} + \mathsf{b}'$, and

$$\mathsf{e}(2l) \le \psi(4\epsilon + 2\mathsf{a} + \mathsf{b}') \le \mathsf{s}(\epsilon), \qquad D_2(2l) = 4\mathsf{a} + 2\mathsf{b}' + \mathsf{e}(2l).$$

ψ and s are power series in x with coefficients ≥ 0 beginning with $\frac{1}{2}x^2$ and $8x^2$, so $\mathsf{s}(x)/x^2$ does not decrease, and $\epsilon \le 0.069$ gives $12.696\,\epsilon^2$ and $19.669\,\epsilon^2$, all arguments staying below $0.293 < \log 2$; since $12.9 \cdot 0.069 < 1$, iteration gives (a). Put $\mathsf{s}_D(x) = 4\psi(x) + 2\psi(2x + \psi(x)) + \mathsf{s}(x)$, a power series in x with coefficients ≥ 0 beginning with $14x^2$, so that $\mathsf{s}_D(x)/x^2$ does not decrease; it is at most 19.668665 at 0.069, the number 19.669 of (a) before rounding. As ψ increases, the display, with $m = 2^i l$, $i \ge 0$, in the place of l, gives $D_2(2m) \le \mathsf{s}_D(\mathsf{e}(m)) \le 19.668665\,\mathsf{e}(m)^2$, as $\mathsf{e}(m) \le \theta^{2^i}/12.9 \le 0.069$ by (a); and e decreases along these sides, as $\mathsf{e}(2m) \le 12.9 \cdot 0.069\,\mathsf{e}(m)$. The series of Prop. 17.31(c) at $q = 2$, $\delta((2^j l)^3) = \sum_{s\ge 0} 8^{-(s+1)} D_2(2^{s+j} l)$, gives for $j \ge 1$

$$\delta((2^j l)^3) \le 19.668665 \sum_{s\ge 0} 8^{-(s+1)} \mathsf{e}(2^{s+j-1} l)^2 \le \frac{19.668665}{7}\,\mathsf{e}(2^{j-1} l)^2 \le \frac{19.668665}{7 \cdot 12.9^2}\,\theta^{2^j} \le 0.016885\,\theta^{2^j},$$

which is below $\frac{20}{7}\mathsf{e}(2^{j-1}l)^2$ and below $\mathsf{c}_0\theta^{2^j}$, $\mathsf{c}_0 = \frac{20}{7\cdot 12.9^2} \approx 0.0171693$. Keeping the decay of the terms, $\mathsf{e}(2^{s+j-1}l)^2 \le \theta^{2^{s+j}}/12.9^2$, the same series gives $\delta((2^j l)^3) \le \frac{19.668665}{8\cdot 12.9^2}\,\theta^{2^j} \sum_{s\ge 0} 8^{-s}\theta^{2^{s+j}-2^j} \le 0.0147743 \cdot 1.10720\,\theta^{2^j} \le 0.01636\,\theta^{2^j}$, the sum being greatest at $j = 1$ and $\theta = 0.8901$. For $2^j l \le N < 2^{j+1} l$, $j \ge 1$, the monotone density gives $\delta(N^3) \le (N/2^j l)^3 \delta((2^j l)^3) < 8 \cdot 0.016885\,\theta^{2^j} < 0.13736\,\theta^{N/2l}$, and boxes follow against the cube of their least side. For $\mathsf{e}(l')$ with $n = 2^k l \le l' < 2n$, $k \ge 0$: $\mathsf{e}(l') \le 2\mathsf{G}(n; 2l', 2l') \le 2\delta(n, 2l', 2l') \le 2(l'/n)^2 \delta(n, 2n, 2n) < 8\delta(n, 2n, 2n) = 4[\mathsf{e}(n) + \delta((2n)^3)]$ by Prop. 17.31(b), (c), and the bound above at $j = k + 1$ with $\mathsf{e}(n) \le 0.069$ gives $4[\mathsf{e}(n) + \delta((2n)^3)] \le 4\,\mathsf{e}(n)(1 + \frac{19.668665}{7}\,0.069) \le \frac{4\cdot 1.193877}{12.9}\,\theta^{2^k} \le 0.370195\,\theta^{2^k} < 0.3702\,\theta^{l'/2l}$. (c) For $\bar{N} = 2^j l \le N < 2\bar{N}$, $j \ge 1$, with the dyadic side as the time, $\mathsf{G}_N \le \mathsf{G}(\bar{N}; N, N) \le \delta(\bar{N}, N, N) \le 4\delta(\bar{N}^3) \le \frac{4\cdot 19.668665}{7\cdot 12.9^2}\,\theta^{2^j} \le 0.0675395\,\theta^{2^j} \le 0.06754\,\theta^{N/2l}$.

Then Prop. 17.31(d): in the signs of its proof, $1 - r_1 \le \frac{4}{3}\mathsf{R}_N$, $1 - r_2 = 4u \le 2(2u + v) \le 2\mathsf{R}_N$ and $1 - r_3 \le (1 - r_1) + (1 - r_2) \le \frac{10}{3}\mathsf{R}_N$, with $\mathsf{R}_N \le \mathsf{G}_N$, which give 0.0900527, 0.135079, 0.225132 times $\theta^{N/2l}$; all seven $1 - r^z \le 3\mathsf{R}_N \le 3\mathsf{G}_N$, and $\mathsf{r}_N = e^{\mathsf{G}_N} - 1$ with $e^{cy} - 1 \le y(e^c - 1)$ for $y \le 1$. At $N = 2^{k+1} l$, with $n = 2^k l$: $\mathsf{r}_N \le \mathsf{r}_n(N, N)^2 \le \varphi(e^{\mathsf{e}(n)} - 1)^2$ by Prop. 17.31(b), and $\varphi(e^x - 1)^2/x^2$ does not decrease and is at most 0.268652 at 0.069; with $\mathsf{e}(n) \le \theta^{2^k}/12.9$ this is $\mathsf{r}_N \le 0.268652\,\theta^{N/l}/12.9^2 \le 0.001615\,\theta^{N/l}$. (d) Iterate $X_{k+1} = \mathsf{s}(X_k)$ from $X_0 = 0.069$: $X_1, \dots, X_5 \approx 0.0604446,\ 0.0432902,\ 0.0195722,\ 0.0034309,\ 0.0000960$; the series gives $\delta((2^j l)^3) \le \sum_s 8^{-(s+1)} \mathsf{s}_D(X_{j-1+s})$, with the s_D above and $\mathsf{e}(2^i l) \le X_i$ (s increases), which at $j = 4$ is at most 0.00073051; so for $N \ge 16l$, $\mathsf{G}_N \le 0.0029221$ and $1 - r_1 \le \frac{4}{3}(1 - e^{-\mathsf{G}_N}) < 0.0039$, and $\mathsf{e}(l') \le 32 \cdot 0.00073051 < 0.0234$. (e) s is star-shaped, and $\mathsf{s}(x)/x$ is approximately 0.99999914 at 0.0748941 and approximately 1.00000135 at 0.0748942.

The two examples satisfy the identities of Prop. 17.31(a)–(c) with two equal top eigenvalues, respectively with an eigenvalue $-\lambda$. □

Proposition 17.33 (Every cross-section: a simple top, a gap, the thermal law)**.** Let $\beta \ge 0$, $l \ge 3$, $\mathsf{e}(l) \le x_0$ at β, and $A \le B$ integers $\ge 2l$; let $n = 2^k l$ with $2n \le A < 4n$ and $n' = 2^j n$ with $2n' \le B < 4n'$; any direction is the time.

(a) Over (A, B) the top λ_0 is simple and lies in the sector 00, and $\lambda_1/\lambda_0 < 0.49067^{1/n}\theta^{1/l} < \theta^{1/l}$; so every level of a sector $e \ne 00$, and every level of the sector 00 but the top, lies more than $\frac{1}{l}\log\frac{1}{\theta} + \frac{1.4239}{A}$ a step above the top. If $A = 2l$: $\lambda_1/\lambda_0 < (2.42\,x_0)^{1/l}$, and $\mathsf{r}_t(2l, B) \le 0.5628\,(2.42\,x_0)^{t/l}$ for $t \ge n'$. Over the square (N, N), $N \ge 2l$, with $2n \le N < 4n$: $\mathsf{r}_n(N, N) \le 0.20395\,\theta^{n/l}$.

(b) $\mathsf{r}_t(A,B) \le 0.2314\,\theta^{t/l}$ for every integer $t \ge n'$, and for every integer $t \ge l$

$$\mathsf{G}(t;A,B) \le 0.37\,\Big\langle\frac{A}{2t}\Big\rangle\Big\langle\frac{B}{2t}\Big\rangle\,\theta^{t/l} \le 0.37\,\frac{AB}{4l^2}\,\theta^{t/l},$$

in detail $0.27263\frac{AB}{4t^2}\theta^{t/l}$ if $2t \le A$, $0.3695\frac{B}{2t}\theta^{t/l}$ if $A < 2t \le B$, and $\mathsf{r}_t(A,B) \le 0.26261\,\theta^{t/l}$ if $B < 2t$.

(c) $\mathsf{e}(l') \le 0.4079\,\theta^{l'/l}$ for every integer $l' \ge l$; $\delta(l',2l',2l') \le 0.27263\,\theta^{l'/l}$; $D_2(N) \le 4.1242\,\theta^{N/l}$ and $\delta(N^3) \le 0.5892\,\theta^{N/l}$ for every integer $N \ge 2l$.

(d) Over the square (N,N), $N \ge 2l$, the vortex free energy $\varepsilon_{\mathrm{v}}(N,N) = \log(\lambda_0/\|\mathsf{T}^{(1)}\|)$ satisfies $N\varepsilon_{\mathrm{v}}(N,N) < 1.0292\,\theta^{N/2l}$.

(e) Conversely, on one lattice: if $\lambda_1/\lambda_0 \le e^{-\mu}$ over the single cross-section $(2l,2l)$ and $3 \le s < l$, then $\mathsf{e}(l) \le 2e^{-\mu(l-s)}(e^{\delta(s,2l,2l)} - 1)$; so $\mathsf{e}(l) \le x_0$ as soon as $\mu(l-s) \ge \delta(s,2l,2l) + \log(2/x_0)$. ■

Proof. Freeze the side A: the boxes (A,s,u) form a two-dimensional system, with the pressure $P_A = \inf F(A,s,u)/su$ and the excess $\delta_A(s,u) = F(A,s,u) - suP_A$, which has the properties of Prop. 17.31(b), (c) in its two sides and bounds $\mathsf{G}(t;A,u)$ from above. The first two doublings of the proof of Prop. 17.32, carried out in this system, give for its doubling defect $\eta = \mathsf{e}_A(m) = 2F(A,m,2m) - F(A,2m,2m)$: if $\eta \le 0.16521$, then $\mathsf{e}_A(2m) \le 3.4522\,\eta^2 \le 0.5704\,\eta$ and $\delta_A(2m,2m) \le 1.5514\,\eta^2$; the map $x \mapsto \psi(2x + \psi(x))$ has its least positive fixed point in $(0.2236, 0.2237)$, the threshold of this recursion. It is started at the scale $A/2$: by Prop. 17.31(b), (c) and Prop. 17.32(b),

$$\mathsf{e}_A(n) \le 2\,\mathsf{G}(n;A,2n) \le 2\,\delta(n,A,2n) \le \frac{A}{n}\,\delta(n,2n,2n) \le 0.185604\,\theta^{n/l} \le 0.16521.$$

Iterating, $\mathsf{e}_A(2^j n) \le 0.185604\,\theta^{2^j n/l}$ and $\delta_A(m,2m) \le 0.11659\,\theta^{m/l}$ along $m = 2^j n$; so for $2m \le u < 4m$, $\mathsf{r}_m(A,u) \le (e^{0.23318} - 1)\theta^{m/l} \le 0.26261\,\theta^{m/l} < 1$. At $m = n'$, $u = B$ this excludes a double top and gives $(\lambda_1/\lambda_0)^{n'} < \theta^{n'/l}$, and $\mathsf{r}_t \le \mathsf{r}_{n'}^{t/n'}$; the sector is that of Prop. 17.31(d), as $\mathsf{A} = \mathsf{K}^{1/2}\mathsf{m}^{1/2}$ commutes with the flips and carries the eigenvectors of D to those of T'. *The constants of (a) and (b).* They come from a finer start and from finer constants of the same recursion. For $2n \le A < 4n$, Prop. 17.31(b) in the thickness and at the time n over the cross-section $(2n,2n)$ give $\mathsf{e}_A(n) \le \frac{A}{2n}[\mathsf{e}(n) + \frac{1}{2}\psi(\mathsf{e}(n))] \le 2.037074\,\mathsf{e}(n) \le 0.140559$, as $\mathsf{e}(n) \le 0.069$.

On $[0, 0.140559]$ the doubling of the slab, $\mathsf{e}_A(2m) \le \psi(2\mathsf{e}_A(m) + \psi(\mathsf{e}_A(m)))$, gives $\mathsf{e}_A(2m) \le 3.1072\,\mathsf{e}_A(m)^2$, the inner argument staying below $0.292638 < \log 2$. So from a start $\mathsf{e}_A(n) \le x_1 \le 0.140559$, with $\vartheta = 3.1072\,x_1 < 1$: $\mathsf{e}_A(2^j n) \le \vartheta^{2^j}/3.1072$; the series of the slab gives $\delta_A(n',2n') \le 0.19314\,\vartheta^{n'/n}$; over (B,A) with $2n' \le B < 4n'$, $\mathsf{r}_{n'} \le e^{2\delta_A(n',2n')} - 1 \le 0.4715\,\vartheta^{n'/n} < 1$, so the top is simple, $\lambda_1/\lambda_0 < \vartheta^{1/n}$, and $\mathsf{r}_t \le 0.4715\,\vartheta^{t/n}$ for every $t \ge n'$. With $x_1 = 2.037074\,\mathsf{e}(n)$ and $\mathsf{e}(n) \le \theta^{n/l}/12.9$ (Prop. 17.32(a)), $\vartheta \le 6.3296\,\mathsf{e}(n) \le 0.49067\,\theta^{n/l}$: this is the factor $0.49067^{1/n}$ in (a), and $0.4715 \cdot 0.49067 \le 0.2314$ is the number of (b).

At $A = 2l$ the hypothesis itself is the start, $\mathsf{e}_{2l}(l) = \mathsf{e}(l) \le x_0 \le 0.069$, and on $[0, 0.069]$ the same recursion has the constants 2.42 and 0.5628 in the places of 3.1072 and 0.4715: $\vartheta = 2.42\,x_0$, $\lambda_1/\lambda_0 < (2.42\,x_0)^{1/l}$ and $\mathsf{r}_t(2l,B) \le 0.5628\,(2.42\,x_0)^{t/l}$ for $t \ge n'$. For the square, the box (n,N,N) with the short side as the time gives $\mathsf{G}(n;N,N) \le \frac{N^2}{4n^2}\delta(n,2n,2n) \le 0.185604\,\theta^{n/l}$ and $\mathsf{r}_n \le (e^{0.185604} - 1)\theta^{n/l}$. The thermal law (b) follows in three zones: if $2t \le A$, over the cross-section $(2t,2t)$, with $m = 2^i l \le t < 2m$, $\mathsf{r}_t(2t,2t) \le 0.20395\,\theta^{t/l}$, so $\mathsf{e}(t) \le 2\mathsf{r}_t \le 0.4079\,\theta^{t/l}$ and $\delta(t,2t,2t) = \frac{1}{2}[\mathsf{e}(t) + \delta((2t)^3)] \le 0.27263\,\theta^{t/l}$, and the monotone density carries this to (A,B); if $A < 2t \le B$, the slab gives $\delta_A(t,2t) \le 0.3695\,\theta^{t/l}$ and $\mathsf{G}(t;A,B) \le \frac{B}{2t}\delta_A(t,2t)$; if $B < 2t$, $\mathsf{r}_t \le 0.26261\,\theta^{t/l}$.

This also gives the first two clauses of (c); since $D_2(N) \le 8\mathsf{G}(N;N,N) + 4\mathsf{G}(N;N,2N) + 2\mathsf{G}(N;2N,2N)$, the three zones and the series give the last two. (d) In the box (N,N,h) with one twisted column of length h and $\zeta = \frac12(1-r)$, the second inequality of step (ii) in the proof of Prop. 17.39 below, which is exact on one lattice, gives $N\varepsilon_{\mathrm{v}}(N,N) \le \mathsf{d}(N;N,N) - \log(1 - 2\zeta(N,N;2N))$, with $\zeta(N,N;2N) \le \delta(N,N,2N) \le 2\delta(N^3)$ and $\mathsf{d}(N;N,N) \le 2\mathsf{G}_N \le 2\delta(N^3)$; with $\delta(N^3) < 0.13736\,y$, $y = \theta^{N/2l} \le 0.8901$, the first term is $< 0.27472\,y$, and $-\log(1-0.54944\,y) \le 0.75442\,y$ by convexity on $[0, 0.8901]$; the sum is $< 1.0292\,y$. (e) $\mathsf{e}(l) \le 2\mathsf{r}_l(2l,2l) \le 2e^{-\mu(l-s)}\mathsf{r}_s(2l,2l)$ and $\mathsf{r}_s = e^{\mathsf{G}(s)} - 1 \le e^{\delta(s,2l,2l)} - 1$. □

The two seminorms on a larger torus. By the setting and (M2), for $K \in \mathbb{N}$, $\beta > 0$, $\ell'' \le \ell$ in $\mathfrak{L}$ and a function F of the bonds of a cell of side $\ell''/2$, with the seminorm $\|F\|_{\mathrm{ch},\ell}^{(\ell'')}$ of all its mirror copies on the torus ℓ under its own board and the seminorm $\|F\|_{\mathrm{ch},\ell}$ of its eight mirror copies under the board of side $\ell/2$ whose cell is centred at the cell of F, the cells of the two boards being nested (Lem. YM3_I:104.1):

$$\|F\|_{\mathrm{ch},\ell} \le \|F\|_{\mathrm{ch},\ell}^{(\ell'')} \le e^{(\ell''/2)^3(p_{\ell''}-p_\ell)}\,\|F\|_{\mathrm{ch},\ell''} \le e^{\delta((\ell''/a_K)^3)/8}\,\|F\|_{\mathrm{ch},\ell''},$$

the last as $p_\ell \ge p_\infty = a_K^{-3}P$ and $(\ell''/2)^3(p_{\ell''} - p_\infty) = \frac18\delta((\ell''/a_K)^3)$.

Proposition 17.34 (The excess bounds the distance from the torus)**.** Let $K \in \mathbb{N}$, $\beta > 0$, $\ell' \in \mathfrak{L}$, $\delta' = \delta((\ell'/a_K)^3)$ and $Q' = e^{\delta'/8}$; let $\mathfrak{s}$ be either $\mu_{K,\ell,\beta}$ with $\ell \in \mathfrak{L}$, $\ell \ge \ell'$, or a periodic Gibbs state at β.

(a) For every bounded function F of the bonds of a cell of side $\ell'/2$, of any board: $|\mathfrak{s}(F)| \le Q'\|F\|_{\mathrm{ch},\ell'} \le Q'\,\mu_{K,\ell',\beta}(|F|^8)^{1/8}$.

(b) On the inner bonds of such a cell $\mathfrak{s} = h\,\mu_{K,\ell',\beta}$ with $\int h^{8/7} d\mu_{K,\ell',\beta} \le e^{\delta'/7}$, and the two laws are at a distance in total variation at most $\frac12(\sqrt{\varepsilon} + \varepsilon)$, $\varepsilon = 22.3\,(e^{\delta'/7} - 1)$.

(c) If $Q' \le 1.11$, then for every real G of the bonds of a cell of side $\ell''/2$, $\ell'' \in \mathfrak{L}$, $\ell'' \le \ell'$:

$$|\mathfrak{s}(G) - \mu_{K,\ell',\beta}(G)| \le 4.84\,[Q'(Q'-1)]^{1/2}\,\|G\|_{\mathrm{ch},\ell'} \le 4.84\,[Q'(Q'-1)]^{1/2}\,Q''\,\|G\|_{\mathrm{ch},\ell''},$$
$$Q'' = e^{\delta((\ell''/a_K)^3)/8};$$

for complex G the same with twice the constant.

(d) Let $\ell_i \in \mathfrak{L}$, $\ell_i \to \infty$, with $\limsup_i \delta((\ell_i/a_K)^3) \le D < \infty$ and $\mu_{K,\ell_i,\beta} \to \mu^*$ weakly. Then μ^* is a periodic Gibbs state; $\mu^*(A) \ge e^{-D}\mathfrak{s}(A)^8$ for every periodic Gibbs state $\mathfrak{s}$ and every Borel set A; $\mu^* \ge e^{-D}\nu$ for every ergodic periodic Gibbs state ν; and $\mathfrak{s} \le e^D\mu^*$ for every periodic Gibbs state $\mathfrak{s}$. So n mutually singular periodic Gibbs states at β have $n \le e^D$, and indeed $n \le \liminf_{\mathfrak{L}\ni\ell'\to\infty} e^{\delta'}$.

■

Proof. (a) By the fine-to-coarse form of (M2), $\|F\|_{\mathrm{ch},\ell}^{(\ell')} \le \|F\|_{\mathrm{ch},\ell'}\exp[(\ell'/2)^3(p_{\ell'} - p_\ell)]$, and since $p_\ell \ge p_\infty = a_K^{-3}P$ the exponent is at most $\frac18\ell'^3(p_{\ell'} - p_\infty) = \delta'/8$. For a torus $|\mu_{K,\ell,\beta}(F)| \le \|F\|_{\mathrm{ch},\ell}^{(\ell')}$, by the array form with the factor 1 in the other cells; and a periodic Gibbs state is dominated by the tori, $|\mathfrak{s}(F)| \le \liminf_\ell \|F\|_{\mathrm{ch},\ell}^{(\ell')}$ (M2). The second inequality is Hölder's in the array form, the mirror copies of $|F|^8$ all having the same mean. (b) By (a), $\mathfrak{s}(A) \le Q'\mu_{K,\ell',\beta}(A)^{1/8}$ on the inner bonds, so $\mathfrak{s} = h\mu$ with $\|h\|_{8/7} \le Q'$ by duality. With $p = \frac87$ and $\phi(u) = u^p - 1 - p(u-1) \ge 0.045\min\{(u-1)^2, |u-1|^p\}$ for $u \ge 0$ (Taylor's formula on $[0,2]$, monotonicity of $\phi(1+v)/v^p$ beyond), $\int\phi(h) \le e^{\delta'/7} - 1$ gives $\int|h-1| \le \sqrt{\varepsilon} + \varepsilon$. (c) We use an abstract form. Let $\mathcal{A}$ be a real vector space with a member 1, N a seminorm and g a linear functional on it with

$$\mathsf{N}(1+tG)^8 \le 1 + 8t\,\mathsf{g}(G) + R(|t|\mathsf{N}(G)), \quad R(x) = (1+x)^8 - 1 - 8x, \qquad |\mathsf{g}(G)| \le \mathsf{N}(G),$$

and $\mathfrak{s}$ a linear functional with $\mathfrak{s}(1)=1$, $\mathfrak{s}(F)\le Q\,\mathsf{N}(F)$, $1\le Q\le 1.11$. As $(1+u)^{1/8}\le 1+\frac{u}{8}$: $t[\mathfrak{s}(G)-\mathsf{g}(G)]\le (Q-1)(1+x)+\frac{Q}{8}R(x)$, $x=|t|\mathsf{N}(G)$; if $\mathsf{N}(G)=0$, the bounds on g and the linearity bound on $\mathfrak{s}$, applied to G and $-G$, give $\mathfrak{s}(G)=\mathsf{g}(G)=0$. For $Q=1$, use both signs of t and let $t\to 0$, since $R(x)=O(x^2)$. For $\mathsf{N}(G)>0$ and $Q>1$, take $t=\pm x/\mathsf{N}(G)$, $x^2=\frac{Q-1}{4.74Q}$ (so $x\le 0.1446$, where $R(x)\le 8\cdot 4.7179\,x^2$); this gives $|\mathfrak{s}(G)-\mathsf{g}(G)|\le [2\sqrt{4.74}+(0.11/1.11)^{1/2}][Q(Q-1)]^{1/2}\mathsf{N}(G)\le 4.6692\,[Q(Q-1)]^{1/2}\mathsf{N}(G)$. For $\mathsf{N}=\|\cdot\|_{\mathrm{ch},\ell'}$, $\mathsf{g}=\mu_{K,\ell',\beta}$ on the real functions of a cell, the product of the eight copies of $1+tG$ expands into $\sum_S t^{|S|}m_S$ with $m_\emptyset=1$, $m_{\{\mathbf{k}\}}=\mu(G)$ for the eight one-point sets and $|m_S|\le \mathsf{N}(G)^{|S|}$ for $|S|\ge 2$ (array form), and $Q=Q'$ by (a).

A function of a cell of side $\ell''/2$ is a function of the cell of side $\ell'/2$ of the setting, centred at its cell, as ℓ'/ℓ'' is a power of the odd L, and $\|G\|_{\mathrm{ch},\ell'}\le \|G\|_{\mathrm{ch},\ell'}^{(\ell'')}\le Q''\|G\|_{\mathrm{ch},\ell''}$ by the chain of (M2) recalled before the Proposition. (d) μ^* is a periodic Gibbs state invariant under $a_K\mathbb{Z}^3$ by (M3). For an event A of the bonds of a cell of side $\ell_i/2$, (a) with $F=1_A$ gives $\mathfrak{s}(A)\le e^{\delta_i/8}\mu_{K,\ell_i,\beta}(A)^{1/8}$, $\delta_i=\delta((\ell_i/a_K)^3)$; the conditional laws of finitely many bonds given the others are continuous in the others, so the means of local events converge, and $\mu^*(A)\ge e^{-D}\mathfrak{s}(A)^8$ for local events, hence for all Borel sets by approximation.

An ergodic ν has an invariant carrier N_ν that carries no other ergodic state, so the ergodic decomposition of μ^* gives $\mu^*(\cdot\cap N_\nu)=\mu^*(N_\nu)\,\nu$ with $\mu^*(N_\nu)\ge e^{-D}\nu(N_\nu)^8=e^{-D}$; every $\mathfrak{s}$ is an integral of ergodic states (M3), each $\le e^D\mu^*$. Mutually singular states have disjoint carriers C_j, and $\sum_j \mu^*(C_j)\le 1$ with $\mu^*(C_j)\ge e^{-D}$; for the last clause take sides along which δ' tends to its lower limit and a weakly convergent subsequence. □

Lemma 17.35 (Boxes of every shape)**.** Let $\beta\ge 0$, $N=2h\ge 4$, c a corner, $\mathsf{C}=\mathsf{C}_h(c)$, and $\underline{n}$ any box with $n_\mu\ge N$; let $M_\mu=2^{j_\mu}h$, $j_\mu\in\mathbb{N}$, be the greatest number of this form that is $\le n_\mu$, so $N\le M_\mu\le n_\mu<2M_\mu$.

(a) Let μ be a direction, $\vartheta\ge 2$ with $2\vartheta\le n_\mu$, θ' the reflection in a plane $x_\mu=c'_\mu$, $c'_\mu\in a(\mathbb{Z}+\frac12)$, and F a bounded Borel function of the bonds with both ends in the ϑ layers below that plane. Then $\langle F\,\overline{\theta' F}\rangle_{\underline{n}}\ge 0$ and $|\langle F\rangle_{\underline{n}}|^2\le\langle F\,\overline{\theta' F}\rangle_{\underline{n}}$, also for odd n_μ. On the cube N^3, $|\langle\prod_\epsilon H_\epsilon^{[\epsilon]}\rangle_{N^3}|\le\prod_\epsilon\|H_\epsilon\|_{\mathrm{ch};N}$, so $\|\cdot\|_{\mathrm{ch};N}$ is a seminorm, and $|\langle\Psi\rangle_{N^3}|\le\|\Psi\|_{\mathrm{ch};N}\le\sup|\Psi|$.

(b) For every function Ψ of the bonds of C:

$$|\langle\Psi\rangle_{\underline{n}}|\le\exp\Big\{\frac{\delta(N^3)}{8}\Big[1+3N\Big(\frac{1}{M_1}+\frac{1}{M_2}+\frac{1}{M_3}\Big)\Big]\Big\}\|\Psi\|_{\mathrm{ch};N}\le e^{\frac54\delta(N^3)}\|\Psi\|_{\mathrm{ch};N};$$

and for the boxes (q_1N,q_2N,q_3N), $q\in\mathbb{N}^3$: $|\langle\Psi\rangle_{\underline{n}}|\le\exp[\frac18(\delta(N^3)-\delta(\underline{n})/q_1q_2q_3)]\|\Psi\|_{\mathrm{ch};N}$.

(c) Let Ψ be real. If $\delta(N^3)\le\frac12$, then $|\langle\Psi\rangle_{\underline{n}}-\langle\Psi\rangle_{N^3}|\le 7.31\,\delta(N^3)^{1/2}\|\Psi\|_{\mathrm{ch};N}$; for the boxes $(q_\mu N)$ and $\delta(N^3)\le 0.8348$, the same with 1.86 for 7.31.

None of these constants depends on the shape of the box. ■

Proof. (a) With the time μ and $\mathsf{v}=\frac12(n_\mu-2\vartheta)$, the trace formula (M1) and the cyclicity of the trace give $Z(\underline{n})\langle F\rangle_{\underline{n}}=\mathrm{Tr}(\mathsf{T}'^{\,n_\mu/2}\cdot Y\mathsf{T}'^{\mathsf{v}})$, $Y=\mathfrak{Y}[\Phi_F]$; Schwarz's inequality in the Hilbert–Schmidt class, with $\|\mathsf{T}'^{\,n_\mu/2}\|_2^2=Z(\underline{n})$ and $\|Y\mathsf{T}'^{\mathsf{v}}\|_2^2=\mathrm{Tr}(\mathsf{T}'^{\,2\mathsf{v}}Y^*Y)=Z(\underline{n})\langle F\overline{\theta' F}\rangle_{\underline{n}}$, is the claim. Applied in the three directions in turn this is the array bound on the cube. (b) *Doubling on a single box.* In the direction 1 let $F_0=\Psi$ and $F_{i+1}=F_i\,\overline{\theta^{(i)}F_i}$, $\theta^{(i)}$ the reflection in $x_1=c_1+(2^i-1)ha$; by (a), as long as the doubled function fits, $|\langle F_i\rangle_{\underline{n}}|^2\le\langle F_{i+1}\rangle_{\underline{n}}$; so $|\langle\Psi\rangle_{\underline{n}}|\le\langle\mathfrak{B}_1\Psi\rangle_{\underline{n}}^{2^{-j_1}}$ with an array $\mathfrak{B}_1\Psi$ of M_1/h cells.

The same in the directions 2, 3 gives an array $\mathfrak{B}\Psi$ on a block of $M_1\times M_2\times M_3$ sites with $\mathcal{N}=M_1M_2M_3/h^3$ cells and $|\langle\Psi\rangle_{\underline{n}}|\le\langle\mathfrak{B}\Psi\rangle_{\underline{n}}^{1/\mathcal{N}}$. *The free layers cost their top eigenvalue.* Let $\underline{m}$ be a box with $m_\mu\ge M_\mu$ for each μ; it is taken in turn as $\underline{n}$, (M_1,n_2,n_3) and (M_1,M_2,n_3). Take the direction 1 as the time over the cross-section (m_2,m_3), let Φ be the slab function of the cell

of $\mathfrak{B}_3\mathfrak{B}_2\Psi$, which lies in the h layers below c_1, and let $Y_\Phi = \mathfrak{Y}[\Phi]$ be its slab operator (another operator than the Y of (a)).

In the direction 1 the array $\mathfrak{B}\Psi$ is the row $\Phi, \Phi^\Theta, \Phi, \Phi^\Theta, \dots$ on M_1/h consecutive slabs of h layers, so its operators close up into $(Y_\Phi^* Y_\Phi)^{M_1/N}$, $M_1/N = 2^{j_1-1}$, and the $m_1 - M_1$ free layers carry $\mathsf{T}'^{m_1-M_1}$ (a free rest of one layer is $\mathfrak{Y}[\Phi^{+1}] = \mathsf{T}'\mathfrak{Y}[\Phi]$ of (M1)). By the trace formula (M1), $Z(\underline{m})\langle\mathfrak{B}\Psi\rangle_{\underline{m}} = \mathrm{Tr}(\mathsf{T}'^{m_1-M_1}(Y_\Phi^* Y_\Phi)^{M_1/N})$ and $\mathrm{Tr}(Y_\Phi^* Y_\Phi)^{M_1/N} = Z(M_1, m_2, m_3)\langle\mathfrak{B}\Psi\rangle_{(M_1,m_2,m_3)}$; and $\mathrm{Tr}(\mathsf{AB}) = \mathrm{Tr}(\mathsf{B}^{1/2}\mathsf{AB}^{1/2}) \le \|\mathsf{A}\|\,\mathrm{Tr}\,\mathsf{B}$ for $\mathsf{A}, \mathsf{B} \ge 0$, B of trace class.

So, direction by direction,

$$Z(\underline{n})\langle\mathfrak{B}\Psi\rangle_{\underline{n}} \le \lambda_0(n_2, n_3)^{n_1-M_1}\lambda_0(M_1, n_3)^{n_2-M_2}\lambda_0(M_1, M_2)^{n_3-M_3}\, Z(M_1, M_2, M_3)\langle\mathfrak{B}\Psi\rangle_{(M_1,M_2,M_3)}.$$

On the box (M_1, M_2, M_3), whose sides lie in $N\mathbb{N}$, the inequality $\mathrm{Tr}(Y_\Phi^* Y_\Phi)^p \le (\mathrm{Tr}\, Y_\Phi^* Y_\Phi)^p$ at $p = M_\mu/N$ in each direction μ, with Φ the cell of the array in that direction, reduces the array to the cube N^3, where it is the product of the eight mirror copies of Ψ: $Z(M_1, M_2, M_3)\langle\mathfrak{B}\Psi\rangle_{(M_1,M_2,M_3)} \le [Z(N^3)\|\Psi\|_{\mathrm{ch};N}^8]^{M_1M_2M_3/N^3}$. *The count.* With $\log\lambda_0(\Sigma) = |\Sigma|P + \varepsilon(\Sigma)$ and $F = |\cdot|P + \delta$ the terms with P cancel, and by the area bound $\varepsilon(\mathsf{A}, \mathsf{B}) \le (\mathsf{A} + \mathsf{B})\delta(N^3)/N^2$ for $\mathsf{A}, \mathsf{B} \ge N$ (Prop. 17.31(c)) the free layers cost at most $3\delta(N^3)N^{-2}(M_1M_2 + M_1M_3 + M_2M_3)$ against $\mathcal{N} = 8M_1M_2M_3/N^3$ cells: an area against a volume.

The boxes (q_1N, q_2N, q_3N), $q \in \mathbb{N}^3$, are treated with another array, which fills the box for every q, so that no layer is free. For a function F of the bonds in the h layers below c_μ, with slab function Φ_F and slab operator $Y_F = \mathfrak{Y}[\Phi_F]$, the time being μ, let $\mathfrak{A}_\mu F$ be the product of the $2q_\mu$ cells $\Phi_F, \Phi_F^\Theta, \Phi_F, \Phi_F^\Theta, \dots$ on all the $2q_\mu$ consecutive slabs of h layers: F and its successive conjugated mirror images in the planes $x_\mu = c_\mu + jha$. By (M1), $Z(\underline{n})\langle\mathfrak{A}_\mu F\rangle_{\underline{n}} = \mathrm{Tr}(Y_F^* Y_F)^{q_\mu} = \|Y_F\|_{2q_\mu}^{2q_\mu}$ and $Z(\underline{n}) = \mathrm{Tr}\,\mathsf{T}'^{2q_\mu h} = \|\mathsf{T}'^h\|_{2q_\mu}^{2q_\mu}$, the norms of the Schatten class of order $2q_\mu$; Hölder's inequality in these classes for the $2q_\mu$ factors $Y_F, \mathsf{T}'^h, \dots, \mathsf{T}'^h$ gives $Z(\underline{n})|\langle F\rangle_{\underline{n}}| = |\,\mathrm{Tr}(\mathsf{T}'^h \cdots \mathsf{T}'^h Y_F)| \le \|Y_F\|_{2q_\mu}\|\mathsf{T}'^h\|_{2q_\mu}^{2q_\mu-1}$, that is $|\langle F\rangle_{\underline{n}}| \le \langle\mathfrak{A}_\mu F\rangle_{\underline{n}}^{1/2q_\mu}$.

Applied on the one box $\underline{n}$ to Ψ in the direction 1, to $\mathfrak{A}_1\Psi$, which lies below c_2, in the direction 2, and to $\mathfrak{A}_2\mathfrak{A}_1\Psi$, which lies below c_3, in the direction 3, this gives $|\langle\Psi\rangle_{\underline{n}}| \le \langle\mathfrak{A}\Psi\rangle_{\underline{n}}^{1/8q_1q_2q_3}$, $\mathfrak{A} = \mathfrak{A}_3\mathfrak{A}_2\mathfrak{A}_1$, the product of the mirror copies of Ψ in all the $8q_1q_2q_3$ cells of the box. Only then is the box made smaller: with the time 1 and $F = \mathfrak{A}_3\mathfrak{A}_2\Psi$, $Z(q_1N, n_2, n_3)\langle\mathfrak{A}\Psi\rangle_{(q_1N,n_2,n_3)} = \mathrm{Tr}(Y_F^* Y_F)^{q_1} \le (\mathrm{Tr}\, Y_F^* Y_F)^{q_1} = [Z(N, n_2, n_3)\langle\mathfrak{A}\Psi\rangle_{(N,n_2,n_3)}]^{q_1}$, and the same in the directions 2, 3 give $Z(\underline{n})\langle\mathfrak{A}\Psi\rangle_{\underline{n}} \le [Z(N^3)\|\Psi\|_{\mathrm{ch};N}^8]^{q_1q_2q_3}$.

As $|\underline{n}| = q_1q_2q_3N^3$, the terms with P cancel, and $|\langle\Psi\rangle_{\underline{n}}| \le \exp\frac{1}{8}[\delta(N^3) - \delta(\underline{n})/q_1q_2q_3]\,\|\Psi\|_{\mathrm{ch};N}$.
(c) The abstract form of the proof of Prop. 17.34(c) with $\mathsf{N} = \|\cdot\|_{\mathrm{ch};N}$, $\mathfrak{g} = \langle\cdot\rangle_{N^3}$, $\mathfrak{s} = \langle\cdot\rangle_{\underline{n}}$: its first condition is the array bound of (a) on the cube, the eight one-point terms being $\langle G\rangle_{N^3}$ by the mirror symmetry of the cube, and $\mathfrak{s}(F) \le Q\,\mathsf{N}(F)$ is (b). With $Q = e^{\frac{5}{4}\delta(N^3)}$, which is ≤ 1.11 if and only if $\delta(N^3) \le \frac{4}{5}\log 1.11$: as $u \mapsto e^u(e^u - 1)/u$ increases, $Q(Q-1) \le \frac{1.11\cdot 0.11}{\log 1.11}\cdot\frac{5}{4}\delta(N^3)$, so $[Q(Q-1)]^{1/2} \le 1.209334\,\delta(N^3)^{1/2}$ and $4.84 \cdot 1.209334 \le 5.86 \le 7.31$; for $\frac{4}{5}\log 1.11 < \delta(N^3) \le \frac{1}{2}$, by (b) and (a) directly, $|\langle\Psi\rangle_{\underline{n}} - \langle\Psi\rangle_{N^3}| \le (e^{\frac{5}{4}\delta} + 1)\|\Psi\|_{\mathrm{ch};N}$, and $(e^{\frac{5}{4}\delta} + 1)\delta^{-1/2}$ decreases on $(0, \frac{1}{2}]$, so it is at most its value at $\frac{4}{5}\log 1.11$, which is less than 7.3025.

For the boxes $(q_\mu N)$ take $Q = e^{\delta(N^3)/8}$ by the second clause of (b): $Q \le 1.11$ if and only if $\delta(N^3) \le 8\log 1.11$, and then $Q(Q-1) \le \frac{1.11\cdot 0.11}{\log 1.11}\cdot\frac{\delta(N^3)}{8}$, $[Q(Q-1)]^{1/2} \le 0.382425\,\delta(N^3)^{1/2}$, and $4.84 \cdot 0.382425 \le 1.85094 \le 1.86$. □

Lemma 17.36 (Cells are nearly independent under every boundary condition)**.**

(a) Let $\mathcal{K}$ be a finite set, Y_κ measurable maps of a probability space (E, R) to spaces E_κ with probability measures ref_κ, and $\Delta \ge 0$ with $\log R(\exp\sum_\kappa \Phi_\kappa \circ Y_\kappa) \le \sum_\kappa[\Delta + \frac{1}{8}\log\mathrm{ref}_\kappa(e^{8\Phi_\kappa})]$

for all bounded real Φ_κ. Then for every probability $P = fR$ with $\mathsf{H} = R(f\log f) < \infty$ and all bounded real non-constant G_κ: $\sum_\kappa [P(G_\kappa \circ Y_\kappa) - \mathrm{ref}_\kappa(G_\kappa)]^2 / \operatorname{osc}(G_\kappa)^2 \le 4\mathsf{H} + 4\#\mathcal{K}\,\Delta$.

(b) Let $K \in \mathbb{N}$, $\beta > 0$, $\ell' \le \ell$ in $\mathfrak{L}$, $n = \ell/a_K$, $n' = \ell'/a_K$ and $\delta' = \delta(n'^3)$; these letters serve in (c) as well. The $(2n/n')^3 = 8(n/n')^3$ cells of a period box of a board of side $\ell'/2$ on the torus ℓ satisfy the hypothesis of (a) with $R = \mu_{K,\ell,\beta}$, ref the law of a cell under $\mu_{K,\ell',\beta}$ and $\Delta = \delta'/8$.

(c) Let D be the set of the sites of a period cube of the torus ℓ, n sites a side, that is the union of the $8(n/n')^3$ cells of side $\ell'/2$ of a period box of the board, let W be the set of the positively oriented bonds with initial point in D, which holds the bonds of these cells, and let $\gamma_W(\cdot)(\xi)$ be the law of the bonds of W given the configuration ξ outside W. For every ξ and all real non-constant $G_{\mathbf{k}}$ of the cells:

$$\sum_{\mathbf{k}} \frac{[(\gamma_W G_{\mathbf{k}})(\xi) - \mu_{K,\ell',\beta}(G_{\mathbf{k}})]^2}{\operatorname{osc}(G_{\mathbf{k}})^2} \le 144\,\beta n^2 + 4\,(n/n')^3\delta';$$

the mean over the cells is at most $\varepsilon_1(n,n')^2 = 18\beta n'^3/n + \delta'/2$.

(d) Let $\lambda \ge 3$ be odd and $\underline{n} = (\mathsf{n}_1\lambda, \mathsf{n}_2\lambda, \mathsf{n}_3\lambda)$ a periodic box with even $\mathsf{n}_1, \mathsf{n}_2, \mathsf{n}_3$, cut into the $\mathsf{n}_1\mathsf{n}_2\mathsf{n}_3$ cells of λ sites a side of a board whose walls are planes of lattice reflections. The cells satisfy the hypothesis of (a) with $R = \mu_{\underline{n}}$, ref the law of one cell of the cube $(2\lambda)^3$ under $\mu_{(2\lambda)^3}$, and $\Delta = \delta((2\lambda)^3)/8$.

■

Proof. (a) By the variational formula for the relative entropy, $P(\Phi) \le \mathsf{H} + \log R(e^\Phi)$ for $\Phi = \sum_\kappa t_\kappa(G_\kappa - \mathrm{ref}_\kappa G_\kappa)\circ Y_\kappa$; the hypothesis and Hoeffding's bound $\log \mathrm{ref}(e^{s(G-\mathrm{ref}G)}) \le s^2 \operatorname{osc}(G)^2/8$ give $\sum_\kappa t_\kappa[P(G_\kappa) - \mathrm{ref}_\kappa(G_\kappa)] \le \mathsf{H} + \#\mathcal{K}\Delta + \sum_\kappa t_\kappa^2 \operatorname{osc}(G_\kappa)^2$; optimise over the t_κ. (b) This is the proof of Prop. 17.34(a) for a product: for real $\Phi_{\mathbf{k}}$ of the cells, the array form of the chessboard estimate on the torus ℓ for the board of side $\ell'/2$ gives $\mu_{K,\ell,\beta}(\prod_{\mathbf{k}} e^{\Phi_{\mathbf{k}}}) \le \prod_{\mathbf{k}} \|e^{\Phi_{\mathbf{k}}}\|^{(\ell')}_{\mathrm{ch},\ell}$, the fine-to-coarse form gives the factor $e^{\delta'/8}$ per cell, $\|e^\Phi\|^{(\ell')}_{\mathrm{ch},\ell} \le e^{\delta'/8}\|e^\Phi\|_{\mathrm{ch},\ell'}$, and Hölder's inequality on the torus ℓ' gives $\|e^\Phi\|_{\mathrm{ch},\ell'} \le \mu_{K,\ell',\beta}(e^{8\Phi})^{1/8}$, the eight mirror copies of $e^{8\Phi}$ having the mean of one cell. (c) Identify the bonds of W with those of the torus ℓ.

The conditional law of the bonds of W and the law of the torus have the same weight but on the plaquettes that are not common to both, the $12n^2 - 3n$ plaquettes with a bond in W that meet the outside and the $6n^2 - 3n$ plaquettes of the torus that wrap around it, a surface; as $a_p \in [0,2]$, the density of the first law against the second lies between $e^{-36\beta n^2}$ and $e^{36\beta n^2}$ (Prop. YM3_I:91.8), so their relative entropy is $\mathsf{H} \le 36\beta n^2$. Then (a), with (b) on the torus ℓ and $\#\mathcal{K} = 8(n/n')^3$: the sum is at most $4\cdot 36\beta n^2 + 4\cdot 8(n/n')^3\delta'/8$, and the mean over the cells is at most $18\beta n'^3/n + \delta'/2$. (d) The reflection in a wall plane is a symmetry of the box, as every n_μ is even, and it is reflection positive by the trace formula (Lem. 17.35(a)).

So the chessboard estimate on the box holds (Prop. YM3_I:86.3): the mean of a product over the cells is at most the product of the seminorms of the factors on the box (equation YM3_I:(1756)), the $(\mathsf{n}_1\mathsf{n}_2\mathsf{n}_3)$-th roots of the means of the products of all their mirror copies. By the subadditivity in the volume (Prop. YM3_I:86.5) at $\underline{\mathsf{n}}' = (2,2,2)$, which is the trace formula with the inequality $\mathrm{Tr}(Y^*Y)^q \le (\mathrm{Tr}\,Y^*Y)^q$ in each direction as in the proof of Lem. 17.35(b), the seminorm on the box of a function G of one cell is at most $\|G\|_{\mathrm{ch};2\lambda}$ times $\exp[\frac{1}{8}F((2\lambda)^3) - \lambda^3 F(\underline{n})/|\underline{n}|] \le e^{\delta((2\lambda)^3)/8}$, as $F(\underline{n})/|\underline{n}| \ge P$.

For $G = e^\Phi$, Hölder's inequality on the cube gives $\|e^\Phi\|_{\mathrm{ch};2\lambda} \le \langle e^{8\Phi}\rangle^{1/8}_{(2\lambda)^3}$, the eight mirror copies of $e^{8\Phi}$ having the mean of one cell; this is the hypothesis of (a) with the reference law of one cell of the cube $(2\lambda)^3$. □

Lemma 17.37 (The operator of a cell; two cells cluster)**.** Let $K \in \mathbb{N}$, $\beta > 0$, a board of side $\mathsf{l} = \ell''/2$, $\ell'' \in \mathfrak{L}$, and $\ell \in \mathfrak{L}$, $\ell \geq 2\mathsf{l}$, $N = \ell/a_K = \mathsf{nw}$ with $\mathsf{w} = \mathsf{l}/a_K$ layers to a cell; a direction as the time of the cube N^3, $\Sigma = (N, N)$.

(a) For F of the bonds of one cell, Φ_F its slab function: $\|\mathfrak{Y}[\Phi_F]\| \leq Z(N^3)^{1/\mathsf{n}} \|F\|_{\mathrm{ch},\ell}^{(\ell'')} = \lambda_0^{\mathsf{w}}(1+\mathsf{r}_N)^{1/\mathsf{n}} \|F\|_{\mathrm{ch},\ell}^{(\ell'')}$, with the seminorm of the setting of all the mirror copies of F on the torus ℓ under the board of side l.

(b) Let $\mathsf{e}(l) \leq x_0$ at β, ν the periodic Gibbs state of Prop. 17.38, $\ell'' \geq 2la_K$, $Q'' = e^{\delta((\ell''/a_K)^3)/8}$. For F, G of the bonds of two cells whose indices differ by $j \geq 1$ in a direction: $|\nu(FG) - \nu(F)\nu(G)| \leq \theta^{(j-1)\mathsf{w}/l} Q''^2 \|F\|_{\mathrm{ch},\ell''} \|G\|_{\mathrm{ch},\ell''}$; on every torus $\ell \geq L\ell''$ of $\mathfrak{L}$, with $j_- = \min\{j, \mathsf{n} - j\} \geq 2$ the distance on the torus, the same with $3.44\,\theta^{(j_- - 1)\mathsf{w}/l}$.

The constants do not depend on K, β, ℓ, F, G or the offset. ■

Proof. (a) The operator norm is at most the Schatten norm of order n ($\mathsf{n} = 2\ell/\ell''$ is even), and by the trace formula (M1) $\mathrm{Tr}(\mathfrak{Y}^*\mathfrak{Y})^{\mathsf{n}/2}$ is $Z(N^3)$ times the mean of the product of the n mirror copies of F along the time, cells of the board of side l in one column, which the array form of (M2) bounds by $(\|F\|_{\mathrm{ch},\ell}^{(\ell'')})^{\mathsf{n}}$. (b) *The state ν.* A function of the second cell is the reflected image of a function of the slab of the first, so the spectral formula of Prop. 17.38(f) applies; over the cross-section (N', N'), $N' = \ell'/a_K$, $\ell' \geq \ell''$ in $\mathfrak{L}$, the covariance is $\lambda_0^{-2\mathsf{w}} \sum_{i \geq 1} (\lambda_i/\lambda_0)^n \overline{\mathsf{a}_i} \mathsf{b}_i$ with $n = (j-1)\mathsf{w}$ layers between the cells (at $n = 0$ with the term of the kernel of T' besides), and Schwarz's inequality bounds it by $(\lambda_1/\lambda_0)^n \lambda_0^{-2\mathsf{w}} \|\mathfrak{Y}[\Phi_F]\| \|\mathfrak{Y}[\Phi_G]\|$.

The gap of Prop. 17.33(a) gives $(\lambda_1/\lambda_0)^n < \theta^{n/l}$, and (a) on the cube N' with the fine-to-coarse form of (M2), $\|F\|_{\mathrm{ch},\ell'}^{(\ell'')} \leq Q'' \|F\|_{\mathrm{ch},\ell''}$ as $p_{\ell'} \geq p_\infty$, gives $\lambda_0^{-\mathsf{w}} \|\mathfrak{Y}[\Phi_F]\| \leq (1+\mathsf{r}_{N'})^{1/\mathsf{n}'} Q'' \|F\|_{\mathrm{ch},\ell''}$, $\mathsf{n}' = N'/\mathsf{w}$, the same for G; as $\ell' \to \infty$ the first factor tends to 1, and the formula passes to ν (Prop. 17.38(c), (f)). *The torus $\ell \geq L\ell''$.* The cube $N = \mathsf{nw}$ has $\mathsf{n} = 2\ell/\ell'' \geq 2L \geq 6$ cells along the time, an even number. The two cells, $j_- \geq 2$ apart the shorter way, leave $n = (j_- - 1)\mathsf{w}$ layers between them on one side and $E = (\mathsf{n} - j_- - 1)\mathsf{w} \geq n$ on the other, and $n, E \geq \mathsf{w} \geq l$, as $\ell'' \geq 2la_K$.

Write, as in the proof of Lem. 17.40, $\mathsf{T}'^m = \lambda_0^m(|e_0\rangle\langle e_0| + \mathsf{R}_{(m)})$, e_0 the top eigenvector, so that $\|\mathsf{R}_{(m)}\| = \varrho^m$, $\varrho = \lambda_1/\lambda_0$, and $\mathrm{Tr}\,|\mathsf{R}_{(m)}| = \mathsf{r}_m$, and put $y_C = \lambda_0^{-\mathsf{w}} \mathfrak{Y}[\Phi_C]$. The trace formula (M1) with the four slabs F, 1_n, G, 1_E gives $\mu_{K,\ell,\beta}(FG) = \mathrm{Tr}\big((|e_0\rangle\langle e_0| + \mathsf{R}_{(E)})\, y_G\, (|e_0\rangle\langle e_0| + \mathsf{R}_{(n)})\, y_F\big)/(1+\mathsf{r}_N)$, and the mean of one cell is $\mu_{K,\ell,\beta}(C) = [\langle e_0, y_C e_0\rangle + \mathrm{Tr}(\mathsf{R}_{(N-\mathsf{w})} y_C)]/(1+\mathsf{r}_N)$.

Expanding, the products $\langle e_0, y_F e_0\rangle\langle e_0, y_G e_0\rangle$ cancel up to the factors $(1+\mathsf{r}_N)^{-1}$ and $(1+\mathsf{r}_N)^{-2}$, and $|\mathrm{Tr}(XW)| \leq \|X\| \,\mathrm{Tr}\,|W|$ bounds the rest:

$$|\mu_{K,\ell,\beta}(FG) - \mu_{K,\ell,\beta}(F)\mu_{K,\ell,\beta}(G)| \leq \|y_F\|\,\|y_G\|\,[\mathsf{r}_N + \varrho^n + \varrho^E + \varrho^n \mathsf{r}_E + 2\mathsf{r}_{N-\mathsf{w}} + \mathsf{r}_{N-\mathsf{w}}^2],$$

the fourth term as the trace norm of $\mathsf{R}_{(E)}$ times the operator norm of $y_G \mathsf{R}_{(n)} y_F$. By (a) and the fine-to-coarse form, $\|y_C\| \leq (1+\mathsf{r}_N)^{1/\mathsf{n}} Q'' \|C\|_{\mathrm{ch},\ell''}$. Prop. 17.33 bounds $\varrho^n, \varrho^E \leq \theta^{n/l}$ by (a), and r_N, $\mathsf{r}_{N-\mathsf{w}}$, r_E by its thermal law (b) over the cross-section (N, N): in the zone $2t > N$ by $0.26261\,\theta^{t/l}$, which serves for $t = N$, $N - \mathsf{w}$ and for $t = E$ if $2E > N$, and in the zone $2t \leq N$ by $\mathsf{r}_t \leq e^{0.27263(N/2t)^2\theta^{t/l}} - 1$. Every term of the bracket, divided by $\theta^{n/l}$, and the factor $(1+\mathsf{r}_N)^{2/\mathsf{n}}$ increase with $u = \theta^{\mathsf{w}/l} \leq \theta \leq 0.8901$; at $u = 0.8901$ the product of the bracket over $\theta^{n/l}$ and $(1+\mathsf{r}_N)^{2/\mathsf{n}}$ is at most 3.33 for all even $\mathsf{n} \geq 6$ and $2 \leq j_- \leq \mathsf{n}/2$, the greatest value 3.3214 being taken at $\mathsf{n} = 6$, $j_- = 3$, where $n = E = 2\mathsf{w}$ and the bracket is at most $u^2[2 + 0.6258 + 0.26261(u^4 + 2u^3 + 0.26261\,u^8)]$. This is the torus clause, with $3.33 \leq 3.44$. □

Proposition 17.38 (One lattice under the inequality)**.** Let $K \in \mathbb{N}$, $\beta > 0$, and $\mathsf{e}(l) \leq x_0$ at β for one integer $l \geq 3$.

(a) The lattice $a_K\mathbb{Z}^3$ has exactly one periodic Gibbs state ν at β; it is ergodic under $a_K\mathbb{Z}^3$, invariant under all isometries of the lattice and reflection positive at every lattice mirror;

there is an open interval $U \ni \beta$ on which $\mathsf{e}(2l) \le 0.069$, P is continuously differentiable on U, and $P'(\beta') = -3\nu_{\beta'}(a_p)$.

(b) For every bounded real Borel F of the bonds of the cell $[-\frac{\ell'}{4}, \frac{\ell'}{4}]^3$, $\ell' \in \mathfrak{L}$, $n' = \ell'/a_K \ge 2l$, every $n = \ell/a_K$ with $\ell \ge \ell'$ in $\mathfrak{L}$, and the cube $Q_M = \{|x|_\infty \le Ma_K\}$, $M \ge n$, of $2M+1$ sites a side: $\|\nu(F \,|\, \text{bonds outside } Q_M) - \nu(F)\|_{L^2(\nu)} \le \operatorname{osc}(F)\, \varepsilon_1(n, n')$, $\varepsilon_1(n,n')^2 < 18\beta n'^3/n + 0.06868\, \theta^{n'/2l}$. So ν is trivial on the tail σ-field and an extreme point of the set of all Gibbs states at β, and for ν-almost every boundary datum the laws in growing cubes converge weakly to ν. The generator $\mathsf{H}_\nu \ge 0$ of the reversible lattice Langevin dynamics of ν, the operator of the closure of the form $\sum_b \nu(\nabla_b F \cdot \nabla_b F')$ on smooth local functions, has $\ker \mathsf{H}_\nu = \mathbb{C}1$, and $e^{-s\mathsf{H}_\nu} F \to \nu(F)$ in $L^2(\nu)$ for every F.

(b′) With a coordinate direction as the time, $\lambda = 2h+1 \ge \max\{3, l\}$, $t \ge \max\{2, l\}$ and $n = h+t$: for every bounded real Borel F of the bonds of $\{|x|_\infty \le ha_K\}$, $\|\nu(F \,|\, \text{bonds outside } \{|x_3| < na_K\}) - \nu(F)\|_{L^2(\nu)} \le \operatorname{osc}(F)\, \varepsilon_2$, $\varepsilon_2^2 = 0.27472\, (\lambda/t)^2 \theta^{t/l} + 0.06868\, \theta^{\lambda/l}$; with $h = \lfloor n/3 \rfloor$, for $n \ge \frac{1}{2}(3l+1)$, this is $\le 0.7057 \operatorname{osc}(F)\, \theta^{(2n-1)/6l}$.

(c) For every even $N \ge 2l$, every corner c, every bounded real Borel Ψ of the bonds of $\mathsf{C}_{N/2}(c)$ and every periodic box $\underline{n}$ with all sides $\ge N$: $|\langle\Psi\rangle_{\underline{n}} - \langle\Psi\rangle_{N^3}| \le 2.71\, \theta^{N/4l} \|\Psi\|_{\mathrm{ch};N}$ and $|\langle\Psi\rangle_{\underline{n}} - \nu(\Psi)| \le 5.42\, \theta^{N/4l} \|\Psi\|_{\mathrm{ch};N} \le 5.42\, \theta^{N/4l} \sup|\Psi|$; for events A of the cell, $|\mu_{\underline{n}}(A) - \nu(A)| \le 2.71\, \theta^{N/4l}$. As all sides tend to ∞ the measures of the periodic boxes converge weakly to ν, uniformly over all boxes with three sides $\ge N_0$.

(d) *Twisted boxes.* Let Γ_n be period lattices and T_n closed twist sets (Γ_n-periodic sets of plaquettes such that every elementary cube has an even number of faces in T_n; the sign of $\operatorname{tr} \partial U$ is reversed on them) that recede: the shortest period of Γ_n tends to ∞ and every finite set of plaquettes misses T_n at last. Then the laws $\mu^{\mathsf{T}_n}_{\Gamma_n,\beta}$, and all mixtures of a bounded number of such sequences with any weights (the sum over the eight sectors among them), converge weakly to ν; and if $\mathsf{T}'_n = \mathsf{T}_n \triangle d\mathsf{S}_n$ with any Γ_n-periodic set S_n of bonds, $d\mathsf{S}$ the plaquettes with an odd number of bonds in S, the joint cumulants of the twisted fields $\mathcal{O}_a^{\mathsf{T}'_n}(f) = a^{-1} \sum_p f(x(p)) a_p^{\mathsf{T}'_n}$, $a_p^{\mathsf{T}} = 1 + \frac{1}{2} \operatorname{tr} \partial U(p)$ on T and a_p elsewhere, under $\mu^{\mathsf{T}'_n}_{\Gamma_n,\beta}$ converge to those of the $\mathcal{O}_a(f)$ under ν. The word *recede* cannot be dropped: $P(\beta) > -3\beta$, so $\nu(\operatorname{tr} \partial U(p)) > 0$, and a column through a fixed plaquette p_0 gives in the limit the law of $-\operatorname{tr} \partial U(p_0)$ under ν, which differs from that of $\operatorname{tr} \partial U(p_0)$.

(e) Over every cross-section (A, B) with $A, B \ge 2l$ the top is simple, lies in the range of P_{00}, and $\lambda_1/\lambda_0 < \theta^{1/l}$ (Prop. 17.33(a)).

(f) Let Sl be a slab of $\vartheta \ge 2$ consecutive layers, Θ_n the lattice reflection such that exactly n layers lie between Sl and Θ_nSl, $A, B \in L^2(\nu)$ functions of the bonds of Sl, and $h_{AB}(n) = \nu(\overline{\Theta_n A}\, B)$. For all integers $n \ge n_0 \ge 0$,

$$|h_{AB}(n) - \overline{\nu(A)}\, \nu(B)| \le \theta^{(n-n_0)/l} \prod_{C=A,B} [h_{CC}(n_0) - |\nu(C)|^2]^{1/2},$$

and $n \mapsto h_{CC}(n) - |\nu(C)|^2$ is nonnegative and log-convex; at $n_0 = 0$, for bounded A, B: $|\operatorname{Cov}_\nu| \le \theta^{n/l} \sup|A| \sup|B|$.

■

Proof. (a) A periodic Gibbs state exists as a limit of tori (M3). If ρ and ν are two of them and A is a local event inside the central cell of side $\ell'/2$, Prop. 17.34(b) gives $|\rho(A) - \nu(A)| \le \sqrt{\varepsilon} + \varepsilon$, $\varepsilon = 22.3(e^{\delta'/7} - 1)$, and $\delta' \to 0$ as $\ell' \to \infty$ by Prop. 17.32(b); so $\rho = \nu$. The symmetries and reflection positivity come from (M3); almost every ergodic component of ν is a periodic Gibbs state, hence ν. By Prop. 17.32(a), $\mathsf{e}(2l) \le 12.9 \cdot 0.069^2 < 0.069$ at β, hence on an open interval U, the box functions being smooth in β; there the derivatives $-3\mu_{K,\ell_m,\beta'}(a_p)$ of $(\ell_m/a_K)^{-3} \log Z_{K,\ell_m}$, $\ell_m = 2L^m$, converge uniformly to $-3\nu_{\beta'}(a_p)$ by Prop. 17.34(b) and the bound of Prop. 17.32(b),

uniform on U. (b) Let D be the cube of n sites a side that is the union of the $8(n/n')^3$ cells $\square_{\mathbf{k}} = [-\frac{\ell'}{4}, \frac{\ell'}{4}]^3 + \frac{\ell'}{2}\mathbf{k}$, $0 \le \mathbf{k}_\mu < 2n/n'$, W the set of the positively oriented bonds with initial point in D, as in Lem. 17.36(c), and $F_{\mathbf{k}}$ the translate of F into $\square_{\mathbf{k}}$.

Lem. 17.36(c), integrated against ν, bounds the mean over $\mathbf{k}$ of $\|\nu(F_{\mathbf{k}}|\text{outside } W) - \mu_{K,\ell',\beta}(F)\|^2$ by $\operatorname{osc}(F)^2\varepsilon_1^2$, and by translation invariance the term of $\mathbf{k}$ is $\|\nu(F|\text{outside } W - \frac{\ell'}{2}\mathbf{k}) - \mu_{K,\ell',\beta}(F)\|^2$. Each translate $W - \frac{\ell'}{2}\mathbf{k}$ holds the cell and has its bonds in $[-\ell,\ell]^3$, so it lies in $Q_n \subset Q_M$; conditioning on the smaller field outside Q_M is a contraction in $L^2(\nu)$, so every term, and with them the mean, is at least $\|\nu(F|\text{outside } Q_M) - \mu_{K,\ell',\beta}(F)\|^2$; $\delta' < 0.13736\,\theta^{n'/2l}$; and the mean $\nu(F)$ is the best constant in $L^2(\nu)$.

Let $n \to \infty$, then $n' \to \infty$: tail triviality, which for a Gibbs state is extremality. A function in $\ker \mathsf{H}_\nu$ has $\nabla_b F = 0$ for every bond, so (the conditional law of one bond being equivalent to Haar measure) it is measurable outside every finite set of bonds, hence constant; the rest is the spectral theorem. (b′) Over the cross-section the top eigenvector e_0 is positive and continuous; in the cylinder the joint density of the two layers $V^{\pm n}$ against $\pi \otimes \pi$, $\pi = e_0^2 dV$, is $p_{2n} = \mathsf{D}^{2n}/\lambda_0^{2n} e_0 \otimes e_0$, and given them the slab of the cells has the density $\varrho = p_t(x,y)p_t(y',x')/p_{2n}(x,x')$ against its own law; the mean relative entropy is $2\iint p_t \log p_t - \iint p_{2n}\log p_{2n} \le 2\log \iint p_t^2 = 2\log(1+\mathsf{r}_{2t})$.

Lem. 17.36(a) for the n_2^2 cells of the slab (their sub-independence is Lem. 17.36(d) on the boxes $(\lambda\mathsf{n}_1, N', N')$, $N' = \lambda\mathsf{n}_2$, with even $\mathsf{n}_1, \mathsf{n}_2$, in the limit $\mathsf{n}_1 \to \infty$, the reference law being that of one cell of the cube $(2\lambda)^3$ and $\Delta = \delta((2\lambda)^3)/8)$, translation invariance of the cylinder along the cross-section, and $\log(1+\mathsf{r}_{2t}) \le \delta(2t, N', N') < 0.13736(N'/2t)^2\theta^{t/l}$ give the bound; then $N' \to \infty$ by (c) and density. (c) Lem. 17.35(c) with $\delta(N^3) < 0.13736\,\theta^{N/2l} \le \frac{1}{2}$, $7.31 \cdot 0.370622 \le 2.71$; a second box with all sides tending to ∞ gives ν; from continuous to Borel Ψ by approximation in L^8 of a measure that dominates both laws; for events take $\Psi = 1_A - \frac{1}{2}$.

The uniform convergence: limit points of box measures are periodic Gibbs states (M3), hence ν. (d) For a Γ-periodic set S of bonds, the flip $U_b \mapsto -U_b$, $b \in \mathsf{S}$, keeps the Haar measure and carries μ_Γ^{T} to $\mu_\Gamma^{\mathsf{T}\triangle d\mathsf{S}}$ (-1 is central). For a closed T and the bonds S whose plaquette swept in the direction μ lies in T, $\tau_{-ae_\mu}\mathsf{T} = \mathsf{T}\triangle d\mathsf{S}$, by counting the faces of the elementary cubes; so the translates of the twisted measure are flips of it, which a local function does not see once T_n has receded. Limit points satisfy the DLR equations away from the twist sets, hence are periodic Gibbs states, hence ν; both identities are linear in the law.

For $P(\beta) > -3\beta$: on the $\prod\lfloor n_i/3\rfloor \ge |\underline{n}|/125$ plaquettes $p_{12}(x)$, $x_i \in 3\mathbb{Z}$, which share no site, Jensen's inequality gives $F/|\underline{n}| \ge -3\beta + \frac{1}{125}\log\int e^{\frac{\beta}{2}\operatorname{tr} u}\,\mathrm{d}u > -3\beta$; P is convex, $P(0) = 0$, so $P'(\beta) > -3$, and $P' = -3\nu(a_p)$ by (a). (e) is Prop. 17.33(a). (f) In the box with $N = 2\vartheta + n + E'$ layers over (N', N'), (M1) gives $\mu(\overline{\Theta_n A}\,B) = \operatorname{Tr}(\mathsf{T}'^{E'}Y_A^*\mathsf{T}'^m Y_B)/\operatorname{Tr}\mathsf{T}'^N$, $Y_C = \mathfrak{Y}[\Phi_C]$ the slab operator of the function C. As $E' \to \infty$ the gap projects onto the top eigenvector e_0:

$$\mu(\overline{\Theta_n A}\,B) \longrightarrow \lambda_0^{-2\vartheta}\Big[\sum_{j\ge 0}(\lambda_j/\lambda_0)^n\,\overline{\mathsf{a}_j}\,\mathsf{b}_j + 1_{n=0}\,\langle \mathsf{P}_{\ker}Y_A e_0, \mathsf{P}_{\ker}Y_B e_0\rangle\Big], \qquad \mathsf{a}_j = \langle e_j, Y_A e_0\rangle,\ \mathsf{b}_j = \langle e_j, Y_B e_0\rangle,$$

e_j the eigenvectors of the nonzero eigenvalues and $\mathsf{P}_{\ker}$ the projection on $\ker\mathsf{T}'$; the term $j = 0$ is the product of the means, which converge in the same way. Schwarz's inequality and $\lambda_j/\lambda_0 < \theta^{1/l}$ for $j \ge 1$ give the bound (for $n > n_0$ the kernel term is absent on the left); $N' \to \infty$ by (c), and $L^2(\nu)$ by density. The same formula exhibits $h_{CC}(n) - |\nu(C)|^2$ as a limit of $\int x^n \varrho(\mathrm{d}x)$, $0^0 = 1$, with $\varrho = \lambda_0^{-2\vartheta}[\sum_{j\ge1}|\mathsf{c}_j|^2\delta_{\lambda_j/\lambda_0} + \|\mathsf{P}_{\ker}Y_C e_0\|^2\delta_0] \ge 0$ on $[0,1)$; such functions are ≥ 0 and log-convex. □

Proposition 17.39 (Flux and loops on one lattice)**.** Let $\beta > 0$, $l \ge 3$, $\mathsf{e}(l) \le x_0$, $\Lambda = \log(1/\theta)$, $\sigma^+ = (2\Lambda + 1.67)/4l^2$, so that $\sigma^+ l^2 = \frac{\Lambda}{2} + 0.4175 \ge 0.4757$, $\mathsf{q} = 1 + 0.835/\Lambda$, and ν as in Prop. 17.38; lengths in lattice units.

(a) $0 \le 1 - r_1(N) \le 2\exp[-2.2 \cdot 10^{-4}(N/l)^2]$ for every integer $N \ge 3$; $\frac{1}{2}(1 - r_1(N)) \le \exp[-1.4268 \cdot 10^{-3}(N/l)^2]$ for $N \ge 256\, l$; and for every $N \ge 2\mathsf{q}l$,

$$\tfrac{1}{2}(1 - r_1(N)) \le \exp\Big[-\sigma^+ N^2 + \frac{2\mathsf{q}N}{l}\Big(\frac{1}{2}\log\frac{2\mathsf{q}N}{l} + 0.86\Big)\Big];$$

and $1 - r^z \le 6\exp[\cdots]$ for all seven classes $z \ne 0$, with each of the three exponents.

(b) $0 \le \nu(W_C) \le e^{-\sigma^+ RT}$ for every rectangle C with $R \times T$ bonds in a coordinate plane; in the finite cube, for $n \ge 2\mathsf{q}l$, $1 \le R \le n/2$, $1 \le T \le n - 1$: $0 \le \langle W_C\rangle_{(n,n,n)} \le 8^{T/n}\exp[-\sigma^+ RT + \frac{2\mathsf{q}RT}{ln}(\frac{1}{2}\log\frac{2\mathsf{q}n}{l} + 0.86)]$; and on every box, with no hypothesis on e, for $1 \le R \le n_1/2$, $1 \le T \le n_3 - 1$ and $\zeta = \frac{1}{2}(1 - r)$ of one twisted column of the plane (13): $0 \le \langle W_{R\times T}\rangle_{\underline{n}} \le (8\,\zeta^{R/n_1})^{T/n_3}$.

(c) $|\nu(W_C)| \le e^{-\sigma^+|A(C)|}$ for every staircase loop of a coordinate plane, and $|\nu(W_C)| \le 2^{c_3(C)-1}e^{-\sigma^+ A_{13}(C)}$ for every closed lattice path C with a bond of the direction 3, with A_{13}, c_3 as in Thm. AZ(4) at unit spacing; the same for every ordered pair of directions. Here a *staircase loop* $C = C(\alpha, R)$ of the plane (13) is the staircase loop of the setting (Twists and loops), read in lattice units: it is given by a site o, an integer $T \ge 1$ and integers α_j and $R_j \ge 1$, $0 \le j < T$; with $o_j = o + \alpha_j e_1$ and $r_j = o + (\alpha_j + R_j)e_1$ it runs at the height 0 (in the direction 3, counted from o) straight from o_0 to r_0; then, for $j = 0, \dots, T - 1$ in turn, one step up above r_j from the height j to the height $j + 1$ and, if $j < T - 1$, straight at that height to above r_{j+1}; at the height T straight back from above r_{T-1} to above o_{T-1}; then, for $j = T - 1, \dots, 0$ in turn, one step down above o_j from the height $j + 1$ to the height j and, if $j > 0$, straight at that height to above o_{j-1}.

Its area is $|A(C)| = \sum_j R_j$; the staircase loops of the other coordinate planes are the images of these under the symmetries of the lattice. A staircase loop winds once about each unit square of the rows $[\alpha_j, \alpha_j + R_j] \times [j, j + 1]$ and about no other, and its steps in the direction 3 are T upward ones followed by T downward ones; so $A_{13}(C) = |A(C)|$, $c_3(C) = 1$, and the first clause is a case of the second.

(d) For every weak limit point of the measures of periodic boxes all of whose sides tend to infinity, the limits of the tori among them, $w(R, T) = \langle W_{R\times T}\rangle$ satisfies $0 \le w \le 1$, $w(R, T)^2 \le w(R, T - 1)w(R, T + 1)$ and $w(R, T)^2 \le w(R - 1, T)w(R + 1, T)$, with $w(R, 0) = w(0, T) = 1$; so $V(R) = \lim_T -T^{-1}\log w(R, T) = \inf_T(-T^{-1}\log w(R, T))$ exists in $[0, \infty]$, $V(0) = 0$, V is either finite everywhere or infinite at every $R \ge 1$, V is concave and non-decreasing, and, in the finite case, $V(R) \ge V(R') + \sigma_\infty(R - R')$ for $R \ge R' \ge 0$, with $\sigma_\infty = \lim_R V(R)/R \in [0, \infty)$. Under the hypothesis, in ν, which is the limit of the tori: $V(R) \ge V(R') + \sigma^+(R - R')$ for $R \ge R' \ge 0$.

(e) With $\varepsilon_{\mathrm{v}}(l') = \varepsilon_{\mathrm{v}}(l', l')$ the vortex free energy of Prop. 17.33(d) and $l_j = 2^{j+1}l$: $l_j\varepsilon_{\mathrm{v}}(l_j) \le e^{-(2\Lambda+1.67)4^j} = e^{-\sigma^+ l_j^2}$ for all $j \ge 0$.

■

Proof. For a box $(t, u; h)$, t, u the sides of a plane with one twisted column of length h, let $\zeta(t, u; h) = \frac{1}{2}(1 - r)$ for that twist, and let $\varepsilon_{\mathrm{v}}(t, u) = \log(\|\mathsf{T}^{(0)}\|/\|\mathsf{T}^{(1)}\|)$ over the cross-section (t, u), the time along h. (i) By Prop. 17.31(d), in each of the two sides t, u of the twisted plane ζZ and $(1 - \zeta)Z$ are sums of powers of numbers ≥ 0; Hölder's inequality for such sums and the excess give

$$\zeta(t', u'; h) \le [\zeta(t, u; h)\, e^{\delta(t,u,h)}]^{t'u'/tu} e^{-\delta(t',u',h)} \qquad (t' \ge t,\ u' \ge u),$$

and $\zeta(t, u; h) \le 1 - e^{-\mathsf{G}(t;u,h)} \le \delta(t, u, h)$. (ii) In the third side $Z = \mathrm{Tr}(\mathsf{T}^{(0)})^h = \lambda_0^h(1 + \mathsf{r}_h(t, u))$ and $Z^z = \mathrm{Tr}(\mathsf{T}^{(1)})^h$, with $\mathsf{T}^{(1)} \ge 0$ of norm $\lambda_0 e^{-\varepsilon_{\mathrm{v}}(t,u)}$. So $1 - 2\zeta(t, u; h) = Z^z/Z \ge e^{-h\varepsilon_{\mathrm{v}}}/(1 + \mathsf{r}_h) \ge 1 - h\varepsilon_{\mathrm{v}} - \mathsf{r}_h$ if $h\varepsilon_{\mathrm{v}} \le 1$, and $2\zeta < 1$ always: the first inequality below. Further $\mathrm{Tr}(\mathsf{T}^{(1)})^{2h} \le \|\mathsf{T}^{(1)}\|^h \mathrm{Tr}(\mathsf{T}^{(1)})^h$, $Z^z \le Z$ at the length h (Prop. 17.31(d), with the time in the twisted plane) and

$Z \ge \lambda_0^{2h}$ at the length $2h$ give $e^{-h\varepsilon_{\rm v}} \ge (1-2\zeta(t,u;2h))/(1+\mathsf{r}_h)$, the second:

$$2\zeta(t,u;h) \le h\,\varepsilon_{\rm v}(t,u) + \mathsf{r}_h(t,u), \qquad h\,\varepsilon_{\rm v}(t,u) \le \mathsf{G}(h;t,u) - \log(1-2\zeta(t,u;2h)) \le \mathsf{d}(h;t,u) - \log(1-2\zeta(t,u;2h)),$$

where $\mathsf{d}(h;t,u) = 2F(t,u,h) - F(t,u,2h) = 2\mathsf{G}(h;t,u) - \mathsf{G}(2h;t,u) \ge \mathsf{G}(h;t,u)$ is taken for the box (t,u,h) with the side h doubled; also $\mathsf{r}_h(t,u) \ge \mathsf{G}(h;t,u)$ may stand for $\mathsf{G}(h;t,u)$. (iii) By (i) and (ii), doubling the cross-section of a long tube, on which the thermal sums lie below the fourth power, replaces $l'\varepsilon_{\rm v}(l')$ by a bounded multiple of its fourth power. Let $\mathsf{t} = \theta^{l'/l}$ at the dyadic sides $l' = l_j = 2^{j+1}l$, and let $\mathsf{k}_1 = 0.01655$ and $\mathsf{k}_2 = 0.001615$ be the constants of the bounds $\delta((2^jl)^3) \le \mathsf{k}_1\theta^{2^j}$, $j \ge 1$, of Prop. 17.32(b) and $\mathsf{r}_N \le \mathsf{k}_2\theta^{N/l}$ at $N = 2^{k+1}l$ of Prop. 17.32(c); so $\delta(l',l',h) \le (h/l')\,\mathsf{k}_1\mathsf{t}$ by the monotone density, $\mathsf{r}_{l'}(l',l') \le \mathsf{k}_2\mathsf{t}$ and $\mathsf{r}_{2l'}(2l',2l') \le \mathsf{k}_2\mathsf{t}^2$; and $\mathsf{r}_{Ms} \le \mathsf{r}_s^M$ for real $M \ge 1$ with Ms an integer, as in Prop. 17.31(b).

The start. The second inequality of (ii) at $t = u = h = 2l$, with $\mathsf{G} \le \mathsf{r}$ and $\zeta(2l,2l;4l) \le \mathsf{R}_{2l}(2l,4l) = \mathsf{r}/(1+\mathsf{r})$, $\mathsf{r} = \mathsf{r}_{2l}(2l,4l)$, by (i), gives $l_0\varepsilon_{\rm v}(l_0) \le \mathsf{r}_{2l}(2l,2l) + \log\frac{1+\mathsf{r}}{1-\mathsf{r}}$. By Prop. 17.31(b), $\mathsf{r}_{2l}(2l,2l) \le \mathsf{r}_l(2l,2l)^2 \le \varphi(e^{x_0}-1)^2$, and $\mathsf{r} \le \mathsf{r}_l(2l,4l)^2 \le \varphi(e^{y_1}-1)^2$ with $y_1 = 2F(l,2l,4l) - F(2l,2l,4l) \le 2x_0 + \psi(x_0)$, as in the proof of Prop. 17.32. Both bounds are power series in x_0 with coefficients ≥ 0 beginning with multiples of x_0^2, and so is $\log\frac{1+\mathsf{r}}{1-\mathsf{r}}$ in r; the sum divided by $\theta^2 = (12.9\,x_0)^2$ is therefore greatest at $x_0 = 0.069$, where it is at most 0.016154: $l_0\varepsilon_{\rm v}(l_0) \le 0.016154\,\theta^2$.

One doubling. Let $\hat N \ge 2$ be an integer. The first inequality of (ii) in the tube $(l',l';2\hat N l')$, with $\mathsf{r}_{2\hat N l'}(l',l') \le (\mathsf{k}_2\mathsf{t})^{2\hat N}$, gives $\zeta(l',l';2\hat N l') \le \bar z_1 = \hat N l'\varepsilon_{\rm v}(l') + \frac12(\mathsf{k}_2\mathsf{t})^{2\hat N}$; (i) with $t'u'/tu = 4$ and $\delta(l',l',2\hat N l') \le 2\hat N\mathsf{k}_1\mathsf{t}$ gives $\zeta(2l',2l';2\hat N l') \le \bar z_2 = \bar z_1^4 e^{8\hat N\mathsf{k}_1\mathsf{t}}$; and the second inequality of (ii) in the tube $(2l',2l';\hat N l')$, with $\mathsf{G} \le \mathsf{r}$, $\mathsf{r}_{\hat N l'}(2l',2l') \le \mathsf{r}_{2l'}(2l',2l')^{\hat N/2} \le (\mathsf{k}_2\mathsf{t}^2)^{\hat N/2}$ and $-\log(1-x) \le x/(1-x)$, gives, if $\bar z_2 < \frac12$,

$$2l'\varepsilon_{\rm v}(2l') \le \mathsf{U} := \frac{2}{\hat N}\Big\{(\mathsf{k}_2\mathsf{t}^2)^{\hat N/2} + \frac{2\bar z_2}{1-2\bar z_2}\Big\}.$$

The iteration. Take $\hat N_j = 4\cdot 3^j$ at $l' = l_j$, and let $\Lambda_0 = \log(1/0.8901) \approx 0.116421$. As $\hat N_j \ge 4\cdot 2^j$ and $2^{j+1}\hat N_j \ge 4^j$, every term of U at $\theta \le 0.8901$ is at most the term at $\theta = 0.8901$ times $e^{-4^{j+1}(2\Lambda-2\Lambda_0)}$, if the bounds on $l_j\varepsilon_{\rm v}(l_j)$ carry the factor $e^{-4^j(2\Lambda-2\Lambda_0)}$; so it is enough to follow numbers E_j with $l_j\varepsilon_{\rm v}(l_j) \le e^{-E_j-4^j(2\Lambda-2\Lambda_0)}$ at $\theta = 0.8901$, $\mathsf{t}_j = 0.8901^{2^{j+1}}$. The start gives such an $E_0 \ge \log(1/0.016154) + 2\Lambda_0 \ge 4.3414$; as U increases with $l'\varepsilon_{\rm v}(l')$, it is enough to take $E_0 = 4.3414$ and $E_{j+1} = -\log\mathsf{U}$ at E_j.

With $y_j = \hat N_j e^{-E_j}$ this reads $E_{j+1} = 4E_j - 3\log\hat N_j - 8\hat N_j\mathsf{k}_1\mathsf{t}_j - \log(2B_j)$, where $B_j = (\mathsf{k}_2\mathsf{t}_j^2)^{\hat N_j/2}y_j^{-4}e^{-8\hat N_j\mathsf{k}_1\mathsf{t}_j} + 2(\bar z_1/y_j)^4/(1-2\bar z_2)$; along this sequence B_j is at most 2.0920 at $j=0$, 2.0001 at $j=1$ and 2 to ten digits from $j=2$ on, $\bar z_2 \le 1.2\cdot 10^{-5}$, and the numbers $4^{-j}E_j - 2\Lambda_0$ are at least 4.1085, 2.6061, 1.9912, 1.7722, 1.7032, 1.6839, 1.6785 at $j = 0,\dots,6$. For $j \ge 6$, $8\hat N_j\mathsf{k}_1\mathsf{t}_j \le 0.000131$ and $B_j \le 2.0023$, so $E_{j+1} \ge 4E_j - 3\log\hat N_j - \log 4.01$, and summing the losses, $4^{-j}E_j \ge 4^{-6}E_6 - \sum_{i\ge6} 4^{-i-1}(3\log 4 + 3i\log 3 + \log 4.01) \ge 1.909266$; so $4^{-j}E_j - 2\Lambda_0 \ge 1.6764 \ge 1.67$ for every $j \ge 0$, and $l_j\varepsilon_{\rm v}(l_j) \le e^{-(2\Lambda_0+1.67)4^j - (2\Lambda-2\Lambda_0)4^j} = e^{-(2\Lambda+1.67)4^j}$: this is (e).

From the tubes to the cubes. For an integer $N \ge 2\mathsf{q}l$ let $j \ge 0$ be the largest integer with $4^j \le N/2\mathsf{q}l$, $w = 2^j$, $l' = l_j = 2wl$ and $M = N/l'$, a real number; then $w\mathsf{q} \le M < 4w\mathsf{q}$ and $M^2 < 2\mathsf{q}N/l$. The first inequality of (ii) in the tube $(l',l';N)$, with $N\varepsilon_{\rm v}(l') = M\,l'\varepsilon_{\rm v}(l') \le Me^{-(2\Lambda+1.67)w^2}$ by (e) and $\mathsf{r}_N(l',l') \le (\mathsf{k}_2\mathsf{t})^M \le e^{-2\Lambda wM} \le e^{-(2\Lambda+1.67)w^2}$, as $M \ge w\mathsf{q}$ and $2\Lambda\mathsf{q} = 2\Lambda + 1.67$, gives $\zeta(l',l';N) \le \frac{M+1}{2}e^{-(2\Lambda+1.67)w^2} \le Me^{-(2\Lambda+1.67)w^2}$; and (i) with $t'u'/tu = M^2$ and $\delta(l',l',N) \le M\mathsf{k}_1\mathsf{t}$ gives $\frac12(1-r_1(N)) = \zeta(N,N;N) \le [Me^{-(2\Lambda+1.67)w^2}e^{M\mathsf{k}_1\mathsf{t}}]^{M^2}$.

Here $M^2(2\Lambda+1.67)w^2 = \sigma^+N^2$; $M\mathsf{k}_1\mathsf{t} < 4\mathsf{q}\mathsf{k}_1we^{-2\Lambda w} \le \frac{4\mathsf{q}\mathsf{k}_1}{2e\Lambda} = \frac{4\mathsf{k}_1}{e}\big(\frac{1}{2\Lambda} + \frac{1.67}{4\Lambda^2}\big) \le 0.85478$, the last member decreasing in $\Lambda \ge \Lambda_0$; and $0 \le \log M < \frac12\log\frac{2\mathsf{q}N}{l}$. So the exponent is at most

$-\sigma^+N^2 + M^2(\log M + 0.855) \le -\sigma^+N^2 + \frac{2\mathsf{q}N}{l}(\frac12 \log\frac{2\mathsf{q}N}{l} + 0.86)$: (a), the last display; the other two bounds of (a) are the same argument with the start at $64\,l$, where $D_2(64l) \le 0.12019\,\theta^{64}$, and Prop. 17.31(d) gives the seven classes. (iv) Two static charges at the ends o, r of the side of length R evolve by an operator $\hat{\mathsf{T}} = \mathsf{m}^{1/2}\hat{\mathsf{K}}\mathsf{m}^{1/2}$ on functions with values in the 2×2 matrices, $(\hat{\mathsf{K}}\Psi)(V) = \iint e^{-\beta A_\times(V,S,V')} S_o \Psi(V') S_r^{-1}\,\mathrm{d}S\,\mathrm{d}V'$, and

$$2Z[W_C] = \mathrm{Tr}\big((\mathsf{T}^{(0)})^{n_3-T}\Phi_\gamma^*\hat{\mathsf{T}}^T\Phi_\gamma\big) \ge 0, \qquad \mathrm{Tr}\,\hat{\mathsf{T}}^{n_3} = 4Z[\mathsf{PP}'],$$

$\Phi_\gamma\psi = \psi\,V(\gamma)$, P, P' the half-traces of the two straight closed lines through o and r; the positivity of $\hat{\mathsf{T}}$ is proved as that of K, with the crossing variables acting by a unitary representation. Hölder's inequality for the two spectral families gives $0 \le \langle W_C\rangle \le (4\langle \mathsf{PP}'\rangle)^{T/n_3}$, and (i) in the direction of R gives $\langle \mathsf{PP}'\rangle \le (1-\zeta)^{1-\varrho}\zeta^\varrho + \zeta^{1-\varrho}(1-\zeta)^\varrho \le 2\zeta^\varrho$, $\varrho = R/n_1 \le \frac12$: the bound on every box. With (a) on the cube n and $n\to\infty$ (Prop. 17.38(c)) the factor in front tends to 1: (b). (c) is the same argument with one charge for each passage of C through a layer: several static charges evolve by a positive operator on functions with values in $(\mathbb{C}^2)^{\otimes\mathcal{V}}$, and the projection of the path to the plane (13) is counted modulo 2 layer by layer; a passage from a downward to an upward bond costs a factor 2. (d) On every periodic box, for $T \le n_3 - 2$ and $R \le n_1 - 2$, the positivity of the operators of (iv) gives the log-convexity in T, and the reflection positivity across a plane between two charges gives it in R; these are inequalities between finitely many means of continuous local functions, and they pass to every weak limit of box measures whose sides tend to infinity.

If $w(R,T_0) = 0$ for one $T_0 \ge 1$, the log-convexity gives $w(R,T) = 0$ for all $T \ge 1$, and $V(R) = \infty$; else $T \mapsto w(R,T)^{1/T}$ does not decrease, and V is the infimum. The concavity holds in $[0,\infty]$, so V is infinite at every $R \ge 1$ as soon as it is infinite at one; with $V(R)/R \to \sigma_\infty$ it gives the slopes. Under the hypothesis $w(R,T) \le e^{-\sigma^+RT}$, so $V(R) \ge \sigma^+R$ for all R, and a concave function with $V(R) \ge \sigma^+R$ has every slope $\ge \sigma^+$. □

Lemma 17.40 (One step on a periodic box)**.** Let $\beta \ge 0$, Σ a cross-section, integers $\vartheta \ge 2$, $d \ge 3$, $N = 2d\vartheta$, $n = (d-1)\vartheta$, $\tau_s = \tau_0 + s\vartheta$; let Φ be a bounded complex Borel function on $\mathcal{Y}_\vartheta$, $\Phi^s = \Phi$ for odd s and $\Phi^s = \Phi^\Theta$ for even s, μ_N the measure of the box (N,Σ), $\varrho = \lambda_1/\lambda_0$, and

$$\mathsf{p} = \mu_N\Big(\prod_{s=1}^{2d}(\Phi^s)_{\tau_{s-1}}\Big), \qquad \mathsf{y} = [(1+\mathsf{r}_N)\,\mathsf{p}]^{1/2d}.$$

Then $\mathsf{p} \ge 0$, $\lambda_0^{-\vartheta}\|\mathfrak{Y}[\Phi]\| \le \mathsf{y}$, and

$$0 \le \mu_N(\Phi_{\tau_0}(\Phi^\Theta)_{\tau_d}) \le \big[(1+\mathsf{r}_N)\,|\mu_N(\Phi_{\tau_0})| + \mathsf{r}_{N-\vartheta}\,\mathsf{y}\big]^2 + (2+\mathsf{r}_n)\,\varrho^n\,\mathsf{y}^2.$$

■

Proof. By (M1), $Z(N,\Sigma)\mathsf{p} = \mathrm{Tr}(Y^*Y)^d = \|Y\|_{2d}^{2d} \ge \|Y\|^{2d}$, $Y = \mathfrak{Y}[\Phi]$, and $Z(N,\Sigma) = \lambda_0^N(1+\mathsf{r}_N)$: the bound on $\|Y\|$. The mean of the two cells d slabs apart is $\mathrm{Tr}(\mathsf{T}'^nY^*\mathsf{T}'^nY)/Z$; write $\mathsf{T}'^n = \lambda_0^n(|e_0\rangle\langle e_0| + \mathsf{R}_{(n)})$ with $\|\mathsf{R}_{(n)}\| = \varrho^n$ and $\mathrm{Tr}\,|\mathsf{R}_{(n)}| = \mathsf{r}_n$, and $\lambda_0^{-\vartheta}\langle e_0, Ye_0\rangle = (1+\mathsf{r}_N)\mu_N(\Phi_{\tau_0}) - \lambda_0^{-\vartheta}\,\mathrm{Tr}(\mathsf{R}_{(N-\vartheta)}Y)$ from the mean of one cell; expanding, the term $|\langle e_0, Ye_0\rangle|^2$ gives the square, and the others are bounded by ϱ^n and r_n times $\|Y\|^2$. □

Lemma 17.41 (Contraction of the seminorm)**.** Let $L' \ge 13$ be an odd integer, $k \in \mathbb{N}$, $\beta > 0$, on the lattice $L'^{-k}\mathbb{Z}^3$ with the sides $2L'^{\mathbb{N}}$. Let $\ell_f, \ell_c \in 2L'^{\mathbb{N}}$ with $d = \ell_c/\ell_f \ge L'$, $\mathsf{h} = \ell_f L'^k/2$ the number of layers of a fine cell, and let $\mathsf{e}(l) \le x_0$ at β with $24l \le \mathsf{h}$. Then for every real G of the bonds of the cell $[-\ell_f/4, \ell_f/4]^3$,

$$\big\|G - \mu_{k,\ell_c,\beta}(G)\big\|_{\mathrm{ch},\ell_c} \le 1.343\,\theta^{(d-1)\mathsf{h}/8l}\,\big\|G - \mu_{k,\ell_f,\beta}(G)\big\|_{\mathrm{ch},\ell_f},$$

where on the left G is regarded as a function of the cell $[-\ell_c/4, \ell_c/4]^3$, which holds the cell $[-\ell_f/4, \ell_f/4]^3$. The constant 1.343 depends on none of G, k, β, d, L'. ■

Proof. Let $X = G - \mu_{k,\ell_c,\beta}(G)$, $B_1 = X$, $B_{2p} = B_p \cdot \Theta_i B_p$ with Θ_i the reflection in the coarse wall plane of the direction i, and $m_p = \mu_{k,\ell_c,\beta}(B_p)$; then $m_1 = 0$, and m_8 is the eighth power of the left member. In the direction i, B_p is a function of one slab of h layers, and $\Theta_i B_p$ lies $n = (d-1)\mathsf{h}$ layers further, on the cube of $N = 2d\mathsf{h}$ sites. Lem. 17.40 with Y the slab operator of B_p, the gap of Prop. 17.33(a), and $\lambda_0^{-\mathsf{h}}\|Y\| \le \mathsf{c}\,u^p$, $\mathsf{c} = (1+\mathsf{r}_N)^{1/2d}$, $u = \|X\|_{\mathrm{ch},\ell_c}^{(\ell_f)}$, the seminorm of X on the torus ℓ_c for the fine board, of side $\ell_f/2$ (the array form of this board, applied to the pile of $2d$ copies of B_p, which are $2dp$ copies of X in cells of the fine board, with the factor 1 in the other cells, bounds the p of Lem. 17.40 by u^{2dp}), give

$$0 \le m_{2p} \le \left[(1+\mathsf{r}_N)\, m_p + \mathsf{r}_{N-\mathsf{h}}\, \mathsf{c}\, u^p\right]^2 + (2+\mathsf{r}_n)\, \theta^{n/l}\, \mathsf{c}^2 u^{2p}.$$

With the bounds of Prop. 17.32 on the r, three steps give $m_8 \le 3.68\, u^8 \theta^{n/l}$. To bound u, put $G_0 = G - \mu_{k,\ell_f,\beta}(G)$ and $Q_f = e^{\delta((2\mathsf{h})^3)/8}$, $2\mathsf{h} = \ell_f L'^k$ being the number of sites of a side of the torus ℓ_f. The fine-to-coarse form gives $u \le Q_f \|X\|_{\mathrm{ch},\ell_f}$; as $X = G_0 - \mu_{k,\ell_c,\beta}(G_0)$ and $\|1\|_{\mathrm{ch},\ell_f} = 1$, $\|X\|_{\mathrm{ch},\ell_f} \le \|G_0\|_{\mathrm{ch},\ell_f} + |\mu_{k,\ell_c,\beta}(G_0)|$; and Prop. 17.34(c) at $\ell' = \ell'' = \ell_f$, with $\mathfrak{s} = \mu_{k,\ell_c,\beta}$ and $\mu_{k,\ell_f,\beta}(G_0) = 0$, gives $|\mu_{k,\ell_c,\beta}(G_0)| \le 4.84\,[Q_f(Q_f-1)]^{1/2}\|G_0\|_{\mathrm{ch},\ell_f}$. By Prop. 17.33(c) at $N = 2\mathsf{h} \ge 48l$, $\delta((2\mathsf{h})^3) \le 0.5892\,\theta^{48} \le 0.0022046$, so $Q_f \le 1.000276$ and $u \le Q_f(1 + 4.84\,[Q_f(Q_f-1)]^{1/2})\|G_0\|_{\mathrm{ch},\ell_f} \le 1.0807\,\|G_0\|_{\mathrm{ch},\ell_f}$. As m_8 is the eighth power of the left member and $n = (d-1)\mathsf{h}$, the left member is at most $3.68^{1/8} \cdot 1.0807\,\theta^{(d-1)\mathsf{h}/8l}\|G_0\|_{\mathrm{ch},\ell_f} \le 1.272\,\theta^{(d-1)\mathsf{h}/8l}\|G_0\|_{\mathrm{ch},\ell_f}$, and $1.272 \le 1.343$. □

Lemma 17.42 (A second blocking factor; dense labels)**.** (a) For every integer $L \ge 2$ there are an odd prime $L' \ge 13$ with $L' > L$ and an admissible choice of the constants with the blocking factor L'; for such L', $\alpha = \log L / \log L' \in (0,1)$ is irrational. (b) Let $\mathsf{b} > 0$, $k(K) = \lfloor K\alpha \rfloor$ and $\mathsf{c}_K = \mathsf{b}\, L'^{K\alpha - k(K)} \in [\mathsf{b}, L'\mathsf{b})$. Then $L^K \mathsf{b} = L'^{k(K)} \mathsf{c}_K$; k does not decrease, $k(K+1) - k(K) \in \{0,1\}$ and $k(K) \to \infty$, so every integer $k > k(K_1)$ is $k(K)$ for some $K > K_1$; and $\{\mathsf{c}_K : K \ge K_1\}$ is dense in $[\mathsf{b}, L'\mathsf{b}]$ for every K_1. ■

Proof. (a) is (M6) with the infinitude of primes; $L^q = L'^p$ is impossible for a prime $L' \nmid L$. (b) is arithmetic; the density is that of $\{K\alpha\}$ modulo 1 for irrational α. □

17.2.5. *Statements uniform in the cutoff.*

Proposition 17.43 (Products of action densities on one torus)**.** Let $\ell'' \in \mathfrak{L}$, $J' = [\mathsf{b}_-, \mathsf{b}_+] \subset (0,\infty)$ and $\mathsf{d} > 0$. For $k \ge 2$ let $\mathsf{B}_k(\ell'', J', \mathsf{d})$ be the bound of (M4)(i) on the k-th cumulants on the torus ℓ'' at the labels of J', for supports at pairwise sup distances $\ge \mathsf{d}$ and unit norms, and $\mathsf{M}_k = \sum_\pi \prod_{B\in\pi} \mathsf{B}_{|B|}$ over the partitions of $\{1,\dots,k\}$ into blocks of at least two members. Let $K \in \mathbb{N}$, $\mathsf{b}' \in J'$, $\beta = L^K \mathsf{b}'$, □ a cell of a board of side $\ell''/2$ with any offset, $f_1, \dots, f_r$ real Lipschitz functions, none 0, with supports in □ at sup distance $\ge \mathsf{d}/2$ from its walls and pairwise $\ge \mathsf{d}$ apart, and $X_i = \mathcal{O}_K(f_i) - \mu_{K,\ell'',\beta}(\mathcal{O}_K(f_i))$. Then for $\emptyset \ne I \subset \{1,\dots,r\}$, $X_I = \prod_{i\in I} X_i$ is a real function of the bonds of □ and

$$\|X_I\|_{\mathrm{ch},\ell''} \le \mathsf{M}_{8|I|}^{1/8} \prod_{i\in I} \|f_i\|_\sharp.$$

■

Proof. The walls of the board lie between lattice sites. Thus a plaquette whose centre lies strictly inside □ has all its corners in the closed cell; the supports lie inside the cell, so X_I depends only on its bonds. By the array form of (M2), $\|X_I\|_{\mathrm{ch},\ell''}^8$ is the mean on the torus ℓ'' of the product of the eight mirror copies of X_I; the mirror copy of $\mathcal{O}_K(f)$ is $\mathcal{O}_K(f \circ \hat{\mathsf{r}})$ for the mirror map $\hat{\mathsf{r}}$, with the same mean. So it is a moment of $8|I|$ centred fields with pairwise disjoint supports on one torus, at distances $\ge \mathsf{d}$ inside one cell and across the walls, hence a sum over the partitions into blocks of at least two members of products of joint cumulants; (M4)(i) bounds each by $\mathsf{B}_{|B|}$ times the norms. □

Proposition 17.44 (The vacuum constants of two tori; the cube number)**.**

(a) Let $\mathsf{b} \geq \gamma^{-2}$, $\ell \in \mathfrak{L}$ with $LM\,R(\mathsf{b}) \leq \ell/2$, and $K \geq 10$ with $L^{\lceil K/1260\rceil}\mathsf{b} \geq \Theta_\star$, a number of the constants, so that the auxiliary sequence of renormalization steps is formed. At every level of the auxiliary sequence started from zero families with zero counterterms, the local numbers on the tori ℓ and $L\ell$ are equal on every region that lifts to both. Consequently

$$|L^3\mathfrak{K}_K(\ell,\mathsf{b}) - \mathfrak{K}_K(L\ell,\mathsf{b})| \leq C\,(L\ell)^3 \exp\bigl[-\kappa_1 \ell L^{\lceil K/1260\rceil}\bigr]$$

with numbers $C, \kappa_1 > 0$ of the constants.

(b) For every $\mathsf{b} > 0$, $\ell \in 2L^{\mathbb{Z}}$ and $K \geq K_\star(\mathsf{b},\ell)$: $|X_{K+1}(\mathsf{b},\ell) - X_K(\mathsf{b},\ell)| \leq L^3\mathfrak{o}_K(\ell/L) + \mathfrak{o}_K(\ell) + C\ell^3 e^{-\kappa_1 \ell L^{\lceil K/1260\rceil - 1}}$ after the dilation of (c), and $\sum_{k\geq K}|X_{k+1} - X_k| \leq \eta_K(\mathsf{b},\ell)$, with the η_K of Thm. BB(1).

(c) The dilation $(\mathsf{b},\ell,K) \mapsto (L^z\mathsf{b}, L^z\ell, K - z)$ names the same lattices at the same couplings, so $X_K(\mathsf{b},\ell) = X_{K-z}(L^z\mathsf{b}, L^z\ell)$, and it brings every label and side into the range of (a).

■

Proof. (a) The zero initial families and zero counterterms have a common infinite-lattice companion and satisfy the input size bound. The induction in Thm. YM3_I:Y, applied to the auxiliary sequence, therefore constructs the same family on each common lift. Its proof transports the entire local input through the chart at every step, including its domain. The floor $L^{\lceil K/1260\rceil}\mathsf{b} \geq \Theta_\star$ is the coupling floor needed for this auxiliary run. The Gaussian numbers also agree under these charts, by the local normalizer construction in equations YM3_I:(1399)–(1400).

To estimate the contact terms, we keep the stopping depth in their vacuum constants. Put $u = \lceil K/1260\rceil$, and mark the cutoffs $K^{\mathrm{A}} = K$ and $K^{\mathrm{B}} = K + 1$. The zero-source chain identity proved in Step 3(iv) of Prop. 13.7, or directly eq. 13.ii summed over its steps, gives

$$c_\lambda^\bullet(0) = E^\bullet_{(K^\bullet - u)}[T_\lambda], \qquad \mathfrak{K}_K(\lambda,\mathsf{b}) = c_\lambda^{\mathrm{B}}(0) - c_\lambda^{\mathrm{A}}(0).$$

Here $E^\bullet$ is built from the line $x_j^\bullet = L^{K^\bullet - j}\mathsf{b}$ on T_λ. These constants are real. The identity uses the actual chains; it does not require the error estimate comparing their masses. The line has zero increments and is admissible by the proof of Lem. YM3_I:118.1. The assumed room $LMR(\mathsf{b}) \leq \ell/2$ admits it on both tori. It also implies the side floor $\ell \geq C_L M$: the retained room condition [7, eq. 215] gives $C_L \leq 2LR(\gamma^{-2}) \leq 2LR(\mathsf{b})$.

Apply eq. 13.iii at each cutoff, with $n = K^\bullet - u$, to the sides ℓ and $L\ell$. Both lower summation indices are u. The triangle inequality gives

$$\left|\frac{\mathfrak{K}_K(\ell,\mathsf{b})}{\ell^3} - \frac{\mathfrak{K}_K(L\ell,\mathsf{b})}{(L\ell)^3}\right| \leq 4C_{\mathrm{tt}}E_0 \sum_{s\geq u} L^{3s} e^{-\kappa\ell L^s/(5M)} \leq 8C_{\mathrm{tt}}E_0 L^{3u} e^{-\kappa\ell L^u/(5M)}.$$

The last inequality is eq. 13.iv. Since $\kappa\ell/(5M) > 4$, the factor L^{3u} can be absorbed in half the exponent. For example, take

$$\kappa_1 = \frac{\kappa}{10M}, \qquad C = 8C_{\mathrm{tt}}E_0 \sup_{v\geq 1} v^3 e^{-2v} < \infty.$$

Multiplication by $(L\ell)^3$ proves (a).

(b) The zero-source read-out (M4)(ii) gives

$$|\log Z_{K+1,\ell} - \log Z_{K,\ell} - \mathfrak{K}_K(\ell,\mathsf{b})| \leq \mathfrak{o}_K(\ell,\mathsf{b}).$$

Apply this on the sides ℓ/L and ℓ, multiply the first identity by L^3, and subtract. The contact terms cancel up to the error in (a), giving the asserted bound for $X_{K+1} - X_K$. The two read-out errors have the summable rate in (M4)(ii). With $\varsigma = \sum_{j\geq 0}(1+j)^{\mathsf{p}_0}L^{-j/10}$, their tail is bounded by η_K once K is above the thresholds where (M4)(ii) and (a) apply and where the exponential term is at most $\mathsf{C}_{\mathrm{bf}}\ell^3 K^{\mathsf{p}_0}L^{-K/10}$. After the dilation in (c), these requirements are imposed on $K - z$ and

on both sides $L^{z-1}\ell$, $L^z\ell$, at label $L^z\mathsf{b}$, including their thresholds $K_{\rm bf}$. This is the choice of $K_\star$ in Thm. BB(1).

(c) The dilation leaves both the bare lattice and its coupling unchanged. This proves the identity for X_K and permits the fixed dilation used in (b). □

Proposition 17.45 (Two cutoffs on boxes with mixed sides)**.** The following comparison remains a sketch at the full interacting Hessian estimate described with Thm. AH. Its intended conclusion is: for every compact set J of labels, every class $z \in \{0,1\}^3$, all sides $s_\mu \in L^{\mathbb{Z}} \cup 2L^{\mathbb{Z}}$ such that each twisted plane has a side in $L^{\mathbb{Z}}$, and every $l \in 2L^{\mathbb{Z}}$, there are C and K_* such that

$$\Big|\log Z^z_{K+1}(\underline{s};\mathsf{b}) - \log Z^z_K(\underline{s};\mathsf{b}) - \frac{|\underline{s}|}{l^3}(\log Z_{K+1,l} - \log Z_{K,l})\Big| \le C\,L^{-K/10} \qquad (\mathsf{b}\in J,\ K \ge K_*),$$

where $Z^z_K(\underline{s};\mathsf{b})$ is the partition function of the box with s_μ/a_K sites along the side μ and the twist z, at $\beta = L^K\mathsf{b}$, and $|\underline{s}| = s_1s_2s_3$. ■

Proof. The box $\underline{s}$ is mixed for z in the sense of Lem. 11.9. After a common dilation by a power of L, choose a periodic covering cube $\ell_C \in 2L^{\mathbb{Z}}$ for both this box and the reference cube l^3. The latter is mixed for class 0. Thm. AH(4), under **(Hess)**, gives the two comparisons with the same extensive term $\Delta_K[\ell_C,\mathsf{b}]$.

Subtract $|\underline{s}|/l^3$ times the comparison for l^3 from the comparison for $(\underline{s},z)$. The coefficients $|\underline{s}|/\ell_C^3$ of Δ_K cancel. The two errors are bounded by $C_1L^{-K/10}$ and $(|\underline{s}|/l^3)C_2L^{-K/10}$, uniformly on J, after increasing the common threshold. This proves the stated estimate.

The errors are $\le CL^{-K/10}$. □

Lemma 17.46 (A summable bound closes the criterion)**.** Let $(\mathsf{e}_K)_{K\ge K_*}$ be real numbers with $|\mathsf{e}_{K+1}-\mathsf{e}_K| \le \mathsf{q}_K$ and $Q_K = \sum_{k\ge K}\mathsf{q}_k < \infty$. Then (a) $\mathsf{e}_\infty = \lim \mathsf{e}_K$ exists and $|\mathsf{e}_K - \mathsf{e}_\infty| \le Q_K$; (b) if $\mathsf{e}_{K_1} \le x_0 - Q_{K_1}$ at one $K_1 \ge K_*$, then $\mathsf{e}_K \le x_0$ for all $K \ge K_1$; (c) if $\mathsf{e}_K \le x_0' < x_0$ for all large K, then $\mathsf{e}_{K_1} \le x_0 - Q_{K_1}$ at every large K_1; (d) $\mathsf{e}_\infty < x_0$ if and only if $\mathsf{e}_{K_1} < x_0 - Q_{K_1}$ at one K_1, and $\mathsf{e}_\infty > x_0$ if and only if $\mathsf{e}_{K_1} > x_0 + Q_{K_1}$ at one K_1, and then $\mathsf{e}_K > x_0$ for all $K \ge K_1$; at $\mathsf{e}_\infty = x_0$ neither holds. ■

Proof. $|\mathsf{e}_K - \mathsf{e}_{K'}| \le Q_K$ for $K' \ge K$, and $Q_K \to 0$. □

Proposition 17.47 (Small tori)**.** For an integer $N \ge 3$ let $\lambda_N(k,u) = \sum_\mu(2-2\cos\frac{2\pi k_\mu+u_\mu}{N})$ for $k \in (\mathbb{Z}/N)^3$, $u \in \mathbb{R}^3$; $\mathrm{Det}'(N) = \prod_{k\ne0}\lambda_N(k,0)$; $\Upsilon_N(u) = N^2\prod_k \lambda_N(k,u)/\mathrm{Det}'(N)$; $\mathscr{J}_N = \int_{[-\pi,\pi]^3} du/\Upsilon_N(u)$; $f_\Delta = (2\pi)^{-3}\int_{[-\pi,\pi]^3}\log\sum_\mu(2-2\cos p_\mu)\,\mathrm{d}p$; and $c'_N = \log(\mathscr{J}_N/8\pi^2) - \frac{3}{2}(\log\mathrm{Det}'(N) - f_\Delta N^3 - 2\log N)$.

(a) There are absolute numbers $c_3 > 0$ and $x_* \in (0,\frac12]$ with the following two properties. On one bare periodic cube: for every integer $N \ge 3$ and every real $\beta \ge 3$ with $\mathsf{er}_N = c_3(N^{66}\log\beta/\beta)^{1/8} \le x_*$,

$$\Big|\frac{\beta^{3N^3-1}Z(N^3)}{\mathcal{Z}(N)} - 1\Big| \le \mathsf{er}_N, \qquad \mathcal{Z}(N) = \frac{(2\pi)^{3N^3-1}\,N^2\,\mathscr{J}_N}{(2\pi^2)^{2N^3}\,4\pi\,\mathrm{Det}'(N)^{3/2}}, \qquad \log\mathcal{Z}(N) = N^3z_\infty - \log N + c'_N,$$

$Z(N^3)$ the partition function at β and z_∞ the number of (d). Consequently, for all integers $N \ge 3$, $q \ge 2$ and real $\beta \ge 3$ with $\mathsf{er} = c_3((qN)^{66}\log\beta/\beta)^{1/8} \le x_*$:

$$|D_q(N) - (q^3-1)\log(\beta/N) - q^3c'_N + c'_{qN} - \log q| \le 2(q^3+1)\,\mathsf{er}.$$

(b) There are numbers $t_0 \in (0,\frac{1}{36}]$ and C_B of the constants such that for every integer $i \ge 1$, $N = 2L^i$, and every real β with $t = N/\beta \le t_0$: $|D_L(N) - (L^3-1)\log(1/t) - L^3c'_N + c'_{LN} - \log L| \le C_Bt^{1/1500}$.

(c) With $t_1 = t_0^2$ and a number C_C of the constants: $|\delta(N^3) - \log(1/t) - c'_N| \le C_C t^{1/1500}$ for $N = 2L^i$, $t = N/\beta \le t_1$. Moreover $c'_N \to c'$ and $|c'_N - c'| \le C_A N^{-2} (\log N)^{5/2}$ with an absolute C_A.

(d) With $z_\infty = \log \frac{2}{\pi} - \frac{3}{2} f_\Delta \approx -2.96167$ there are numbers β_1, C of the constants with $|P(\beta) + 3\log\beta - z_\infty| \le C\beta^{-1/1500}$ for every real $\beta \ge \beta_1$.

■

Proof. (a) *The value.* As $\beta \to \infty$ the measure of the bare cube concentrates on the flat fields. Up to gauge these are the commuting triples of holonomies; at a generic triple the orbit is that of a maximal torus, parametrised by $u \in [0, 2\pi]^3$, and the transverse fluctuations are Gaussian with the quadratic form of the lattice Laplacian twisted by u, whose lowest eigenvalue $\lambda_N(0,u)$ is of the order $|u|^2/N^2$. The volume of the orbits, the Haar measure near them and the Gaussian integral give $\beta^{3N^3-1} Z(N^3) \to \mathcal{Z}(N)$ and $\log \mathcal{Z}(N) = (3N^3-1)\log 2\pi - 2N^3 \log 2\pi^2 - \log 4\pi - \frac{3}{2}\log \mathrm{Det}'(N) + 2\log N + \log \mathscr{J}_N = N^3 z_\infty - \log N + c'_N$, by $3\log 2\pi - 2\log 2\pi^2 = \log \frac{2}{\pi}$, $\log 2\pi + \log 4\pi = \log 8\pi^2$ and the definition of c'_N.

The error, with all its powers of N. (1) *The cut.* In the gauge in which the bonds of a maximal tree carry $\mathbf{1}$, which removes the gauge group exactly, with no gauge copies and no Jacobian, the field is bounded by its curvature: with $A = \sum_p a_p$, every other bond variable lies within $2NA^{1/2}$ of $\mathbf{1}$ or, at a bond that crosses the boundary of the fundamental cube, of the holonomy h_μ of its direction, and $|h_\mu h_\nu h_\mu^{-1} h_\nu^{-1} - \mathbf{1}| \le N(2A)^{1/2}$. The fields with $A \ge \alpha_\beta = 4N^3 \log\beta/\beta$ carry at most β^{-4N^3}, which is $(C/\beta)^{N^3}$ times $\mathcal{Z}(N)\beta^{1-3N^3}$: this cut is the source of $\log\beta$. (2) *The generic stratum.* On $\{A < \alpha_\beta\}$ the integral is squeezed between two Gaussian integrals: in $d_\nu \le 6N^3$ transverse variables ν with $\|\nu\|^2 \le \Lambda_\delta A$ and $|A - Q| \le 43N^2 |\nu|_\infty \|\nu\|^2$, Q the quadratic part of A and $43N^2$ the bound of the cubic remainder of the plaquettes, the integral of $e^{-\beta A}$ over $\{A < \alpha_\beta\}$ lies between $e^{\mp(d_\nu \epsilon + C\rho_\delta)}$ times the Gaussian integral of Q, $\rho_\delta = (\Lambda_\delta \alpha_\beta)^{1/2}$, $\epsilon = 43N^2 \Lambda_\delta \rho_\delta$; the Gaussian determinants need not be computed, as the limit $\mathcal{Z}(N)$ names them.

Where some holonomy has $1 - (\frac{1}{2}\operatorname{tr} h_\mu)^2 \ge \delta^2$, the base is the commuting triple, there are $6N^3 - 2$ transverse variables, and the softest of them costs of the order δ^2/N^2: $\Lambda_\delta \le 2\pi^2 N^5 + \frac{\pi^2}{4} N^2 \delta^{-2}$. (3) *The eight points* at which every h_μ is $\pm\mathbf{1}$: there the stabiliser is all of SU(2), the nine constant modes $c = (c_\mu)$ have the quartic action $N^3 |c \wedge c|^2$, $|c \wedge c|^2 = \sum_{\mu<\nu} |c_\mu \times c_\nu|^2$, and the Gaussian picture fails for $|u| \lesssim (N/\beta)^{1/4}$. An upper bound suffices there. In Landau's gauge the action is at least $\frac{1}{2}(1-\epsilon')\|d_1 Y'\|^2 + N^3 |c \wedge c|^2$ for the non-constant part Y' of the field, d_1 the lattice exterior derivative of 1-forms, the Jacobian is at most $(\mathrm{Det}'(N)/N^3)^{3/2}(1 + 7N^2 r_\delta)^{3N^3}$ (Kirchhoff's theorem), $r_\delta^2 = 6\pi^2 N^2 \delta^2 + 24 N^5 \alpha_\beta$, and the integral over the constant modes is at most $48\pi^3 r_\delta N^{-3/2} (\beta N^3)^{-2}$; measured against $\mathcal{Z}(N)\beta^{1-3N^3}$, in which $\mathscr{J}_N = \int \mathrm{d}u / \Upsilon_N(u)$ lies between two absolute numbers, as $c_0 |u|^2 \le \Upsilon_N(u) \le c_0^{-1}$ with an absolute $c_0 > 0$ and $|u|^{-2}$ is integrable in three dimensions, the weight of these fields is at most $C\, N^{-1/2} r_\delta\, e^{C N^5 r_\delta}$. (4) *The balance.* The error of (2) is of the order of $N^8 \delta^{-3} (N^3 \log\beta/\beta)^{1/2}$, that of (3) of the order of $N^{1/2}\delta$; with $\delta = N^{-6}(N^{66} \log\beta/\beta)^{1/8}$ both, and the cut, are at most an absolute multiple of $(N^{66}\log\beta/\beta)^{1/8}$: the exponent $\frac{1}{8}$ is the balance of $\delta^{-3}\beta^{-1/2}$ against δ, all the dependence on N sits in N^{66}, and c_3, x_* are absolute.

The consequence. With $|\log(1+x)| \le 2|x|$ for $|x| \le \frac{1}{2}$, the bound at N and at qN (the condition at qN implies the one at N) gives $\log Z(N^3) = -(3N^3-1)\log\beta + \log \mathcal{Z}(N) + O(2\mathsf{er})$ and the same at qN; as $-q^3(3N^3-1) + (3q^3N^3 - 1) = q^3 - 1$, the terms in N^3 cancel in $D_q(N) = q^3 F(N^3) - F((qN)^3)$, and $-q^3 \log N + \log(qN) = -(q^3-1)\log N + \log q$. (b) Let $t \le t_0$. *The frame.* Let j_t be the least integer $j \ge 1$ with $L^j \ge LM\, R(2L^j/t)$. As $R(Lx) \le L\, R(x)$ once $\log x \ge r$, the exponent of $R(2L^j/t)$ grows by at most one when j grows by one, so equality holds at j_t: $\ell' = 2L^{j_t}$, $\mathsf{b}' = \ell'/t$ and $y' = \log \mathsf{b}'$ satisfy $\ell' = 2LM\, R(\mathsf{b}')$, which is L times the least side at which (M4)(ii), (iii) apply at the label b', and $2LMy'^r \le \ell' < 2L^2 M y'^r$, $\log\frac{1}{t} < y' < 2\log\frac{1}{t}$ for small t.

Every pair (N,β) with $N=2L^i$ and $N/\beta=t$ is the pair $(\ell'/a_K, L^K\mathsf{b}')$ of the cutoff $K=i-j_t$, of either sign, on the line of b' (Def. 17.28). Write $D_K=D_L(\ell'/a_K)$ at $\beta=L^K\mathsf{b}'$, which is $X_K(\mathsf{b}',L\ell')$. *Two cutoffs, uniformly in the label.* The number $\mathfrak{o}_K$ of (M4)(ii) is $8\mathsf{R}_{t_1}+12\epsilon_{\rm fg}+8\epsilon_{\rm cl}+12\epsilon_{\rm sh}$ ((2.xiv)), with the explicit numbers of §2.3.1 at $n=1$: with $y=\log\mathsf{b}$, $u=\lceil K/1260\rceil$, $s=\lceil K/9\rceil$ and the top level $t_1=K-u$ of (M4)(ii) in R_{t_1}, $\epsilon_{\rm fg}\le c\,\ell^3L^{-34K/315}$ and $\epsilon_{\rm cl}\le c\,(y+K\log L)^{2\mathfrak{p}_0}K^{1/2}\ell^3L^{-K/9}$, while R_{t_1} carries the factor $e^{-c'A_0^2(y+u\log L)^{2\mathfrak{p}_0}}$ against $e^{(C+\frac92 y)\ell^3}$, and $\epsilon_{\rm sh}$ the factor $e^{-\frac14\kappa_{\mathfrak{b}}A_1^2(y+u\log L)^{2\mathfrak{p}_0}}$.

On the sides $2MR(\mathsf{b})\le\ell\le 2L^3My^r$ one has $\ell^3\le 8L^9M^3y^{3r}$ and $y^{2\mathfrak{p}_0}\le(\ell/2M)^{2\mathfrak{p}_0/r}$, and the condition $2\mathfrak{p}_0>3r+2$ of the list of (H3) lets $e^{-c'A_0^2y^{2\mathfrak{p}_0}}$ beat $e^{(C+\frac92 y)\ell^3}$. So there are numbers $y_\sharp$, $C_{\mathfrak{o}}$ of the constants such that at every label with $y\ge y_\sharp$, on every such side ℓ and at every $K\ge 11(5+2\mathfrak{p}_0/r)\log_L\ell$, the conditions (k0)–(k4), (k6) of §2.3.1 hold and $\mathfrak{o}_K(\ell)\le C_{\mathfrak{o}}\,\ell^{3+2\mathfrak{p}_0/r}L^{-K/11}$, uniformly in the label; this is the form needed here, as $\mathsf{b}'\to\infty$ when $t\to0$, while the constant $\mathsf{C}_{\rm bf}$ of (M4)(ii) is formed on bounded sets of labels.

The two sides ℓ', $L\ell'$ lie in this range, and (M4)(ii) on both, with Prop. 17.44(a), gives

$$|D_{K+1}-D_K|\le L^3\mathfrak{o}_K(\ell')+\mathfrak{o}_K(L\ell')+C\ell'^3L^{-K}\le C\,\ell'^{3+2\mathfrak{p}_0/r}L^{-K/11}\qquad(K\ge 11(5+2\mathfrak{p}_0/r)\log_L(L\ell')).$$

The base. Let $K_\circ$ be the least integer with $N_\circ=\ell'L^{K_\circ}\ge t^{-1/130}$, so that $t^{-1/130}\le N_\circ<Lt^{-1/130}$; as ℓ' is a power of $\log\frac1t$, $K_\circ$ lies above the bound on K of the display once $t\le t_0$. Let $N=2L^i$ and $\beta=N/t$. (1) If $N\le N_\circ$, then $(LN)^{66}\log\beta/\beta=L^{66}N^{65}t\log\frac Nt\le L^{131}t^{1/2}(\log L+\frac{131}{130}\log\frac1t)$, and (a) at $q=L$ applies for $t\le t_0$ and bounds the left member of (b) by $2(L^3+1)c_3L^{17}t^{1/16}(\log L+\frac{131}{130}\log\frac1t)^{1/8}$. (2) If $N>N_\circ$, then $K=i-j_t>K_\circ$, and with $\mathsf{k}_M=L^3c'_M-c'_{LM}+\log L$,

$$D_L(N)-(L^3-1)\log\tfrac1t-\mathsf{k}_N=[D_K-D_{K_\circ}]+[D_L(N_\circ)-(L^3-1)\log\tfrac1t-\mathsf{k}_{N_\circ}]+[\mathsf{k}_{N_\circ}-\mathsf{k}_N]:$$

the first bracket is at most $C(1-L^{-1/11})^{-1}\ell'^{3+2\mathfrak{p}_0/r+1/11}t^{1/1430}$ by the display, as $L^{-K_\circ}\le\ell't^{1/130}$; the second is case (1) at $N_\circ$; the third is at most $2(L^3+1)C_AN_\circ^{-2}(\log N_\circ)^{5/2}\le 2(L^3+1)C_At^{1/65}(\log L+\frac{1}{130}\log\frac1t)^{5/2}$ by the rate of (c), whose proof does not use (b). The exponents $\frac{1}{16}$, $\frac{1}{1430}$, $\frac{1}{65}$ exceed $\frac{1}{1500}$, and the powers of $\log\frac1t$ are absorbed into C_B; t_0 is fixed by $\log\frac{1}{t_0}\ge y_\sharp$, by the place of $K_\circ$ and by the condition of (a) in case (1). (c) By Prop. 17.31(c) and $\delta(M^3)\le 3(M/N)^2\delta(N^3)$, $(1-3L^{-S-1})\delta(N^3)\le\sum_{s=0}^S L^{-3(s+1)}D_L(L^sN)\le\delta(N^3)$, and with $Y(M)=\log(\beta/M)+c'_M$ the main terms of (b) telescope:

$$\sum_{s=0}^{S}L^{-3(s+1)}\big[(L^3-1)\log(\beta/L^sN)+L^3c'_{L^sN}-c'_{L^{s+1}N}+\log L\big]=Y(N)-L^{-3(S+1)}Y(L^{S+1}N);$$

choosing L^S of the order $t^{-1/2}$ gives (c). The limit c' and the rate are those of Riemann sums for lattice determinants, written through heat kernels: $\log\mathrm{Det}'(N)$, $f_\Delta N^3$ and $2\log N$ are integrals $\int_0^\infty[\cdots]\frac{d\tau}{\tau}$ of one-dimensional heat kernels, which converge to those of $\vartheta(\tau,\cdot)$. (d) At $N=2L$ and $\beta\ge 2L/t_1$, (a) gives $F(N^3)=-(3N^3-1)\log\beta+N^3z_\infty-\log N+c'_N+O((\log\beta/\beta)^{1/8})$ and (c) gives $\delta(N^3)=\log(\beta/N)+c'_N+O(\beta^{-1/1500})$; the difference is $N^3P=-3N^3\log\beta+N^3z_\infty+O(\beta^{-1/1500})$. □

Proposition 17.48 (The flux quotient of small cubes at every cutoff)**.**

(a) There are numbers $t_2>0$, $C_{\mathfrak{b}}$ of the constants, and $\mathsf{a}=\frac92 r+\mathfrak{p}_0$, such that for every integer $j\ge1$ and every real β with $t=2L^j/\beta\le t_2$: $r_1(2L^j)\le\eta_{\mathfrak{b}}(t)=C_{\mathfrak{b}}(\log\frac1t)^{\mathsf{a}}t^{1/500}$ at β. Equivalently: for every side $\ell=2L^m$, $m\in\mathbb{Z}$, every real label b with $\ell/\mathsf{b}\le t_2$, and every cutoff $K\ge1-m$.

(b) To obtain the following sharper bound, one must establish the **(Heaviest class)** probability estimate. The intended conclusion is that there are numbers $t_4>0$, C of the constants, and $\mathsf{q}=1116\,r+720\,\mathfrak{p}_0+366$, such that for every integer $j\ge1$ and every real β with $t=2L^j/\beta\le t_4$, over the cross-section (N,N), $N=2L^j$: $\lambda_0^N/Z(N^3)\le C\,t\,(\log\frac1t)^{\mathsf{q}}$. ■

Proof. (a) *On one lattice.* (i) Multiplying by -1 the bonds of a sheet (a half-plane of bonds bounded by two columns) moves a twisted column; so Z^z does not depend on the place of its column, and reflection positivity across two layers with the column in the cut gives $0 \le Z^z[\chi\chi'] \le Z[\chi]^{1/2} Z[\chi']^{1/2}$ for $[0,1]$-valued χ, χ' of the two halves. On configurations whose block plaquettes at a level q (or the bare plaquettes) lie within ω of $\mathbf{1}$, a twist forces the holonomies P_1, P_3 of the block field around the twisted plane to anticommute up to $\varpi = (1+\omega)^{\mathsf{n}^2} - 1 \le \frac{1}{20}$, n the number of block sites a side; hence $|W_1| \le \varpi/2$ and $W_2^2 \ge 1 - 0.52\,\varpi^2$ for the half-traces $W_\mu(y)$ of the straight closed lines of the block field through a site, and

$$r_1(N) \le \max_y \mu_{N^3}(\mathcal{C}^\varpi(y)) + 3\mathsf{n}^3 \mathsf{R}^{1/2}, \qquad \mathcal{C}^\varpi(y) = \{|W_1(y)| \le \tfrac{\varpi}{2},\ W_2(y)^2 \ge 1 - 0.52\,\varpi^2\},$$

R the largest probability of a rough block plaquette. (ii) On a bare cube small against β: with $\Xi_\beta = 3N^3 \log(8e^8\beta^{3/2}) + 2\log(3N^3\beta)$ and $\omega_0 = (2\Xi_\beta/\beta)^{1/2}$, $Z \ge (8e^8\beta^{3/2})^{-3N^3}$, so a plaquette is rough, $|\partial U(p) - \mathbf{1}| \ge \omega_0$, with probability $\le (3N^3\beta)^{-2}$. Then the angle of P_1 is shifted along the seam: with $P_1(y_0) = e^{i\alpha_0 \hat n \cdot \sigma}$ at the site y_0 of the event, $0 < \alpha_0 < \pi$, σ the Pauli matrices, $\mathsf{N}(x)$ the matrix $\hat n \cdot \sigma$ carried to x along a path from y_0 that uses no seam bond $\langle x, x + e_k\rangle$, $x_k = 0$, $k = 1, 2$, and $V(b) \mapsto V(b) e^{-i s_k \mathsf{N}(b_+)}$ on the seam bonds of the direction k, this map, defined for $|s|_\infty \le \frac{1}{10}$, commutes with gauge transformations, turns $P_1(y_0)$ by $-s_1$ and $P_2(y_0)$ by $-s_2$ about $\hat n$, changes the action by at most $131N^4\beta\omega_0^2|s|_\infty$ on the fields whose plaquettes all lie within ω_0 of $\mathbf{1}$, and changes the Haar measure by the factor $\sin^2(\alpha_0 - s_1)/\sin^2\alpha_0$.

Let D be the event $\mathcal{C}^\varpi(y_0)$ intersected with that of no rough plaquette. For $s \in 2\varpi\mathbb{Z}^2$ with $|s|_\infty \le s_0 = (131N^4\beta\omega_0^2)^{-1}$, which is $< \frac{1}{10}$, the action rises by at most 1, so the image of D has the measure $\ge e^{-1}\cos^2(0.13)\,\mu_{N^3}(D) \ge 0.36\,\mu_{N^3}(D)$; on D the angles of $P_1(y_0)$ and $P_2(y_0)$ about $\hat n$ fix s up to 1.02ϖ and 1.46ϖ, so the images of distinct points of the grid are disjoint, and there are at least $(s_0/2\varpi)^2$ of them. Hence $\mu_{N^3}(D) \le \frac{4}{0.36}\varpi^2(131N^4\beta\omega_0^2)^2$, which is of the order $N^{12}\Xi_\beta^3/\beta$, as $\beta\omega_0^2 = 2\Xi_\beta$ and $\varpi \le 2.1N^2\omega_0$; with the rough plaquettes, $\mu_{N^3}(\mathcal{C}^\varpi) \le [6.8 \cdot 10^6 N^{12}\Xi_\beta^3 + 1]\beta^{-1}$, for the block field of a bare lattice that is not too large against β as well, by (M4)(v). (iii) *Through the cutoffs.* Write $2L^j = \ell L^K$ with $\ell = 2L^m$ the least side at which (M4) applies at the label $\mathsf{b} = \ell/t$, $y = \log \mathsf{b}$, $\ell \le 2L^2 M y^r$.

At the cutoffs $K \le K_1 = \lceil y/(25\log L)\rceil$ the lattice is a bare cube small against β, and (ii) applies. Above K_1 we use (M4)(iii) at the depth $d = 0$: at the cutoff K the block field is $\mathcal{M}^K U$, on the unit lattice of the torus ℓ, with ℓ sites a side at every cutoff; the roughness ω and the width ϖ are chosen at K_1 and do not depend on K. The events $\mathcal{C}^\varpi(y')$ of this block field and the events that one of its plaquettes lies at a distance $\ge \omega$ from $\mathbf{1}$ are closed and gauge invariant, and the same at all cutoffs; so by (M4)(iii) their probabilities move by at most $\mathfrak{o}_K$ from one cutoff to the next, and $\sum_{K \ge K_1} \mathfrak{o}_K \le Q(y) e^{-y/250}$, Q a polynomial formed from the constants; (i) at the cutoff K then gives $r_1 \le 4\bar\ell(y)^3 Q(y)^{1/2} e^{-y/500}$, $\bar\ell(y) = 2L^2 M y^r$, which is $\le C_\flat (\log \frac{1}{t})^{\mathfrak{a}} t^{1/500}$. (b) The proposed sharper estimate still requires **(Heaviest class)**; the remaining reduction uses another label of a layer and a multiplicative comparison through the cutoffs.

The top level against the heaviest cell of a label. Let Φ map the configurations on the bonds of the directions $1, 2$ of one layer into a set X, let $\mathcal{P}$ be a finite partition of X into cells whose preimages are Borel, $\sim$ a reflexive and symmetric relation on $\mathcal{P}$ with at most ν neighbours to each cell, and ι_k the cell of the label of the layer $x_3 = k$. Then over the cross-section (N, N) of an even cube $N = 2h$

$$e^{-\mathsf{G}_N} = \frac{\lambda_0^N}{Z(N^3)} \le \big(\nu^2\sqrt{p^\sharp} + \nu\sqrt{\varepsilon_2} + \sqrt{\varepsilon_1}\big)^2 \le 2\nu^4(p^\sharp + \max\{\varepsilon_1, \varepsilon_2\}) \quad (\nu \ge 2),$$

$p^\sharp = \max_I \mu_{N^3}(\iota_1 = I)$, $\varepsilon_1 = \mu_{N^3}(\iota_1 \not\sim \iota_{\mathsf{n}/2-1})$, $\varepsilon_2 = \mu_{N^3}(\iota_{\mathsf{n}/2-1} \not\sim \iota_{\mathsf{n}/2+1})$, in two cases: ($\alpha$) the label of a bare layer, $\mathsf{n} = N$; (β) the label of a layer of the block field $\mathcal{M}^q U$ of the bare cube, with $\mathsf{n} \ge 8$ block sites a side. Indeed, let the first slab be the bare layers $1, \dots, s$, with $s = 2$ in (α), $s = \frac{1}{2}(3L^q - 1)$ in (β), and $2s < h$, which in (β) follows from $\mathsf{n} \ge 8$. The label ι_1 is a Borel function

of the bonds with both ends in the first slab: in (α) it reads the layer $x_3 = 1$ alone, and in (β), by the locality of the averaging map (Prop. YM3_I:4.5), only the bare bonds of the blocks of the block layer 1, which, centred at the height L^q, lie in the bare layers $\frac{1}{2}(L^q+1), \dots, \frac{1}{2}(3L^q-1)$.

The reflection in the plane $x_3 = \frac{h}{2}$, the translation by he_3 and the reflection in the plane $x_3 = 0$ carry the first slab onto the layers $h-s, \dots, h-1$, the layers $h+1, \dots, h+s$ and the layers $N-s, \dots, N-1$; the layers 0 and h lie in none of these four slabs. The three maps are isometries of the bare lattice and, in (β), as $h = \frac{\mathsf{n}}{2}L^q$ is a multiple of L^q, of the block lattices, and the averaging maps commute with them ([7, Lem. G.1]); so the label ι_1, read on the configuration moved by them, is $\iota_{\mathsf{n}/2-1}$, $\iota_{\mathsf{n}/2+1}$, $\iota_{\mathsf{n}-1}$ respectively. Let χ_I be the indicator function of the label I on the first slab, $\mathfrak{Y}[\chi_I]$ its slab operator of (M1), and $Y_I = \mathfrak{Y}[\chi_I]\,\mathsf{T}'^{1/2}$, the operator $\mathsf{T}' = \mathsf{K}^{1/2}\mathsf{m}\,\mathsf{K}^{1/2}$ being ≥ 0; then $\sum_I Y_I = \mathsf{T}'^{s+1/2}$, $R = \mathsf{T}'^{h-2s-1} \geq 0$ and $\mathsf{T}'^{h} = \sum_{I,J} Y_J^* R Y_I$.

The conjugated mirror image χ_J^Θ of (M1), placed on the layers $h-s, \dots, h-1$, is χ_J read on the configuration mirrored in the plane $x_3 = \frac{h}{2}$ midway between these layers and the first slab, that is the indicator of $\iota_{\mathsf{n}/2-1} = J$; placed on the layers $N-s, \dots, N-1$, it is χ_J read on the configuration mirrored in the plane $x_3 = h$, which on the box of $N = 2h$ layers is the reflection in the plane $x_3 = 0$, that is the indicator of $\iota_{\mathsf{n}-1} = J$; and $\chi_{I'}$ placed on the layers $h+1, \dots, h+s$ is the indicator of $\iota_{\mathsf{n}/2+1} = I'$. So the trace formula of (M1), in which the first slab stands rightmost, for the functions $\chi_I^{+(h-2s-1)}$, $(\chi_J^\Theta)^{+1}$, $\chi_{I'}^{+(h-2s-1)}$, $(\chi_{J'}^\Theta)^{+1}$ on the consecutive slabs of $h-s-1$, $s+1$, $h-s-1$, $s+1$ layers from the layer 1 on, with $\mathfrak{Y}[\Phi^{+j}] = \mathsf{T}'^j\mathfrak{Y}[\Phi]$ (the j added layers lying above those of Φ), $\mathfrak{Y}[\chi_J^\Theta] = \mathfrak{Y}[\chi_J]^*$ and the cyclicity of the trace, gives $\mathrm{Tr}(Y_{J'}^* R Y_{I'}\, Y_J^* R Y_I) = \mathrm{Tr}(\mathsf{T}'\mathfrak{Y}[\chi_{J'}^\Theta]\, R\, \mathfrak{Y}[\chi_{I'}]\, \mathsf{T}'\mathfrak{Y}[\chi_J^\Theta]\, R\, \mathfrak{Y}[\chi_I]) = Z(N^3)\,\mu_{N^3}(\iota_1 = I, \iota_{\mathsf{n}/2-1} = J, \iota_{\mathsf{n}/2+1} = I', \iota_{\mathsf{n}-1} = J')$: probabilities of one and the same cube.

The terms with $I \not\sim J$ have together the Hilbert–Schmidt norm $\leq (Z\varepsilon_1)^{1/2}$. The terms with $I \sim J$ are $\mathbb{X}\mathbb{B}\mathbb{X}^*$, with $\mathbb{X}(\varphi_I)_I = \sum_I Y_I^* R^{1/2}\varphi_I$ and the neighbour matrix $\mathbb{B}$ of norm $\leq \nu$ (Schur's test); $\mathbb{X}^*\mathbb{X}$ is the matrix of the $R^{1/2}Y_I Y_J^* R^{1/2}$, whose Hilbert–Schmidt norms are $(Z\mu_{N^3}(\iota_1 = \iota_{\mathsf{n}/2-1} = I,\ \iota_{\mathsf{n}/2+1} = \iota_{\mathsf{n}-1} = J))^{1/2}$, so Schur's test on the neighbouring entries and the Hilbert–Schmidt norm of the others give $\|\mathbb{X}^*\mathbb{X}\| \leq \nu(Zp^\sharp)^{1/2} + (Z\varepsilon_2)^{1/2}$. Hence $\lambda_0^h = \|\mathsf{T}'^h\| \leq Z^{1/2}[\nu(\nu\sqrt{p^\sharp} + \sqrt{\varepsilon_2}) + \sqrt{\varepsilon_1}]$.

The label: the class of the pair of holonomies. For pairs $P = (P_1, P_2)$, Q in $\mathrm{SU}(2)^2$ let $\mathsf{D}(P,Q) = \min_g \max_{i=1,2} |P_i - gQ_ig^{-1}|$, a distance between the classes under simultaneous conjugation, $\mathcal{O}_w(Q) = \{P : \mathsf{D}(P,Q) \leq w\}$, and $\mathsf{v}(r)$ the volume of a ball of radius r of SU(2). For $0 < w \leq \frac{2}{35}$ a maximal family of points $Q^{(k)}$ at mutual class distances $> w$ gives a finite partition of $\mathrm{SU}(2)^2$ into Borel cells $I_k \subset \mathcal{O}_w(Q^{(k)})$, invariant under simultaneous conjugation; with $I_k \sim I_l$ if and only if $\mathsf{D}(Q^{(k)}, Q^{(l)}) \leq 3w$, two pairs at the class distance $\leq w$ lie in neighbouring cells, and $\nu \leq \mathsf{v}(\frac{7}{2}w)^2/\mathsf{v}(\frac{1}{2}w)^2 \leq 1.21 \cdot 10^5$.

The label of a layer is the cell of the pair (P_1, P_2) of the holonomies of its straight closed lines through one site, and E_k is the event that this pair lies in I_k. The label is rigid across the layers: if all plaquettes of a lattice of n sites a side lie within ϖ of $\mathbf{1}$, one conjugation carries both holonomies at $a + ke_3$ to within $k\mathsf{n}\varpi$ of those at a, so that $\mathsf{D} \leq k\mathsf{n}\varpi$. *No class is heavy on a bare even cube.* Let ρ_ω be the density, against the Haar measure of $\mathrm{SU}(2)^3$, of the three holonomies (P_1, P_2, P_3) through a site on the event that all plaquettes lie within ω of $\mathbf{1}$; it vanishes unless $|[P_\mu, P_\nu]| \leq N^2\omega$, and it is greatest at $(\mathbf{1}, \mathbf{1}, \mathbf{1})$, as follows. Choose a pointwise version of ρ_ω by solving one seam bond on each of the three straight winding loops for P_μ and integrating over all other bonds. The loops have no bonds in common, and these substitutions preserve product Haar measure. Fix μ and cut at the site planes $x_\mu = 0, h$, where $N = 2h$. Let B be their tangential bonds and X_+, X_- the private bonds in the two halves, identified by reflection. No plaquette crosses a site plane, so the cut Wilson weight factors as $w_0(B)w_+(B, X_+)w_+(B, X_-)$, with $dU = dB\,\mathrm{d}X_+\,\mathrm{d}X_-$ and nonnegative factors bounded by one. The plaquette indicators factor in the same way. At fixed B, solve one private bond on the half-path from 0 to he_μ for its transport. Its weighted Haar density k_B is bounded and hence belongs

to $L^2(G)$. If the two half-transports from 0 to he_μ are g_+, g_-, then $P_\mu = g_+ g_-^{-1}$ and its unnormalised conditional density is $q_B(p) = \int k_B(pg)k_B(g)\,\mathrm{d}g \le \int k_B(g)^2\,\mathrm{d}g = q_B(\mathbf{1})$ by Schwarz and Haar invariance. The other two loops lie in $x_\mu = 0$, so their holonomies and their solved seam bonds are functions of B. Integrating this inequality over the remaining boundary bonds with those holonomies fixed proves $\rho_\omega(P) \le \rho_\omega(P_1, \dots, P_{\mu-1}, \mathbf{1}, P_{\mu+1}, \dots, P_3)$ in the pointwise version just specified. Apply it for $\mu = 1, 2, 3$. The factorization is also the site-mirror case of the proof of Prop. YM3_I:91.4, which keeps the boundary bonds as separate Haar variables. To complete **(Heaviest class)**, one must establish the following quantitative class-probability estimate; the subsequent calculation describes its use. Take $\Xi' = \beta\omega_0^2 \ge 1$ with $\Xi' N^5 \omega_0 \le 3/640$ and $N^2\omega_0 \le w \le 1/10$.

The estimate required here is, for every pair Q and every site y,

$$\mu_{N^3}(\mathsf{D}((P_1, P_2)(y), Q) \le w, \text{ no rough plaquette}) \le 10^{11}\,\Xi'^5 N^7 w^6 \omega_0^{-4}.$$

Given this estimate, on the bare cube with ω_0 and Ξ_β of (a)(ii), $\Xi' = 2\Xi_\beta$ and $w = N^2\omega_0$, as long as $2\Xi_\beta N^5\omega_0 \le \frac{3}{640}$: where no plaquette is rough, D between the labels of the layers 1 and $\frac{N}{2} - 1$ is $< w$ and between those of the layers $\frac{N}{2} \mp 1$ it is $\le 2N\omega_0 \le w$, so $\varepsilon_1, \varepsilon_2$ are at most the probability, $\le \beta^{-2}$, that some plaquette is rough, $p^\sharp \le 10^{11}(2\Xi_\beta)^6 N^{19}\beta^{-1} + \beta^{-2}$, and, the bound increasing with ν, with $1.21 \cdot 10^5$ for ν and $2\nu^4 = 4.2872 \cdot 10^{20}$: $e^{-\mathsf{G}_N} \le 2.8 \cdot 10^{33}\Xi_\beta^6 N^{18}\, t$ on the bare cube. *Through the cutoffs.* With $y = \log \mathsf{b}$ and the side ℓ of (a)(iii), this serves at the cutoffs below the cutoff $K_1(y)$ of (M4)(vi), Prop. 17.30(c), which in (b) we call K_1: the least $K \ge 10$ with $L^{K/10} \ge \bar\ell(y)^3 y^{2\mathfrak{p}_0+1}$, so that $L^{K_1} < L\,(\bar\ell(y)^3 y^{2\mathfrak{p}_0+1})^{10}$ and the bare cube has $N_1 = \ell L^{K_1} < \mathsf{N}(y) = L\,\bar\ell(y)^{31} y^{10(2\mathfrak{p}_0+1)}$ sites a side, a fixed power of y; at the bare cubes $N \le N_1$ one has $\Xi_\beta \le 10N^3 y$, and the condition $2\Xi_\beta N^5\omega_0 \le \frac{3}{640}$ holds once y is large, as $t \le \bar\ell(y)e^{-y}$.

Above K_1 the additive transport of (a) does not serve: even summed from the higher cutoff $\lceil y/(25\log L)\rceil$ of (a)(iii), its error $\sum_K \mathfrak{o}_K \le Q(y)e^{-y/250}$ is of the order of $t^{1/250}$ up to powers of $\log\frac{1}{t}$, and swamps the first power of t; summed from K_1 it is only of the order $1/y$. We use instead the comparison with a factor of (M4)(vi), Prop. 17.30(c): from K_1 on its factors multiply to at most $e^{0.53} < 1.7$, the sums from K_1 on of the numbers of §2.3.1 being of the order $1/y$, and its remainders add up to at most e^{-4y}. At K_1 take ω_0 of (a)(ii) at $\beta_1 = N_1/t$, $w = N_1^2\omega_0$, the cells I_k of this w, and for the block field the roughness $\omega = 1.003\,L^{2K_1}\omega_0$; none of these reads K.

By (M4)(v), where all bare plaquettes lie within ω_0 of $\mathbf{1}$ (for large y, $L^{2K_1}\omega_0 \le N_1^2\omega_0$ lies below the number of L that (M4)(v) asks), the block plaquettes of $\mathcal{M}^{K_1}U$ lie within ω of $\mathbf{1}$ and its holonomies within $13.3\,N_1L^{K_1}\omega_0 \le 0.512\,w$ of the bare ones; so the bound on the classes of the bare cube N_1, taken at $1.52\,w$, gives for each of the finitely many events E_k of the block field of depth 0 at a site $\mu_0^{K_1}(E_k) \le \beta_1^{-2} + 7.9 \cdot 10^{19} N_1^{36} y^6\, t$, and for the event $\mathfrak{R}$ of a rough block plaquette $\mu_0^{K_1}(\mathfrak{R}) \le \beta_1^{-2}$. By (M4)(vi), in the form of Prop. 17.30(c), used for each of these gauge-invariant events apart (nothing is summed over the cells: $p^\sharp$ is a maximum), at every $K \ge K_1$ each has a probability at most 1.7 times its probability at K_1 plus $1.7\,e^{-4y}$.

At the cutoff K the label (β) of the block field of depth 0, on the torus ℓ with $\mathsf{n} = \ell$ block sites a side, is rigid with ω for ϖ: between the layers 1 and $\frac{\mathsf{n}}{2} - 1$ the class distance is $< \frac{1}{2}\ell^2\omega < w$, between $\frac{\mathsf{n}}{2} \mp 1$ it is $\le 2\ell\omega < w$, so $\varepsilon_1, \varepsilon_2 \le \mu_0^K(\mathfrak{R})$. As $\beta_1^{-2} \le t$ and $e^{-4y} \le t$, the bound of the top level by the heaviest cell gives $e^{-\mathsf{G}_N} \le 6 \cdot 10^{40} N_1^{36} y^6\, t$, which is at most $C\,t\,(\log\frac{1}{t})^{\mathfrak{q}}$, as $N_1 < \mathsf{N}(y)$ and $\log\frac{1}{t} \le y \le 2\log\frac{1}{t}$; the bound $2.8 \cdot 10^{33}\Xi_\beta^6 N^{18} t \le 2.8 \cdot 10^{39}\mathsf{N}(y)^{36} y^6 t$ of the bare cubes below K_1 is smaller. □

17.2.6. *Proof of the theorems. Step 1: Thm. AZ(1).* BI is the hypothesis $\mathsf{e}(l) \le x_0$ of Props. 17.32, 17.33, 17.38, 17.39 and of Lem. 17.37 at $l = l_K$, $\beta = L^K\mathsf{b}$, with one x_0 for all K. For $N = \ell/a_K$,

$$\frac{N}{2l_K} = \frac{\ell}{\ell_0}, \qquad \theta^{1/l_K} = e^{-m_* a_K}, \qquad N \ge 2l_K \iff \ell \ge \ell_0.$$

(a) is Prop. 17.32(b), (c) and Prop. 17.33(c), with $X_K(\mathsf{b},\ell) \le L^3\delta((\ell/La_K)^3)$ (Prop. 17.31(c)). (b) is Prop. 17.38(a), (b). (c): with $y = \theta^{\ell/\ell_0} \le 0.8901$, convexity gives $\varepsilon \le 22.3(e^{0.13736/7}-1)\,y \le 0.441912\,y$ in Prop. 17.34(b), and $\frac12(\sqrt{\varepsilon}+\varepsilon) \le 0.540843\sqrt{y}$; with $y = \theta^{\ell'/\ell_0}$, $Q', Q'' \le e^{0.13736/8} \le 1.017319$ and $Q'(Q'-1) \le 0.0176182\,y$, so Prop. 17.34(c) gives $4.84\cdot 0.132734\cdot 1.017319 \le 0.66$. The boxes are Prop. 17.38(c) with $\theta^{N/4l_K} = \theta^{\ell/2\ell_0}$, the twisted boxes Prop. 17.38(d). (d) is Prop. 17.33(a), (b) with $A = l_1/a_K$, $B = l_2/a_K$ and t/a_K for t: $\frac{A}{2(t/a_K)} = \frac{l_1}{2t}$, $\frac{AB}{4l_K^2} = \frac{l_1 l_2}{\ell_0^2}$, $\theta^{(t/a_K)/l_K} = e^{-m_* t}$, $\frac{1.4239}{A} = a_K\frac{1.4239}{l_1}$, and $\sum_{i\ge1}(\lambda_i/\lambda_0)^{t/a_K} = e^{\mathsf{G}} - 1$; at $l_1 = \ell_0$, $(2.42x_0)^{1/l_K} = \exp[-a_K\frac{2}{\ell_0}\log\frac{1}{2.42x_0}]$, and $2\log(1/(2.42\cdot 0.069)) \approx 3.5798$.

For the square, $n = s_\ell/a_K = 2^k l_K$ and $(\lambda_i/\lambda_0)^n \le i^{-1}\mathsf{r}_n \le 0.20395\,i^{-1}\theta^{n/l_K}$, which is the bound on E_i and on their number; $\log(1/0.20395) \ge 1.5898$. The vortex line: Prop. 17.33(d) and Prop. 17.39(e), at $\ell = 2^j\ell_0$, $\ell/a_K = 2^{j+1}l_K$, $\sigma^+ a_K^{-2} = \sigma_*$. (e) is Prop. 17.38(f) at $n_0 = 0$; Lem. 17.37(b) with $\theta^{(j-1)\mathsf{w}/l_K} = e^{-m_*(j-1)\ell''/2}$ and $Q''^2 \le 1.0350$; and Prop. 17.38(b′), $\theta^{(2n-1)/6l_K} = e^{-m_*(2n-1)a_K/6}$, $n \ge \frac12(3l_K+1)$ being $na_K \ge \frac34\ell_0 + \frac12 a_K$. (f) With the time e_3, the lattice Γ is the box $(\ell/2a_K; 2\ell/a_K, \ell/a_K)$ closed up with the translation by $\frac{\ell}{2}e_1$ (its periods are also $2\ell e_1$, ℓe_2, $\frac{\ell}{2}(e_1+e_3)$).

With $l' = \ell/2a_K$, Prop. 17.31(f) over the cross-section $(4l', 2l')$ gives $\lambda_0^{l'}(1-\mathsf{r}) \le Z_\Gamma \le Z(l', 4l', 2l')$, $\mathsf{r} = \mathsf{r}_{l'}(2l', 4l')$. Above: $F(l', 4l', 2l') \le 2F(l', 2l', 2l')$ (Prop. 17.31(b)), so $E \le \mathsf{e}(l')$. Below: $\log\lambda_0 = 8l'^2P + \varepsilon(2l', 4l') \ge 8l'^2P$ and $\log Z((2l')^3) = 8l'^3P + \delta_K(\ell)$, so $E \ge \log(1-\mathsf{r}) - \delta_K(\ell)$; by Prop. 17.33(b) in the zone $2t \le A$, $\mathsf{r} \le e^c - 1$ with $c = 0.54526\,y$, $y = \theta^{\ell/\ell_0}$; as $c \mapsto \log(2-e^c)$ is concave and vanishes at 0, $\log(2-e^c) \ge -2.0196\,c$ for $0 \le c \le 0.54526\cdot 0.8901$; with $\delta_K(\ell) < 0.13736\,y$ the sum is $\ge -1.24\,y$.

The sign $E \ge 0$ is Prop. 17.31(g) at $N = \ell/a_K$, the lattice Γ being $\Gamma^\diamond$ in physical units.

Step 2: Thm. AZ(2). Fix $K \ge \max\{K_0, 1\}$, $\beta = L^K\mathsf{b}$, boards of the offset 0. The X_i and G_I are real functions of the cell $[-\ell''/4, \ell''/4]^3$ at every cutoff. *(i)* $M_I < \infty$: $\|G_I\|^8_{\mathrm{ch},\ell''}$ is a moment of $8|I|$ centred fields with disjoint supports on the single torus ℓ'', a polynomial in their cumulants of orders ≥ 2, which converge as $K \to \infty$ by (M4)(i) (Prop. 17.43). *(ii) One factor.* With $y = \theta^{\ell'/\ell_0}$, by Step 1, $[Q'(Q'-1)]^{1/2} \le 0.132734\sqrt{y}$ and $Q'' \le 1.0174$; Prop. 17.34(a), (c) give $|\nu_K(G_I)|, |\mu_{K,\ell',\beta}(G_I)| \le 1.0174\,M_I$ and $|\nu_K(G_I) - \mu_{K,\ell',\beta}(G_I)| \le 0.65\sqrt{y}\,1.0174\,M_I$. *(iii) The cumulant.* A cumulant of order $n \ge 2$ does not see the centring, nor, for $n = 1$, does the difference of the means of two laws; and

$$\kappa_n = \sum_\pi (-1)^{|\pi|-1}(|\pi|-1)!\prod_{I\in\pi}\mathbb{E}\Big(\prod_{i\in I}X_i\Big), \qquad \Big|\prod_I \mathsf{a}_I - \prod_I \mathsf{b}_I\Big| \le \sum_I |\mathsf{a}_I - \mathsf{b}_I| \prod_{I'\ne I}\max\{|\mathsf{a}_{I'}|, |\mathsf{b}_{I'}|\},$$

so the bound holds with $C(X)$. *(iv) Limits.* As the torus cumulants converge at each fixed ℓ' by (M4)(i), $\limsup_K - \liminf_K$ of $S_n^T[\nu_K](X)$ is at most $2C(X)\theta^{\ell'/2\ell_0}$ for every ℓ', hence 0; letting $K \to \infty$ in the bound gives the iterated limit, and along (K_j, ℓ_j) the difference is $\le C(X)\theta^{\ell_j/2\ell_0}$. *(v) Every shape.* At $N' = \ell'/a_K$ the corner $c' = \frac{\ell'}{4}(1,1,1)$ has $\mathsf{C}_{N'/2}(c') = [-\frac{\ell'}{4}, \frac{\ell'}{4}]^3$, and $\|\cdot\|_{\mathrm{ch};N'} = \|\cdot\|_{\mathrm{ch},\ell'}$ there; by Lem. 17.35(b), (c) with $\delta(N'^3) < 0.13736\,y \le \frac12$: $|\langle G_I\rangle_{\underline{n}}| \le e^{0.1717}\,1.0174\,M_I \le 1.208\,M_I$ and $|\langle G_I\rangle_{\underline{n}} - \mu_{K,\ell',\beta}(G_I)| \le 7.31\cdot 0.370622\sqrt{y}\,1.0174\,M_I$; with (ii), $|\langle G_I\rangle_{\underline{n}} - \nu_K(G_I)| \le 3.36\sqrt{y}\,1.0174\,M_I$, and (iii) gives $C^{\mathrm{sh}}(X)$.

For boxes of any shape with $a_{K_j}\min_\mu n_\mu^{(j)} \to \infty$ take ℓ_j the greatest member of $\mathfrak{L}$ below that length. *(vi) A constant free of label, side and place.* For $\mathsf{b} \in I(g)$ the pairs are first-passage data at g. Put the supports by a corner of the cell, $c_\mu = \lfloor z_\mu + R\rfloor + \frac32$, z the centre of the ball: one corner serves all cutoffs because L is odd; the cell $c + [-\frac{\ell'}{2}, 0]^3$ holds the supports farther than $\frac12$ from its walls; and the $8n$ mirror images of the f_i in the planes $x_\mu = c_\mu$ have the same norms, supports each in a ball of radius R, pairwise $\ge \mathsf{d}'$ apart (two images on the two sides of a wall are more than 1 apart), all in $c + [-(2R+\frac32), 2R+\frac32]^3$, which a lattice translation carries into $(-\frac{\ell'}{4}, \frac{\ell'}{4})^3$.

So the expansion of Prop. 17.43, with the bounds (M5)(i) in the place of (M4)(i), gives $\|G_I\|_{\mathrm{ch},\ell'} \le \mathsf{m}_I^\flat$, centring by the mean on the torus ℓ' itself (the floor $128n(R+1)$ is the floor $16k(R+1)$ of (M5)(i) at $k=8n$). Then (ii), (iii) at $\ell''=\ell'$, where $4.84\cdot 0.132734 = 0.642433$ and no factor Q'' enters, give $C^\flat(X)$, for ν_K and for a torus $\ell^+ \ge \ell'$ alike, both being states $\mathfrak{s}$ of Prop. 17.34; for the boxes $(q_\mu N)$, Lem. 17.35(b), (c) give $1.86\cdot 0.370622 = 0.68936$ in the place of 0.642433; for every box, Lem. 17.35(b), (c) and (ii) give $|\langle G_I\rangle_{\underline{n}} - \nu_K(G_I)| \le (2.70925 + 0.642433)\sqrt{y}\,\mathsf{m}_I^\flat$ and $e^{\frac{5}{4}\cdot 0.13736} \le 1.19$.

For $n\ge 2$, $|S_n(X)| \le C_n^g \prod \|f_i\|_\sharp$ is the limit of (M5)(i) along the tori.

Step 3: Thm. AZ(2′). For bounded $Y, X_1, \dots, X_n$, with $X_I = \prod_{i\in I} X_i$,

$$\kappa(Y, X_1, \dots, X_n) = \sum_{\emptyset\ne I\subset[n]} \mathrm{Cov}(Y, X_I)\,\mathsf{c}([n]\setminus I), \qquad \mathsf{c}(S) = \sum_{\pi\in \mathrm{Part}(S)} (-1)^{|\pi|}|\pi|! \prod_{B\in\pi} \mathbb{E}[X_B],$$
$$\mathsf{c}(\emptyset) = 1.$$

Take a board of side $\ell''/2$ with a cell $\square$ about the tuple and a cell $\square'$ about the support of h; centring by the means on the torus ℓ'', Prop. 17.43 bounds the seminorms of the products of the centred fields in each cell, Prop. 17.34(a) bounds the means $\mathbb{E}[X_B]$, and Lem. 17.37(b) bounds $\mathrm{Cov}(Y, X_I)$ by $e^{-m_*(j-1)\ell''/2}$ times the seminorms, the indices of $\square$, $\square'$ differing by $j \ge 2(|v|_\infty - \ell'')/\ell'' + 1$ in some direction; on a torus both ways around enter. The constants depend on the label only through the compact set of Prop. 17.43. For W in the place of h the same argument runs with $Y = W$, whose centred seminorm in its cell takes the place of the bound of Prop. 17.43 for h. Summing over the plaquettes of a far region with a partition of unity by translates of a fixed bump gives the absolute convergence and the decay: with the tents χ_v, $v\in\rho\mathbb{Z}^3$, of (2′) and u vanishing on $\{|x|_\infty < r\}$, $r \ge \ell'' + \rho$, the bound for $h = u\chi_v$, which vanishes unless $|v|_\infty \ge r - \rho \ge \ell''$, summed over v, gives

$$\sum_{v\in\rho\mathbb{Z}^3} |S^T_{n+1}[\nu_K](u\chi_v, X)| \le \mathsf{C}_n \sup_v \|u\chi_v\|_\sharp \prod_i \|f_i\|_\sharp \sum_{v\in\rho\mathbb{Z}^3,\ |v|_\infty \ge r-\rho} e^{-m_*(|v|_\infty - \ell'')},$$

On the torus use V and χ_v^{per} from (2′). The conditions $\ell \ge L\ell''$ and $\ell'' \ge 8\rho + 4\mathsf{d} + 4$ give $2\rho < \ell$, so each periodized tent is a single local tent in its torus chart and $\sum_{v\in V}\chi_v^{\mathrm{per}} = 1$. Choose half-open representatives of V with minimal sup norm. They form a subset of $\rho\mathbb{Z}^3$ and satisfy $|v|_\infty = |v|_{\infty,\ell}$. The one-far-insertion bound summed over this finite set, for $r \ge \frac{3}{2}\ell'' + \rho$, is therefore bounded by the displayed infinite-grid tail, with the same $3.44\,\mathsf{C}_n$.

Step 4: Thm. AZ(3), the vacuum and the Euclidean group. For $\mathsf{b}\in I(g)$ all pairs $(K, L^K\mathsf{b})$ are first-passage data, and by Step 1 the only periodic Gibbs state there is ν_K. The moments of the centred fields under ν_K are polynomials in the cumulants $S^T_{|I|}[\nu_K]$, $|I|\ge 2$, which converge by Step 2; so (ν_K) converges, and $S_n^\sigma = S_n$. By (M5)(ii) each ergodic component of σ is a limit along the full sequence whose approximants are periodic Gibbs states at the same pairs, that is ν_K; so σ is its own component, and Thm. YM3_I:AP gives the invariance under $\mathbb{R}^3 \rtimes \mathrm{O}(3)$, reflection positivity at every plane, $\ker H_\sigma = \mathbb{C}\Omega_\sigma$ and the Wightman theory with a unique vacuum. Step 2 (iv), with its iterated limit and its bound along every pair of sequences $K_j\to\infty$, $\mathfrak{L}\ni\ell_j\to\infty$, identifies every continuum limit at g along growing tori with the pairs $(K_j, L^{K_j}\mathsf{b})$ with $(S_n^\sigma)_{n\ge 2}$, the limits with the spacing removed first among them; so each of them has the Schwinger functions of σ, and with them its invariance under $\mathbb{R}^3\rtimes\mathrm{O}(3)$, its reflection positivity, its reconstruction with a unique vacuum and, by Step 5, its gap.

Step 5: Thm. AZ(3), the gap. Let $F = \sum_i \zeta_i X_i$ be a finite combination of separated tuples of fields supported in $\{\epsilon < x_3 < \mathsf{h}'\}$, Θ the reflection $x_3\mapsto -x_3$, τ_t the translation by te_3 with $t\in a_K\mathbb{N}$, and F_K the same combination of the lattice fields $\mathcal{O}_K(f)$, centred by their means in ν_K, a function of one slab above the plane $x_3 = 0$, with n_0 layers between the slab and its mirror image. By translation invariance $\nu_K(\overline{\Theta F_K}\,\tau_t F_K)$ is $h_{F_KF_K}(n_0 + t/a_K)$, the mirror being moved to the plane

$x_3 = -t/2$; so Prop. 17.38(f) with $A = B = F_K$, $n = n_0 + t/a_K$ and $l = l_K$ gives

$$\nu_K(\overline{\Theta F_K}\,\tau_t F_K) - |\nu_K(F_K)|^2 \le e^{-m_* t}[\nu_K(\overline{\Theta F_K}\,F_K) - |\nu_K(F_K)|^2],$$

with a rate that does not depend on K and a prefactor that converges. Fix $t \in a_{K_*}\mathbb{N}$. It belongs to every finer time grid, so we may let $K \to \infty$ at this fixed time. With $\psi = (1 - P_\Omega)[F] \in \mathcal{H}(\sigma)$: $\langle \psi, e^{-tH_\sigma}\psi\rangle \le e^{-m_* t}\|\psi\|^2$ on the unbounded set $\bigcup_K a_K\mathbb{N}$ of times; so the spectral measure of ψ gives mass at most $e^{-\eta t}\|\psi\|^2$ to $[0, m_* - \eta]$ for arbitrarily large t, that is none, and such ψ are dense in $\Omega_\sigma^\perp$. The bilinear bound is the spectral theorem on $\Omega_\sigma^\perp$; the other directions follow by the invariance.

Step 6: Thm. AZ(4). Prop. 17.39 at $l = l_K$, lengths in units of a_K: $\sigma^+ a_K^{-2} = (2\Lambda + 1.67)/4l_K^2 a_K^2 = \sigma_*$, and $\sigma_* \ge (2 \cdot 0.116421 + 1.67)/\ell_0^2$ at $\theta \le 0.8901$; the areas become physical areas. For the flux quotient, $N/l_K = 2\ell/\ell_0$ turns $2.2 \cdot 10^{-4}(N/l_K)^2$ into $8.8 \cdot 10^{-4}\ell^2/\ell_0^2$, $1.4268 \cdot 10^{-3}$ into $5.707 \cdot 10^{-3}$ at $N \ge 256 l_K$, that is $\ell \ge 128\ell_0$, and $2\mathsf{q}N/l_K$ into $4\mathsf{q}\ell/\ell_0$. For the potential, $V_K(r) = a_K^{-1}V(r/a_K)$ with the V of Prop. 17.39(d), whose slopes are $\ge \sigma^+ = \sigma_* a_K^2$.

Step 7: Thm. BA(1). By Lem. 17.42 take a second admitted blocking factor $L' > L$, a prime with $\alpha = \log L/\log L'$ irrational; Thm. YM3_I:D holds in the scheme of L' (spacings L'^{-k}, sides $2L'^{\mathbb{N}}$), and $L^K\mathsf{b} = L'^{k(K)}\mathsf{c}_K$ with the labels $\mathsf{c}_K \in [\mathsf{b}, L'\mathsf{b})$ dense. In the scheme of L' let $\ell_f \in 2L'^{\mathbb{N}}$, $\ell_f \ge 24L'\ell_0$, $w_0 = \ell_f/2L'$, $f(x) = \prod_i \max\{0, 1 - |x_i|/w_0\}$ (the tent), and $\mathsf{M}_k(\ell; c) = \|\mathcal{O}_k(f) - \mu_{k,\ell,L'^k c}(\mathcal{O}_k(f))\|_{\mathrm{ch},\ell}$. (i) $\mathsf{M}_k(\ell;\cdot)^8$ is a polynomial in torus cumulants of orders 2 to 8, which by (M4)(i) at L' converges, uniformly on $[\mathsf{b}, L'\mathsf{b}]$, to a continuous function; so $\mathsf{M}_f = \sup_{k\in\mathbb{N},\ c\in[\mathsf{b},L'\mathsf{b}]} \mathsf{M}_k(\ell_f; c) < \infty$. (ii) At the labels c_K, BI gives $\mathsf{e}(l_K) \le x_0$ at $\beta = L'^{k(K)}\mathsf{c}_K$ with $l_K = \ell_0 L^K/2$, and a fine cell has $\mathsf{h} = \ell_f L'^{k(K)}/2$ layers with $\mathsf{h}/l_K \ge \ell_f/L'\ell_0 \ge 24$; Lem. 17.41 with $\ell_c = d\ell_f$, $d = L'^j$, gives

$$\mathsf{M}_{k(K)}(\ell_c; \mathsf{c}_K) \le \epsilon_\star(d) = 1.343\,\mathsf{M}_f\,\theta^{(d-1)\ell_f/8L'\ell_0}.$$

(iii) Let $x(c) = L'^{-3}D_{L'}(N)$, $N = \ell_c L'^k$, at $\beta = L'^k c$. Since $\partial_\beta \log Z(n^3)$ is $-3n^3$ times the mean plaquette variable, which is the same for all plaquettes of a torus, and the translates of the tent are a partition of unity,

$$x'(c) = -(\ell_c/w_0)^3[\mu_{k,\ell_c,\beta}(\mathcal{O}_k(f)) - \mu_{k,L'\ell_c,\beta}(\mathcal{O}_k(f))], \qquad \ell_c/w_0 = 2L'd.$$

Wherever $x \le 0.0064$, $\delta(N^3) \le (L'/(L'-1))^3 x \le 0.0086$ by Thm. BC(1), and Prop. 17.34(c) bounds the bracket by $0.16\,\mathsf{M}_k(\ell_c; c)$; so $|x'| \le 0.0058/((L'-1)\mathsf{b})$ there as soon as $\mathsf{M}_k(\ell_c; c) \le \epsilon_{\mathrm{req}}(d) = 0.036/[(2L'd)^3(L'-1)\mathsf{b}]$. The required smallness shrinks with d like d^{-3}, while $\epsilon_\star(d)/\epsilon_{\mathrm{req}}(d)$ is a constant times $d^3\theta^{(d-1)\ell_f/8L'\ell_0}$, which tends to 0 as $d = L'^j \to \infty$: fix d with $\epsilon_\star(d) \le \frac{1}{2}\epsilon_{\mathrm{req}}(d)$. By (i) the functions $\mathsf{M}_k(\ell_c;\cdot)$ converge uniformly on $[\mathsf{b}, L'\mathsf{b}]$ to a continuous limit; at the labels c_K, $K \ge K_0$, which are dense, with $k(K) \to \infty$, they are at most $\frac{1}{2}\epsilon_{\mathrm{req}}(d)$; so the limit is at most $\frac{1}{2}\epsilon_{\mathrm{req}}(d)$ everywhere, and there is $\bar{k} \ge k(K_0)$ with $\mathsf{M}_k(\ell_c; c) \le \epsilon_{\mathrm{req}}(d)$ for all $c \in [\mathsf{b}, L'\mathsf{b}]$ and all $k \ge \bar{k}$. (iv) At each $k \ge \bar{k}$ there is K with $k(K) = k$, and Prop. 17.32(b) gives $x(\mathsf{c}_K) < 0.000514$; by the mean value theorem the component of $\{x \le 0.0064\}$ that contains c_K carries $x \le 0.006314$, so it is all of $[\mathsf{b}, L'\mathsf{b}]$.

Hence $\delta(N^3) \le 0.008625$ for all c and all $k \ge \bar{k}$, and every $\beta \ge \beta_0 = L'^{\bar{k}}\mathsf{b}$ equals $L'^k c$ with $l = N \le C_+\beta$, $C_+ = \ell_c/\mathsf{b}$. Of L the argument uses only that $\log L/\log L'$ is irrational.

Step 8: Thm. BA(2), (2′), (3). At $\beta = L^K\mathsf{b}' \ge \beta_0$ there is $l \le C_+\beta$ with $\mathsf{e}(l) \le 0.069$, and Prop. 17.32(b) gives $\delta(N'^3) \le 0.13736 \cdot 0.8901^{24} < 0.008625$, so $\mathsf{e}(N') \le 0.069$, for all $N' \ge 48l$. Since $L^{m+K} \ge 48C_+\mathsf{b}'L^K \ge 48l$, the cube of BI at the side $2L^m$ qualifies; on $[\mathsf{b}_-, \mathsf{b}_+]$ take $L^m \ge 48C_+\mathsf{b}_+$ and the threshold of b_-. If BI holds at one label, it holds at all: the set of the labels is empty or $(0, \infty)$. (2′): $\mathsf{M} < \infty$ by Prop. 17.43 and (M4)(i). Fix $K \ge \max\{K_0, 1\}$ and write $\delta(s)$ for $\delta_K(\ell_1)$ at the label s. The derivative of the excess in the label is L^K times the sum over the plaquettes of the torus of the differences between the mean plaquette variable on the torus and in the periodic Gibbs state at the label s (Prop. 17.38(a)); all plaquettes having one such difference, by the symmetries of

both laws, it is a multiple R_K, $|R_K| \le 1458$, of the difference of the means of $\mathcal{O}_K(f)$ on the torus and in that state:

$$\delta(\mathsf{b}_2) - \delta(\mathsf{b}_1) = -\int_{\mathsf{b}_1}^{\mathsf{b}_2} R_K \left[\mu_{K,\ell_1,L^K s}(\mathcal{O}_K(f)) - \nu_{K,s}(\mathcal{O}_K(f))\right] \mathrm{d}s.$$

While $\delta(s) \le 0.008625$, Prop. 17.34(c) bounds the bracket by $0.17516\,\mathsf{M}$, with constants free of K. At $s = \mathsf{b}$, $\delta(\mathsf{b}) < 0.13736\,\theta^{\ell_1/\ell_0} \le 0.13736 \cdot 0.8901^{75} < 0.000025$; so δ cannot reach 0.008625 within η of b, at every cutoff. The continuity and the limits along labels follow from Step 2, made with a supremum over the labels of $[\mathsf{b} - \eta, \mathsf{b} + \eta]$ (one side $2\ell_1$, one threshold, $\theta = 0.8901$), and the continuity in the label of (M4)(i). For the second form put $N = \ell_1^\flat / a_K$. At b, Prop. 17.32(b) gives $D_L(N) < L^3\, 0.13736\, \theta^{\ell_1^\flat/\ell_0} \le 0.03$.

At a label s with $D_L(N) \le 0.069$, $\delta(N^3) \le 0.069/(L-1)^3$ by Thm. BC(1), and the derivative of $D_L(N) = L^3 F(N^3) - F((LN)^3)$ in the label is $-L^3 R_K$ times the difference of the means of $\mathcal{O}_K(f^\flat)$ on the tori $\ell_1^\flat$ and $L\ell_1^\flat$, with the number R_K of the first form, now for $f^\flat$, $|R_K| \le 1458$; Prop. 17.34(c) bounds that difference by $4.84\,[Q'(Q'-1)]^{1/2}\mathsf{M}^\flat \le 0.010813\,\mathsf{M}^\flat$. So $D_L(N)$ rises by at most 0.03 within r of b and stays below 0.06; then $\mathsf{e}(N) \le \frac{8}{L^3} D_L(N) < 0.48/L^3 < 2.2 \cdot 10^{-4}$ by Thm. BC(1), and Prop. 17.32(b) at $l = N$, with $\theta_1 = 12.9 \cdot 2.2 \cdot 10^{-4}$, gives $\mathsf{e}(L^z N/2) < 0.3702\,\theta_1^{L^z/4} \le 6.1 \cdot 10^{-9}$, which is the inequality of BI at the side $L^z \ell_1^\flat$. (3): Prop. 17.38 at this l: the rate $\theta^{n/l}$ with $\theta = 0.8901$ and $l \le C_+\beta$ is at most $e^{-c_* n/\beta}$; the transfer operator is the operator T_ν of the setting, whose matrix elements are the numbers $h_{AB}(n)$ of Prop. 17.38(f): at $\theta = 0.8901$ and $l \le C_+\beta$, $\ker(1 - T_\nu) = \mathbb{C}\Omega$ and $\|T_\nu\| \le 0.8901^{1/l} \le e^{-c_*/\beta}$ on $\Omega^\perp$; and Prop. 17.39(a) with $l \le C_+\beta$ gives the flux quotient; Prop. 17.39(d) gives the slopes, $\sigma^+ l^2 = \frac{1}{2}\log\frac{1}{0.8901} + 0.4175 \ge 0.4757$.

The labels $a_K\beta$ of all first-passage data (K, β) at g lie in the window $(g^{-2} + B_\sharp \frac{L-2}{L-1},\ L(g^{-2} + \bar{B})]$ (YM3_I:(1531) in Prop. YM3_I:74.1), so at a datum with $\beta \ge \beta_0$ the cube of the side $2la_K \le 2C_+\beta a_K \le 2C_+ L(g^{-2} + \bar{B}) = \ell_0^g$ satisfies the inequality: Thm. AZ(1) and Step 2 hold there with ℓ_0^g for ℓ_0 and 0.8901 for θ, uniformly over these data, the seminorms of Prop. 17.43 being bounded over the window.

Step 9: Thm. BA(4). On $a\mathbb{Z}^3$ the weight does not contain a, and $\mathcal{O}_a(f(\cdot/t)) = t^{-1}\mathcal{O}_{a/t}(f)$; hence

$$\kappa_n(\beta, a/t; X) = t^n\, \kappa_n(\beta, a; X_t)$$

for the cumulants in the unique periodic Gibbs state at $\beta \ge \beta_0$. By Step 8, BI holds near every label with one side and one threshold, and Step 2, taken with a supremum over a compact set of labels and of dilations of X, gives one limit along every sequence of pairs whose labels converge, continuous in the label and the dilation. The supremum over the dilations is had through the rate of (M4)(i): by the Cauchy estimate in the proof of Thm. YM3_I:AS in Thm. YM3_I:AS, on one torus and on a compact interval of labels, $|S^T_{n;K',\ell,L^{K'}\mathsf{b}}(Y) - S^T_{n;K,\ell,L^K\mathsf{b}}(Y)| \le C\, K^{2\mathfrak{p}_0(n+1)+\frac{1}{2}} L^{-K/10} \prod_i \|y_i\|_\sharp$ for all $K' \ge K$ above a threshold, where C and the threshold depend on n, the side, the interval and a floor of the spread of the supports of $Y = (y_1, \dots, y_n)$, and on Y otherwise only through these norms.

For $Y = X_{t'}$ with t' in a compact interval $J'' \subset (0, \infty)$,

$$\|f_i(\cdot/t')\|_\sharp \le \max\{\sup|f_i|, 40M(\inf J'')^{-1} \operatorname{Lip} f_i\}$$

and the spread is at least $\inf J''$ times that of X; so the torus cumulants converge uniformly in the label and the dilation. At a fixed cutoff they are continuous in both, being finite sums with the coefficients $f_i(x(p)/t')$; so the limit is jointly continuous, and the seminorms M_I of Step 2 are bounded uniformly in $t' \in J''$ in the same way. In the scheme of L' the lattices of the line of b are the lattices of the dense labels c_K, dilated by b/c_K; so the limit of the scheme of L' at every label c is the dilation of σ_b by c/b.

The dilations by L and by L', which are trivial in their own schemes, generate a dense subgroup of $(0,\infty)$, and by continuity σ_{tc} is the dilation of σ_c for every real t; the identity above reduces arbitrary real spacings to the scheme of L, and H_n is $S_n^{\sigma_1}$, so $S_n^{\sigma_c}(X) = c^{-n} H_n(X_{1/c})$. At $c \in I(g)$, Step 4 identifies σ_c; the gap of σ_{tc} is that of σ_c divided by t.

Step 10: Thm. BA(5). For φ vanishing outside $v + [-\rho,\rho]^3$ the insertion of the rotation weighted by φ depends only on the bonds within $2a_K$ of that cube and is bounded by $3402(1 + |v|_\infty)\rho^4 L^{4K} |\omega| \sup|\varphi|$, and $\sup|\mathcal{O}_K(f)| \le 162\rho^3 L^{4K} \sup|f|$ for f vanishing outside $v + [-\rho,\rho]^3$; so in every state, for χ vanishing outside $v + [-\rho,\rho]^3$ and the f_i outside $v + [-R,R]^3$, $|\mathfrak{U}| \le \mathsf{c}_n(1+\mathsf{b})(1+|v|_\infty)\rho^4 R^{3n} L^{(4n+5)K} |\omega| \sup|\chi| \prod \sup|f_i|$, with $\mathsf{c}_n = 3402 \cdot 162^n \, \mathsf{F}_{n+1}$ and $\mathsf{F}_m = \sum_\pi |\pi|!$, the sum over the partitions π of $\{1,\dots,m\}$; in the theorem $\rho = R$. (i) *Torus against state.* The bulk term is a polynomial in means of products of local functions of one cube; by Thm. AZ(1)(c), in total variation, on all tori $\ell \ge \ell''$ and in ν_K it agrees up to $2.164\,\mathsf{c}_n(1+\mathsf{b})(1+|v|_\infty)\rho^4 R^{3n} L^{(4n+5)K} e^{-m_* \ell''/4}$ times the sup norms, which is $\le$ the same expression with L^{-K} for $L^{(4n+5)K} e^{-m_* \ell''/4}$ once $\ell'' \ge \Lambda_0 K$, $\Lambda_0 = 4(4n+6)\log L/m_*$. (ii) *The place.* For a state invariant under $a_K\mathbb{Z}^3$, translating the tuple by v adds the translation $\omega v = \sum_\lambda v_\lambda \, \omega e_\lambda$ to the generator of the insertion, and the insertion of the translation by the vector ωe_λ is the difference of the bulk terms of the tuple moved by e_λ and of the tuple, both carried by $[-R-1, R+1]^3$; summed over the components of v this gives the factor $1 + 2|v|_1$. (iii) So it suffices to bound the bulk term of tuples carried by a fixed cube about the origin on one side in $[\Lambda_0 K, L\Lambda_0 K]$ of $\mathfrak{L}(g)$, which by (i) serves for ν_K and all larger sides, and on the sides $\ell \le L\Lambda_0 K$ a power of ℓ is a power of K.

There $\mathfrak{U}$ of YM3_I:(2108) is split as follows, with the objects of (M8). A joint cumulant with the $\mathcal{O}_K(f_i)$ is the derivative in the z_i of a mean at the source $w_z = \sum_i z_i f_i$, so the bulk term of YM3_I:(2107) in equation YM3_I:(2107) and the source calculation in the proof of Prop. YM3_I:112.1 is $-\partial_z^n$ at $z = 0$ of the mean at the source w_z of the bulk insertion $(\mathfrak{S}_{\omega,\chi} + \mathfrak{K}_{\omega,\chi})[\beta - a_K^{-1} w_z]$ (equation YM3_I:(2107) and the source calculation in the proof of Prop. YM3_I:112.1). With the orbital potential $\Psi_\rho(p)$ and the remainder of third order $\mathfrak{r}_\rho^\sharp(p) = \mathfrak{r}_\rho(p) - \Psi_\rho(p) + \Psi_\rho(p_-)$ of [7, §H], the summation by parts of [7, Prop. H.1] writes this insertion as the sum of three members, affine in z: the spin part $\mathfrak{S}_\omega[\phi_z]$, $\phi_z = \beta\chi - a_K^{-1} w_z$; the member $-\sum_p \sum_\rho \tilde{c}_\rho(x(p)) \Psi_\rho(p)$, $\tilde{c}_\rho(y) = (\omega y)_\rho \, a_K^{-1}[\phi_z(y + a_K e_\rho) - \phi_z(y)]$, of order 2 in the curvature with the weight β; and the cubic member $\mathfrak{K}^\sharp[\phi_z \, \omega y]$ of [7, eq. 297], of order 3 with the weight $\beta/a_K = \mathsf{b} L^{2K}$.

Accordingly $\mathfrak{U} = \mathfrak{U}^\sharp + (\mathfrak{U} - \mathfrak{U}^\sharp)$ with

$$\mathfrak{U}^\sharp_{\omega,\chi}(f) = -\beta \langle \mathfrak{K}^\sharp[\chi \, \omega y]; \mathcal{O}_K(f_1); \dots; \mathcal{O}_K(f_n) \rangle + a_K^{-1} \sum_{i=1}^n \langle \mathfrak{K}^\sharp[f_i \, \omega y]; (\mathcal{O}_K(f_l))_{l \ne i} \rangle .$$

All but the cubic member. Use the exact lattice decomposition in Lem. 5.9(b,c,e,f), as in Step 8 of the proof of Thm. O. For $\varphi \in \{\chi, f_1, \dots, f_n\}$, antisymmetry of ω rewrites $a_K^{-1}\mathfrak{S}_\omega[\varphi]$ as an order-2 entry with weights $k^\varphi_{b,p,\rho} = a_K^{-1}(\varphi(x(p)) - \varphi(x_b)) \sum_\lambda \omega_{\rho\lambda} a_K^{-1}(x_b - x(p))_\lambda$, bounded by $|\omega| \operatorname{Lip}\varphi/4$. The bilinear orbital entry has the vector weight $\mathsf{k}^{\varphi,\rho}(y) = (\omega y)_\rho \nabla^+_\rho \varphi(y)$, whose Lipschitz norm is at most $5|\omega|(1+\ell)\|\varphi\|_{C^{1,1}}$. Lem. 5.9(c) gives $\mathfrak{J}^{\mathrm{bl}}[\mathsf{k}] = -\mathfrak{N}[\mathsf{k}]/4 + \sum_{v=1}^5 \mathfrak{J}_v[\mathsf{k}] - c_{\mathsf{k}}/4$: the five entries have orders $2,2,2,3,4$, and only the last two carry β. The null term is evaluated by the contact formulas (N3), (N4) of that lemma. They leave numbers, action densities and order-2 entries without a factor β; the numbers drop from the cumulants. Terms absorbing all the sources vanish, and merging the absorbed supports leaves spread at least $\mathsf{d} - 3a_K \ge \mathsf{d}/2$. Thus Lem. 5.15, applied in its spread form, bounds every remaining term.

For the dependence on ℓ, use the proof of Lem. 5.15 before its constants are collected. A local insertion of order m is carried to depth $u = \lceil \phi K \rceil$, $\phi = (\frac{1}{2} - c_1)/(3n+4)$. The entry contributes at most a factor ℓ^3 from its sites, and the source radii are $(2nN_t \mathsf{C}_t \|f_q\|_\sharp)^{-1}$, with $N_t = \ell^3 L^{3u}$ and $\mathsf{C}_t \le C K^{2\mathfrak{p}_0}$. Their Cauchy cost contributes ℓ^{3n}; the powers of L are $L^{(3n+4)u - \mathsf{g}_m K}$, where $\mathsf{g}_2 = 1$ and $\mathsf{g}_m = 3/2$ for $m \ge 3$. The factors β in the orders $3,4$ leave the decay $L^{-c_1 K}$. The discarded mass of

the definitions preceding Prop. YM3_I:115.2 has the form $2M^{-3}\ell^{3}L^{3u}\exp[-c\{\log(L^{u}\mathfrak{b}')\}^{2\mathfrak{p}_0}+C_g\ell^{3}]$. Since $\mathfrak{p}_0\ge 13$, the labels lie in a compact first-passage interval and $\ell\le L\Lambda_0 K$, this mass and its fixed-order moment factors decay faster than every L^{-AK}, uniformly in these sides. The locality remainders have the same property. Collecting the weights from the preceding paragraph gives, times the norms, $|\mathfrak{U}-\mathfrak{U}^{\sharp}|\le C\ell^{3(n+1)}(R+5)|\omega|K^{(2n+1)\mathfrak{p}_0}L^{-c_1K}$ for every $0<c_1<\frac12$ on $2R+4\le\ell\le L\Lambda_0K$, uniformly over first-passage data at g, with C free of the side.

The cubic member obeys an estimate on all the sides at once, the bound (M7), which is Lem. 5.16 of the section on plane fields and the stress tensor (§5.1) taken at the field $\chi\,\omega y$: for $n\ge 2$, $\mathsf{d}>0$ and $\rho_0\ge 1$ there are $C_\sharp$ and a threshold, depending on g, n, d, ρ_0 and the constants and on no side, such that for all real $\chi, f_i\in C^{1,1}$ vanishing outside $[-\rho_0,\rho_0]^3$, χ covering the f_i, the supports of the f_i at pairwise sup distances $\ge\mathsf{d}$,

$$|\mathfrak{U}^{\sharp}_{\omega,\chi}(f)|\le C_\sharp|\omega|L^{-K/16}\|\chi\|_{C^{1,1}}\prod_i\|f_i\|_{C^{1,1}}$$

at all first-passage data at g with K above the threshold, on all sides $\ell\ge 2\rho_0+2$ of $\mathfrak{L}(g)$. It is proved in three steps, as in the idea of the proof of (M7). On one torus, the conditional mean of the cubic insertion given the block field of the level $K-\lceil\phi' K\rceil$, $\phi'>0$ small, under the small-field chain of Thm. YM3_I:D, differs from a constant by at most a power of K times L^{-cK}, for every $c<\frac{1}{14}$ (Lem. 5.10(b)): the density is of third order, $|\mathfrak{r}^{\sharp}_{\rho(p)}(p)|\le C_{\mathrm{orb}}\,\bar a(p)^{3/2}$ ([7, eq. 295]), plain power counting against the weight $\mathfrak{b}L^{2K}$ falls short by the factor $a_K^{-1/2}$, and the parity under the lattice mirrors, the covariance of the renormalisation step and a Hölder bound of a background against its mirror image win this factor back.

The joint cumulants of the insertion with the sources then obey the same bound, for every $c<\frac{1}{14}$, by the two-constants inequality of Lem. YM3_I:116.2 in the source variables; this is the bound of one torus, Lem. 5.11. Last, the bound on one torus serves on the finitely many sides of $\mathfrak{L}(g)$ from $2\rho_0+2$ up to a fixed side ℓ', where (M7) is Lem. 5.11, and it passes from ℓ' to every larger side (Lem. 5.16) by the chessboard estimate (M2) on the board of side $\ell'/2$, which writes the difference of a cumulant on the torus ℓ and on the torus ℓ' through cumulants on the torus ℓ' of mirror copies of the entries that join cells, every block that holds a copy of the cubic insertion carrying the small factor, at the cost of the factor $e^{(\ell'/2)^3(p_{\ell'}-p_\ell)}\le e^{\delta_K(\ell')/8}$ of the fine-to-coarse form, which Thm. BC(5)(a), (6) bound at the fixed side ℓ', uniformly in the cutoff and over the window of the labels at g.

With $\rho_0=R+1$ the sum is $\le C|\omega|K^{p'}L^{-\kappa K}$ times the norms for every $\kappa<\frac{1}{16}$. The condition $|v|_\infty+R+2\le\ell/4$ keeps the moved tuples and the insertion away from the seam of the torus, the planes $x_\mu=\pm\ell/2$ along which the cube $[-\ell/2,\ell/2]^3$ is closed up.

Step 11: Thm. BB(1)–(4). (1) is Prop. 17.44(b), (c); the statements on a height y follow from $|X_{K'}-X_K|\le\eta_K$ for $K'\ge K\ge K_\star$ and $\eta_K\to 0$. (2) If $D_L(N)\le\frac{L^3}{8}x$ with $x\le 0.069$, then $\mathsf{e}(N)\le D_2(N)\le\frac{8}{L^3}D_L(N)\le x$, because $D_L(N)-\frac{L^3}{8}D_2(N)=\frac{L^3}{8}\delta((2N)^3)-\delta((LN)^3)\ge 0$ by the monotone density; Prop. 17.32 at $l=N$ gives $\mathsf{e}(2^kN)\le(12.9x)^{2^k}/12.9=\epsilon$, and since $2^kN\le LN/2<2^{k+1}N$,

$$\mathsf{e}(LN/2)\le 2\,\delta(\tfrac{LN}{2},LN,LN)\le\Big(\frac{L}{2^{k+1}}\Big)^3[\epsilon+\tfrac{20}{7}\epsilon^2]=\Phi_L(x),\qquad D_L(2l)\le L^3\delta((2l)^3)\le\tfrac{20}{7}L^3\mathsf{e}(l)^2.$$

At $N=\ell/La_K$ we have $LN/2=\ell/2a_K$, and by (1) $X_K\le X_{K_1}+\eta_{K_1}\le y_1$ for all $K\ge K_1$; as $\Phi_L(x_1)\le x_0$, this gives BI[$\mathfrak{b},\ell,K_1;x_0$]; with y_0, $\mathsf{e}(\ell/La_K)\le x_0$, which is BI at the side $2\ell/L$ with $c=2$, and Thm. AZ holds at every side $2cL^{m_0}$. Conversely BI at the side $2\ell/L$ has $l_K=\ell/La_K$, and $X_K(\mathfrak{b},L\ell)=D_L(Ll_K)\le L^3\delta((Ll_K)^3)\le L^3\bar\delta_{x_0}(L)$ by the proof of Prop. 17.32(b). The bracket: the upper members are Thm. BC(1) at $l=\ell/2a_K$, $2l/L=\ell/La_K$; the lower member is the contrapositive of $D_L(2l)\le\frac{20}{7}L^3\mathsf{e}(l)^2$ for $\mathsf{e}(l)\le 0.069$, at $2l=\ell/a_K$.

So BI gives $X_K(\mathsf{b}, L\ell) \le \frac{20}{7} L^3 x_0^2$, and (1) excludes this for $K \ge K_1$ when $X_{K_1}(\mathsf{b}, L\ell) > \frac{20}{7} L^3 x_0^2 + \eta_{K_1}$; the members of the bracket are continuous and monotone in X_K, and $X_K \to X_\infty$, which gives the bracket for $\liminf_K \mathsf{e}_K$ and $\limsup_K \mathsf{e}_K$. (3) At the single cutoff K_1, Prop. 17.32(b) at $l = l_{K_1}$ gives $X_{K_1}(\mathsf{b}, L^i\ell_0) = D_L(2L^{i-1} l_{K_1}) \le L^3 \bar\delta_{x_0}(2L^{i-1})$; with the margin, (1) gives $X_K \le y_1$ for all $K \ge K_1$, and (2) applies. At $i = 2$, $\bar\delta_{x_0}(2L) < 8\mathsf{c}_0 \theta^L \le 0.13736\,\theta^L$, which at $x_0 = 0.069$ and $L \ge 33$ is at most 0.0030; and for $L \ge 33$, $2^k \ge 16$, so $\Phi_L(0.05) \le 8 \cdot 1.01\,(0.645)^{16}/12.9 < 0.069$ and $x_1 \ge 0.05$, $\frac{1}{8} x_1 \ge 0.00625$: the margin condition holds once $\eta_{K_1} \le 0.003 L^3$.

At $i = 1$ it never holds at $x_0 = 0.069$, as $\bar\delta_{0.069}(2) = \frac{20}{7} \cdot 0.069^2 > \frac{1}{8} \cdot 0.069$. (4) (iii) and (1) give $X_K \le y_0$ for $K \ge K_1$, hence $\mathsf{e}(\ell/La_K) \le x_0$, which is BI at the side $\ell_0 = 2\ell/L \in 2 \cdot 2L^{\mathbb{Z}}$; (i) gives $X_K(\mathsf{b}, \ell) \le L^3 \bar\delta_{x_0}(2\ell/L\ell_0) < 0.13736 L^3 \theta^{\ell/L\ell_0}$ for $\ell \ge L\ell_0$ by Prop. 17.32(b), hence (iv); (iv) implies (ii); and (ii) implies (iii) by (1).

Step 12: Thm. BB(5), (6). (5): the reduction, requiring the interacting Hessian estimate, applies Prop. 17.45 at $\underline{s} = (\ell_0/2, \ell_0, \ell_0)$, $z = 0$, $l = \ell_0$, where $|\underline{s}|/l^3 = \frac{1}{2}$, gives

$$\mathsf{e}_{K+1} - \mathsf{e}_K = 2\Big[\log Z_{K+1}(\underline{s}; \mathsf{b}) - \log Z_K(\underline{s}; \mathsf{b}) - \tfrac{1}{2}\big(\log Z_{K+1,\ell_0} - \log Z_{K,\ell_0}\big)\Big],$$

so $|\mathsf{e}_{K+1} - \mathsf{e}_K| \le 2CL^{-K/10}$ uniformly on J, and Lem. 17.46 gives the rest. (6): $D_L(\ell/a_K) = X_K(\mathsf{b}, L\ell)$ converges uniformly on compact sets of labels by (1), with the rate of Prop. 17.44(b); the pairs $(\ell/a_K, L^K\mathsf{b})$ depend on (ℓ, b) only through ℓ/b up to the index of the cutoff, so D_∞ is a continuous function of t. The series for $\delta_K(\ell)$ of Prop. 17.31(c) at $q = L$, $\delta_K(\ell) = \sum_s L^{-3(s+1)} D_L(L^s\ell/a_K)$, has the majorant $L^{-3(s+1)} D_L(L^s\ell/a_K) \le L^{-3s}\delta_K(L^s\ell) \le C(t)\,L^{-s}$, uniformly in the large K, with $C(t)$ bounded on compact sets, by the bounds at a fixed cutoff of Thm. BC(5)(a) and (6), whose proofs do not use the present clause; dominated convergence gives $\delta_K(\ell) \to \delta_\infty(t)$, locally uniformly, and $L^3\delta_\infty(t) - \delta_\infty(Lt) = D_\infty(t)$; the inequalities $(L-1)^3\delta \le D_L \le L^3\delta$ of Thm. BC(1) pass to the limit.

One function for all block sizes. Let L' be a second admitted blocking factor with $\log L/\log L'$ irrational. At one coupling, cubes $N \le M$ with $M/N \le \rho$ have $\delta(M^3) \le \rho^3\delta(N^3)$ by the monotone density. Pass to a subsequence of the lattices (N, β) that converge to $\delta_\infty^{(L)}(t)$, and choose along it cubes $M = 2L'^j$ with $M/N \to \rho_0 \in [1, \rho]$, which the density of $\{L'^j/L^i\}$ allows; the lattices (M, β) are lattices of the scheme of L' whose labels converge, so $\delta_\infty^{(L')}(\rho_0 t) \le \rho^3 \delta_\infty^{(L)}(t)$. Letting $\rho \to 1$ and using the continuity, $\delta_\infty^{(L')} \le \delta_\infty^{(L)}$, and by symmetry the two are equal. The same comparison of nearly equal cubes, now with the lattice inequalities of Prop. 17.31(c) and Thm. BC(1),(2) between the cubes N and $M = \lfloor \rho N \rfloor$, gives that $t^{-3}\delta_\infty(t)$ does not increase, the bound $(3\rho^2 - 3\rho + 1)$ for real ρ, and the alternative for real $t \ge 2t_0$.

Positivity. $\delta_\infty \ge 0$ from the series. At every t, choosing by a dilation a label in $I(g_1) \cup I(g_2) = (\gamma_W^{-2} + \bar B, \kappa_0]$ and the side $\ell = t\mathsf{b}$, Thm. BC(1), (3) give $8\delta_K(\ell) \ge \mathsf{e}(\ell/a_K) \ge \min\{0.069, 0.0775\, e^{-2.6\ell/\mathsf{d}_\circ}\}$ at all large K, so $\delta_\infty(t) > 0$; this uses Thms. YM3_I:AJ and YM3_I:AD through (M5)(iii). *The case of BI.* If BI holds at (b, ℓ_0), then $\delta_\infty(\ell/\mathsf{b}) \le 0.13736\,\theta^{\ell/\ell_0}$ for large ℓ by Thm. AZ(1); conversely, $\delta_\infty(t_0) < 0.008625$ and $\ell/\mathsf{b} = t_0$ give $\delta_K(\ell) \le 0.008625$ for all large K, hence $\mathsf{e}(\ell/a_K) \le 0.069$: BI at the side 2ℓ.

If $D_{q,\infty}(t_0) < (q-1)^3 x_0/8$ for an admitted q, then $\delta_\infty(t_0) < x_0/8 \le 0.008625$, as $(q-1)^3\delta_\infty \le D_{q,\infty}$. In the second case $\delta_\infty < 0.008625$ on a whole interval $[t_2', Lt_2']$, and the uniform convergence on the compact set of labels $[\mathsf{b}, L\mathsf{b}]$ at one side gives, for every real β above a threshold, a cube $N \le C\beta$ with $\delta(N^3) \le 0.008625$: Thm. BA(1) a second time.

Step 13: Thm. BB(7). The conditions of the list (H3), each attached to its constant, are inequalities between numbers; the one that binds L alone, with its constant 4096, is $L > 48 \cdot 4096^2 e^{24} \approx 21\,331\,858\,733\,892\,671\,081.7\ldots$, and every odd integer above it is admitted. The list also forces floors on the other constants that enter $K_\star$ and η_K: $r \ge 2$, $\mathfrak{p}_0 \ge 13$ (so $\mathsf{p}_0 \ge 26.5$), $M \ge L^7$, $\gamma^{-2} \ge (2L)^{1602}$, $A_0 \ge 256 L^5 A_1$, and three constants: $\mathsf{c}_\mathrm{a} = \mathsf{C}_\mathrm{ex}$, the expansion constant preceding equation YM3_I:

(705), with $\mathsf{C}_{\rm ex} \geq 8e^8$; $\mathsf{c}_{\rm c} = \kappa > 0$, the constant of the list that enters $\lambda_{\rm out} = (1+4\beta_{\rm s})\kappa$ of YM3_I:(889); and $\mathsf{c}_{\rm b} = \lambda_1 = \lambda_{\rm out} + 2^3 c_{\rm w} + \mathsf{C}_{\rm ex} + \lambda_{\rm s}$ of YM3_I:(705), where $c_{\rm w} = c_{\rm v} + 3$, $c_{\rm v} = 2 + \mathsf{C}_{\rm ex} c_G (LM)^3 u$ with $c_G = \mathsf{C}_{\rm ex}(\gamma_{\rm r}^{-1} + c_{\rm r}^2) \geq 2\mathsf{C}_{\rm ex}$ and $(LM)^3 u = \mathsf{u}_{\rm S}^* = 3 + c_{\rm r} + \mathsf{u}_{\rm G} > 4$ by YM3_I:(889), so that $\mathsf{c}_{\rm b} > \mathsf{c}_{\rm c} + 64\,\mathsf{c}_{\rm a}^2 \geq \mathsf{c}_{\rm c} + 4096\,e^{16}$, where $4096\,e^{16} \approx 3.6397 \cdot 10^{10}$.

The threshold $K_\star$ is the least cutoff at which the conditions of (M4)(ii)–(iii) on the construction constants hold for both tori, with the thresholds $K_{\rm bf}$ of (M4)(ii) on both after the dilation by z, as in Thm. BB(1), together with the comparison of Prop. 17.44. At their floors these conditions give $(K-z)\log L > 9\,\mathsf{c}_{\rm b} > 36864\,e^{16} \approx 3.2757 \cdot 10^{11}$ for every $K \geq K_\star(\mathsf{b}, \ell)$. Indeed, at the dilated data $(L^z\mathsf{b}, L^z\ell)$, whose cutoff $K - z$ is written K in this sentence: the number $\kappa_{\rm b}$ of YM3_I:(2181) is $w_\star e^{-\lambda_V}/32M^3$ with $w_\star = w_0 e^{-4\lambda_1}/(\mathsf{C}_{\rm ex}(L+2)^3 S_{\rm s})$, $w_0 = (4S_{\rm s}L^3)^{-1}$ (equation YM3_I:(705)), so $\kappa_{\rm b}^{-1} > L^6 M^3 e^{4\mathsf{c}_{\rm b}}$; the condition $\epsilon_{\rm sh} \leq \frac{1}{20}$ of (k3) forces $\exp[\frac{1}{4}\kappa_{\rm b} A_1^2 \mathsf{y}_{[u]}] \geq 60$, so $A_1^2 \mathsf{y}_{[u]} > 16/\kappa_{\rm b}$ and $A_0^2 \mathsf{y}_{[u]} > L^{16} M^3 e^{4\mathsf{c}_{\rm b}}$; then $\epsilon_{\rm cl} \leq \frac{1}{20}$ forces $L^{(K-s)/2} \geq 80 A_0^2 \mathsf{y}_{[u]} > e^{4\mathsf{c}_{\rm b}}$, $s = \lceil K/9 \rceil$, and as $K - s \leq \frac{8}{9}K$, $K \log L > 9\,\mathsf{c}_{\rm b}$.

So the small cube of the criterion of (2) has $2L^{m+K-1} \geq 2L^{K-z+1}$ sites a side, as $m + z \geq 2$, hence more than $e^{9\mathsf{c}_{\rm b}} > 10^{1.4226 \cdot 10^{11}}$. Where the margin η_K is below the height of the criterion, as the margin condition of (3) requires of $\eta_{K_1}(\mathsf{b}, L^2\ell_0)$, the same conditions, with $\mathsf{C}_{\rm bf} \geq 64 \mathsf{K}_{\rm w} c_\rho^2 A_0^2 \mathsf{y}_{[1]} L^{7/2}$ from (2.xv) and $\mathsf{y}_{[1]}(K-z)^{2\mathsf{p}_0} \geq \mathsf{y}_{[u]}$, make $L^{(K-z)/10}$ larger than $e^{4\mathsf{c}_{\rm b}} \geq e^{4(\mathsf{c}_{\rm b} - \mathsf{c}_{\rm c})}$ times a power of L and of M, and $e^{4(\mathsf{c}_{\rm b} - \mathsf{c}_{\rm c})} > e^{256\,\mathsf{c}_{\rm a}^2} \geq e^{16384\,e^{16}}$; so $(K-z)\log L > 163840\,e^{16} \approx 1.4559 \cdot 10^{12}$.

At the cutoff of (3) the half side $l = \ell_0/2a_{K_1}$ of the cube of BI is then $> 10^{6.3228 \cdot 10^{11}}$, and the two boxes $(l, 2l, 2l)$ and $(2l)^3$, of $4l^3$ and $8l^3$ sites, have more than $10^{1.8968 \cdot 10^{12}}$ sites each. For the floor of η_K: $\varsigma \geq \varsigma_\flat(L)$ as $\mathsf{p}_0 \geq \frac{5}{2}$, $\mathsf{C}_{\rm bf} \geq 2$, and $L^z\ell = 2L^{m+z} \geq 2L^2$ as $m + z \geq 2$; so $\eta_K \geq 3\varsigma_\flat \cdot 2 \cdot 8L^6 (K-z)^{5/2} L^{-(K-z)/10}$. An inequality $X_{K_1} \leq y - \eta_{K_1}$ with $X_{K_1} \geq 0$, $y \leq y_0$, forces $\eta_{K_1} \leq \frac{L^3}{8}\,0.069$, hence $K_1 - z \geq K_\flat(L)$ for the least $K_\flat$ at which the floor drops below that number, and the small cube then has $2L^{m+K_1-1} \geq 2L^{1+K_\flat}$ sites a side; at every admitted L this exceeds 10^{152} (already at $L = 13$, $2L^{1+K_\flat} > 10^{152.9}$).

Step 14: Thm. BC(1)–(4). (1): $D_2(N) = 4\mathsf{d}^{(3)}(N,N,N) + 2\mathsf{d}^{(2)}(N,N,2N) + \mathsf{d}^{(1)}(N,2N,2N)$, three doubling defects ≥ 0 by Prop. 17.31(b), the last being $\mathsf{e}(N)$; $D_2 \leq 8\delta$ and $D_q - \frac{q^3}{8} D_2 = \frac{q^3}{8}\delta((2N)^3) - \delta((qN)^3) \geq 0$ by Prop. 17.31(c); $(q-1)^3 \delta(N^3) \leq D_q(N)$ is $\delta((qN)^3) \leq (3q^2 - 3q + 1)\delta(N^3)$, and the box and cube bounds are Prop. 17.31(c); $\mathsf{e}(l) \leq 2\delta(l, 2l, 2l) \leq 16(l/N)^2 \delta(N^3)$. For $l = Ll'$, $n = 2l/L$, with the time along a side of the cube $Ln = 2l$: $D_L(n) \geq LF(n, 2l, 2l) - F(2l, 2l, 2l) = L\mathsf{G}(n) - \mathsf{G}(2l) \geq L\mathsf{G}(l) - \mathsf{G}(2l) \geq \frac{L}{2}\mathsf{e}(l)$ over the cross-section $(2l, 2l)$, as $n \leq l$ and $\mathsf{e}(l) = 2\mathsf{G}(l) - \mathsf{G}(2l)$, the two other thermal defects of D_L being ≥ 0; this is $\mathsf{e}(l) \leq \frac{2}{L} D_L(2l/L)$.

The cube criterion and $D_L(2l) \leq \frac{20}{7} L^3 x^2$ are Step 11; $\mathsf{e} \leq 8\delta$; and $0.13736 \cdot 0.8901^{24} \leq 0.0084022$. Finally $F \leq 0$ and, by Jensen's inequality for the Haar measure, $F \geq -3\beta|\underline{n}|$, so $\mathsf{e}(l) \leq -F((2l)^3) \leq 24\beta l^3$. (2) is Prop. 17.32 with $x_0 = 8\delta(N^3)$, $\theta = 103.2\,\delta(N^3)$ (if $\delta(N^3) = 0$ the excess vanishes for all larger cubes), $\delta((2N)^3) \leq \frac{20}{7}\mathsf{e}(N)^2 \leq \frac{20}{7} \cdot 64\,\delta(N^3)^2$, and Prop. 17.32(e) for 0.07489. Two periodic Gibbs states exclude the first alternative by Prop. 17.38(a); by (M3) each is an integral of ergodic ones, two different ergodic ones are mutually singular, and Prop. 17.34(d) gives $2 \leq \liminf e^\delta$.

The last sentence is Prop. 17.34(d), the sides being chosen with δ tending to its lower limit and the laws converging, by the compactness of the laws on a compact space. (3): if $\mathsf{e}(l) > 0.069$ there is nothing to prove; otherwise let ν be the state of Prop. 17.38, f the bump of (M5)(iii) at radius $\mathsf{d}_\circ$ and height $2\mathsf{d}_\circ$, and $C(n)$ the covariance under ν of $\mathcal{O}_K(f \circ \Theta)$ and $\mathcal{O}_K(f(\cdot - na_K e_3))$, Θ the reflection $x_3 \mapsto -x_3$. For $0 \leq n \leq N_4$ the pair is a test pair at $(\mathsf{d}_\circ; \vartheta_1)$ and two points of the supports are between $2\mathsf{d}_\circ + na_K$ and $6\mathsf{d}_\circ + na_K$ apart; so (M5)(iii) gives $C(n) > 0$ and

$$\frac{C(0)}{C(N_4)} \leq \frac{4/3}{2/3}\Big(\frac{10\,\mathsf{d}_\circ}{2\,\mathsf{d}_\circ}\Big)^6 = 2 \cdot 5^6 = 31250.$$

By translation invariance $C(n)$ is the covariance of $\mathcal{O}_K(f)$ and its mirror image in the plane $x_3 = -\frac{n}{2}a_K$, so Prop. 17.38(f) with $A = B = \mathcal{O}_K(f)$, as in Step 5, gives $C(n) \le \theta^{n/l}C(0)$, $C \ge 0$, and C is log-convex, so all $C(n) > 0$ and the quotients $C(n+1)/C(n)$ do not decrease: $C(n) \ge C(N_4)\,31250^{-(n-N_4)/N_4}$. Taking n-th roots, $\theta^{1/l} \ge 31250^{-1/N_4}$, with $\theta = 12.9\,\mathsf{e}(l)$; and $\log 31250 < 10.35 \le 2.6\,N_4 a_K/\mathsf{d}_\circ$ as $a_K/\mathsf{d}_\circ \le \frac{1}{52}$. With $\mathsf{d}_\circ = \mathsf{d}_0$, $l = \ell/2a_K$; (1) carries the floor to D_2, 8δ, $\frac{8}{L^3}D_L$; and $\frac{1}{12.9}31250^{-l/N_4} > 0.069$ if and only if $l/N_4 < \log(1/(12.9\cdot 0.069))/\log 31250$, which $la_K < 0.0449\,\mathsf{d}_\circ$ gives, as $N_4 > 4\mathsf{d}_\circ/a_K - 1$ and $\mathsf{d}_\circ/a_K > 4L^3M$. (4): dilating by L^z, the label enters the period $(\gamma_W^{-2} + \bar{B}, \kappa_0]$, which $I(g_1)\cup I(g_2)$ covers by the form of the intervals $I(g)$ in (M5); there (3) at the side $L^z\ell_0$ gives $L^{-z}m_* \le 2.6/\mathsf{d}_0^\star$, and $L^z \le \kappa_0/\mathsf{b}$, so $m_* \le 2.6\kappa_0/(\mathsf{d}_0^\star\mathsf{b})$, which is the bound since $\log(1/\theta)/1.3 \ge 0.0895$.

On the cube $(2l)^3$, Prop. 17.31(d), (e) give $w_{00} = \frac{1}{4}(1+2r_1+r_2)$, $w_{10} = w_{01} = \frac{1}{4}(1-r_2) = u$, $w_{11} = \frac{1}{4}(1-2r_1+r_2) = v$; with $x = 1-r_1 = 2(u+v)$ the sum $\sum_f w_f^{1/2} = (1-u-\frac{x}{2})^{1/2} + 2u^{1/2} + (\frac{x}{2}-u)^{1/2}$ is concave in u on the range $\frac{x}{4} \le u \le \frac{x}{2}$ allowed by $r_2 \le r_1$ and $v \ge 0$, so least at an end of it, which is $u = \frac{x}{2}$ for $x \le \frac{1}{2}$; this gives $\mathsf{e}(l) \ge 2\log(\sqrt{1-x} + \sqrt{2x})$, which exceeds 0.069 for $x > 0.00062714$ and is at least $\log 2$ for $\frac{1}{9} \le x \le \frac{1}{2}$; for $x > \frac{1}{2}$ both end values of the sum are at least $\sqrt{2}$, so $\mathsf{e}(l) \ge \log 2$ there; and $\mathsf{e}(l) \ge \mathsf{G}_{2l} \ge \log\frac{1}{w_{00}} \ge \log\frac{4}{1+3r_1}$.

Then Prop. 17.31(d) for r_2, r_3, Prop. 17.32(b) for $\delta((2l)^3) \le \frac{20}{7}\cdot 0.069^2 \le 0.0136029$, and Prop. 17.31(b) for $\mathsf{r}_l(2l, 2l) \le \varphi(e^{0.069} - 1) \le 0.0357638$, $\log(1/0.0357638) \approx 3.33082$, $l_K a_K = \ell_0/2$.

Step 15: Thm. BC(5), (6). (5)(a) is Prop. 17.47(c) at $N = \ell/a_K$, $\beta = L^K\mathsf{b}$, where $N/\beta = \ell/\mathsf{b}$, with $|c'_N - c'| \le C_A N^{-2}(\log N)^{5/2}$; and the limit $K \to \infty$ by Thm. BB(6). (b) Prop. 17.48(a) and Prop. 17.31(d), (e): as $r_2 \le r_1$, w_{00} is the largest weight and $\frac{1}{4} \le w_{00} \le \frac{1}{4}(1+3r_1)$, $|4w_f - 1| \le 3r_1$; $\delta_K(\ell) \ge \mathsf{G}_N \ge \log\frac{1}{w_{00}} \ge \log\frac{4}{1+3r_1}$, and $\mathsf{e}(\ell/2a_K) \ge \mathsf{G}(\ell/2a_K; N, N) \ge \mathsf{G}_N$; the last assertion follows from (4): $\eta_\flat(\ell_0/\mathsf{b}) < 0.99937$ gives $1 - r_1 > 0.000628$ on the cube ℓ_0/a_K at every cutoff. (c) Completing the **(Heaviest class)** probability estimate would make the reduction in Prop. 17.48(b) give $\mathsf{G}_N = \log(Z/\lambda_0^N) \ge \log\frac{1}{t} - \mathsf{q}\log\log\frac{1}{t} - \log C$. (d) Choose $t_\circ > 0$ with $16Lt_\circ \le t_2$ and $\eta_\flat(t) \le 0.9961$ for $t \le 16Lt_\circ$, and $\beta_\flat = 1/8t_\circ$.

For $\beta \ge \beta_\flat$ there is $j \ge 1$ with $2L^j/\beta \in (16t_\circ, 16Lt_\circ]$; then $1 - r_1(2L^j) \ge 0.0039$ by (b), and Prop. 17.32(d), by contraposition, excludes $\mathsf{e}(l) \le 0.069$ for every $l \le 2L^j/16$, which includes $3 \le l \le t_\circ\beta$. For BI take K with $L^K\mathsf{b} \ge \beta_\flat$: $l_K = \ell_0 L^K/2 > t_\circ L^K\mathsf{b}$. The exact statement on one lattice is the contrapositive of Prop. 17.32(d). (e) is Prop. 17.47(d). (6): with $N = L^{-j}\ell/a_K$ at the same β, (a) at the side $L^{-j}\ell$, where $t_1/L < L^{-j}t \le t_1$, bounds $\delta(N^3)$ by $\log(L/t_1) + c' + C$, and Thm. BC(1) gives $\delta_K(\ell) \le 3L^{2j}\delta(N^3)$ with $L^j \le Lt/t_1$; then $\mathsf{e} \le 8\delta$ and $D_L \le L^3\delta$.

Remark 17.49 (Scope). The theorems do not assert BI at any label; by Thm. BC it fails at every cutoff on cubes small against the label, and it can hold only on cubes of side at least $0.0895\,(\mathsf{d}_0^\star/\kappa_0)\,\mathsf{b}$. Thm. BA(2) carries BI from one label to every other label at other sides and from other thresholds, with numbers β_0, C_+ that are not explicit. Uniqueness in Thm. AZ(1)(b) is uniqueness among the periodic Gibbs states; of Gibbs states without periods it says only that ν_K is extreme and trivial at infinity. The area law bounds the loops in the state ν_K at each cutoff. Thm. BA(5) concerns tuples carried by a cube that keeps away from the seam of the torus.

18. Further propositions

This section develops further results for the lattice construction and its continuum limits. The proofs give the additional arguments for the stated hypotheses, including the box inequality, the lattice gap and the uniform Poincaré bound where they are used. The effective-density and source-stability inputs are Theorems YM3_I:D and YM3_I:AD.

18.1. **Further lattice statements: the adjoint weight of $SU(2)$, plaquette weights that coincide with Wilson's at small plaquette action, and lattices of all dimensions.** This

subsection states, and sketches the proofs of, statements on one lattice that complement Section 9.1 in three directions. For $SO(3) = SU(2)/\{\pm\mathbf{1}\}$ in its defining representation, whose Wilson weight is the adjoint weight of $SU(2)$, it expands the partition function on a single periodic lattice with even sides into a sum, over sign fields on the plaquettes, of integrals with a weight of one well, and shows that at a cube where the cube number of Proposition 9.33 (i) is $-\mathbf{1}$, a $\mathbb{Z}_2$ monopole, the rotation angles of the six faces add up to at least 2π, a bound that some configuration attains, so that one of the faces turns by at least $\frac{\pi}{3}$ (Proposition 18.3); that on such a lattice r prescribed cubes are monopoles together with probability at most $(C_0\beta^{9/2}e^{-\beta/6})^r$ whenever $\beta \geq 1$, where $\beta := \frac{8}{3}\beta_A$, β_A being the coupling at which this Wilson weight is taken, and where C_0 does not depend on the lattice size, so that on the tori of the main text the expected number of monopoles per unit volume vanishes in the limit of infinite cutoff at a fixed label, whereas no bound of this shape can hold uniformly as $\beta \to 0$ (Proposition 18.4); and that, conditioned on the absence of monopoles, the adjoint measure is a mixture of eight measures of one well, indexed by the fluxes through the three coordinate planes, so that replacing the adjoint measure by this mixture changes the joint cumulants of the plaquette observables by an explicit amount that vanishes in the limit (Proposition 18.5). For a probability measure on the configurations over $a\mathbb{Z}^d$, $d \geq 2$, with values in a compact metrisable group, which is invariant under the translations of $a\mathbb{Z}^d$ and need not be a Gibbs state, it derives $(1-T)^2 \geq T(2 - V(ae_\lambda) - V(ae_\lambda)^*)$ from reflection positivity at two coordinate mirrors and at one diagonal mirror (Proposition 18.6), and, for $d \geq 3$ and positivity at the coordinate mirrors and at one diagonal mirror across each coordinate plane, the decay of the correlations of arbitrary bounded Borel functions of finitely many bonds like $(ra/|x|)^{d-2}$, with constants determined by d only; if the group contains an element of order two, no larger exponent is possible (Proposition 18.7). For the Wilson weight of any closed subgroup of $U(N)$, at any $\beta \geq 0$ and in any dimension $d \geq 2$, all periodic Gibbs states are reflection positive at all lattice mirrors; in four dimensions their correlations therefore decay like $(ra/|x|)^2$, the three-dimensional rate $ra/|x|$ squared (Proposition 18.8). For $SU(2)$ on one torus of the main text, the probability of $a_p \geq \delta$ is bounded for a whole class of plaquette weights, so that two weights of the class that agree below a cut of the plaquette action give measures whose distance these bounds control (Proposition 18.9); a weight that equals Wilson's weight $e^{-\beta s}$ at plaquette actions $s < s_0$, for a fixed $s_0 > 0$, and does not exceed $(2+\beta)^{C_v}e^{-c_0\beta s}$ at $s \geq s_0$, for fixed $c_0 \in (0,1]$ and $C_v \geq 0$, has, at an unchanged label, the limits of Wilson's action, at Wilson's rate, as the cutoff runs through all integers and along arbitrary sequences of bare couplings, and its block fields have, in total variation, the limiting laws of Wilson's action (Proposition 18.10). Proposition 18.1 contains the facts on the planes through the sites that these arguments share.

Planes through the sites. The first proposition is stated for $SU(2)$ and for every bounded plaquette weight that is a Borel function of the trace; its clauses (a) and (b) serve the adjoint weight and the class of weights of Proposition 18.9, its clause (c) every comparison of two measures below.

Proposition 18.1 (Planes through the sites; cumulants under a change of measure)**.** Let $G = SU(2)$ with its Haar probability measure, let $\kappa\colon [-1,1] \to [0,\infty)$ be a bounded Borel function, and put $k(g) := \kappa(\frac{1}{2}\operatorname{tr} g)$ for $g \in G$; since the trace on $SU(2)$ is real and is unchanged by conjugation and by inversion, $k(hgh^{-1}) = k(g) = k(g^{-1})$ for all $g, h \in G$. Let $\Lambda = \prod_{\mu\leq 3}\mathbb{Z}/N_\mu$ with even $N_\mu \geq 2$, and let $|\Lambda|$ be its number of sites. Bonds and plaquettes are the labels (x,μ) and $(x;\mu\nu)$, $\mu < \nu$: the bond (x,μ) runs from x to $x+e_\mu$, a configuration U takes the value $U(x,\mu) \in G$ on it and $U(x,\mu)^{-1}$ on its reverse, and $\partial U(x;\mu\nu) = U(x,\mu)U(x+e_\mu,\nu)U(x+e_\nu,\mu)^{-1}U(x,\nu)^{-1}$. The cube c_x has the sites $x+\{0,1\}^3$, the twelve bonds (y,μ) with $y \in x+\{0,1\}^3$ and $y_\mu = x_\mu$, and the six faces $(x;\mu\nu)$ and $(x+e_\lambda;\mu\nu)$, $\{\lambda,\mu,\nu\} = \{1,2,3\}$. For a bounded Borel function F of the configuration put $\langle F\rangle := \int F \prod_p k(\partial U(p))\, dU$, and suppose $\langle 1\rangle > 0$.

(a) Let μ be a direction, $t \in \mathbb{Z}/N_\mu$, and θ the reflection in the plane $x_\mu = t$: on sites $x_\mu \mapsto 2t - x_\mu$; on bonds $(x,\nu) \mapsto (\theta x,\nu)$ for $\nu \neq \mu$, while (x,μ) goes to the reverse of $(\theta x - e_\mu,\mu)$; on

configurations $(\theta^*U)(b) = U(\theta b)$; and $(\theta F)(U) = F(\theta^*U)$. Let B_+ consist of the bonds (x,μ) with $x_\mu \in \{t, \dots, t + \frac{1}{2}N_\mu - 1\}$ and the bonds (x,ν), $\nu \neq \mu$, with $x_\mu \in \{t, \dots, t + \frac{1}{2}N_\mu\}$. Then $\langle \theta F\rangle = \langle F\rangle$ for every F, and $\langle \overline{\theta F}\, F\rangle \geq 0$ whenever F depends on the values of the configuration on B_+ alone.

(b) For $x \in \Lambda$ let ρ_x map the sites of c_x onto the model cube $\{0,1\}^3$ by $(\rho_x y)_\mu = y_\mu - x_\mu$ for even x_μ and $(\rho_x y)_\mu = x_\mu + 1 - y_\mu$ for odd x_μ; for a function F of the configurations of the model cube let $F^{(x)}(U)$ be the value of F at the configuration that takes on the bond of the model cube from y_0 to y_0' the value of U on the bond of c_x from $\rho_x^{-1}y_0$ to $\rho_x^{-1}y_0'$. Then, whenever each F_x, $x \in \Lambda$, is a non-negative bounded Borel function on the configurations of the model cube,

$$\Big\langle \prod_x F_x^{(x)} \Big\rangle \leq \prod_x \Big\langle \prod_{x'} F_x^{(x')} \Big\rangle^{1/|\Lambda|}.$$

(c) Let two probability measures μ_1, μ_2 on a common measurable space satisfy $|\mu_1(E) - \mu_2(E)| \leq \varepsilon$ at every event E, and let $X_1, \dots, X_n$ be real measurable functions bounded by $|X_i| \leq \mathsf{s}_i$. Then the joint cumulant of $X_1, \dots, X_n$ under μ_1 lies within $2\,\mathsf{fu}_n\,\varepsilon \prod_i \mathsf{s}_i$ of that under μ_2, where $\mathsf{fu}_n := \sum_\pi |\pi|!$, the sum running over the partitions π of $\{1, \dots, n\}$ and $|\pi|$ being the number of blocks; $\mathsf{fu}_1, \dots, \mathsf{fu}_5$ are $1, 3, 13, 75, 541$.

■

Sketch of proof. Step 1: clause (a). The map θ is an involution of the labels that respects the incidences of sites, bonds, plaquettes and cubes and fixes the two planes $x_\mu = t$ and $x_\mu = t + \frac{1}{2}N_\mu$ pointwise. It permutes the factors of the product Haar measure and inverts some of them, so dU is preserved; and $\partial(\theta^*U)(p)$ is $\partial U(\theta p)$ read from another corner or in the other sense, so that $k(\partial(\theta^*U)(p)) = k(\partial U(\theta p))$ by the two invariances of k. Hence $\langle \theta F\rangle = \langle F\rangle$. Put $\mathsf{B}_- := \theta\mathsf{B}_+$ and $\mathsf{B}_0 := \mathsf{B}_+ \cap \mathsf{B}_-$; the latter consists of the bonds of the directions $\nu \neq \mu$ in the two fixed planes, each mapped to itself with its orientation, and $\mathsf{B}_+ \cup \mathsf{B}_-$ is the set of all bonds. Each plaquette has its four bonds in B_+ or in B_-, and in both precisely when it lies in a fixed plane. Accordingly $\prod_p k(\partial U(p)) = W_0\, W_+\, \theta W_+$, where $W_0 \geq 0$, the product over the plaquettes of the fixed planes, is a function of $U_0 := U|_{\mathsf{B}_0}$, and W_+ is the product over the remaining plaquettes with bonds in B_+. Splitting $U = (U_0, U_1, U_2)$ with U_1 on $\mathsf{B}_+ \setminus \mathsf{B}_0$ and U_2 on $\mathsf{B}_- \setminus \mathsf{B}_0$, and using that $U_2 \mapsto (\theta^*U)|_{\mathsf{B}_+ \setminus \mathsf{B}_0}$ carries dU_2 to the Haar measure of U_1, Fubini's theorem gives

$$\langle \overline{\theta F}\, F\rangle = \int dU_0\, W_0(U_0) \Big| \int (F W_+)(U_0, U_1)\, dU_1 \Big|^2 \geq 0.$$

Only the two invariances of k enter, so the weight is subject to no condition at a site mirror; Proposition 9.27 (i) notes the same of every real even class weight.

Step 2: a lemma on families indexed by a cycle. Let $m \geq 1$, X a set and $\Phi\colon \mathsf{X}^{\mathbb{Z}/2m} \to [0,\infty)$ with $\mathsf{N}(e) := \Phi(e, \dots, e)^{1/2m} > 0$ for every $e \in \mathsf{X}$. For $t \in \mathbb{Z}/2m$ let $R_t^+ g$ be the family that agrees with g at the $j \in \{t, \dots, t + m - 1\}$ and takes the value g_j at $2t - 1 - j$, and $R_t^- g$ the family that agrees with g at the $j \in \{t - m, \dots, t - 1\}$ and takes the value g_j at $2t - 1 - j$. If $\Phi(g)^2 \leq \Phi(R_t^+ g)\, \Phi(R_t^- g)$ for all t and g, then $\Phi(g) \leq \prod_j \mathsf{N}(g_j)$. Indeed $Q(g) := \Phi(g) / \prod_j \mathsf{N}(g_j)$ satisfies the same inequality, as $\prod_j \mathsf{N}((R_t^+ g)_j)\, \mathsf{N}((R_t^- g)_j) = \prod_j \mathsf{N}(g_j)^2$. Among the finitely many families whose entries are taken from those of a given g, choose one, g^*, at which Q is maximal and which, among the maximisers, has a run of equal neighbouring entries of the greatest length r, beginning at t. If $r < 2m$, then $Q(g^*)^2 \leq Q(R_t^+ g^*)\, Q(R_t^- g^*) \leq Q(R_t^+ g^*)\, Q(g^*)$ shows that $R_t^+ g^*$ is a maximiser too, while its run has the length $\min\{2r, 2m\} > r$; hence g^* is constant and $Q \leq 1$. The chessboard estimate of Proposition YM3_I:86.3 rests on the same principle, applied there at walls between the sites.

Step 3: clause (b). Assume first that all $F_x \geq \epsilon > 0$, and put $\Phi((F_x)_x) := \langle \prod_x F_x^{(x)} \rangle > 0$. Fix μ, put $m = \frac{1}{2}N_\mu$, and regard the family as $(g_j)_{j \in \mathbb{Z}/N_\mu}$ with $g_j := (F_x)_{x_\mu = j}$. The reflection in $x_\mu = t$ maps c_x onto $\mathsf{c}_{x'}$, where $x'_\mu = 2t - 1 - x_\mu$ and the other coordinates are kept, and $\rho_{x'} \circ \theta = \rho_x$ on

c_x for either parity of x_μ, whence $\theta F^{(x)} = F^{(x')}$; moreover the cubes with $x_\mu \in \{t, \dots, t+m-1\}$ have all their bonds in B_+. Thus $\prod_x F_x^{(x)} = A \cdot \theta A'$ with real functions A, A' of the configuration on B_+; by (a), $(F, F') \mapsto \langle \theta F \cdot F' \rangle$ is a symmetric positive form on such real functions, and Schwarz's inequality yields $\Phi(g)^2 \le \langle \theta A \cdot A \rangle \langle \theta A' \cdot A' \rangle = \Phi(R_t^+ g)\, \Phi(R_t^- g)$. Applying Step 2 successively in the directions 1, 2, 3 gives (b) for these F_x, and letting $\epsilon \to 0$, both sides being continuous in ϵ, gives it for $F_x \ge 0$.

Step 4: clause (c). The joint cumulant equals $\sum_\pi (-1)^{|\pi|-1}(|\pi|-1)! \prod_{B\in\pi} \mu(\prod_{i\in B} X_i)$ by expanding the logarithm of the moment generating function in squarefree coefficients. For bounded real Y, $|\mu_1(Y) - \mu_2(Y)| \le (\sup Y - \inf Y)\, \varepsilon \le 2\varepsilon \sup |Y|$. In the term of π each of the $|\pi|$ factors is bounded by $\prod_{i\in B} \mathsf{s}_i$ and changes by at most $2\varepsilon \prod_{i\in B} \mathsf{s}_i$, so the product changes by at most $2|\pi|\, \varepsilon \prod_i \mathsf{s}_i$; the weights $(|\pi|-1)!\, |\pi|$ add up to fu_n. □

The adjoint weight of $SU(2)$ on a single periodic lattice. In Propositions 18.3 to 18.5, $G = SO(3) \subset U(3)$ is the image of $SU(2)$ under the adjoint representation Ad; it is the quotient $\tilde{G}/\mathsf{Z}$ of Proposition 9.33 with $\tilde{G} = SU(2)$ and $\mathsf{Z} = \{\pm \mathbf{1}\}$, and for the pair $SO(3)$ on $\mathbb{C}^3$ of Definition 9.1 the action density is $a(X) = 1 - \frac{1}{3}\mathrm{tr}\, X$. For $u \in SU(2)$ let $w(u) := \frac{1}{2}\mathrm{tr}\, u \in [-1, 1]$ and let $\alpha(u) \in [0, \pi]$ be the angle with $\cos \alpha(u) = w(u)$, so that u has the eigenvalues $e^{\pm i\alpha(u)}$; then $\mathrm{tr}\, \mathrm{Ad}(u) = 4w(u)^2 - 1$, $a(\mathrm{Ad}(u)) = \frac{4}{3}(1 - w(u)^2)$, and $\mathrm{Ad}(u)$ is the rotation by the angle $2\min\{\alpha(u), \pi - \alpha(u)\} \in [0, \pi]$, which belongs to G^π if and only if $w(u) \ne 0$. The lattice $\Lambda = \prod_{\mu\le 3} \mathbb{Z}/N_\mu$ has even sides $N_\mu \ge 2$, as in Proposition 18.1, and its bonds, plaquettes and cubes carry the labels of that proposition; we write Bd for its set of bonds, which has $3|\Lambda|$ members (x, μ), and Pl for its set of plaquettes $(x; \mu\nu)$, which has $3|\Lambda|$ members as well; there are $|\Lambda|$ cubes, each plaquette borders two cubes and each bond belongs to four plaquettes. A configuration U of $SO(3)$ is $\mathrm{Ad} \circ \tilde{U}$ for a configuration $\tilde{U}$ of $SU(2)$, its lift, determined by U up to a sign field $\gamma \in \{\pm 1\}^{\mathrm{Bd}}$ acting by $(\gamma\tilde{U})(b) = \gamma_b \tilde{U}(b)$; the map $\tilde{U} \mapsto \mathrm{Ad} \circ \tilde{U}$ carries the Haar measure $d\tilde{U}$ to the Haar measure dU, and composition with it makes the bounded Borel functions of U correspond to the bounded Borel functions of $\tilde{U}$ that are *centre-blind*, $F(\gamma\tilde{U}) = F(\tilde{U})$ for every γ. Write $w_p := w(\partial\tilde{U}(p))$, $\alpha_p := \alpha(\partial\tilde{U}(p))$ and $\tilde{\alpha}_p := \min\{\alpha_p, \pi - \alpha_p\}$, so that $\vartheta_p := 2\tilde{\alpha}_p$ is the rotation angle of $\partial U(p) = \mathrm{Ad}(\partial\tilde{U}(p))$, and $(\delta\gamma)_p := \prod_{b\in p} \gamma_b$, so that $w_p(\gamma\tilde{U}) = (\delta\gamma)_p w_p(\tilde{U})$. Let $\beta_A > 0$ be the coupling of the Wilson weight $\prod_p e^{-\beta_A a_p}$ of the pair, and $\beta := \frac{8}{3}\beta_A$; then $\beta_A a_p = \frac{\beta}{2}(1 - w_p^2) = \frac{\beta}{2}\sin^2 \alpha_p$, whose quadratic part at $\alpha_p = 0$, $\frac{\beta}{2}\alpha_p^2$, is that of the exponent $\beta(1 - w_p)$ of the Wilson weight of $SU(2)$ at the same β. Let $W^A(\tilde{U}) := \prod_p e^{-\frac{\beta}{2}(1-w_p^2)}$, $Z^A := \int W^A\, d\tilde{U} = \int \prod_p e^{-\beta_A a_p}\, dU$ and $\mu^A := (Z^A)^{-1} W^A\, d\tilde{U}$, whose image under $\tilde{U} \mapsto \mathrm{Ad} \circ \tilde{U}$ is the Wilson measure of $SO(3)$ at β_A; the *one-well weight* is $\mathsf{h}_\beta(s) := \mathbf{1}\{s > 0\}\, e^{-\frac{\beta}{2}(1-s^2)}$, $s \in [-1, 1]$.

Lemma 18.2 (Site-mirror dissemination for closed blocks)**.** Let every period of a rectangular torus be an even multiple of an integer $R \ge 1$, and use the closed blocks of side R with boundaries on site planes. For a bounded nonnegative function F of the bonds of one block, its normalized mean is at most the normalized mean of the product of its alternating reflected copies, raised to the reciprocal of the number of blocks. ■

Proof. In one direction let there be $2k$ slabs. For a function F_j in slab j, integrate over the bonds off its two end slices against the plaquette weights, using half the exponent for the plaquettes in an end slice. This gives an integral kernel A_j on the end-slice variables. The integral of the product is $\mathrm{Tr}(A_1 \cdots A_{2k})$. Reflection reverses the order of the two slice variables, so the partition integral for the alternating reflected copies of one slab function is $\mathrm{Tr}[(A_j A_j^*)^k]$. The kernels are bounded on probability spaces, hence Hilbert–Schmidt. Schatten Hölder bounds the product trace by $\prod_j (\mathrm{Tr}[(A_j A_j^*)^k])^{1/(2k)}$. The term for an unmarked slab is the partition function raised to $1/(2k)$. Divide by the partition function and apply this estimate successively in the three directions. The plaquette weights that lie on a wall are counted exactly once because the adjacent slab kernels each include half of their exponent. □

Proposition 18.3 (The adjoint weight: sign fields and the cube number)**.** In this setting let $\mathcal{N} := \bigcup_p \{w_p = 0\}$, let $\eta_p(\tilde U) := \operatorname{sign} w_p(\tilde U)$ off $\mathcal{N}$, and for a cube c with the set $\partial\mathsf{c}$ of its six faces let E_c be the event that $w_p \neq 0$ at each of the six faces $p \in \partial\mathsf{c}$ and $\prod_{p\in\partial\mathsf{c}} \operatorname{sign} w_p = -1$.

(a) $\mathcal{N}$ is a null set, and off $\mathcal{N}$

$$W^A(\tilde U) = \sum_{\eta\in\{\pm1\}^{\mathrm{Pl}}} \prod_p \mathsf{h}_\beta(\eta_p w_p(\tilde U)),$$

with $\eta = \eta(\tilde U)$ as the single non-vanishing term; hence $Z^A = \sum_\eta \int \prod_p \mathsf{h}_\beta(\eta_p w_p)\, d\tilde U$.

(b) Off $\mathcal{N}$ every plaquette variable $\partial U(p)$ of $U = \mathrm{Ad}\circ\tilde U$ lies in G^π, the central part of Proposition 9.33 is $z_{\tilde U}(p) = \eta_p(\tilde U)\,\mathbf{1}$, and the cube number of U at c is $\prod_{p\in\partial\mathsf{c}} \eta_p(\tilde U)\,\mathbf{1}$. So, off $\mathcal{N}$, E_c is the event that the cube number at c equals $-\mathbf{1}$, a $\mathbb{Z}_2$ monopole at c; it is an open centre-blind event determined by the configuration on c.

(c) If $\tilde U \notin \mathcal{N}$ and c is a monopole, then $\sum_{p\in\partial\mathsf{c}} \vartheta_p \geq 2\pi$; consequently one of its faces has $\vartheta_p \geq \frac{\pi}{3}$, which means $1 - w_p^2 \geq \frac14$ and $a_p = 1 - \frac13 \operatorname{tr} \partial U(p) \geq \frac13$; and $\sum_{p\in\partial\mathsf{c}}(1-w_p^2) \geq \frac23$. Put otherwise, if all six faces of a cube have rotation angles below $\frac{\pi}{3}$, its cube number is $\mathbf{1}$: for $SO(3)$ the threshold $\frac{\pi}{6}$ of the eigen-angles in Proposition 9.33 (i) may be raised to $\frac{\pi}{3}$. Some configuration of the twelve bonds of c makes c a monopole at which $\sum_{p\in\partial\mathsf{c}} \vartheta_p = 2\pi$; so the bound on the sum of the six angles is attained.

■

Sketch of proof. Step 1: clause (a). Freeze all bonds but one bond b of a plaquette p: then $\partial\tilde U(p)$ or its inverse is a conjugate of $\tilde U(b)g$ for a frozen g, hence Haar distributed. Under the Haar measure of $SU(2)$ the angle α has the law $\frac{2}{\pi}\sin^2\alpha\, d\alpha$ on $[0,\pi]$, by Lemma 9.14 (i) applied to the pair $SU(2)$ on $\mathbb{C}^2$, where $j_{SU(2)}(Y) = (\frac{\sin|Y|}{|Y|})^2$ and $\mathrm{vol}(SU(2)) = 2\pi^2$, as recorded after Definition 9.1; so $\{w_p = 0\} = \{\alpha_p = \frac{\pi}{2}\}$ is null, and by Fubini's theorem so is $\mathcal{N}$. For $s \neq 0$ the sum $\mathsf{h}_\beta(s) + \mathsf{h}_\beta(-s)$ has a single non-zero term, equal to $e^{-\frac{\beta}{2}(1-s^2)}$; so off $\mathcal{N}$, $W^A = \prod_p(\mathsf{h}_\beta(w_p) + \mathsf{h}_\beta(-w_p)) = \sum_\eta \prod_p \mathsf{h}_\beta(\eta_p w_p)$, and a term can be non-zero only if $\eta_p w_p > 0$ for all p, that is, only for $\eta = \eta(\tilde U)$.

Step 2: clause (b). Let $g = e^{iY} \in G^\pi$ with $Y \in \mathfrak{g}$ and $|Y| = \vartheta < \pi$, the rotation angle of g. The element $\tilde Y$ of the Lie algebra of $SU(2)$ that the covering sends to Y has the eigenvalues $\pm\frac{\vartheta}{2}$, since $\operatorname{ad}\tilde Y$, which the covering identifies with Y, has the eigenvalues $0, \pm\vartheta$; therefore the canonical lift $s(g) = e^{i\tilde Y}$ of Proposition 9.33 is the lift of g with $w(s(g)) = \cos\frac{\vartheta}{2} > 0$. As g has the two lifts $\pm s(g)$, $s(\mathrm{Ad}(u)) = \operatorname{sign}(w(u))\, u$ whenever $w(u) \neq 0$; hence $z_{\tilde U}(p) = \partial\tilde U(p)\, s(\partial U(p))^{-1} = \eta_p \mathbf{1}$, and the cube number, the product of the $z_{\tilde U}(p)^{\pm1}$ over the six faces, is $\prod_{p\in\partial\mathsf{c}} \eta_p\, \mathbf{1}$, the signs being central and their own inverses. Each of the twelve bonds of c borders exactly two faces of c, so a sign field multiplies the product by a square and E_c is centre-blind; and E_c is the union of the open sets $\{\epsilon_p w_p > 0 \text{ for } p \in \partial\mathsf{c}\}$ over the sign patterns (ϵ_p) with $\prod_p \epsilon_p = -1$.

Step 3: the identity of the six faces. Label the sites of c by $(i,j,k) \in \{0,1\}^3$ and let t be the tree of seven bonds of c consisting of the four bonds of the direction 3, the two bonds of the direction 2 at $k = 0$ and the bond of the direction 1 at $j = k = 0$. A gauge transformation of the eight sites, $\mathbf{1}$ at $(0,0,0)$ and propagated along t, makes $\tilde U$ trivial on t; it conjugates every face variable and so changes no w_p, α_p or η_p. Call A_i the new value on the bond from $(i,0,1)$ to $(i,1,1)$, $i = 0, 1$, and B, C, D the new values on the bonds of the direction 1 that start at $(0,1,0)$, $(0,0,1)$ and $(0,1,1)$. Taken from a suitable corner and in a suitable sense, the faces $x_1 = 0$, $x_1 = 1$, $x_3 = 0$, $x_2 = 0$, $x_2 = 1$ and $x_3 = 1$ carry

$$h_1 = A_0, \quad h_2 = A_1, \quad h_3 = B, \quad h_4 = C, \quad h_5 = BD^{-1}, \quad h_6 = CA_1D^{-1}A_0^{-1},$$

and eliminating D yields $h_6 = h_4 h_2 h_3^{-1} h_5 h_1^{-1}$: the lattice form of the identity of Bianchi that underlies the cube number of Proposition 9.33 (i).

Step 4: clause (c). Let $\tilde U \notin \mathcal{N}$, $\eta_i := \operatorname{sign} w(h_i)$ and $v_i := \eta_i h_i$; then $w(v_i) = |w(h_i)| > 0$, $\alpha(v_i) = \tilde\alpha_i < \frac{\pi}{2}$, and the identity of Step 3 turns into $v_6^{-1}v_4v_2v_3^{-1}v_5v_1^{-1} = \prod_i \eta_i\,\mathbf{1}$, which equals $-\mathbf{1}$ at a monopole. Viewing $SU(2)$ as the unit quaternions in $\mathbb{R}^4$, $w(u^{-1}u')$ is the Euclidean inner product of u and u', so $\alpha(u^{-1}u')$ is their spherical distance, which left and right multiplications preserve; hence $\alpha(u_1\cdots u_6) \le \sum_i \alpha(u_i)$ and $\alpha(u^{-1}) = \alpha(u)$, and at a monopole $\pi = \alpha(-\mathbf{1}) \le \sum_i \tilde\alpha_i$, that is, $\sum_p \vartheta_p \ge 2\pi$. Then some $\tilde\alpha_i \ge \frac{\pi}{6}$, where $1 - w^2 = \sin^2\tilde\alpha_i \ge \frac14$ and $a_p = \frac43(1-w_p^2) \ge \frac13$; and $\sin x \ge \frac{2}{\pi}x$ on $[0,\frac{\pi}{2}]$ with the inequality of Cauchy and Schwarz gives $\sum_i \sin^2\tilde\alpha_i \ge \frac{4}{\pi^2}\sum_i \tilde\alpha_i^2 \ge \frac{4}{\pi^2}\cdot\frac16\big(\sum_i\tilde\alpha_i\big)^2 \ge \frac23$. To attain the bound on the sum take $u := \operatorname{diag}(e^{i\pi/6}, e^{-i\pi/6})$, $\mathbf{1}$ on t, $A_0 = B = u^{-1}$, $A_1 = C = u$ and $D = u^{-2}$: then $h_1 = h_3 = u^{-1}$, $h_2 = h_4 = h_5 = u$ and $h_6 = u^5$, so $w(h_i) = \cos\frac{\pi}{6} > 0$ for $i \le 5$ and $w(h_6) = \cos\frac{5\pi}{6} < 0$; the cube is a monopole, $\tilde\alpha_i = \frac{\pi}{6}$ at each face, and $\sum_p \vartheta_p = 2\pi$. □

Proposition 18.4 (The rarity of $\mathbb{Z}_2$ monopoles)**.** In the setting of Proposition 18.3, with its even sides, put $C_0 := (\frac{3\pi^3}{8})^3 e^{24}$.

(a) For $\beta \ge 1$ and any $r \ge 1$ distinct cubes $\mathsf{c}_1, \dots, \mathsf{c}_r$,

$$\mu^A(\mathsf{E}_{\mathsf{c}_1} \cap \cdots \cap \mathsf{E}_{\mathsf{c}_r}) \le \big(C_0\,\beta^{9/2}e^{-\beta/6}\big)^r,$$

and $(Z^A)^{1/|\Lambda|} \ge C_0^{-1}\beta^{-9/2}$; neither C_0 nor the exponents $\frac92$ and $\frac16$ involve the sides. In the coupling of the pair, $\beta^{9/2}e^{-\beta/6} = (\frac83)^{9/2}\beta_A^{9/2}e^{-4\beta_A/9}$. At every $\beta > 0$, $\mu^A(\mathsf{E}_{\mathsf{c}}) \le C_0 \max\{1,\beta\}^{9/2}e^{-\beta/6}$.

(b) For a given lattice, $\mu^A(\mathsf{E}_{\mathsf{c}}) \to \int \mathbf{1}_{\mathsf{E}_{\mathsf{c}}}\,d\tilde U > 0$ as $\beta \to 0$; hence no choice of C, c and $q > 0$ makes $\mu^A(\mathsf{E}_{\mathsf{c}}) \le C\beta^q e^{-c\beta}$ valid at all $\beta > 0$.

(c) On the lattice $\Lambda_{K,\ell}$ of the main text, $\ell = 2L^m$, which has $\ell/a_K = 2L^{m+K}$ sites on an axis, at $\beta = L^K\mathsf{b} \ge 1$, $\mathsf{b} > 0$, the expected number of monopoles, and with it the probability that at least one cube carries an odd number of faces on which $\operatorname{tr}\partial\tilde U(p)$ is negative, is at most

$$(\ell/a_K)^3\,C_0\,\beta^{9/2}\,e^{-\mathsf{b}/(6a_K)},$$

and the expected number per unit volume of T_ℓ is at most $a_K^{-3}C_0\beta^{9/2}e^{-\mathsf{b}/(6a_K)}$; as $K \to \infty$ both vanish, uniformly on compact sets of labels in $(0,\infty)$, the first also uniformly on bounded sets of sides.

■

Sketch of proof. Step 1: a lower bound for Z^A. Let $\beta \ge 1$ and $\varrho := \beta^{-1/2} \le 1$. If $\alpha(\tilde U(b)) \le \varrho$ at every bond, the subadditivity of the spherical distance (Step 4 of the proof of Proposition 18.3) gives $\alpha_p \le 4\varrho$, so $1 - w_p^2 = \sin^2\alpha_p \le 16\varrho^2$ and $W^A \ge e^{-\frac{\beta}{2}\cdot 16\varrho^2\cdot 3|\Lambda|} = e^{-24|\Lambda|}$; since α has the density $\frac{2}{\pi}\sin^2\alpha$ and $\sin\alpha \ge \frac{2}{\pi}\alpha$ on $[0,\frac{\pi}{2}]$, the Haar measure of $\{\alpha(u) \le \varrho\}$ is at least $\frac{8}{3\pi^3}\varrho^3$. Therefore $(Z^A)^{1/|\Lambda|} \ge (\frac{8}{3\pi^3})^3 e^{-24}\beta^{-9/2} = C_0^{-1}\beta^{-9/2}$.

Step 2: all cubes at once. Let F_{M} be the function on the configurations of the model cube that is 1 when w vanishes at none of its six faces and the signs of w at these faces multiply to -1, and 0 otherwise. The maps ρ_x of Proposition 18.1 (b) send faces to faces, and the value of w at a face does not depend on the corner or the sense in which the face is read; so $F_{\mathsf{M}}^{(x)} = \mathbf{1}_{\mathsf{E}_{\mathsf{c}_x}}$. On the event that all cubes are monopoles, Proposition 18.3 (c) at each cube, together with the two cubes bordering each plaquette, gives $2\sum_p(1-w_p^2) \ge \frac23|\Lambda|$, hence $W^A \le e^{-\beta|\Lambda|/6}$; thus $\langle\prod_x F_{\mathsf{M}}^{(x)}\rangle \le e^{-\beta|\Lambda|/6}$, where the bracket of Proposition 18.1 is formed with $\kappa(s) := e^{-\frac{\beta}{2}(1-s^2)}$, that is, with $k(u) = e^{-\frac{\beta}{2}(1-w(u)^2)}$, so that $\langle 1\rangle = Z^A$.

Step 3: clause (a). Proposition 18.1 (b) with $F_x := F_{\mathsf{M}}$ at the r cubes and $F_x := 1$ at all others yields $Z^A\mu^A(\bigcap_i \mathsf{E}_{\mathsf{c}_i}) \le e^{-\beta r/6}(Z^A)^{1-r/|\Lambda|}$, that is, $\mu^A(\bigcap_i \mathsf{E}_{\mathsf{c}_i}) \le (e^{-\beta/6}(Z^A)^{-1/|\Lambda|})^r \le (C_0\beta^{9/2}e^{-\beta/6})^r$ by Step 1. For $\beta < 1$ simply $\mu^A(\mathsf{E}_{\mathsf{c}}) \le 1 \le C_0e^{-1/6}$. The formula in β_A is the substitution $\beta = \frac83\beta_A$.

Step 4: clause (b). Since $e^{-\frac{3}{2}|\Lambda|\beta} \le W^A \le 1$, the quotient W^A/Z^A stays between $e^{-\frac{3}{2}|\Lambda|\beta}$ and $e^{\frac{3}{2}|\Lambda|\beta}$, so $|\mu^A(E) - \int \mathbf{1}_E \, d\tilde{U}| \le e^{\frac{3}{2}|\Lambda|\beta} - 1$ for every event E, which tends to 0 with β. The set $\mathsf{E_c}$ is open (Proposition 18.3 (b)) and contains the configuration of Proposition 18.3 (c), so it has positive Haar measure, whereas $C\beta^q e^{-c\beta} \to 0$.

Step 5: clause (c). The sides $2L^{m+K}$ of $\Lambda_{K,\ell}$ are even and $|\Lambda| = (\ell/a_K)^3$. By (a) the expected number of monopoles, $\sum_{\mathsf{c}} \mu^A(\mathsf{E_c})$, is at most $|\Lambda| \, C_0 \beta^{9/2} e^{-\beta/6}$, and by Markov's inequality it dominates the probability of at least one monopole; moreover $\beta/6 = \mathsf{b}/(6a_K)$, and off the null set $\mathcal{N}$ a cube is a monopole exactly when its faces with negative trace are odd in number. Division by the volume ℓ^3 of T_ℓ gives the density, and $L^{3K}(L^K\mathsf{b})^{9/2} e^{-L^K\mathsf{b}/6} \to 0$ uniformly on compact sets of labels. □

Proposition 18.5 (Sectors of the adjoint measure)**.** In the setting of Proposition 18.3, with its even sides $N_\mu \ge 2$, call a sign field $\eta \in \{\pm 1\}^{\mathrm{Pl}}$ closed if $\prod_{p \in \partial \mathsf{c}} \eta_p = 1$ at every cube, let $\mathcal{Z}^2$ be the set of closed sign fields and $\mathcal{B}^2 := \{\delta\gamma\}$. For $\{\lambda,\mu,\nu\} = \{1,2,3\}$, $\mu < \nu$, let the column C_λ be the set of the plaquettes $(x;\mu\nu)$ with $x_\mu = x_\nu = 0$, and let $\Phi_{\lambda,t}(\eta) := \prod_{x:\, x_\lambda = t} \eta_{(x;\mu\nu)}$ be the flux of η through the plane $x_\lambda = t$; for $n \in \{0,1\}^3$ let $\sigma^n_p := -1$ if $p \in \mathsf{C}_\lambda$ for a λ with $n_\lambda = 1$, and $\sigma^n_p := 1$ otherwise. For bounded Borel F put $Z^+[n;F] := \int F \prod_p \mathsf{h}_\beta(\sigma^n_p w_p)\, d\tilde{U}$ and $Z^+[n] := Z^+[n;1]$, and let $\mu^+_{\mathrm{mix}} := \sum_n Z^+[n;\,\cdot\,]/\sum_n Z^+[n]$, the mixture of the eight one-well weights $Z^+[n;\,\cdot\,]$.

(a) $|\mathcal{Z}^2| = 2^{2|\Lambda|+1}$ and $|\mathcal{B}^2| = 2^{2|\Lambda|-2}$. On closed fields the flux through $x_\lambda = t$ is the same for all t; call it $\Phi_\lambda(\eta)$. The map $\eta \mapsto (\Phi_\lambda(\eta))_{\lambda \le 3}$ from $\mathcal{Z}^2$ to $\{\pm1\}^3$ is a surjective homomorphism whose kernel is exactly $\mathcal{B}^2$, and $\Phi_\lambda(\sigma^n) = (-1)^{n_\lambda}$; hence each closed field lies in exactly one of the eight cosets $\sigma^n\mathcal{B}^2$.

(b) Let F be bounded, Borel and centre-blind. Then

$$\int F\, \mathbf{1}\{\text{no cube is a monopole}\}\, W^A \, d\tilde{U} = 2^{2|\Lambda|-2} \sum_{n \in \{0,1\}^3} Z^+[n;F],$$

and replacing σ^n in $Z^+[n;F]$ by another closed sign field with the same three fluxes leaves $Z^+[n;F]$ unchanged. Off $\mathcal{N}$ and where no cube is a monopole, let the sector $\mathsf{n}(\tilde{U}) \in \{0,1\}^3$ be given by $(-1)^{\mathsf{n}_\lambda} = \Phi_\lambda(\eta(\tilde{U}))$; it is a centre-blind function, and under μ^A the event that no cube is a monopole and $\mathsf{n} = n$ has the probability $2^{2|\Lambda|-2} Z^+[n]/Z^A$.

(c) Let $\varepsilon = \mu^A(\text{some cube is a monopole})$. For centre-blind F,

$$\mu^+_{\mathrm{mix}}(F) = \mu^A(F \mid \text{no monopole}), \qquad |\mu^A(F) - \mu^+_{\mathrm{mix}}(F)| \le 2\varepsilon \|F\|_\infty.$$

Centre-blind variables $X_1, \dots, X_r$ bounded by M have joint cumulants under μ^A and under μ^+_{mix} within $2\,\mathsf{fu}_r\, \mathsf{M}^r \varepsilon$ of each other. The mixture gives the class n the weight $\mu^A(\mathsf{n} = n \mid \text{no monopole}) = Z^+[n]/\sum_{n'} Z^+[n']$.

(d) On $\Lambda_{K,\ell}$ at $\beta = L^K\mathsf{b} \ge 1$, for real bounded $f_1, \dots, f_r$ on T_ℓ and the observables $\mathcal{O}^A(f_i) := a_K^{-1} \sum_p f_i(x(p)) \, \frac{3}{8} a_p = a_K^{-1} \sum_p f_i(x(p)) \, \frac{1}{2}(1 - w_p^2)$, $x(p)$ the barycentre of p, the joint cumulants of $\mathcal{O}^A(f_1), \dots, \mathcal{O}^A(f_r)$ under μ^A and under μ^+_{mix} differ by at most

$$2\,\mathsf{fu}_r \Big(\tfrac{3}{2} \ell^3 L^{4K} \max_i \|f_i\|_\infty \Big)^r \ell^3 L^{3K} \, C_0 \, (L^K\mathsf{b})^{9/2} \, e^{-L^K\mathsf{b}/6},$$

a quantity that tends to 0 as $K \to \infty$ with no condition on the supports of the f_i, uniformly on compact sets of labels and on bounded sets of sides.

■

Sketch of proof. Step 1: the complex of sign fields. Sign fields on the sites, bonds, plaquettes and cubes, written multiplicatively, are vector spaces $\mathcal{C}^0, \dots, \mathcal{C}^3$ over the field of two elements, of the dimensions $|\Lambda|$, $3|\Lambda|$, $3|\Lambda|$ and $|\Lambda|$, linked by $(\delta_0 g)_{(x,\mu)} := g_x g_{x+e_\mu}$, $\delta_1 := \delta$ and $(\delta_2\eta)_{\mathsf{c}} := \prod_{p \in \partial \mathsf{c}} \eta_p$. One has $\delta_1\delta_0 = 1$, and $\delta_2\delta_1 = 1$ since each edge of a cube borders exactly two of its faces; so $\mathcal{B}^2 \subset \mathcal{Z}^2 = \ker \delta_2$. The sign field equal to -1 at a single plaquette is sent by δ_2 to the field equal

to -1 at the two cubes bordering it; the cubes form a connected graph when cubes sharing a face are joined, and $\prod_{\mathsf{c}}(\delta_2\eta)_{\mathsf{c}} = \prod_p \eta_p^2 = 1$. Hence the range of δ_2 is the set of cube fields with an even number of entries -1, its rank is $|\Lambda|-1$, and $\dim \mathcal{Z}^2 = 2|\Lambda|+1$.

Step 2: the fluxes. Multiply the conditions $(\delta_2\eta)_{\mathsf{c}} = 1$ of a closed η over the layer of cubes c_x with $x_\lambda = t$: the faces containing the direction λ are each shared by two cubes of the layer, while every face lying in one of the planes $x_\lambda = t$ and $x_\lambda = t+1$, distinct since $N_\lambda \geq 2$, belongs to one cube of the layer; so $\Phi_{\lambda,t}(\eta) = \Phi_{\lambda,t+1}(\eta)$. Each bond of the plane $x_\lambda = t$ is shared by exactly two plaquettes of that plane, so $\Phi_\lambda(\delta\gamma) = 1$; every cube meets the column C_λ in none or two of its faces, so σ^n is closed; and the plane $x_\lambda = t$ contains one plaquette of C_λ and no plaquette of the two other columns, so $\Phi_\lambda(\sigma^n) = (-1)^{n_\lambda}$. Therefore Φ is onto $\{\pm1\}^3$, $\mathcal{B}^2 \subset \ker\Phi$, and $\dim\ker\Phi = 2|\Lambda| - 2$. For $\eta = \eta(\tilde U)$, $\Phi_{\lambda,t}$ is the product of the central parts over the plane $x_\lambda = t$, which is the plane number of Proposition 9.33 (i), and $\Phi(\eta(\tilde U))$ is the sector of Lemma 9.11 (iv), here available at every configuration without monopoles.

Step 3: $\mathcal{B}^2 = \ker\Phi$. With coordinates in $\{0,\dots,N_\mu - 1\}$ let t consist of the bonds $(x,1)$ with $x_1 \leq N_1 - 2$, the bonds $(x,2)$ with $x_1 = 0$ and $x_2 \leq N_2 - 2$, and the bonds $(x,3)$ with $x_1 = x_2 = 0$ and $x_3 \leq N_3 - 2$, a spanning tree with $|\Lambda| - 1$ bonds. Any $\gamma \in \ker\delta_1$ is the product of some $\delta_0 g$, g constructed along t, with an element of $\ker\delta_1$ that is 1 on t; and $\dim\operatorname{im}\delta_0 = |\Lambda| - 1$ as the lattice is connected. An element γ of $\ker\delta_1$ that equals 1 on t is determined by three signs: the plaquettes $(x;1\nu)$ with $x_1 \leq N_1 - 2$ force γ on the bonds of the directions 2 and 3 to be independent of x_1; the plaquettes $(x;23)$ with $x_2 \leq N_2 - 2$ then force γ on the bonds of the direction 3 to depend on x_3 only, hence to be 1 except at $x_3 = N_3 - 1$, where it takes one value ϵ_3; the plaquettes $(x;23)$ with $x_2 = N_2 - 1$ force γ to take one value ϵ_2 on the bonds $(x,2)$ with $x_2 = N_2 - 1$, it being 1 on the other bonds of the direction 2; and the plaquettes $(x;1\nu)$ with $x_1 = N_1 - 1$ force one value ϵ_1 on the bonds $(x,1)$ with $x_1 = N_1 - 1$. So $\dim\ker\delta_1 \leq |\Lambda| + 2$, $\dim\mathcal{B}^2 = 3|\Lambda| - \dim\ker\delta_1 \geq 2|\Lambda| - 2 = \dim\ker\Phi$, and $\mathcal{B}^2 = \ker\Phi$, which is (a).

Step 4: clause (b). By Proposition 18.3 (a), off $\mathcal{N}$ the product $\mathbf{1}\{\text{no monopole}\}\,W^A$ equals $\sum_{\eta\in\mathcal{Z}^2}\prod_p \mathsf{h}_\beta(\eta_p w_p)$, the only possibly non-zero term being that of $\eta(\tilde U)$, and $\eta(\tilde U)$ is closed exactly when there is no monopole. By (a), each $\eta \in \mathcal{Z}^2$ has the form $\sigma^n\delta\gamma$ for a unique n, and each coset has $2^{2|\Lambda|-2}$ elements. For $\eta = \sigma^n\delta\gamma$ the change of variables $\tilde U = \gamma\tilde U'$ preserves $d\tilde U$ and the centre-blind F and turns $\eta_p w_p(\tilde U)$ into $\sigma_p^n w_p(\tilde U')$; hence $\int F\prod_p \mathsf{h}_\beta(\eta_p w_p)\,d\tilde U = Z^+[n;F]$, and the sum over η gives the identity. The same change of variables shows that only the coset of σ^n matters. Since $\Phi_\lambda(\eta(\gamma\tilde U)) = \Phi_\lambda(\eta(\tilde U))\Phi_\lambda(\delta\gamma) = \Phi_\lambda(\eta(\tilde U))$, the sector is centre-blind; where $\prod_p \mathsf{h}_\beta(\sigma_p^{n'} w_p) \neq 0$ one has $\eta(\tilde U) = \sigma^{n'}$ and $\mathsf{n} = n'$; and the identity applied to $F = \mathbf{1}\{\mathsf{n} = n\}$, extended by 0 at monopoles and on $\mathcal{N}$, gives the probability of the sector.

Step 5: clause (c). Let A be the event without monopoles. Applying (b) to F and to 1 gives $\mu^A(F\mathbf{1}_{\mathsf{A}})/\mu^A(\mathsf{A}) = \mu^+_{\mathrm{mix}}(F)$. From $\mu^A(F) - \mu^A(F \mid \mathsf{A}) = \mu^A(F\mathbf{1}_{\mathsf{A}^c}) - \mu^A(F\mathbf{1}_{\mathsf{A}})\,\mu^A(\mathsf{A}^c)/\mu^A(\mathsf{A})$ the difference is at most $2\varepsilon\|F\|_\infty$, and similarly $|\mu^A(E) - \mu^A(E \mid \mathsf{A})| \leq \varepsilon$ at every event E; so Proposition 18.1 (c), on the centre-blind functions, bounds the change of the cumulants. The weights of the classes follow from (b) at $F = \mathbf{1}\{\mathsf{n} = n\}$.

Step 6: clause (d). Each $\mathcal{O}^A(f)$ is centre-blind, and $|\mathcal{O}^A(f)| \leq a_K^{-1}\cdot 3|\Lambda|\cdot\frac12\|f\|_\infty = \frac32\ell^3L^{4K}\|f\|_\infty$ because $|\Lambda| = \ell^3L^{3K}$; inserting $\varepsilon \leq \ell^3L^{3K}C_0(L^K\mathsf{b})^{9/2}e^{-L^K\mathsf{b}/6}$ from Proposition 18.4 (c) into (c) gives the display, whose exponential factor beats every power of L^K uniformly on compact sets of labels. For the joint cumulants of the plaquette observables the Wilson measure of $SO(3)$ may thus be traded for the mixture of the eight one-well weights, at this rate. □

Lattices of every dimension. In Propositions 18.6 to 18.8 let $d \geq 2$, $a > 0$, and let G be a compact metrisable group. Let $\mathcal{V} = \mathcal{V}(a\mathbb{Z}^d)$ be the product space of G-valued configurations on nearest-neighbour bonds. A reversed bond carries the inverse of its forward value. An isometry r acts by $(\mathsf{r}U)_b = U_{\mathsf{r}^{-1}b}$ and $(\mathsf{r}F)(U) = F(\mathsf{r}^{-1}U)$. In particular τ_x is translation by $x \in a\mathbb{Z}^d$. For

$S \subset \mathbb{R}^d$, $\mathsf{Bd}(S)$ consists of the bonds contained in S as closed segments. Write $\mathcal{F}(B)$ for the bounded complex Borel functions depending only on bonds in the finite set B, and $\mathcal{F}_{\mathrm{loc}}(S)$ for their union over finite $B \subset \mathsf{Bd}(S)$.

A mirror $\Sigma(n,c)$ is the plane $n \cdot x = c$ with reflection $\theta_{n,c}$ and closed sides $\mathbb{H}^{\pm}(n,c) = \{x : \pm(n \cdot x - c) \geq 0\}$. The normals are $\pm e_\mu$ with $c \in (a/2)\mathbb{Z}$, and $\pm(e_\mu + s e_\lambda)$ with $s = \pm 1$, $\mu \neq \lambda$ and $c \in a\mathbb{Z}$. For a coordinate normal the mirror is a site mirror when $c \in a\mathbb{Z}$, and a bond mirror otherwise. There are d coordinate and $d(d-1)$ diagonal families. Reflection positivity at a mirror means $\nu(\overline{\theta_{n,c}F}F) \geq 0$ for $F \in \mathcal{F}_{\mathrm{loc}}(\mathbb{H}^+(n,c))$.

For an inward normal lattice vector v assume invariance under translations and the mirror reflection, and reflection positivity both at $\Sigma(n,c)$ and at $\Sigma(n, c+n\cdot v/2)$. The picture (n,c,v) is the Hilbert space obtained by completing $\mathcal{F}_{\mathrm{loc}}(\mathbb{H}^+(n,c))$ for the inner product $\langle [F],[G]\rangle = \nu(\overline{\theta_{n,c}F}G)$ after quotienting the null space. Reflection invariance gives $\|[F]\|^2 \leq \nu(|F|^2)$. On local functions the normal translation is symmetric for this form and reflection Cauchy–Schwarz gives $\|[\tau_v F]\|^2 \leq \|[F]\|\|[\tau_{2v}F]\|$. Iterating this inequality and using $\|[\tau_{2^k v}F]\| \leq \|F\|_\infty$ shows $\|[\tau_v F]\| \leq \|[F]\|$, including when $[F]=0$. Thus $T[F] = [\tau_v F]$ is a self-adjoint contraction. Reflection positivity at the half-way mirror applied to $\tau_v F$ gives $\langle [F], T[F]\rangle \geq 0$. Tangential lattice translations w preserve the form, and their inverses are also tangential. They give commuting unitaries $V(w)[F] = [\tau_w F]$ that commute with T. In a coordinate picture $(e_\mu, c, a e_\mu)$ the joint spectral theorem gives the projection-valued measure $\mathfrak{E}$ on $[0,1]\times(S^1)^{d-1}$ with

$$T^k V(ay) = \int t^k \zeta^y \, d\mathfrak{E}(t,\zeta) \qquad (k \geq 0,\ y \in \mathbb{Z}^d,\ y_\mu = 0).$$

The diagonal picture uses $v = an$. The same construction in dimension three is Lemma YM3_I: 99.1. W_d is the group of signed permutations of the coordinates, $\theta_\mu := \theta_{e_\mu,0}$, S_{2^d} the group of the 2^d sign changes, generated by the θ_μ, $\mathcal{I}$ the σ-field of the translation invariant Borel sets, and $Q_r := [-ra, ra]^d$ for an integer $r \geq 1$. In the site picture $(e_\mu, 0)$ the cube vector of $A \in \mathcal{F}(\mathsf{Bd}(Q_r))$ is $\psi^\mu_A := [\tau_{rae_\mu} A]$; its reflection size is $\mathcal{N}_r(A) := \max_\mu \max_{\mathsf{g}\in\mathsf{S}_{2^d}} \|\psi^\mu_{\mathsf{g}A}\|^2$, and $\mathcal{N}'_{r,\mu}(A) := \max\{\|\psi^\mu_A\|^2, \max_{\lambda\neq\mu}\|\psi^\lambda_{\theta_\lambda A}\|\,\|\psi^\lambda_A\|\}$, as in YM3_I:(1959). A Borel probability measure ν on $\mathcal{V}$ is said to have (Mir) if it is invariant under the translations of $a\mathbb{Z}^d$, reflection positive at $\Sigma(e_\mu,0)$ and at $\Sigma(e_\mu, \frac{a}{2})$ for $\mu = 1,\dots,d$, and, for every pair $\mu<\lambda$, reflection positive at some mirror $\Sigma(e_\mu + s e_\lambda, c)$ with $s=\pm1$ and $c \in a\mathbb{Z}$.

Proposition 18.6 (A spectral inequality from one diagonal mirror, in dimension d)**.** Fix two different directions μ,λ and a sign $\epsilon \in \{1,-1\}$, and let ν be a Borel probability measure on $\mathcal{V}(a\mathbb{Z}^d)$, Gibbs state or not, which does not change under the translations of $a\mathbb{Z}^d$ and is reflection positive at $\Sigma(e_\mu,0)$, at $\Sigma(e_\mu,\frac{a}{2})$ and at the diagonal mirror $\Sigma(e_\mu + \epsilon e_\lambda, 0)$.

(a) The reflection positivity of ν extends to all mirrors $\Sigma(e_\mu, c)$, $c \in \frac{a}{2}\mathbb{Z}$, and $\Sigma(e_\mu + \epsilon e_\lambda, c)$, $c \in a\mathbb{Z}$, and ν is invariant under their reflections; in particular ν has the picture (e_μ, c_0) for each $c_0 \in \frac{a}{2}\mathbb{Z}$.

(b) In each picture (e_μ, c_0),

$$(1-T)^2 \ \geq\ T\big(2 - V(ae_\lambda) - V(ae_\lambda)^*\big),$$

which is the same as $\mathfrak{E}(\{(t,\zeta) : (1-t)^2 < t\,|1-\zeta_\lambda|^2\}) = 0$; moreover $\mathfrak{E}$ lives on $\{t \leq e^{-\mathsf{k}|\arg\zeta_\lambda|}\}$, $\mathsf{k} = \frac{2}{\pi}\log(1+\sqrt{2})$.

(c) If ν has (Mir), its symmetry group contains $a\mathbb{Z}^d \rtimes W_d$ and it is reflection positive at all lattice mirrors of $a\mathbb{Z}^d$, for the functions of the bonds of either closed side; in each picture (e_μ, c_0) the inequality of (b) holds for all $d-1$ directions $\lambda \neq \mu$, and $\mathfrak{E}$ lives on

$$\mathcal{C}_\mu := \{(t,\zeta) : (1-t)^2 \geq t\,|1-\zeta_\lambda|^2 \text{ for all } \lambda \neq \mu\};$$

writing a point of $\mathcal{C}_\mu$ with $t > 0$ as $t = e^{-x}$ and $\zeta_\lambda = e^{i\alpha_\lambda}$, $\alpha_\lambda \in (-\pi, \pi]$, one has $x \geq \mathsf{k} \max_{\lambda \neq \mu} |\alpha_\lambda|$.

■

Sketch of proof. Step 1: invariance from positivity. (i) Reflection positivity at $\Sigma(n, c)$ and at $\Sigma(-n, -c)$ are the same condition: for F on $\mathbb{H}^-(n, c)$, $G := \theta_{n,c} F$ is a function on $\mathbb{H}^+(n, c)$, and $\nu(\overline{\theta F} F) = \overline{\nu(\overline{\theta G} G)}$. (ii) If ν is reflection positive at a lattice mirror and invariant under an isometry r, then it is reflection positive at the image of the mirror under r. (iii) At a site or diagonal mirror, $n \cdot x$ moves by 0 or $\pm a$ along a bond and lies in $c + a\mathbb{Z}$ at sites, so each bond is contained in one of the two closed sides; since a positive form is Hermitian, $\nu(\theta F \cdot F') = \nu(\theta F' \cdot F)$ for F, F' on $\mathbb{H}^+$, that is, $\nu(\theta\Phi) = \nu(\Phi)$ for $\Phi = F' \cdot \theta F$; the indicator of a set given by conditions $U_b \in E_b$ at finitely many bonds b, with Borel sets $E_b \subset G$, is of this form: the conditions at the bonds contained in $\mathbb{H}^+$ give F', and those at the other bonds, which are contained in $\mathbb{H}^- = \theta_{n,c}\mathbb{H}^+$, give θF; these sets form a family stable under intersections that generates the Borel σ-field, as the coordinates generate it, so ν and its image under $\theta_{n,c}$, which agree on this family, agree on all Borel sets, and ν is invariant under $\theta_{n,c}$. Applying (ii) to the translations τ_{kae_μ} moves $\Sigma(e_\mu, 0)$ and $\Sigma(e_\mu, \frac{a}{2})$ onto all $\Sigma(e_\mu, c)$, $c \in \frac{a}{2}\mathbb{Z}$, and $\Sigma(e_\mu + \epsilon e_\lambda, 0)$ onto all $\Sigma(e_\mu + \epsilon e_\lambda, c)$, $c \in a\mathbb{Z}$, since $(e_\mu + \epsilon e_\lambda) \cdot kae_\mu = ka$; the reflection in a bond mirror is a site reflection composed with a translation. The half-way mirror of the picture $(e_\mu, c_0) = (e_\mu, c_0, ae_\mu)$ is $\Sigma(e_\mu, c_0 + \frac{a}{2})$. This gives (a).

Step 2: two pictures. By the construction of the pictures, the transfer operator of the picture (e_μ, c_0) satisfies $0 \leq T \leq 1$, the tangential unitaries $V(v')$, $v' \perp e_\mu$, commute with T, and $\langle [F], T^k V(v')[F'] \rangle = \nu(\overline{\theta_{e_\mu,c_0} F}\, \tau_{kae_\mu + v'} F')$. The same is true in the picture (n, c, an) of the diagonal normal $n := e_\mu + \epsilon e_\lambda$, $c \in a\mathbb{Z}$, whose half-way mirror is $\Sigma(n, c + a)$; call its transfer operator $T_\parallel$, and $V_\perp := V(an^\perp)$ with $n^\perp := e_\mu - \epsilon e_\lambda$.

Step 3: a lemma on the closed disc. Suppose η is a finite positive Borel measure on $\overline{\mathbb{D}}$ and $C \geq 0$ is such that $\int |\mathfrak{q}|^2 d\eta \leq C \sup_{[0,1]} |\mathfrak{q}| \sup_{S^1} |\mathfrak{q}|$ for all polynomials $\mathfrak{q}$. Then η gives no mass to $\{z : |1+z|^2 < 4|z|\}$ (Lemma YM3_I:99.2). To see this, write $\operatorname{Log} \frac{1+\zeta}{1-\zeta} = x + i\phi$ with $|\phi| < \frac{\pi}{2}$ for $\zeta \in \mathbb{D}$, an odd function of ζ. For $s > 0$ the function $\cos(s(x + i\phi))$ is even in ζ, so $\cos(s(x + i\phi)) = g_s(\zeta^2)$ for a function g_s holomorphic in the disc, and $|g_s|^2 = \cos^2(sx) + \sinh^2(s\phi)$ is at least $\sinh^2(s\phi)$ and at most $\cosh^2 \frac{s\pi}{2}$, while $|g_s| \leq 1$ on $[0, 1)$, where ζ is real. In the variable $z = \zeta^2$, $\tan|\phi| = \sqrt{2(|z| - \operatorname{Re} z)}/(1 - |z|)$, so $|\phi| > \frac{\pi}{4}$ if and only if $|1 + z|^2 < 4|z|$. The assumed inequality extends to $z \mapsto g_s(\varrho z)$, $0 < \varrho < 1$, which are uniform limits of polynomials on $\overline{\mathbb{D}}$, and Fatou's lemma as $\varrho \to 1$ yields $\int \sinh^2(s\Phi)\, d\eta \leq C \cosh \frac{s\pi}{2}$, with Φ the function $|\phi|$ of z, set equal to $\frac{\pi}{2}$ on $S^1 \setminus \{1\}$ and to 0 at 1, so that $\liminf_{\varrho \to 1} |g_s(\varrho z)|^2 \geq \sinh^2(s\Phi(z))$ at every $z \in \overline{\mathbb{D}}$, Φ being continuous on $\overline{\mathbb{D}} \setminus \{1\}$. Hence $\eta(\{\Phi \geq \frac{\pi}{4} + \delta\}) \leq C \cosh(\frac{s\pi}{2}) / \sinh^2(s(\frac{\pi}{4} + \delta))$, which vanishes as $s \to \infty$, for each $\delta > 0$; as $\delta \downarrow 0$ these sets exhaust $\{z : |1 + z|^2 < 4|z|\}$, which contains $S^1 \setminus \{1\}$, where $\Phi = \frac{\pi}{2}$, but not the point 1.

Step 4: the inequality. Let $F \in \mathcal{F}_{\mathrm{loc}}(\mathbb{H}^+(e_\mu, c_0))$, $\psi := [F]$, $\varrho_\psi := \langle \psi, \mathfrak{E}(\cdot)\psi \rangle$, and let ς be the image of ϱ_ψ under $(t, \zeta) \mapsto z := t\zeta_\lambda^\epsilon \in \overline{\mathbb{D}}$. For a polynomial $\mathfrak{q} = \sum_k \mathfrak{q}_k z^k$ and an integer $N \geq 0$, as $(k + l)e_\mu + \epsilon(k - l)e_\lambda = kn + ln^\perp$,

$$\int |\mathfrak{q}|^2 |z|^{2N}\, d\varsigma = \sum_{k,l} \mathfrak{q}_k \bar{\mathfrak{q}}_l\, \nu\big(\overline{\theta_{e_\mu,c_0} F}\, \tau_{kan + lan^\perp} \tau_{2Nae_\mu} F\big).$$

Choose $c \in a\mathbb{Z}$ with $c \geq n \cdot x$ at the end points of the bonds on which $\theta_{e_\mu,c_0} F$ depends, and N with $n \cdot x + 2Na \geq c$ at those of the bonds on which F depends; then $F_1 := \theta_{n,c}\theta_{e_\mu,c_0} F$ and $F_2 := \tau_{2Nae_\mu} F$ are functions of the bonds of $\mathbb{H}^+(n, c)$, $\theta_{n,c} F_1 = \theta_{e_\mu,c_0} F$, and in the picture (n, c, an) the sum equals

$\langle [F_1], \mathfrak{q}(T_\parallel)\bar{\mathfrak{q}}(V_\perp)[F_2]\rangle$, $\bar{\mathfrak{q}}(z) := \sum_l \bar{\mathfrak{q}}_l z^l$. As $0 \le T_\parallel \le 1$, $V_\perp$ is unitary and $\|[F_i]\| \le \|F\|_\infty$,

$$\int |\mathfrak{q}|^2 |z|^{2N}\, d\varsigma \le \|F\|_\infty^2 \sup_{[0,1]} |\mathfrak{q}| \sup_{S^1} |\mathfrak{q}|.$$

Step 3 applied to $|z|^{2N}\varsigma$ gives $\varsigma(\{|1+z|^2 < 4|z|\}) = 0$, the point 0 not lying in this set. At $z = t\zeta_\lambda^\epsilon$, $|1+z|^2 - 4|z| = (1-t)^2 - t|1-\zeta_\lambda|^2$; so $\mathfrak{E}(\{(1-t)^2 < t|1-\zeta_\lambda|^2\})[F] = 0$ for all F, the classes $[F]$ are dense, and the spectral form of the inequality follows; it is equivalent to $(1-T)^2 - T(2 - V(ae_\lambda) - V(ae_\lambda)^*) \ge 0$. For $d = 3$ this is Proposition YM3_I:99.3, whose argument involves two directions only.

Step 5: the chord. Put $t = e^{-x}$ and $\zeta_\lambda = e^{i\alpha_\lambda}$; then $(1-t)^2 - t|1-\zeta_\lambda|^2 = 4t(\sinh^2\frac{x}{2} - \sin^2\frac{\alpha_\lambda}{2})$. The function $\alpha \mapsto 2\,\mathrm{arsinh}(\sin\frac{\alpha}{2})$ is zero at 0 and concave on $[0,\pi]$, since its derivative $\cos\frac{\alpha}{2}\,(1 + \sin^2\frac{\alpha}{2})^{-1/2}$ decreases; a concave function vanishing at 0 dominates its secant through the point at π, here $\alpha \mapsto \frac{\alpha}{\pi}\,2\,\mathrm{arsinh}\,1 = \mathsf{k}\alpha$. So $x \ge \mathsf{k}|\alpha_\lambda|$ wherever $\mathfrak{E}$ lives.

Step 6: clause (c). Under (Mir), Step 1 gives positivity at all coordinate mirrors and invariance under the θ_μ, which generate S_{2^d}. In each plane (μ,λ) translations move the given diagonal mirror $\Sigma(e_\mu + se_\lambda, c)$ to all offsets in $a\mathbb{Z}$; the reflection $\theta_{e_\mu + se_\lambda, 0}$, which leaves ν invariant, sends e_μ to $-se_\lambda$ and e_λ to $-se_\mu$, and composed with sign changes it exchanges the two coordinates; transpositions and sign changes generate W_d. Since θ_λ maps $\Sigma(e_\mu + se_\lambda, c)$ onto $\Sigma(e_\mu - se_\lambda, c)$, (ii) yields the other diagonal family of the plane, and (i) both closed sides. Now (b) applies to every ordered pair of directions, and finitely many null sets have a null union. □

Proposition 18.7 (Decay of correlations like $(ra/|x|)^{d-2}$, and optimality of the exponent)**.** Let $d \ge 3$, and let ν be a Borel probability measure on $\mathcal{V}(a\mathbb{Z}^d)$ with (Mir); ν need not be a Gibbs state. Use the function Ψ constructed in Step 2 below, $\mathsf{c}_\Psi = (1+\sqrt{2})^{-1}$ and the chord constant k of Proposition 18.6. Put $D := d-1$,

$$\mathsf{s}_d := \int_0^\infty (5+9s)^D e^{-s}\, ds = \sum_{i=0}^{D} \binom{D}{i} 5^{D-i} 9^i\, i!, \qquad \mathsf{C}'_d := \frac{8\,D\,(D-2)!\,\mathsf{s}_d}{\mathsf{c}_\Psi\,(\pi\mathsf{k})^D}, \qquad C_d := 2D\,\mathsf{C}'_d\,(2\sqrt{d})^{d-2}, \qquad c_d := 4\sqrt{d},$$

numbers determined by d. Let $r \ge 1$ be an integer and $A, B \in \mathcal{F}(\mathsf{Bd}(Q_r))$, bounded Borel functions of finitely many bonds of Q_r.

(a) In the site picture of e_μ let Π_0 denote the projection on $\ker(1-T)$. Then $\Pi_0 = \mathfrak{E}(\{(1,1,\dots,1)\})$, $T^n \to \Pi_0$ strongly, $V(v')\Pi_0 = \Pi_0$, the vectors of $L^2(\nu)$ fixed by τ_{ae_μ} are those fixed by all of $a\mathbb{Z}^d$, $\langle \psi^\mu_{\theta_\mu A}, \Pi_0 \psi^\mu_B\rangle = \nu(\overline{E_\nu[A|\mathcal{I}]}\,E_\nu[B|\mathcal{I}])$, and, for every integer $n \ge 1$,

$$0 \le \langle \psi^\mu_A, T^n(1-\Pi_0)\psi^\mu_A\rangle \le 4\,\mathsf{C}'_d\,\mathcal{N}_r(A)\Big[(D-1)\Big(\frac{r}{n}\Big)^D + \frac{1}{2}\Big(\frac{r}{n}\Big)^{D-1}\Big].$$

(b) Let $x \in a\mathbb{Z}^d$ and $n := |x|_\infty/a - 2r \ge 1$. Then

$$\Big|\nu(\bar{A}\,\tau_x B) - \nu(\overline{E_\nu[A|\mathcal{I}]}\,E_\nu[B|\mathcal{I}])\Big| \le 4\,\mathsf{C}'_d\,\mathcal{N}_r(A)^{1/2}\mathcal{N}_r(B)^{1/2}\Big[(D-1)\Big(\frac{r}{n}\Big)^D + \frac{1}{2}\Big(\frac{r}{n}\Big)^{D-1}\Big].$$

(c) If $x \in a\mathbb{Z}^d$ and $|x| \ge c_d\, ra$, then

$$\Big|\nu(\bar{A}\,\tau_x B) - \nu(\overline{E_\nu[A|\mathcal{I}]}\,E_\nu[B|\mathcal{I}])\Big| \le C_d\,\mathcal{N}_r(A)^{1/2}\mathcal{N}_r(B)^{1/2}\Big(\frac{ra}{|x|}\Big)^{d-2} \le C_d\,\|A\|_\infty\|B\|_\infty\Big(\frac{ra}{|x|}\Big)^{d-2},$$

and for ergodic ν the subtracted term equals $\nu(\bar{A})\nu(B)$. The numbers c_d and C_d are independent of G, a, ν, r, A, B and x; $C_3 < 4.8\cdot 10^4$ and $C_4 < 7.8\cdot 10^6$.

(d) If some $g_0 \ne e$ in G satisfies $g_0^2 = e$, no larger exponent is possible: for some ergodic ν on $\mathcal{V}(\mathbb{Z}^d)$ with (Mir), some real $A \in \mathcal{F}(\mathsf{Bd}(Q_1))$ with $|A| \le 1$ and $\nu(A) = 0$, and some number $c > 0$, one has $\nu(A\,\tau_x A) \ge c\,|x|^{-(d-2)}$ at every $x \in \mathbb{Z}^d \setminus \{0\}$.

■

Sketch of proof. Step 1: the projection at $t=1$. By Proposition 18.6 (c), ν is invariant under $a\mathbb{Z}^d \rtimes W_d$ and reflection positive at all lattice mirrors, and in the site picture of e_μ, $\mathfrak{E}$ lives on $\mathcal{C}_\mu$, where $t=1$ only if every $\zeta_\lambda = 1$; hence $\Pi_0 = \mathfrak{E}(\{t=1\})$ equals $\mathfrak{E}(\{(1,1,\dots,1)\})$, $V(v')\Pi_0 = \Pi_0$, and $T^n \to \Pi_0$ strongly by bounded convergence of t^n to $\mathbf{1}\{t=1\}$. For $A, B \in \mathcal{F}(\mathsf{Bd}(Q_r))$ and $x \in a\mathbb{Z}^d$ with $x_\mu \geq 2ra$, $x_\perp := x - x_\mu e_\mu$, the definitions of the picture and the invariance under τ_x give (translate both entries by rae_μ in the reflection form)

$$\nu(\bar{A}\,\tau_x B) = \langle \psi^\mu_{\theta_\mu A}, T^{x_\mu/a-2r} V(x_\perp)\psi^\mu_B\rangle, \qquad \nu(\bar{A}\,\tau_{-x}B) = \overline{\nu(\bar{B}\,\tau_x A)}.$$

Letting $k\to\infty$, $\nu(\bar{A}\,\tau_{kae_\mu+y}B) \to \langle \psi^\mu_{\theta_\mu A}, \Pi_0 \psi^\mu_B\rangle$ for $y \perp e_\mu$; the ergodic theorem of von Neumann for the unitary τ_{ae_μ} of $L^2(\nu)$ identifies the limit of the Cesàro means with $\langle A, \mathsf{P}_\mu \tau_y B\rangle_{L^2(\nu)}$, P_μ projecting on the vectors fixed by τ_{ae_μ}. The limit is the same for every $y \perp e_\mu$, and local functions are dense in $L^2(\nu)$; so $\mathsf{P}_\mu \tau_y = \mathsf{P}_\mu$, the range of P_μ is invariant under all of $a\mathbb{Z}^d$, P_μ coincides with the projection $E_\nu[\,\cdot\,|\mathcal{I}]$ on the invariant vectors by the characterization of conditional expectation as an orthogonal projection, and $\langle \psi^\mu_{\theta_\mu A}, \Pi_0 \psi^\mu_B\rangle = \nu(\overline{E_\nu[A|\mathcal{I}]}\, E_\nu[B|\mathcal{I}])$.

Step 2: the kernel. Let z_m be the even period-four sequence with $(z_0,z_1,z_2,z_3) = (0,1,-2,1)$. Let $\mathsf{B}(u) = 8(1-4|u|/\pi)_+$ on $[-\pi,\pi]$, extended periodically. Its Fourier coefficients are $b_0 = 1$ and $b_m = (8\sin(m\pi/8)/(m\pi))^2$ for $m \neq 0$. Put $\gamma_m = z_m b_m$ and

$$\mathsf{B}_z(u) = \sum_{m\in\mathbb{Z}} \gamma_m e^{imu}, \qquad \Psi(t) = 2\sum_{m\geq 1} \gamma_m t^{m-1} \quad (0 \leq t \leq 1),$$

with $0^0 = 1$. The series converge absolutely. The scalar calculation of Lemma YM3_I:99.5 gives $\gamma_0 = 0$, $\gamma_{-m} = \gamma_m$, $\sum_m |\gamma_m| = 8$, $|\mathsf{B}_z| \leq 8$, $\mathsf{B}_z(u) = 0$ whenever $\operatorname{dist}(u, 2\pi\mathbb{Z}) \leq \frac{\pi}{4}$, $0 \leq \Psi \leq 8$, $\Psi(1) = 0$, and $\Psi(e^{-x}) \geq \mathsf{c}_\Psi \tanh x$ for $x > 0$.

Step 3: the density in the momenta. Let $\Phi \in \mathcal{F}(\mathsf{Bd}(Q_r))$ satisfy $\theta_\mu \Phi = \epsilon\Phi$, $\epsilon = \pm 1$; put $\psi := \psi^\mu_\Phi$ and $\varrho_\psi := \langle \psi, \mathfrak{E}(\cdot)\psi\rangle$ in the site picture of e_μ, and let $\tilde{\varrho}_\psi$ be the image on $(S^1)^D$, under $(t,\zeta) \mapsto \zeta$, of $\Psi(t^{2r})\, d\varrho_\psi$, a positive measure of total mass at most $8\|\psi\|^2$. With $K(x) := \nu(\bar{\Phi}\,\tau_x\Phi)$ one has $K(-x) = \overline{K(x)}$, K is unchanged under the linear part of θ_μ because ν is invariant under θ_μ and $\theta_\mu\Phi = \epsilon\Phi$, and Step 1 gives $\langle \psi, T^j V(ay)\psi\rangle = \epsilon K((j+2r)ae_\mu + ay)$ for $j \geq 0$ and $y \in \mathbb{Z}^d$ with $y_\mu = 0$. Hence $\tilde{\varrho}_\psi$ has the Fourier coefficients

$$c(y) = 2\sum_{m\geq 1} \gamma_m \langle \psi, T^{2r(m-1)} V(ay)\psi\rangle = \epsilon \sum_{m\in\mathbb{Z}} \gamma_m K(2rmae_\mu + ay),$$

and $|c(y)| \leq 8\|\psi\|^2$. For $|y|_\infty \geq 2r$ pick λ with $|y_\lambda| = |y|_\infty$; as $c(-y) = \overline{c(y)}$ we may let $y_\lambda > 0$. With $y' := y - y_\lambda e_\lambda$ and $n' := y_\lambda - 2r$, Step 1 in the site picture of e_λ gives

$$\epsilon\, c(y) = \Big\langle \psi^\lambda_{\theta_\lambda\Phi}, \int t^{n'} \zeta^{y'}\, \mathsf{B}_z(2ru)\, d\mathfrak{E}_\lambda(t,\zeta)\, \psi^\lambda_\Phi \Big\rangle, \qquad \zeta_\mu = e^{iu},\ u \in (-\pi,\pi].$$

If $\mathsf{B}_z(2ru) \neq 0$, then $|u| > \frac{\pi}{8r}$ and $|\sin\frac{u}{2}| \geq \frac{1}{8r}$; on $\mathcal{C}_\lambda$ (Proposition 18.6 (c)) every point with $t > 0$ then has $t = e^{-x}$ and $\sinh\frac{x}{2} \geq \frac{1}{8r}$, whence $x \geq 2\log(1+\frac{1}{8r}) \geq \frac{2}{9r}$ and $|c(y)| \leq 8e^{-2(|y|_\infty - 2r)/(9r)} \|\psi^\lambda_{\theta_\lambda\Phi}\|\, \|\psi^\lambda_\Phi\|$. Summation by parts over the shells $|y|_\infty = k$ of $\mathbb{Z}^D$, together with $4r + 2i + 1 \leq r(5 + 9\beta' i)$ for $\beta' := \frac{2}{9r}$, gives $\sum_y |c(y)| \leq 8\,\mathsf{s}_d\, r^D\, \mathcal{N}'_{r,\mu}(\Phi)$. Therefore $\tilde{\varrho}_\psi = h\, d\alpha$ on $(-\pi,\pi]^D$ with the continuous function $h(e^{i\alpha}) = (2\pi)^{-D}\sum_y c(y) e^{-iy\cdot\alpha}$, and

$$0 \leq h \leq 8\,(2\pi)^{-D}\, \mathsf{s}_d\, r^D\, \mathcal{N}'_{r,\mu}(\Phi).$$

For $d = 3$ this is Lemma YM3_I:99.6; only the number of circles and the sums over the shells are different.

Step 4: clause (a). For A with $\theta_\mu A = \epsilon A$ and $\psi = \psi^\mu_A$, $\mathfrak{q}_n(\psi) := \langle \psi, T^n(1-\Pi_0)\psi\rangle = \int_{\{0<t<1\}} t^n\, d\varrho_\psi$. On $\mathcal{C}_\mu \cap \{0 < t < 1\}$, with $t = e^{-x}$ and $|\alpha|_\infty := \max_{\lambda\neq\mu} |\alpha_\lambda|$, $x \geq \mathsf{k}|\alpha|_\infty$ (Proposition 18.6 (c))

and, by Step 2, $t^n = e^{-nx}\Psi(t^{2r})/\Psi(e^{-2rx}) \le g(\alpha)\Psi(t^{2r})$ with $g(\alpha) := e^{-n\mathsf{k}|\alpha|_\infty}/(\mathsf{c}_\Psi \tanh(2r\mathsf{k}|\alpha|_\infty))$, because $e^{-nx}/\tanh(2rx)$ is a decreasing function of x. By Step 3 and $\coth s \le 1 + \frac{1}{s}$,

$$\mathsf{q}_n(\psi) \le \int g\, h\, d\alpha \le \|h\|_\infty\, \mathsf{c}_\Psi^{-1} \int_{\mathbb{R}^D} e^{-n\mathsf{k}|\alpha|_\infty}\Big(1 + \frac{1}{2r\mathsf{k}|\alpha|_\infty}\Big) d\alpha = \|h\|_\infty\, \mathsf{c}_\Psi^{-1} D 2^D \Big[\frac{(D-1)!}{(n\mathsf{k})^D} + \frac{(D-2)!}{2r\mathsf{k}\,(n\mathsf{k})^{D-1}}\Big],$$

where the integral converges only because $D \ge 2$, that is, $d \ge 3$; with the bound on h this is $\mathsf{C}'_d \mathcal{N}'_{r,\mu}(A)\,[(D-1)(\frac{r}{n})^D + \frac{1}{2}(\frac{r}{n})^{D-1}]$. A general A splits as $A_+ + A_-$ with $A_\pm := \frac{1}{2}(A \pm \theta_\mu A)$ and $\theta_\mu A_\pm = \pm A_\pm$; q_n being a positive quadratic form, $\mathsf{q}_n(\psi^\mu_A) \le 2\mathsf{q}_n(\psi^\mu_{A_+}) + 2\mathsf{q}_n(\psi^\mu_{A_-})$, and $\mathcal{N}'_{r,\mu}(A_\pm) \le \mathcal{N}_r(A)$ since $\|\psi^\kappa_{\mathsf{g}A_\pm}\| \le \frac{1}{2}(\|\psi^\kappa_{\mathsf{g}A}\| + \|\psi^\kappa_{\mathsf{g}\theta_\mu A}\|)$ and $\mathsf{g}\theta_\mu \in \mathsf{S}_{2^d}$.

Step 5: clauses (b) and (c). Choose μ with $|x_\mu| = |x|_\infty$. If $x_\mu > 0$, Step 1 and $V\Pi_0 = \Pi_0$ express the difference as $\langle \psi^\mu_{\theta_\mu A}, T^n V(x_\perp)(1-\Pi_0)\psi^\mu_B\rangle$; since $V(x_\perp)$ is unitary and commutes with $T^{n/2}(1-\Pi_0)$, its modulus is at most $\mathsf{q}_n(\psi^\mu_{\theta_\mu A})^{1/2}\mathsf{q}_n(\psi^\mu_B)^{1/2}$, and $\mathcal{N}_r(\theta_\mu A) = \mathcal{N}_r(A)$; if $x_\mu < 0$, the second identity of Step 1 exchanges A and B. For (c): $|x|_\infty \ge |x|/\sqrt{d} \ge 4ra$, hence $n \ge \frac{|x|_\infty}{2a}$ and $\frac{r}{n} \le \frac{2ra}{|x|_\infty} \le \frac{1}{2}$, and $(D-1)(\frac{r}{n})^D + \frac{1}{2}(\frac{r}{n})^{D-1} \le \frac{D}{2}(\frac{r}{n})^{D-1} \le \frac{D}{2}(2\sqrt{d})^{d-2}(\frac{ra}{|x|})^{d-2}$; moreover $\mathcal{N}_r(A) \le \nu(|A|^2) \le \|A\|^2_\infty$, as $\|\psi^\mu_A\|^2 = \nu(\overline{\theta_\mu A}\,\tau_{2rae_\mu}A)$. For ergodic ν, $E_\nu[A|\mathcal{I}] = \nu(A)$. Numerically $\mathsf{s}_3 = 277$, $\mathsf{s}_4 = 7604$, $\mathsf{C}'_3 < 3444$, $\mathsf{C}'_4 < 80438$, $C_3 < 4.8\cdot 10^4$ and $C_4 < 7.73\cdot 10^6$. For $d = 3$, (b) and (c) are the bounds of Proposition YM3_I:99.7, with different constants.

Step 6: clause (d). Let ϕ be the centred Gaussian field on $\mathbb{Z}^d$, $d \ge 3$, with covariance $\mathsf{C} = (-\Delta)^{-1}$, Δ the lattice Laplacian. $\mathsf{C}(x,y) = \mathsf{C}(x-y)$ is $(2d)^{-1}$ times the mean number of visits to x of the simple random walk started at y; thus $\mathsf{C} > 0$, $\mathsf{C}(x) \to 0$, and the classical asymptotics of the lattice Green function give $|x|^{d-2}\mathsf{C}(x) \to \mathsf{c}_d > 0$. The law of ϕ is reflection positive at all lattice mirrors. At a site or diagonal mirror $\Sigma(n,c)$, $n\cdot x$ moves by 0 or ± 1 along a bond, so a walk going from one closed side to the other visits $\mathsf{M} := \mathbb{Z}^d \cap \Sigma(n,c)$; the strong Markov property yields $\mathsf{C}(x,y) = \sum_{z\in\mathsf{M}} g_y(z)\,\mathsf{C}(x,z)$ for $n\cdot x \le c \le n\cdot y$, g_y being the law of the first point of M that the walk from y visits; since $\theta_{n,c}$ fixes every point of M and preserves C, for real f of finite support in $\mathbb{H}^+(n,c)$ and $\hat f := \sum_y f(y)g_y$ one obtains $\langle \theta f, \mathsf{C}f\rangle = \langle \hat f, \mathsf{C}\hat f\rangle \ge 0$. At a bond mirror $\Sigma(e_\mu, \frac{1}{2})$,

$$\mathsf{C}(x) = \int_{[-\pi,\pi]^{d-1}} e^{i\alpha\cdot x_\perp}\, \frac{e^{-\varepsilon(\alpha)|x_\mu|}}{2\sinh\varepsilon(\alpha)}\, \frac{d\alpha}{(2\pi)^{d-1}}, \qquad \cosh\varepsilon(\alpha) = 1 + \sum_{\lambda\ne\mu}(1-\cos\alpha_\lambda),$$

and $|(\theta x)_\mu - y_\mu| = x_\mu + y_\mu - 1$ when x, y lie in the closed side, so that $\langle \theta f, \mathsf{C}f\rangle = \int |\sum_x f(x) e^{i\alpha\cdot x_\perp} e^{-\varepsilon(\alpha)(x_\mu - \frac{1}{2})}|^2 \frac{d\alpha}{(2\pi)^{d-1}2\sinh\varepsilon(\alpha)} \ge 0$. In either case $(\langle \theta f_k, \mathsf{C}f_l\rangle)_{k,l}$ is a positive semidefinite Gram matrix; by Schur's product theorem so is its entrywise exponential, and for $F = \sum_k c_k e^{i\phi(f_k)}$ one gets $\mathbb{E}[\overline{\theta F} F] = \sum_{k,l} \bar c'_k c'_l \exp\langle \theta f_k, \mathsf{C}f_l\rangle \ge 0$ with $c'_k := c_k e^{-\frac{1}{2}\langle f_k, \mathsf{C}f_k\rangle}$; such F are dense. Now set $U_{(x,y)} := g_0$ when $\phi_x + \phi_y < 0$ and $U_{(x,y)} := e$ otherwise, so that $U_{\bar b} = U_b = U_b^{-1}$, and let ν be the law of U. Since U is built bond by bond from the values of ϕ at the two ends, every isometry of $\mathbb{Z}^d$ acts compatibly on ϕ and on U, and every function of the bonds in a closed side depends only on the values of ϕ at the sites of that side; hence ν is translation invariant and reflection positive at all lattice mirrors, and it inherits from ϕ, whose covariance vanishes at infinity, the mixing property, so it is ergodic. Take $b = (0, e_1)$ and $A := \mathbf{1}\{U_b = e\} - \mathbf{1}\{U_b = g_0\}$, which is almost surely $\operatorname{sign}(\phi_0 + \phi_{e_1})$; then $|A| \le 1$ and $\nu(A) = 0$ by the symmetry $\phi \mapsto -\phi$. For two centred jointly Gaussian variables of correlation $\varrho \ge 0$ the expectation of the product of their signs is $\frac{2}{\pi}\arcsin\varrho \ge \frac{2}{\pi}\varrho$; here

$$\varrho_x = \frac{2\mathsf{C}(x) + \mathsf{C}(x+e_1) + \mathsf{C}(x-e_1)}{2\mathsf{C}(0) + 2\mathsf{C}(e_1)}$$

is positive for every x and $|x|^{d-2}\varrho_x$ has a positive limit, so $\inf_{x\ne 0}|x|^{d-2}\varrho_x > 0$. Combined with (c), this shows that when G has an element of order two the exponent $d-2$ cannot be raised in a bound valid for all measures with (Mir). □

Gibbs states in dimension d. Let dg be the Haar probability measure of G and $w\colon G \to (0,\infty)$ a continuous class function with $w(g^{-1}) = w(g)$. For a plaquette p of $a\mathbb{Z}^d$ write U_p for the holonomy of U around the boundary of p, taken from any of its corners and in either orientation; by the two invariances of w, $w(U_p)$ is the same for all these choices. For a finite set B of bonds let γ_B be the kernel that resamples the bonds of B with the normalised density $\prod_p w(U_p)$, over the plaquettes p containing a bond of B, against $\prod_{b\in B} dU_b$. A Gibbs state of w is a Borel probability measure ν on $\mathcal{V}$ that every γ_B leaves unchanged, $\nu(\gamma_B F) = \nu(F)$ for continuous local F; it is periodic if some sublattice of $a\mathbb{Z}^d$ of finite index leaves it invariant. Here $\mathcal{G}(w)$ denotes the set of Gibbs states and $\mathcal{G}^{\mathrm{per}}(w)$ that of the periodic ones. For an irreducible unitary representation π of G, of dimension d_π and character χ_π, let $c_\pi(w) := d_\pi^{-1} \int w\chi_\pi \, dg$, a real number, as in Proposition 9.27 (i).

Proposition 18.8 (Wilson weights in d dimensions: the mirrors of their periodic Gibbs states)**.** Let $d \geq 2$, $a > 0$, G a compact metrisable group and w as above.

(a) Let N be a closed normal subgroup of G such that w is constant on the cosets $g\mathsf{N}$ and $c_\pi(w) > 0$ for each irreducible π whose kernel contains N. Then $\mathcal{G}^{\mathrm{per}}(w) \neq \emptyset$, and each of its members is reflection positive at all lattice mirrors $\Sigma(n,c)$ of the three kinds, for the functions in $\mathcal{F}_{\mathrm{loc}}(\mathbb{H}^+(n,c))$ and in $\mathcal{F}_{\mathrm{loc}}(\mathbb{H}^-(n,c))$, and is invariant under $a\mathbb{Z}^d \rtimes W_d$; in particular it has (Mir). Moreover $\mathcal{G}^{\mathrm{per}}(w)$ coincides with the set of translation invariant Gibbs states of w, a convex weakly compact set.

(b) For every finite-dimensional unitary representation ρ of G and every $\beta \geq 0$, the weight $w = e^{\beta \operatorname{Re}\chi_\rho}$ meets the hypothesis of (a), with $\mathsf{N} = \ker\rho$ if $\beta > 0$ and $\mathsf{N} = G$ if $\beta = 0$. This covers, for every $\beta \geq 0$, the Wilson weight $e^{-\beta a(U_p)}$ of every closed subgroup G of $U(N)$, which for $G \neq \{\mathbf{1}\}$ is the weight of the Wilson measure of Proposition 9.27; here $a(X) = 1 - \frac{1}{N}\operatorname{Re}\operatorname{tr} X$, the formula that Definition 9.1 uses for the action density. In particular the Wilson weight of $SU(2)$ is covered.

(c) Let $d = 4$ and ν a periodic Gibbs state of a weight as in (a), for instance of the Wilson weight of $SU(2)$ at some $\beta \geq 0$. In every picture (e_μ, c_0) of ν, $c_0 \in \frac{a}{2}\mathbb{Z}$, and for each of the three directions $\lambda \neq \mu$,

$$(1-T)^2 \geq T\big(2 - V(ae_\lambda) - V(ae_\lambda)^*\big);$$

and for every integer $r \geq 1$, all $A, B \in \mathcal{F}(\mathsf{Bd}([-ra, ra]^4))$ and every $x \in a\mathbb{Z}^4$ with $|x| \geq 8ra$,

$$\Big|\nu(\bar{A}\,\tau_x B) - \nu\big(\overline{E_\nu[A|\mathcal{I}]}\,E_\nu[B|\mathcal{I}]\big)\Big| \leq C_4\,\|A\|_\infty\|B\|_\infty\Big(\frac{ra}{|x|}\Big)^2, \qquad C_4 < 7.8\cdot 10^6,$$

which is the three-dimensional rate $ra/|x|$ of Proposition YM3_I:99.7 squared; if ν is ergodic, the subtracted term is $\nu(\bar{A})\nu(B)$.

■

Sketch of proof. Step 1: Gibbs states. For a family $\Psi = (A_i)$ of real continuous local functions such that each bond lies in finitely many of their supports, the kernel of (w,Ψ) carries in addition the factor $\exp\sum A_i$ over the A_i whose support meets B, and Gibbs states of (w,Ψ) are defined in the same manner. The kernels map continuous local functions to continuous local functions. For a finite set B consider two kernels of this kind, the density of each being the product of the factors of the plaquettes that contain a bond of B with its exponential factor. If at every configuration the quotient of the two densities lies between $e^{-\epsilon}$ and e^{ϵ}, then after normalisation it lies between $e^{-2\epsilon}$ and $e^{2\epsilon}$, and the values of the two kernels at F differ by no more than $(e^{2\epsilon}-1)\|F\|_\infty$. For B fixed, $w_k \to w$ uniformly and $t_k \to 0$, the quotient for the kernels of B of $(w_k, t_k\Psi)$ and of w tends to 1 uniformly, since w is continuous and positive on a compact group and only finitely many of the bounded A_i meet B; consequently any weak limit of Gibbs states of $(w_k, t_k\Psi)$ is a Gibbs state of w, and $\mathcal{G}(w)$ is convex and weakly compact. Isometries map Gibbs states to Gibbs states. A gauge transformation at a single site leaves the kernel of the bonds at that site unchanged, and so

does $U_b \mapsto U_b z$, $z \in \mathsf{N}$, at a single bond b when w is constant on the cosets of the closed normal subgroup N; hence every Gibbs state is invariant under both.

Step 2: kernels of positive type. Schur's lemma gives $\int w(vg^{-1})\pi_{ij}(v)\,dv = c_\pi(w)\,\pi_{ij}(g)$ for the matrix coefficients of π. If every $c_\pi(w) \ge 0$, the integral operator with the kernel $w(gh^{-1})$ is positive on $L^2(G)$ by the theorem of Peter and Weyl, and, w being continuous, $(g,h) \mapsto w(gh^{-1})$ is a positive definite kernel. A product of positive definite kernels, or the composition of one with a map, is again positive definite, and a bounded positive definite kernel $\mathcal{K}$ on a probability space satisfies $\iint \overline{\Phi(y)}\,\mathcal{K}(y,y')\,\Phi(y') \ge 0$ for bounded Borel Φ, as sampling independent points shows. The hypothesis of (a) entails $c_\pi(w) \ge 0$ for every π: when π is not trivial on N, $\int_{\mathsf{N}} \pi(z)\,dz = 0$ and hence $c_\pi(w) = 0$.

Step 3: tori adapted to one normal. Put $a = 1$, let $\nu \in \mathcal{G}^{\mathrm{per}}(w)$ be invariant under $\mathsf{N}_0\mathbb{Z}^d$, let $n = e_\mu$ or $n = e_\mu + se_\lambda$, $c \in \mathrm{Adm}(n)$, and let h be a multiple of $|n|^2\mathsf{N}_0$, $M \ge 2$, and $\ell \ge 3$ a multiple of N_0. With $\mathsf{p}(x) := n \cdot x$, $z_0 := \frac{h}{|n|^2} n$ and the rank-$(d-1)$ lattice $\Gamma_\perp := \{z \in \mathbb{Z}^d : n \cdot z = 0\}$, set $\Gamma := 2Mz_0\mathbb{Z} + \ell\Gamma_\perp$ and $\mathbb{T} := \mathbb{Z}^d/\Gamma$. Every non-zero vector of Γ has a coordinate of modulus at least 3, so near each site the quotient map is injective on bonds and plaquettes. The reflections $\theta_k := \theta_{n,c+kh}$ and the translation τ_{z_0} act on $\mathbb{T}$; each of them moves points along n by an amount that depends on $\mathsf{p}(x)$ alone, so it is determined by what it does to p, which gives $\theta_k\theta_l = \tau_{2(k-l)z_0}$ and $\theta_{k+M} = \theta_k$ on $\mathbb{T}$. The slabs $\mathsf{Sl}_j := \{c + (j-1)h \le \mathsf{p} \le c + jh\}$, $j \in \mathbb{Z}/2M$, the halves $\mathbb{T}^+_k := \mathsf{Sl}_{k+1} \cup \cdots \cup \mathsf{Sl}_{k+M}$ and the maps $\mathsf{s}_j := \theta_{j-1}\cdots\theta_1$ satisfy $\mathsf{s}_j\mathsf{Sl}_1 = \mathsf{Sl}_j$ and $\theta_k\mathsf{s}_j = \mathsf{s}_{2k+1-j}$. Let $\mu_0 \propto \prod_p w(U_p)\prod_b dU_b$ on the configurations of $\mathbb{T}$, a measure invariant under the isometries of $\mathbb{T}$. For $d = 3$ these are the adapted tori of Proposition YM3_I:91.4.

Step 4: positivity on these tori. Suppose every $c_\pi(w) \ge 0$. Let $k \in \mathbb{Z}/2M$, S_+ a real bounded Borel function of the bonds of $\mathbb{T}^+_k$, and $\mu \propto e^{\mathsf{S}_+ + \theta_k\mathsf{S}_+}\mu_0$. Then μ is invariant under θ_k, and $\mu(\overline{\theta_k F}F) \ge 0$ for every bounded Borel F of the bonds of $\mathbb{T}^+_k$. At a site mirror no plaquette crosses the mirror, and Fubini's theorem writes the integral as $\int dU_0\, W_0\,|\int F\,W_+ e^{\mathsf{S}_+}\,dU_+|^2$, by the computation of Step 1 of the proof of Proposition 18.1, which uses of the group its Haar measure alone and of the weight only its two invariances. At a diagonal mirror the plaquettes of the plane (μ,λ) whose corners have $\mathsf{p} = m-1, m, m, m+1$ with $m \in \{c+kh, c+(k+M)h\}$ cross the mirror: two corners y, y' lie on it, one corner x^+ in $\mathbb{T}^+_k$, the last is $\theta_k x^+$; with $\mathsf{A}_p(U) := U(\langle y, x^+\rangle)U(\langle x^+, y'\rangle)$ their variables are $\mathsf{A}_p(U_+)\mathsf{A}_p(U'_+)^{-1}$, U'_+ denoting the reflected half, and the product of $w(\mathsf{A}_p(U_+)\mathsf{A}_p(U'_+)^{-1})$ over these plaquettes is a positive definite kernel in (U_+, U'_+) by Step 2. At a bond mirror the bonds crossing the two mirrors act on the reflected half as a gauge transformation V of its two outermost layers, and the crossing plaquettes contribute $w(U_+(b)\,[(V\cdot U'_+)(b)]^{-1})$; since W_+ and this kernel are gauge invariant, one may replace $F\,W_+e^{\mathsf{S}_+}$ by its average Φ^{av} over these gauge transformations, and the integral becomes $\iint \Phi^{\mathrm{av}}(U_+)\,\overline{\Phi^{\mathrm{av}}(U'_+)}\prod_b w(U_+(b)U'_+(b)^{-1}) \ge 0$. For $d = 3$ this is Proposition YM3_I:91.4 and Corollary YM3_I:85.3.

Step 5: a chessboard estimate along the normal. Under the same assumption, for bounded Borel functions $\mathsf{g}_j > 0$ of the bonds of Sl_1, $j \in \mathbb{Z}/2M$, the quantity $\Phi(\mathsf{g}_1, \dots, \mathsf{g}_{2M}) := \mu_0(\prod_j \mathsf{s}_j\mathsf{g}_j)$ satisfies $\Phi \le \prod_j \Phi(\mathsf{g}_j, \dots, \mathsf{g}_j)^{1/2M}$: by $\theta_k\mathsf{s}_j = \mathsf{s}_{2k+1-j}$ and Step 4 with $\mathsf{S}_+ = 0$, Schwarz's inequality supplies the hypothesis of Step 2 of the proof of Proposition 18.1. For $d = 3$ this is Proposition YM3_I:91.7.

Step 6: a reflection positive state above ν. Suppose every $c_\pi(w) \ge 0$, let $\nu \in \mathcal{G}^{\mathrm{per}}(w)$, $\Sigma(n,c)$ a lattice mirror and A a real continuous local function of the bonds of $\mathbb{H}^+(n,c)$ that depends on bonds in $[-r,r]^d$ only. We find $\nu_0 \in \mathcal{G}^{\mathrm{per}}(w)$, reflection positive at $\Sigma(n,c)$, with $\nu_0(A) \ge \nu(A)$, and see that $\mathcal{G}^{\mathrm{per}}(w) \ne \emptyset$. Take h large enough that A depends on bonds of Sl_1 only, let A_1 be the sum of the translates of A by $\mathsf{N}_0\Gamma_\perp/\ell\Gamma_\perp$, $\mathsf{S}_{\mathrm{alt}} := \sum_j \mathsf{s}_j A_1$ and $\mathsf{S}_{\mathrm{uni}} := \sum_j \tau_{(j-1)z_0}A_1$, each a sum of $\mathcal{N} := 2M(\ell/\mathsf{N}_0)^{d-1}$ copies of A, and $\mu_t \propto e^{t\mathsf{S}_{\mathrm{alt}}}\mu_0$ for $t > 0$. Since $t\mathsf{S}_{\mathrm{alt}} = \mathsf{S}_+ + \theta_k\mathsf{S}_+$ with $\mathsf{S}_+ := t\sum_{i=1}^M \mathsf{s}_{k+i}A_1$, Step 4 shows that μ_t is invariant under all θ_k and reflection positive at them; it is also invariant under $\mathsf{N}_0\Gamma_\perp$, whence $\mu_t(\mathsf{S}_{\mathrm{alt}}) = \mathcal{N}\mu_t(A)$. (i) With $\mathsf{m} := \theta_1\tau_{z_0}$, which mirrors

Sl_1 onto itself, $e^{t\mathsf{S}_{\rm uni}} = \prod_{j\ \rm odd} \mathsf{s}_j e^{tA_1} \prod_{j\ \rm even} \mathsf{s}_j \mathsf{m} e^{tA_1}$, and Step 5 together with the invariance of μ_0 under m gives $\mu_0(e^{t\mathsf{S}_{\rm uni}}) \le \mu_0(e^{t\mathsf{S}_{\rm alt}})$. (ii) A fundamental domain D of Γ has $2Mh\ell^{d-1} = h\mathsf{N}_0^{d-1}\mathcal{N}$ sites. Let B_D be the set of the bonds based in D; a plaquette of the infinite lattice whose four bonds all belong to B_D is said to be inner. Put $n_\partial := n_1 + n_2$, where n_1 counts the plaquettes having some, but not all, of their four bonds in B_D, and n_2 counts the plaquettes of $\mathbb{T}$ that do not arise from an inner plaquette under the quotient map. Both n_∂ and the number $\mathcal{N}_\partial$ of copies of A whose lifts are not inside D at distance $r+1$ from the boundary are at most $(\frac{1}{M} + \frac{1}{\ell})\mathcal{N}$ times a number depending on d, r, h and N_0. The densities of the kernel $\gamma_{B_D}(\cdot\,|U)$ and of μ_0 have in common the product over the inner plaquettes; besides it the first has n_1 factors and the second n_2, each between $\min w$ and $\max w$, so that the normalised density of μ_0 is at least $\kappa_w^{-n_\partial}$ times that of the kernel, $\kappa_w := \max w / \min w$. As ν is a Gibbs state, $\mu_0(f) \ge \kappa_w^{-n_\partial}\nu(f \circ \mathrm{res})$ for $f \ge 0$, where res is the restriction to B_D (Proposition YM3_I:91.8 for $d = 3$); with Jensen's inequality and the periodicity of ν, $\mu_0(e^{t\mathsf{S}_{\rm uni}}) \ge \exp(-n_\partial \log \kappa_w + t\mathcal{N}\nu(A) - 2t\mathcal{N}_\partial \|A\|_\infty)$. (iii) The function $\psi(t) := \log \mu_0(e^{t\mathsf{S}_{\rm alt}})$ is convex, $\psi(0) = 0$ and $\psi'(t) = \mathcal{N}\mu_t(A)$, so $\psi(t) \le t\mathcal{N}\mu_t(A)$, and together with (i) and (ii)

$$\mu_t(A) \ge \nu(A) - 2\frac{\mathcal{N}_\partial}{\mathcal{N}}\|A\|_\infty - \frac{n_\partial \log \kappa_w}{t\mathcal{N}}.$$

(iv) Let $M = \ell \to \infty$ along multiples of N_0 with t fixed, and let ν_t be a weak limit point of the periodic extensions of μ_t: it is invariant under the finite-index lattice $2z_0\mathbb{Z} + \mathsf{N}_0\Gamma_\perp$, reflection positive at $\Sigma(n,c)$, a Gibbs state of $(w, t\Psi)$ for the family Ψ of the copies $\tau_z \mathsf{s}_j A$, and $\nu_t(A) \ge \nu(A)$. (v) Any weak limit point ν_0 of $(\nu_{1/k})_k$ is by Step 1 a periodic Gibbs state of w, reflection positive at $\Sigma(n,c)$, with $\nu_0(A) \ge \nu(A)$. At $A = 0$, (iv) and (v) do not use ν, so $\mathcal{G}^{\rm per}(w) \ne \emptyset$. For $d = 3$ this is Proposition YM3_I:102.5.

Step 7: agreement on a half space forces equality. Under the hypothesis of (a), if two Gibbs states ν_1, ν_2 of w agree on all functions of the bonds of a half space $\{\epsilon x_\mu \ge c\}$, $c \in \mathbb{Z}$, then $\nu_1 = \nu_2$. Suppose first $\mathsf{N} = \{e\}$, $\mu = d$ and $\epsilon = 1$. For a bond b of $\mathbb{Z}^{d-1}$ let $v(b)$ and $u'(b)$ be the values of U on its copies at the heights c and $c-1$, D_y the value on the vertical bond from (y,c) to $(y,c-1)$, and $\mathsf{g}(b) := \mathsf{D}_{b_-} u'(b) \mathsf{D}_{b_+}^{-1}$, so that the plaquette below b has the variable $v(b)\mathsf{g}(b)^{-1}$. For a finite set S of bonds of $\mathbb{Z}^{d-1}$ with copies B at the height c, and continuous local $\psi(\mathsf{g}|_S, v, \mathsf{r})$, r standing for the values on the remaining bonds of $\{x_d \ge c\}$, the invariance under γ_B reads

$$\nu_i(\psi) = \int \varsigma_i(d\mathsf{g}, d\mathsf{r}) \int \prod_{b \in S} w(v(b)\mathsf{g}(b)^{-1})\, \Phi(v;\mathsf{r})\, \psi(\mathsf{g}, v, \mathsf{r})\, dv,$$

with a continuous $\Phi > 0$ and finite positive measures ς_i. Choose $\psi = \phi(v)\chi(\mathsf{r})/\Phi(v;\mathsf{r})$ with ϕ a product of matrix coefficients $\pi^b_{ij}(v(b))$: then ψ depends on bonds of the half space only, so $\nu_1(\psi) = \nu_2(\psi)$, while by Step 2 the right side is $\prod_b c_{\pi^b}(w) \int \phi(\mathsf{g})\chi(\mathsf{r})\, d\varsigma_i$. As all $c_\pi(w) > 0$, the theorems of Peter and Weyl and of Stone and Weierstrass give $\varsigma_1 = \varsigma_2$, so ν_1 and ν_2 agree on the functions of g, v and r. A gauge transformation at the sites $(y, c-1)$ fixes these variables and moves the D_y; averaging over it (Step 1), the two states agree on the functions of the bonds of $\{x_d \ge c-1\}$, because $u'(b) = \mathsf{D}_{b_-}^{-1}\mathsf{g}(b)\mathsf{D}_{b_+}$; induction downwards gives $\nu_1 = \nu_2$. For general N pass to G/N, whose irreducible representations are the π trivial on N, using the invariance under N from Step 1. For $d = 3$ and $\beta > 0$ the main text has the analogue for the chain of layers: by Lemma YM3_I:103.2, among the Borel probability measures that solve the equations of that chain, each is singled out by its image on any two adjacent layers; a half space needs neither layers nor a gauge fixing.

Step 8: clause (a). Let $\nu \in \mathcal{G}^{\rm per}(w)$. For a site or bond mirror $\Sigma = \Sigma(e_\mu, c)$ let $\mathcal{R}$ be the set of the $\nu' \in \mathcal{G}(w)$ that are reflection positive at Σ on the continuous local functions of $\mathbb{H}^+$; by Step 1 it is convex and weakly compact, and by Step 6 it is not empty. Its restrictions to the bonds of $\mathbb{H}^+$ form a convex weak-$*$ compact set; were the restriction of ν outside it, a continuous function of these bonds, approximated by a real continuous local A, would separate them, $\nu(A) \ge \nu'(A) + \delta$ for all $\nu' \in \mathcal{R}$ and some $\delta > 0$, contradicting Step 6. Hence some $\nu' \in \mathcal{R}$ has the restriction of ν to the

bonds of $\mathbb{H}^+$, which are the bonds of $\{x_\mu \geq \lceil c \rceil\}$, and Step 7 gives $\nu' = \nu$; L^2 approximation with respect to $\nu + \theta_*\nu$ carries positivity from continuous to bounded Borel local functions. Hermiticity of the positive form gives $\nu(\theta F) = \nu(F)$ for local functions on the positive side. For any local A, choose a sufficiently large lattice period v along the positive normal so that $\tau_v A$ lies on this side. Since $\theta\tau_v = \tau_{-v}\theta$, periodicity gives $\nu(\theta A) = \nu(\theta\tau_v A) = \nu(\tau_v A) = \nu(A)$. This gives full reflection invariance and positivity on the other closed side. From $\theta_{e_\mu,1/2}\theta_{e_\mu,0} = \tau_{e_\mu}$, every periodic Gibbs state is translation invariant, and $\mathcal{G}^{\mathrm{per}}(w)$ is the convex, weakly compact set of translation invariant Gibbs states. For a diagonal mirror let $\mathcal{R}$ be the set of members of $\mathcal{G}^{\mathrm{per}}(w)$ that are reflection positive at it; it contains the ν_0 of Step 6, and the same separation yields $\nu' \in \mathcal{R}$ with the restriction of ν to the bonds of $\mathbb{H}^+(n,c)$; both being translation invariant, $\nu'(f) = \nu'(\tau_{ke_\mu} f) = \nu(\tau_{ke_\mu} f) = \nu(f)$ for every continuous local f and large k, so $\nu = \nu'$. The reflections in $\Sigma(e_\mu, 0)$ and $\Sigma(e_\mu - e_\lambda, 0)$ generate W_d. In three dimensions see Proposition YM3_I:103.4 for the $SU(2)$ Wilson weight and Proposition 9.27 (iii) for closed $G \subset U(N)$.

Step 9: clause (b). Since $\operatorname{Re}\chi_\rho = \frac{1}{2}\chi_{\rho\oplus\bar\rho}$, $e^{\beta \operatorname{Re}\chi_\rho} = \sum_m \frac{(\beta/2)^m}{m!}\chi_{(\rho\oplus\bar\rho)^{\otimes m}}$ and $d_\pi c_\pi(w) = \sum_m \frac{(\beta/2)^m}{m!}\operatorname{mult}(\pi, (\rho\oplus\bar\rho)^{\otimes m}) \geq 0$; also w is constant on the cosets of $\ker\rho$. The functions $g \mapsto \langle u, (\rho\oplus\bar\rho)^{\otimes m}(g)u'\rangle$, $m \geq 0$, together form a subalgebra of the continuous functions on $G/\ker\rho$ that contains the constants, is stable under complex conjugation and separates points, ρ being faithful on $G/\ker\rho$; it is dense by the theorem of Stone and Weierstrass, while an irreducible π trivial on $\ker\rho$ that occurred in no tensor power would have a matrix coefficient orthogonal to it, by the relations of Schur. Hence $c_\pi(w) > 0$ for $\beta > 0$; at $\beta = 0$, $w = 1$ and $\mathsf{N} = G$. The Wilson weight of a closed $G \subset U(N)$ equals $e^{-\beta} e^{\frac{\beta}{N}\operatorname{Re}\chi_\rho}$ with ρ the inclusion, and a constant factor does not affect Gibbs states; Proposition 9.27 (i) records the same positivity of its coefficients.

Step 10: clause (c). By (a) and (b), ν has (Mir); Proposition 18.6 (c) gives the inequality for the three directions $\lambda \neq \mu$ in every picture (e_μ, c_0), and Proposition 18.7 (c) for $d = 4$, with $c_4 = 8$, $(ra/|x|)^{d-2} = (ra/|x|)^2$ and $C_4 < 7.8 \cdot 10^6$, gives the decay of correlations. □

Other plaquette weights of $SU(2)$. In Propositions 18.9 and 18.10, $G = SU(2)$; a torus Λ with even sides $N_\mu \geq 4$, its configurations, the Haar measure dU and $a_p = 1 - \frac{1}{2}\operatorname{tr}\partial U(p) \in [0,2]$ are as in Proposition 18.1; on the torus $\Lambda_{K,\ell}$, $\ell = 2L^m$, with $2L^{K+m}$ sites on an axis, $\mathcal{O}(f) = a_K^{-1}\sum_p f(x(p))\, a_p$, and $S^T_{n;K,\ell,\beta}$ is the joint cumulant of $\mathcal{O}(f_1), \dots, \mathcal{O}(f_n)$ under the Wilson measure; for a function f on T_ℓ, $\|f\|_\sharp$ denotes $\max\{\sup|f|, 40M \operatorname{Lip} f\}$ with the construction constant M. A *plaquette weight* is a bounded Borel function $\mathsf{w}\colon [0,2] \to [0,\infty)$ with $Z_\Lambda[\mathsf{w}] := \int \prod_p \mathsf{w}(a_p)\, dU > 0$; $\mu^{\mathsf{w}}_\Lambda := Z_\Lambda[\mathsf{w}]^{-1}\prod_p \mathsf{w}(a_p)\, dU$, and $S^{\mathsf{w}}_{n;K,\ell}$ is the joint cumulant of $\mathcal{O}(f_1), \dots, \mathcal{O}(f_n)$ under $\mu^{\mathsf{w}}_{\Lambda_{K,\ell}}$; Wilson's weight at β is $e^{-\beta s}$. Given $c_0 \in (0,1]$, $C_v \geq 0$, $r_0 \in (0,2]$, $M_\phi > 0$ and $\beta > 0$, the class $\mathcal{W}_\beta(c_0, C_v, r_0, M_\phi)$ is formed by the weights $\mathsf{w} = e^{-\beta\phi - v_\beta}$ in which $\phi\colon [0,2] \to [0,\infty)$ and $v_\beta\colon [0,2] \to (-\infty, \infty]$ are Borel, $\phi(s) \geq c_0 s$, $v_\beta \geq -C_v \log(2+\beta)$, and, on $[0, r_0)$, ϕ and v_β extend holomorphically to the disc $D(0, r_0)$ with $\phi(0) = 0$, $|\phi| \leq M_\phi$ and $|v_\beta| \leq C_v$ on it; ϕ and v_β may vary with β. Put $\mathsf{a} := 3C_v + \frac{9}{2}$, $\mathsf{A} := 9C_v + 24M_\phi/r_0 + 3\log 7$ and $q_\beta(\delta) := \exp[-\frac{1}{2}c_0\beta\delta + \mathsf{a}\log(2+\beta) + \mathsf{A}]$.

Proposition 18.9 (Tails of the plaquette action; weights that differ only at large plaquette action)**.** Let Λ be a torus with even sides $N_\mu \geq 4$.

(a) Let $\mathsf{w} \in \mathcal{W}_\beta(c_0, C_v, r_0, M_\phi)$ with $\beta \geq 1$ and $\beta > 8/r_0$, and $0 < \delta \leq 2$. Then, for each plaquette p and each family Y of plaquettes,

$$\mu^{\mathsf{w}}_\Lambda(a_p \geq \delta) \leq q_\beta(\delta), \qquad \mu^{\mathsf{w}}_\Lambda(a_p \geq \delta \text{ for all } p \in Y) \leq q_\beta(\delta)^{|Y|/3} \text{ if } q_\beta(\delta) \leq 1, \qquad \mu^{\mathsf{w}}_\Lambda(\max_p a_p \geq \delta) \leq 3|\Lambda|\, q_\beta(\delta).$$

Neither the sides nor any feature of w other than the four numbers of its class enters $q_\beta(\delta)$.

(b) Let $\mathsf{w}_i \in \mathcal{W}_\beta(c_0^{(i)}, C_v^{(i)}, r_0^{(i)}, M_\phi^{(i)})$, $i = 1, 2$, with $\beta \geq 1$ and $\beta > 8/r_0^{(i)}$, let $0 < \delta \leq 2$ and $\epsilon \geq 0$, and assume that both weights are positive on $[0, \delta)$ and that some real c satisfies

$|\log \mathsf{w}_1(s) - \log \mathsf{w}_2(s) - c| \le \epsilon$ for $0 \le s < \delta$. Then for every event E

$$|\mu_\Lambda^{\mathsf{w}_1}(E) - \mu_\Lambda^{\mathsf{w}_2}(E)| \le \mathsf{E} := 3|\Lambda|(q_\beta^{(1)}(\delta) + q_\beta^{(2)}(\delta)) + e^{6|\Lambda|\epsilon} - 1,$$

where $q_\beta^{(i)}$ is q_β formed with the numbers of w_i. Consequently any Borel function of U, in particular the block field of any depth, has laws under the two measures whose distance on events is at most E; and on $\Lambda_{K,\ell}$, for $n \ge 1$ and real bounded $f_1, \dots, f_n$ with no condition on their supports, $|S^{\mathsf{w}_1}_{n;K,\ell}(\underline{f}) - S^{\mathsf{w}_2}_{n;K,\ell}(\underline{f})| \le 2\,\mathsf{fu}_n\,\mathsf{E}\prod_i 6\ell^3 L^{4K}\|f_i\|_\infty$. The same holds for $\mathsf{w}_2 := \mathbf{1}_{[0,\delta)}\mathsf{w}_1$, without the term $q_\beta^{(2)}(\delta)$.

■

Sketch of proof. Step 1: the planes through the sites. On $SU(2)$, $k(g) := \mathsf{w}(1 - \frac{1}{2}\mathrm{tr}\, g)$ equals $\kappa(\frac{1}{2}\mathrm{tr}\, g)$ for the bounded Borel function $\kappa(t) := \mathsf{w}(1-t)$ on $[-1,1]$, so Proposition 18.1 (a), (b) applies to μ_Λ^{w}, which is moreover invariant under the translations of Λ.

Step 2: bounds on the weight. Multiplying w by the constant $e^{v_\beta(0)}$ leaves μ_Λ^{w} as it is; afterwards $\mathsf{w} = e^{-g}$ with $g = \beta\phi + v_\beta - v_\beta(0)$. From $\phi \ge c_0 s$, $-v_\beta \le C_v \log(2+\beta)$ and $v_\beta(0) \le C_v$, $\mathsf{w}(s) \le \mathsf{B}e^{-c_0\beta s}$ with $\mathsf{B} := e^{C_v(1+\log(2+\beta))} \ge 1$. In the other direction, if $|U(b) - \mathbf{1}| \le \beta^{-1/2}$ at all bonds, then $|\partial U(p) - \mathbf{1}| \le 4\beta^{-1/2}$ and $a_p = \frac{1}{2}|\partial U(p) - \mathbf{1}|^2 \le 8/\beta < r_0$, so the lemma of Schwarz gives $\beta\phi(a_p) \le \beta M_\phi a_p / r_0 \le 8M_\phi/r_0$, while $|v_\beta(a_p) - v_\beta(0)| \le 2C_v$. The set $\{|g - \mathbf{1}| \le \varrho\}$, $\varrho \le 1$, has Haar measure at least $\frac{2}{\pi}\int_0^\varrho \sin^2\vartheta\, d\vartheta \ge \frac{1}{7}\varrho^3$, because $|g - \mathbf{1}| = 2\sin\frac{\vartheta}{2} \le \vartheta$ for the class angle ϑ of g and $\sin\vartheta \ge \frac{5}{6}\vartheta$ on $[0,1]$. Hence

$$Z_\Lambda[\mathsf{w}] \ge \left(\tfrac{1}{7}\beta^{-3/2}\right)^{3|\Lambda|} e^{-(8M_\phi/r_0 + 2C_v)\,3|\Lambda|}.$$

Step 3: one plaquette. Let the plaquette p span the directions μ, ν and let λ be the remaining direction; by translation invariance we may take for p the face p_0 of c_0 in the plane $x_\lambda = 0$. Proposition 18.1 (b) with $F_0 := \mathbf{1}[a_{p_0} \ge \delta]$, read on the model cube, and $F_x := 1$ for $x \ne 0$, gives $\mu_\Lambda^{\mathsf{w}}(a_{p_0} \ge \delta) \le \mathfrak{z}(F_0)^{1/|\Lambda|}$ with $\mathfrak{z}(F) := \langle \prod_x F^{(x)} \rangle / \langle 1 \rangle$. As x runs over Λ, the faces $\rho_x^{-1} p_0$ run over the plaquettes spanned by μ, ν that lie in planes with even x_λ, $\frac{1}{2}|\Lambda|$ of them; bounding w by B on all plaquettes and by $\mathsf{B}e^{-c_0\beta\delta}$ on those,

$$\begin{aligned}\mathfrak{z}(F_0)^{1/|\Lambda|} &\le \mathsf{B}^3 e^{-\frac{1}{2}c_0\beta\delta} Z_\Lambda[\mathsf{w}]^{-1/|\Lambda|} \\ &\le \exp\big[-\tfrac{1}{2}c_0\beta\delta + 3C_v(1+\log(2+\beta)) \\ &\qquad + \tfrac{9}{2}\log\beta + 3\log 7 + 24M_\phi/r_0 + 6C_v\big] \le q_\beta(\delta).\end{aligned}$$

A face of the model cube at $x_\lambda = 1$ leads in the same way to the planes with odd x_λ, with as many plaquettes.

Step 4: families of plaquettes. Assign the plaquette $(x; \mu\nu)$ to the cube c_x, so that each cube is assigned three plaquettes, and let F_x, read on the model cube, be the product of the indicators $\mathbf{1}[a_p \ge \delta]$ over the plaquettes of Y assigned to c_x. Whenever $F_x \ne 1$ it is dominated by the indicator for one face of the model cube, so $\mathfrak{z}(F_x)^{1/|\Lambda|} \le q_\beta(\delta)$ by Step 3 and the monotonicity of $\mathfrak{z}$; at least $|Y|/3$ cubes are assigned a plaquette of Y, and Proposition 18.1 (b) gives the second bound. Summing the first bound over the $3|\Lambda|$ plaquettes gives the third.

Step 5: clause (b). Let $\mathsf{G} := \{a_p < \delta \text{ for all } p\}$ and $\mu_i := \mu_\Lambda^{\mathsf{w}_i}$. By (a), $\mu_i(\mathsf{G}^c) \le 3|\Lambda| q_\beta^{(i)}(\delta)$, and $|\mu_i(E) - \mu_i(E \mid \mathsf{G})| \le \mu_i(\mathsf{G}^c)$ for every event E. On G the two products $\prod_p \mathsf{w}_i(a_p)$ differ by a factor in $e^{3|\Lambda|c}[e^{-3|\Lambda|\epsilon}, e^{3|\Lambda|\epsilon}]$; after normalisation the conditioned measures $\mu_1(\cdot \mid \mathsf{G})$ and $\mu_2(\cdot \mid \mathsf{G})$ have a mutual density between $e^{-6|\Lambda|\epsilon}$ and $e^{6|\Lambda|\epsilon}$, so they differ by at most $e^{6|\Lambda|\epsilon} - 1$ on every event. Passing to the law of a Borel function of U can only diminish this distance, and block fields are Borel functions of U (Definition 2.7). For the cumulants use Proposition 18.1 (c) with $|\mathcal{O}(f_i)| \le a_K^{-1} \cdot 3|\Lambda| \cdot 2\|f_i\|_\infty = 6\ell^3 L^{4K}\|f_i\|_\infty$. If $\mathsf{w}_2 = \mathbf{1}_{[0,\delta)}\mathsf{w}_1$, then $\mu_2 = \mu_1(\cdot \mid \mathsf{G})$. □

Proposition 18.10 (The limits of Wilson's action for weights that coincide with Wilson's at small plaquette action)**.** Let $0 < s_0 \le 2$, $c_0 \in (0,1]$ and $C_v \ge 0$, and call a plaquette weight w *admitted at* β if $\mathsf{w}(s) = e^{-\beta s}$ for $0 \le s < s_0$ and $0 \le \mathsf{w}(s) \le (2+\beta)^{C_v} e^{-c_0 \beta s}$ for $s_0 \le s \le 2$; the values of w on $[s_0, 2]$ may vary with β arbitrarily. Such a weight belongs to $\mathcal{W}_\beta(c_0, C_v, s_0, s_0)$; let q_β be formed with these numbers, so that $\mathsf{A} = 9C_v + 24 + 3\log 7$, and q_β^W with the numbers $(1, 0, s_0, s_0)$ of Wilson's weight. Let $m \in \mathbb{N}$, $\ell = 2L^m$, $n \ge 2$, and let $f_1, \dots, f_n$ be real Lipschitz functions on T_ℓ, each different from 0, such that no point of T_ℓ lies in all of their supports; let $S_n^{(\ell,\mathsf{b})}(\underline{f})$ be the limit of the cutoffs of Wilson's action at the label $\mathsf{b} > 0$ on the side ℓ and $\mathsf{d}_\infty(\underline{f}) > 0$ the spread of the tuple, $\min_{x_i \in \operatorname{supp} f_i} \max_{i,j} \operatorname{dist}_\infty(x_i, x_j)$ on T_ℓ, with the constants of the main text as in Theorem YM3_I:AS.

(a) For each $\mathsf{b} > 0$ and any choice of weights w_K admitted at $\beta = L^K \mathsf{b}$, $S^{\mathsf{w}_K}_{n;K,\ell}(\underline{f}) \to S_n^{(\ell,\mathsf{b})}(\underline{f})$ as $K \to \infty$ through all integers, uniformly on compact sets of labels in $(0,\infty)$. Quantitatively, let $0 < \mathsf{b}_- \le \mathsf{b}_+$, let $s \ge 0$ be an integer with YM3_I:(2210), $0 < \mathsf{d} \le \mathsf{d}_\infty(\underline{f})$, and let C'_s, $K_{1,s}(\mathsf{d})$ and p_n be the numbers of Theorem YM3_I:AS. For $\mathsf{b} \in [\mathsf{b}_-, \mathsf{b}_+]$, integers $K \ge K_{1,s}(\mathsf{d}) + s$ with $\beta = L^K \mathsf{b} > 8/s_0$, and every weight w admitted at β,

$$|S^{\mathsf{w}}_{n;K,\ell}(\underline{f}) - S_n^{(\ell,\mathsf{b})}(\underline{f})| \le L^{sn} \mathsf{C}'_s (L^s \ell)^{3(n+1)} (K-s)^{\mathsf{p}_n} L^{-(K-s)/10} \prod_i \|f_i\|_\sharp$$
$$+ 6\,\mathsf{fu}_n\, \ell^3 L^{3K} \big(q_\beta(s_0) + q_\beta^W(s_0)\big) \prod_i 6\ell^3 L^{4K} \|f_i\|_\infty;$$

here the first term is the bound that Theorem YM3_I:AS gives for Wilson's action, and the second is at most $e^{-\frac{1}{2}c_0 s_0 \mathsf{b}_- L^K} \prod_i \|f_i\|_\infty$ times a sum of two powers of L^K whose exponents and coefficients are formed from n, ℓ, b_+ and C_v.

(b) Let $\mathsf{b} > 0$, let $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}$, where the K_j need not increase and may repeat, and let w_j be admitted at β_j. Then $S^{\mathsf{w}_j}_{n;K_j,\ell}(\underline{f}) \to S_n^{(\ell,\mathsf{b})}(\underline{f})$ along the given sequence itself.

(c) For each $\mathsf{b} > 0$ and each integer $d \ge 0$ there is a Borel probability measure $\mu_d[\ell, \mathsf{b}]$ on $\mathcal{V}(\Lambda_{d,\ell})$, the limiting law of the block field of depth d of Wilson's action, such that, for weights w_K admitted at $\beta = L^K \mathsf{b}$, the law of $\mathcal{M}^{K-d}U$ under $\mu^{\mathsf{w}_K}_{\Lambda_{K,\ell}}$ converges to $\mu_d[\ell, \mathsf{b}]$ in total variation as $K \to \infty$. In the setting (E) at the label b (§2.3.1) the distance is at most $\sum_{K' \ge K} \mathfrak{o}_{K'} + 3\ell^3 L^{3K}(q_\beta(s_0) + q_\beta^W(s_0))$ for every integer $K \ge K_{\mathrm{bf}}$ with $\lceil K/1260 \rceil \ge d$ and $\beta > 8/s_0$, where $\mathfrak{o}_{K'}$ is the number of Definition 2.7 (4) and K_{bf} the threshold of Definition 2.7 (5) formed for the interval $\mathsf{J} = \{\mathsf{b}\}$ that consists of the label alone, as in Corollary 2.8 (b).

■

Sketch of proof. Step 1: admitted weights belong to the class. Set $\phi(s) := s$ and $v_\beta(s) := 0$ on $[0, s_0)$, $\phi(s) := c_0 s$ and $v_\beta(s) := -\log(\mathsf{w}(s) e^{c_0 \beta s}) \in (-\infty, \infty]$ on $[s_0, 2]$. Then $\phi \ge c_0 s$ because $c_0 \le 1$, $v_\beta \ge -C_v \log(2+\beta)$, and on $[0, s_0)$ the two functions are the restrictions of the entire functions s and 0, with $|\phi| \le s_0$ and $v_\beta = 0$ on $D(0, s_0)$; thus $\mathsf{w} \in \mathcal{W}_\beta(c_0, C_v, s_0, s_0)$, and Wilson's weight lies in $\mathcal{W}_\beta(1, 0, s_0, s_0)$. Since $s_0 \le 2$, the condition $\beta > 8/s_0$ implies $\beta > 1$.

Step 2: a single cutoff. Proposition 18.9 (b) with $\mathsf{w}_1 = \mathsf{w}$, $\mathsf{w}_2 = e^{-\beta s}$, $\delta = s_0$ and $c = \epsilon = 0$ gives, on $\Lambda_{K,\ell}$, where $|\Lambda_{K,\ell}| = \ell^3 L^{3K}$, and for every event E,

$$|\mu^{\mathsf{w}}_{\Lambda_{K,\ell}}(E) - \mu^{e^{-\beta s}}_{\Lambda_{K,\ell}}(E)| \le 3\ell^3 L^{3K} \big(q_\beta(s_0) + q_\beta^W(s_0)\big),$$
$$|S^{\mathsf{w}}_{n;K,\ell}(\underline{f}) - S^T_{n;K,\ell,\beta}(\underline{f})| \le 6\,\mathsf{fu}_n\, \ell^3 L^{3K} \big(q_\beta(s_0) + q_\beta^W(s_0)\big)$$
$$\times \prod_i 6\ell^3 L^{4K} \|f_i\|_\infty.$$

For $\beta = L^K\mathsf{b}$ with $\mathsf{b} \in [\mathsf{b}_-, \mathsf{b}_+]$, using $c_0 \le 1$ and $2+\beta \le L^K(2+\mathsf{b}_+)$, $q_\beta(s_0) + q^W_\beta(s_0) \le e^{-\frac12 c_0 s_0 \mathsf{b}_- L^K}((L^K(2+\mathsf{b}_+))^{\mathsf{a}} e^{\mathsf{A}} + 7^3 e^{24}(L^K(2+\mathsf{b}_+))^{9/2})$.

Step 3: clauses (a) and (b). For Wilson's action, YM3_I:(2213) bounds $|S^T_{n;K,\ell,L^K\mathsf{b}}(\underline{f}) - S^{(\ell,\mathsf{b})}_n(\underline{f})|$ by the first term of the display, for $\mathsf{b} \in [\mathsf{b}_-, \mathsf{b}_+]$ and $K \ge K_{1,s}(\mathsf{d}) + s$, with s chosen as in YM3_I:(2210). Step 2 contributes the second term, which decays faster than any power of L^{-K}. Theorem YM3_I:AS provides the limit at each $\mathsf{b} > 0$ and the uniformity on compact sets. For (b), YM3_I:(2216) gives $S^T_{n;K_j,\ell,\beta_j}(\underline{f}) \to S^{(\ell,\mathsf{b})}_n(\underline{f})$ along the given sequence, and Step 2 at (K_j, β_j), where $\beta_j = L^{K_j} a_{K_j} \beta_j \ge \frac12 \mathsf{b} L^{K_j}$ for large j, contributes a term tending to 0.

Step 4: clause (c) in the setting (E). Corollary 2.8 (b), (c) supplies Borel probability measures μ_d on $\mathcal{V}(\Lambda_{d,\ell})$ with $|\mu^K_d(E) - \mu_d(E)| \le \sum_{K' \ge K} \mathfrak{o}_{K'}$ for every Borel E and every cutoff K named in (c), where μ^K_d is the law of $\mathcal{M}^{K-d}U$ under Wilson's measure at $\beta = L^K\mathsf{b}$ (Definition 2.7); by Step 2 the law of the same Borel function of U under $\mu^{\mathsf{w}}_{\Lambda_{K,\ell}}$ is within $3\ell^3 L^{3K}(q_\beta(s_0) + q^W_\beta(s_0))$ of μ^K_d.

Step 5: clause (c) at every label on every side. Fix $\mathsf{b} > 0$ and $d \ge 0$, and choose $s \ge d$ so large that $L^s\mathsf{b} \ge \gamma^{-2}$ and $MR(L^s\mathsf{b}) \le L^{m+s}$. Such s exists because $R(x)$ grows at most as a power of $\log x$. Then the setting (E) of §2.3.1 holds at label $L^s\mathsf{b}$ and side $L^s\ell$. The torus $\Lambda_{K,\ell}$ at $\beta = L^K\mathsf{b}$ and the torus $\Lambda_{K-s,L^s\ell}$ at $\beta = L^{K-s}(L^s\mathsf{b})$ are the same lattice with the same Haar measure and the same weight, the dilation δ_s carrying $\Lambda_{j,\ell}$ onto $\Lambda_{j-s,L^s\ell}$; at a bond c of the coarse lattice the averaging map of Section YM3_I:4 is formed from the configuration on the bonds of the double block of c, through plaquette variables, products along contours and their group means, and from the constants ω_M and L^{-3}, while the cutoff and the level occur in that definition only as names of the fine and the coarse lattice. Hence the map $\mathcal{V}(\Lambda_{j,\ell}) \to \mathcal{V}(\Lambda_{j-1,\ell})$ is the same for every cutoff $K \ge j$; and as δ_s maps each block and each contour of $\Lambda_{j,\ell}$, with its sites, bonds and plaquettes, onto the corresponding block or contour of $\Lambda_{j-s,L^s\ell}$, the averaging maps of the two sides are conjugate under δ_s. So the block field of depth s on the side ℓ is the block field of depth 0 on the side $L^s\ell$. By Step 4 on the side $L^s\ell$, its law converges in total variation as $K - s \to \infty$; the block field of depth d is its image under $\mathcal{M}^{s-d}$, and pushing measures forward by a Borel map does not enlarge their distance. So the laws at depth d converge in total variation to the image $\mu_d[\ell, \mathsf{b}]$ of the depth-0 limit on the side $L^s\ell$, which does not depend on s since limits are unique; Step 2 transfers the convergence to admitted weights. □

18.2. **The action density on $\mathbb{R}^3$: its two-point function at and near the diagonal.** For the scalar part of every limit through periodic Gibbs states at a coupling $0 < g \le \gamma_W$ (with γ_W the ceiling of the two-point estimate), that is at the entries $f\mathbf{1}$ of the tensor field $\mathcal{O}^T_K$, $\mathbf{1}$ being the unit 3×3 matrix, where $\mathcal{O}^T_K(f\mathbf{1}) = \mathcal{O}_K(f)$ is the action density, for each component of each canonical decomposition (Theorem YM3_I:AL) of this scalar part, and more generally for every limit in the frame of a Gibbs sequence at g, we describe the connected two-point function S_2 of the action density at and near the diagonal. Away from the diagonal it is the integral of a radial kernel $\mathbf{s}$, the Laplace transform of a positive measure, and $r^6\mathbf{s}(r) \to \frac{9}{16\pi^2\mathsf{b}^2}$ as $r \downarrow 0$, b being the label (Proposition 18.11). For every small $\mathsf{d} > 0$ there is a separated pair of functions with values in $[0,1]$, both supported in one fixed ball and with supports d apart, at which S_2 is at least a fixed positive multiple of d^{-3}; hence S_2 is represented neither by a complex Radon measure nor by a locally integrable function on $\mathbb{R}^3 \times \mathbb{R}^3$. The two functions of such a pair have the norm $\|\cdot\|_\sharp$ equal to one fixed multiple of d^{-1}, so that the product of their norms is a fixed multiple of d^{-2}; since d^{-3} outgrows d^{-2}, no continuation of S_2 is continuous for the norm $\|\cdot\|_\sharp$ (Proposition 18.12). The kernel becomes a distribution in the difference of the two points once two local terms are removed whose coefficients grow like $\frac{3}{4\pi\mathsf{b}^2}\epsilon^{-3}$ and $\frac{3}{8\pi\mathsf{b}^2}\epsilon^{-1}$ as the excised radius ϵ tends to 0, and every extension of it has order at least 4 at the origin and scaling degree at least 6 (Proposition 18.13). Those extensions which are invariant under O(3) and of scaling degree at most 6 form precisely the plane of the distributions $\mathbf{T}_0 + c_0\delta + c_1\Delta\delta$, $(c_0, c_1) \in \mathbb{R}^2$; they share one scaling limit, $\frac{9}{16\pi^2\mathsf{b}^2}$ times the

finite part of $|u|^{-6}$, which acts as $\varphi \mapsto \frac{3}{64\mathsf{b}^2}\int |p|^3\hat{\varphi}(p)\frac{dp}{(2\pi)^3}$ (Proposition 18.14). The points (c_0, c_1) at which the bilinear form of $\mathbf{T}_0 + c_0\delta + c_1\Delta\delta$ is of positive type, that is non-negative at every pair (f, f) with f real, smooth and compactly supported, form a convex set which is not empty and contains with each of its points a whole quadrant; so asking for positive type leaves admissible extensions and does not pick out one of them (Proposition 18.15). The torus, with all six entries, is treated in (F8) of Theorem D; here the space is $\mathbb{R}^3$ and the entries are scalar.

Setting. Fix the construction of the scalar field in YM3 I and the ceiling γ_W of its two-point estimate (Section YM3_I:127). Write $\bar{\varepsilon}_{g,\vartheta}(\mathsf{d})$ and $\mathsf{d}_0(g,\vartheta)$ for its tolerance and threshold, as in YM3_I:(2349)–(2350). The tolerance depends only on the construction, g, ϑ and d. It is non-decreasing in d, tends to zero as $\mathsf{d} \downarrow 0$ and is at most $1/3$ for $0 < \mathsf{d} \le \mathsf{d}_0(g,\vartheta)$, where $0 < \mathsf{d}_0(g,\vartheta) \le 1/200$.

The test pairs $\mathfrak{T}_{\mathbb{R}^3}(\mathsf{d};\vartheta)$ in the estimate consist of two nonzero nonnegative Lipschitz functions f, h supported in closed balls of radius d. The distance of their supports lies in $[\mathsf{d}, 6\mathsf{d}]$. Each entry u satisfies $\int u \ge \vartheta\|u\|_\infty \mathsf{d}^3$ and $\operatorname{Lip} u \le \|u\|_\infty/(\vartheta\mathsf{d})$. The superscript 1 requires both functions to be of class C^1. Set $\mathcal{K}_{\mathrm{free}}(f,h) = \iint f(x)h(y)|x-y|^{-6}\,dx\,dy$ and $\mathsf{c}_2 = 9/(16\pi^2)$.

Write $\mathfrak{S}_n(\mathbb{R}^3)$ for the tuples of n real C^1 functions with compact pairwise disjoint supports, including zero entries. Let $\mathfrak{S} = \bigcup_{n\ge 0}\mathfrak{S}_n(\mathbb{R}^3)$, where $\mathfrak{S}_0(\mathbb{R}^3) = \{\varnothing\}$. Put $\|f\|_\sharp = \max\{\sup|f|, 40M\operatorname{Lip} f\}$, let $\mathbb{B}(x,R)$ be the closed ball and B_R the open ball about zero, and write $(f\otimes h)(x,y) = f(x)h(y)$. For $\eta > 0$, let $\mathsf{v}^\eta_z(y) = (1-|y-z|^2/\eta^2)^2$ on $\mathbb{B}(z,\eta)$ and zero outside. The derivative vanishes on the boundary, so this function is C^1. It has supremum 1, integral $4\pi\eta^3(1/3-2/5+1/7) = 32\pi\eta^3/105$, and Lipschitz constant $8/(3\sqrt{3}\,\eta)$, the maximum of $4s(1-s^2)/\eta$ for $0 \le s \le 1$.

Limits in a frame. For $0 < g \le \gamma_W$, a Gibbs sequence consists of first-passage data $(K_j, \beta_j) \in \mathfrak{d}(g)$ with $K_j \to \infty$ and periodic Gibbs laws $\nu_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$. For $X = (f_1,\dots,f_n) \in \mathfrak{S}$ and a law ν at cutoff K, set $X^\nu_K = \prod_i(\mathcal{O}_K(f_i) - \nu(\mathcal{O}_K(f_i)))$, with the empty product equal to one. A limit in the frame is a functional $\sigma'(X) = \lim_j \rho_j(X^{\nu_j}_{K_j})$ on all these tuples for some approximants $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$. We use three cases.

(i) If the Gibbs sequence converges in its own centering, its limit is obtained with $\rho_j = \nu_j$.

(ii) Theorem YM3_I:AP, with Theorem YM3_I:AL, supplies canonical decompositions of such a limit and obtains every component along the same sequence of cutoffs. Its approximants are $\rho_j = \nu_j(\,\cdot\,|E_j)$ for Borel events E_j invariant under all lattice translations and of positive ν_j-probability. These conditional laws are periodic Gibbs laws.

(iii) For a tensor limit through periodic Gibbs states, the scalar part is $X \mapsto \sigma^T(f_1\mathbf{1},\dots,f_n\mathbf{1})$. At cutoff K_j the scalar tensor insertion $\mathcal{O}^T_{K_j}(f\mathbf{1})$ is exactly $\mathcal{O}_{K_j}(f)$. The moment–cumulant formula for products centered in ν_j sums only over partitions with no singleton blocks. Thus convergence of the tensor cumulants on separated tuples gives convergence of the scalar centered products, with limit equal to the scalar part. This is case (i). The approximants in (F6) of Theorem D likewise give the scalar parts of its components as limits in the same frame when $g \le \min\{\gamma_2, \gamma_W\}$, where γ_2 is the ceiling in (F6).

The two-point function and the label. For a limit in the frame define $S_2(f,h) = \sigma'(f,h) - \sigma'((f))\sigma'((h))$ on separated pairs. Subtracting the product of the two one-point expectations cancels the choice of centering at each cutoff. Hence $S_2(f,h) = \lim_j\langle\mathcal{O}_{K_j}(f);\mathcal{O}_{K_j}(h)\rangle_{\rho_j}$. Proposition YM3_I:127.8 gives convergence of the physical labels $a_{K_j}\beta_j$ to a single b and the leading law for S_2. The limit label depends only on the sequence of data and lies in $I^{\mathrm{lab}}(g) \subset [g^{-2}, \bar{x}_0]$, where $\bar{x}_0 = L(g^{-2}+\bar{B})$, by the first-passage bounds (Corollary YM3_I:74.2). In case (iii), $S_2(f,h) = S_2^T(f\mathbf{1}, h\mathbf{1})$ and b is the label of the tensor limit in (F1) of Theorem D. Write $\mathfrak{a} = \mathsf{c}_2\mathsf{b}^{-2}$.

Words of analysis. $\mathcal{D} = C^\infty_c(\mathbb{R}^3)$ is the space of the real smooth functions with compact support, $\mathcal{S}(\mathbb{R}^3)$ the Schwartz space, and $\hat{\psi}(p) = \int e^{-ip\cdot u}\psi(u)\,du$; $\|\varphi\|_{C^N} = \max_{|\alpha|\le N}\sup|\partial^\alpha\varphi|$, $\|\varphi\|_{(4)} = \sup_u \max_{|e|=1}|(e\cdot\nabla)^4\varphi(u)|$, and $\mathrm{av}_r\varphi = \frac{1}{4\pi}\int_{\mathbb{S}^2}\varphi(r\mathbf{n})\,d\mathbf{n}$ is the mean of φ over the sphere of

radius r about 0. By a distribution we mean a real linear functional $\mathbf{T}$ on $\mathcal{D}$ which, on the functions supported in each ball $\mathbb{B}(0,R)$, obeys a bound $|\mathbf{T}(\varphi)| \le C\|\varphi\|_{C^N}$ with some N and C depending on R; when such a bound is available at $R=1$ with a given N, $\mathbf{T}$ has order $\le N$ near 0. δ and $\Delta\delta$ denote $\varphi \mapsto \varphi(0)$ and $\varphi \mapsto \Delta\varphi(0)$. A distribution $\mathbf{T}$ extends a continuous function $\mathbf{s}$ on $(0,\infty)$, and is then called an extension of $\mathbf{s}$, when $\mathbf{T}(\varphi) = \int \mathbf{s}(|u|)\varphi(u)\,du$ for all $\varphi \in \mathcal{D}$ whose support avoids some ball about 0. For $f, h \in \mathcal{D}$ let $\varphi_{f,h}(u) = \int f(y+u)h(y)\,dy$; then $\varphi_{f,h} \in \mathcal{D}$, $\varphi_{f,h}(0) = \int fh$, $\Delta\varphi_{f,h}(0) = \int(\Delta f)h = -\int \nabla f \cdot \nabla h$, $\int \varphi_{f,f} = (\int f)^2$, $\hat\varphi_{f,f} = |\hat f|^2$, a common translation of f and h leaves $\varphi_{f,h}$ unchanged, and $\varphi_{f\circ\mathsf{R}^{-1},h\circ\mathsf{R}^{-1}} = \varphi_{f,h}\circ\mathsf{R}^{-1}$ for $\mathsf{R} \in \mathrm{O}(3)$; the letter R always denotes an element of $\mathrm{O}(3)$, while R and R_0 are radii. To a distribution $\mathbf{T}$ we attach the bilinear form $\mathbf{S}_{\mathbf{T}}(f,h) = \mathbf{T}(\varphi_{f,h})$ on $\mathcal{D}$. When $\operatorname{dist}(\operatorname{supp} f, \operatorname{supp} h) = d' > 0$, $\varphi_{f,h}$ vanishes on $B_{d'}$, and if $\mathbf{T}$ extends $\mathbf{s}$, Fubini's theorem turns $\mathbf{S}_{\mathbf{T}}(f,h)$ into $\iint f(x)h(y)\mathbf{s}(|x-y|)\,dx\,dy$.

For $t>0$ the dilate of a distribution $\mathbf{T}$ is $\mathbf{T}_t(\varphi) = t^{-3}\mathbf{T}(\varphi(\cdot/t))$; we say that $\mathbf{T}$ is of scaling degree at most ω_0 when $t^\omega \mathbf{T}_t(\varphi) \to 0$ as $t \downarrow 0$ for all $\omega > \omega_0$ and all $\varphi \in \mathcal{D}$. We call an extension admissible when $\mathbf{T}(\varphi\circ\mathsf{R}) = \mathbf{T}(\varphi)$ for every $\mathsf{R} \in \mathrm{O}(3)$ and its scaling degree is at most 6; and $\mathbf{T}$ has positive type when $\mathbf{S}_{\mathbf{T}}(f,f) \ge 0$ for all $f \in \mathcal{D}$. Hadamard's finite part of $|u|^{-6}$ is the functional $\mathrm{Pf}|u|^{-6}(\varphi) = 4\pi\int_0^\infty r^{-4}[\mathrm{av}_r\varphi - \varphi(0) - \frac{r^2}{6}\Delta\varphi(0)]\,dr$, defined for φ in $\mathcal{D}$ and in $\mathcal{S}(\mathbb{R}^3)$; the integral converges absolutely, by Step 6 of the proof of Proposition 18.14. By a complex Radon measure on $\mathbb{R}^3\times\mathbb{R}^3$ we mean a $\mathbb{C}$-linear functional m on the continuous compactly supported complex functions on $\mathbb{R}^6$ that is bounded on each compact set: for each compact $\mathcal{C} \subset \mathbb{R}^6$ there is $C_{\mathcal{C}}$ with $|m(F)| \le C_{\mathcal{C}} \sup|F|$ whenever $\operatorname{supp} F \subset \mathcal{C}$. Integration against a locally integrable function k is one, with $C_{\mathcal{C}} = \int_{\mathcal{C}} |k|$. e is Euler's number.

Proposition 18.11 (The radial kernel at short distance)**.** Let $0 < g \le \gamma_W$, and let σ' be a limit in the frame of a Gibbs sequence at g, with S_2, $\mathfrak{b}$ and $\mathfrak{a}$ as above.

(a) A unique continuous function $\mathbf{s}:(0,\infty)\to\mathbb{R}$ represents S_2 on separated pairs: $S_2(f,h) = \iint f(x)h(y)\,\mathbf{s}(|x-y|)\,dx\,dy$ for every $(f,h) \in \mathfrak{S}_2(\mathbb{R}^3)$. This $\mathbf{s}$ is real-analytic on $(0,\infty)$ and satisfies $0 \le \mathbf{s}(r) \le C_{\mathrm{pt}}^2 \min\{1, \frac{r}{2}\}^{-8}$, where $C_{\mathrm{pt}} = C_{\mathrm{pt}}^g$ is the point-field constant in YM3_I:(2097).

(b) The kernel is a Laplace transform: $\mathbf{s}(r) = \int_{[0,\infty)} e^{-rE}\,d\mathfrak{m}(E)$ for all $r>0$, with a positive Borel measure $\mathfrak{m}$ on $[0,\infty)$ that gives finite mass to bounded sets; hence $\mathbf{s}$ is non-increasing.

(c) As $r \downarrow 0$, $r^6\mathbf{s}(r) \to \mathfrak{a} = \frac{9}{16\pi^2\mathfrak{b}^2}$. Quantitatively: given $\zeta \in (0, \frac12]$, with $\vartheta_\zeta := \frac{32\pi}{105}\zeta^3$ and $q_\zeta := \frac{3+2\zeta}{3-2\zeta}$, every $r \in (0, (3-2\zeta)\,\mathfrak{d}_0(g,\vartheta_\zeta)]$ satisfies $q_\zeta^{-6}(1-\bar\varepsilon_{g,\vartheta_\zeta}(\frac{r}{3-2\zeta})) \le r^6\mathbf{s}(r)/\mathfrak{a} \le q_\zeta^6(1+\bar\varepsilon_{g,\vartheta_\zeta}(\frac{r}{3+2\zeta}))$. For $\zeta = \frac12$ this yields $\frac{1}{96}\mathfrak{a}\,r^{-6} \le \mathbf{s}(r) \le \frac{256}{3}\mathfrak{a}\,r^{-6}$ on $0 < r \le \mathbf{r}_g := 2\,\mathfrak{d}_0(g, \frac{4\pi}{105})$, and $\mathbf{c}_6 := \sup_{0<r\le1} r^6\mathbf{s}(r) \le \frac{256}{3}\mathfrak{a}\,\mathbf{r}_g^{-6}$. The numbers ϑ_ζ, q_ζ, $\bar\varepsilon_{g,\vartheta}$, $\mathfrak{d}_0(g,\vartheta)$ and $\mathbf{r}_g$ are common to all Gibbs sequences at g and all limits in their frames.

■

Proof. Step 1: the centred functional. For each f, the difference $\rho_j(\mathcal{O}_{K_j}(f)) - \nu_j(\mathcal{O}_{K_j}(f))$ converges to $\sigma'((f))$. Expanding a product centered in ρ_j in terms of products centered in ν_j thus gives a limit on every separated tuple. Denote it by σ'^{c}. It has zero one-point function and equals S_2 on separated pairs. Proposition YM3_I:111.1 gives scalar reconstruction data for this centred limit, with exponent $\wp = 4$ and point-field constant C_{pt}^g. Its proof gives the centred insertion estimates required for the point fields of Proposition YM3_I:97.2.

Step 2: the radial kernel. Proposition YM3_I:108.3 represents σ'^{c} on separated pairs by a unique real-analytic kernel on $\{(x,y) : x \ne y\}$. Euclidean invariance makes this kernel $\mathbf{s}(|x-y|)$. To identify its value, let $u = (r/2)e_3$ and let h_δ be nonnegative smooth approximate identities at u of integral 1, carried by $0 < x_3 < r$. Write $\theta x = (x_1, x_2, -x_3)$. In the reflection Hilbert space of σ'^{c}, $\|[(h_\delta)]\|^2 = \sigma'^{\mathrm{c}}(\theta h_\delta, h_\delta) \to \mathbf{s}(r)$. The slab insertion formula and the point-field integral of

Proposition YM3_I:97.2 give

$$[(h_\delta)] = \int h_\delta(x)\, B(x, re_3 - x)\Omega_{\mathrm{c}}\, dx \;\longrightarrow\; B(u,u)\Omega_{\mathrm{c}}.$$

Here the slab operator for h_δ applied to the vacuum is its one-entry vector, and the convergence follows from norm continuity of B near (u,u). The shift law and $\mathsf{T}_3(te_3)\Omega_{\mathrm{c}} = \Omega_{\mathrm{c}}$ allow the second argument to be changed from u to e_3. Apply the shift law from the smaller to the larger height in the second slot. Therefore $\mathbf{s}(r) = \|B((r/2)e_3, e_3)\Omega_{\mathrm{c}}\|^2$, and the norm estimate in Proposition YM3_I:97.2 gives (a).

Step 3: the semigroup and its spectral measure. Put $\psi_\epsilon = B(\epsilon e_3, e_3)\Omega_{\mathrm{c}}$ for $\epsilon > 0$. The shift law in the first slot gives $\psi_\epsilon = e^{-(\epsilon-\epsilon')H}\psi_{\epsilon'}$ for $0 < \epsilon' \le \epsilon$. Here $H \ge 0$ is the generator of the reflection semigroup. Let $\mathfrak{m}_\epsilon$ be the positive spectral measure of H in ψ_ϵ. By the spectral theorem,

$$d\mathfrak{m}_\epsilon(E) = e^{-2(\epsilon-\epsilon')E}\, d\mathfrak{m}_{\epsilon'}(E).$$

Thus $e^{2\epsilon E} d\mathfrak{m}_\epsilon(E)$ is independent of ϵ. Denote this positive measure by $d\mathfrak{m}(E)$. Its mass on $[0,N]$ is at most $e^{2\epsilon N}\|\psi_\epsilon\|^2$ for every $\epsilon > 0$. Since $\mathbf{s}(r) = \|\psi_{r/2}\|^2$, we obtain $\mathbf{s}(r) = \int e^{-rE} d\mathfrak{m}(E)$ and monotonicity, proving (b).

Step 4: the two-point law, at each shape. Proposition YM3_I:127.8 applies to the converging covariances in the frame. It gives, at each $0 < \mathsf{d} \le \mathsf{d}_0(g,\vartheta)$ and each $(f,h) \in \mathfrak{T}^1_{\mathbb{R}^3}(\mathsf{d};\vartheta)$,

$$|S_2(f,h) - \mathfrak{a}\,\mathcal{K}_{\mathrm{free}}(f,h)| \le \bar\varepsilon_{g,\vartheta}(\mathsf{d})\,\mathfrak{a}\,\mathcal{K}_{\mathrm{free}}(f,h). \tag{L}$$

Step 5: a test pair made of two small bumps. Let $0 < \zeta \le \frac12$ and $\mathsf{d} > 0$, and consider $f = \mathsf{v}_0^{\zeta\mathsf{d}}$ and $h = \mathsf{v}_{3\mathsf{d}e_3}^{\zeta\mathsf{d}}$, with the centres 0 and $3\mathsf{d}e_3$. The test-pair conditions at $(\mathsf{d};\vartheta_\zeta)$ hold. Each support is the ball of radius $\zeta\mathsf{d} \le \mathsf{d}$ about its centre, and the two supports are $(3-2\zeta)\mathsf{d} \in [2\mathsf{d}, 3\mathsf{d})$ apart; $\int f = \int h = \vartheta_\zeta \mathsf{d}^3$, both suprema being 1; and $\operatorname{Lip} f = \operatorname{Lip} h = \frac{8}{3\sqrt3\,\zeta\mathsf{d}}$ does not exceed $\frac{1}{\vartheta_\zeta\mathsf{d}}$, because $\vartheta_\zeta \le \frac{32\pi}{420}\zeta < 0.24\,\zeta < \frac{3\sqrt3}{8}\zeta$. Also $0 < \vartheta_\zeta \le \frac{4\pi}{105} < 1$, and f, h are non-negative, non-zero and of class C^1. Thus $(f,h) \in \mathfrak{T}^1_{\mathbb{R}^3}(\mathsf{d};\vartheta_\zeta)$.

Step 6: (c). Take $0 < \mathsf{d} \le \mathsf{d}_0(g,\vartheta_\zeta)$, the pair (f,h) of Step 5, and $m = \int f \int h > 0$. For $x \in \operatorname{supp} f$ and $y \in \operatorname{supp} h$ the distance $|x-y|$ lies between $(3-2\zeta)\mathsf{d}$ and $(3+2\zeta)\mathsf{d}$. Since f and h are non-negative and $\mathbf{s}$ is non-increasing, the representation (a) squeezes $S_2(f,h)$ between $\mathbf{s}((3+2\zeta)\mathsf{d})\,m$ and $\mathbf{s}((3-2\zeta)\mathsf{d})\,m$, and the same reasoning squeezes $\mathcal{K}_{\mathrm{free}}(f,h)$ between $((3+2\zeta)\mathsf{d})^{-6}m$ and $((3-2\zeta)\mathsf{d})^{-6}m$. Combined with (L) at $\vartheta = \vartheta_\zeta$ this gives $\mathbf{s}((3+2\zeta)\mathsf{d}) \le (1+\bar\varepsilon_{g,\vartheta_\zeta}(\mathsf{d}))\,\mathfrak{a}\,((3-2\zeta)\mathsf{d})^{-6}$ and $\mathbf{s}((3-2\zeta)\mathsf{d}) \ge (1-\bar\varepsilon_{g,\vartheta_\zeta}(\mathsf{d}))\,\mathfrak{a}\,((3+2\zeta)\mathsf{d})^{-6}$. Writing r for $(3+2\zeta)\mathsf{d}$ in the upper and for $(3-2\zeta)\mathsf{d}$ in the lower inequality turns them into the two bounds of (c), valid for r up to $(3+2\zeta)\mathsf{d}_0(g,\vartheta_\zeta)$ and up to $(3-2\zeta)\mathsf{d}_0(g,\vartheta_\zeta)$ respectively. Letting $r \downarrow 0$ at fixed ζ, where $\bar\varepsilon_{g,\vartheta_\zeta} \to 0$, shows that the lower and upper limits of $r^6\mathbf{s}(r)/\mathfrak{a}$ lie in $[q_\zeta^{-6}, q_\zeta^6]$; as $q_\zeta \to 1$ for $\zeta \to 0$, the limit is 1. For $\zeta = \frac12$ one has $q_\zeta = 2$, $\vartheta_\zeta = \frac{4\pi}{105}$ and $3-2\zeta = 2$, and the tolerances at $\frac{r}{2}$ and $\frac{r}{4}$, both $\le \mathsf{d}_0(g, \frac{4\pi}{105})$ when $r \le \mathbf{r}_g$, are at most $\frac13$; this gives the factors $\frac23 \cdot 2^{-6} = \frac{1}{96}$ and $\frac43 \cdot 2^6 = \frac{256}{3}$. Finally $\mathbf{r}_g \le \frac{1}{100}$: on $[\mathbf{r}_g, 1]$, $r^6\mathbf{s}(r) \le \mathbf{s}(r) \le \mathbf{s}(\mathbf{r}_g) \le \frac{256}{3}\mathfrak{a}\,\mathbf{r}_g^{-6}$ by (b), and on $(0, \mathbf{r}_g]$, $r^6\mathbf{s}(r) \le \frac{256}{3}\mathfrak{a} \le \frac{256}{3}\mathfrak{a}\,\mathbf{r}_g^{-6}$. The numbers listed at the end of (c) are built from the radius, the constants and g (YM3_I:(2349)), not from the sequence or the limit. □

Proposition 18.12 (Neither a measure nor a locally integrable function; no continuous continuation)**.** Let g, σ', S_2, $\mathfrak{a}$ and $\mathbf{s}$ be as in Proposition 18.11. For $0 < \mathsf{d} \le \mathsf{d}_0(g, \frac12)$ let $N = \lfloor \frac{1}{8\mathsf{d}} \rfloor$, $\mathsf{G} = \{0, \dots, N-1\}^3$, $x_\iota = 8\mathsf{d}\,\iota$ and $y_\iota = x_\iota + 3\mathsf{d}\,e_3$ for $\iota \in \mathsf{G}$, and $f_\mathsf{d} = \sum_{\iota\in\mathsf{G}} \mathsf{v}^{\mathsf{d}}_{x_\iota}$, $h_\mathsf{d} = \sum_{\iota\in\mathsf{G}} \mathsf{v}^{\mathsf{d}}_{y_\iota}$.

(a) The pair $(f_\mathsf{d}, h_\mathsf{d})$ is separated; both functions take values in $[0,1]$, both supports lie in $\mathbb{B}(0,3)$ and are d apart, $\operatorname{Lip} f_\mathsf{d} = \operatorname{Lip} h_\mathsf{d} = \frac{8}{3\sqrt3}\mathsf{d}^{-1}$, $\|f_\mathsf{d}\|_\sharp = \|h_\mathsf{d}\|_\sharp = \frac{320M}{3\sqrt3\,\mathsf{d}}$, and $S_2(f_\mathsf{d}, h_\mathsf{d}) \ge \frac{10^{-6}}{24576}\,\mathfrak{a}\,\mathsf{d}^{-3}$.

(b) There is no complex Radon measure m on $\mathbb{R}^3\times\mathbb{R}^3$ such that $S_2(f,h)=m(f\otimes h)$ on all of $\mathfrak{S}_2(\mathbb{R}^3)$; a fortiori no locally integrable k on $\mathbb{R}^3\times\mathbb{R}^3$ gives $S_2(f,h)=\iint f(x)h(y)k(x,y)\,dx\,dy$ on these pairs. Moreover $\int_{B_R}\mathfrak{s}(|u|)\,du=\infty$ for every $R>0$.

(c) Fix $0<\mathsf{d}\le\mathsf{d}_0(g,\frac12)$. A number C with $|S_2(f,h)|\le C\|f\|_\sharp\|h\|_\sharp$ for every $(f,h)\in\mathfrak{S}_2(\mathbb{R}^3)$ whose supports lie in $\mathbb{B}(0,3)$ and are at least d apart must be $\ge 10^{-14}\mathfrak{a}\,M^{-2}\mathsf{d}^{-1}$; with $\sup|f|\sup|h|$ instead of $\|f\|_\sharp\|h\|_\sharp$ it must be $\ge\frac{10^{-6}}{24576}\mathfrak{a}\,\mathsf{d}^{-3}$. Hence $|S_2(f,h)|$ admits no bound $C\|f\|_\sharp\|h\|_\sharp$ with one C for all separated pairs supported in $\mathbb{B}(0,3)$. In particular, for $R\ge3$, the number $C_2^g(\mathsf{d};R)$ of the uniform cumulant bound in Proposition YM3_I: 91.13 is at least $10^{-14}\mathsf{c}_2\,\bar{x}_0^{-2}M^{-2}\mathsf{d}^{-1}$; and when moreover $g\le\gamma_1$, γ_1 being the bound on the coupling in (C1) and (D1) of Theorem C, the number $C_2^T(\mathsf{d};R)$ of (C1) obeys $3600\,C_2^T(\mathsf{d};R)\ge\frac{10^{-6}}{24576}\mathsf{c}_2\,\mathsf{d}^{-3}$.

(d) The separated pairs $(\mathsf{d}^{5/4}f_\mathsf{d},\mathsf{d}^{5/4}h_\mathsf{d})$ satisfy $\|\mathsf{d}^{5/4}f_\mathsf{d}\|_\sharp=\|\mathsf{d}^{5/4}h_\mathsf{d}\|_\sharp=\frac{320M}{3\sqrt3}\mathsf{d}^{1/4}\to0$ and $S_2(\mathsf{d}^{5/4}f_\mathsf{d},\mathsf{d}^{5/4}h_\mathsf{d})\ge\frac{10^{-6}}{24576}\mathfrak{a}\,\mathsf{d}^{-1/2}\to\infty$ as $\mathsf{d}\to0$. Consequently, if Φ is any map into $\mathbb{R}$ defined on a set of pairs of real C^1 functions supported in $\mathbb{B}(0,3)$ which contains $(0,0)$ and all these pairs, and $\Phi=S_2$ at the separated pairs of that set, then Φ is discontinuous at $(0,0)$ for the distance $\max\{\|f-f'\|_\sharp,\|h-h'\|_\sharp\}$. In particular no bilinear form on these functions, continuous for $\|\cdot\|_\sharp$, coincides with S_2 on separated pairs, and S_2 itself is discontinuous at the separated pair $(0,0)$, where its value is 0.

■

Proof. Step 1: geometry of the bumps. From $\mathsf{d}\le\mathsf{d}_0(g,\frac12)\le\frac{1}{200}$ we get $N\ge\frac{1}{8\mathsf{d}}-1\ge\frac{1}{16\mathsf{d}}\ge1$. Every coordinate of an x_ι is in $[0,1)$, and $y_\iota\in[0,1)^2\times[3\mathsf{d},1+3\mathsf{d})$, so each ball $\mathbb{B}(x_\iota,\mathsf{d})$ or $\mathbb{B}(y_\iota,\mathsf{d})$ is contained in $\mathbb{B}(0,\sqrt3+4\mathsf{d})\subset\mathbb{B}(0,3)$. Two different x_ι, or two different y_ι, are at least $8\mathsf{d}$ apart. The vector $x_\iota-y_{\iota'}=8\mathsf{d}(\iota-\iota')-3\mathsf{d}e_3$ has length $3\mathsf{d}$ for $\iota=\iota'$; for $\iota\ne\iota'$ its length is $\ge5\mathsf{d}$: if ι and ι' differ in the third entry only, $|8n-3|\ge5$ for each integer $n\ne0$, and otherwise some other coordinate has modulus $\ge8\mathsf{d}$. Hence no two of the $2N^3$ balls meet; the support of f_d is the union of the balls centred at the x_ι, that of h_d the union of those centred at the y_ι, both compact, and their distance is $3\mathsf{d}-2\mathsf{d}=\mathsf{d}$; so $(f_\mathsf{d},h_\mathsf{d})\in\mathfrak{S}_2(\mathbb{R}^3)$. As the bumps of one sum have disjoint supports, f_d and h_d are C^1 with values in $[0,1]$ and gradients of supremum $\frac{8}{3\sqrt3}\mathsf{d}^{-1}$, which is their Lipschitz constant by the mean-value formula. The definition of $\|\cdot\|_\sharp$ gives $\|f_\mathsf{d}\|_\sharp=\|h_\mathsf{d}\|_\sharp=\max\{1,\frac{320M}{3\sqrt3\,\mathsf{d}}\}=\frac{320M}{3\sqrt3\,\mathsf{d}}$.

Step 2: (a). Expanding f_d and h_d in the representation of Proposition 18.11(a) writes $S_2(f_\mathsf{d},h_\mathsf{d})$ as $\sum_{\iota,\iota'\in\mathsf{G}}\iint\mathsf{v}^\mathsf{d}_{x_\iota}(x)\mathsf{v}^\mathsf{d}_{y_{\iota'}}(y)\,\mathfrak{s}(|x-y|)\,dx\,dy$, a sum of non-negative numbers since $\mathfrak{s}\ge0$; the summand with $\iota=\iota'$ equals $S_2(\mathsf{v}^\mathsf{d}_{x_\iota},\mathsf{v}^\mathsf{d}_{y_\iota})$. Each diagonal pair is in $\mathfrak{T}^1_{\mathbb{R}^3}(\mathsf{d};\frac12)$. Its two supports have radius d and distance d, and the bump integral and Lipschitz bounds above give the remaining two conditions. Inequality (L) of the proof of Proposition 18.11 at $\vartheta=\frac12$, with $\bar\varepsilon_{g,1/2}(\mathsf{d})\le\frac13$, together with $\mathcal{K}_{\text{free}}\ge(32\pi/105)^2 5^{-6}>10^{-6}/4$ (all point distances are at most $5\mathsf{d}$), bounds each diagonal summand below by $\frac23\,\mathfrak{a}\,10^{-6}\cdot\frac14=\frac{10^{-6}}{6}\mathfrak{a}$. There are $N^3\ge(16\mathsf{d})^{-3}$ of them, so $S_2(f_\mathsf{d},h_\mathsf{d})\ge\frac{10^{-6}}{6\cdot16^3}\mathfrak{a}\,\mathsf{d}^{-3}$, where $6\cdot16^3=24576$.

Step 3: (b). Suppose m were a measure as excluded in (b), and let $\mathcal{C}=\mathbb{B}(0,3)\times\mathbb{B}(0,3)$. The continuous function $f_\mathsf{d}\otimes h_\mathsf{d}$ is supported in $\mathcal{C}$ and bounded by 1, so $S_2(f_\mathsf{d},h_\mathsf{d})=m(f_\mathsf{d}\otimes h_\mathsf{d})$ would stay below $C_\mathcal{C}$ for all $\mathsf{d}\in(0,\mathsf{d}_0(g,\frac12)]$, which (a) contradicts for small d. Since integration against a locally integrable k is such a measure, no such k exists either. For the last claim, Proposition 18.11(c) gives $\mathfrak{s}(r)\ge\frac{1}{96}\mathfrak{a}\,r^{-6}$ on $(0,\mathbf{r}_g]$, hence $\int_{B_R}\mathfrak{s}(|u|)\,du\ge\frac{4\pi}{96}\mathfrak{a}\int_0^{\min\{R,\mathbf{r}_g\}}r^{-4}dr=\infty$.

Step 4: (c). The hypothesis on C covers the pair $(f_\mathsf{d},h_\mathsf{d})$. From (a) and Step 1, $C\ge\frac{10^{-6}}{24576}\mathfrak{a}\,\mathsf{d}^{-3}\cdot\frac{27\,\mathsf{d}^2}{320^2M^2}=\frac{27\cdot10^{-6}}{24576\cdot102400}\mathfrak{a}\,M^{-2}\mathsf{d}^{-1}\ge10^{-14}\mathfrak{a}\,M^{-2}\mathsf{d}^{-1}$, since $\frac{27}{24576\cdot102400}>1.07\cdot10^{-8}$; with suprema, both equal to 1, one gets $C\ge\frac{10^{-6}}{24576}\mathfrak{a}\,\mathsf{d}^{-3}$. A single C valid for all separated pairs in $\mathbb{B}(0,3)$ would be admissible at every d, which these lower bounds forbid as $\mathsf{d}\to0$. For the two consequences,

note that the pair has supports in $\mathbb{B}(0,R)$ at distance d for every $R \geq 3$. Choose a Gibbs sequence at a fixed label in $I(g)$ and extract a convergent subsequence by Theorem YM3_I:AP. Its limit has $\mathfrak{a} \geq \mathsf{c}_2 \bar{x}_0^{-2}$. The uniform bound of Proposition YM3_I:91.13 passes to its S_2 with the same $C_2^g(\mathsf{d};R)$, so the first estimate of (c) applies with $C = C_2^g(\mathsf{d};R)$. If also $g \leq \gamma_1$, (D1) of Theorem C extracts from any Gibbs sequence at g a subsequence along which all $S_n^T[\nu_j](X)$ converge, that is a limit through periodic Gibbs states, whose scalar part is a case (iii) of σ'; by (D1) its S_2^T obeys the bound of (C1) with b for b, so that $S_2(f_\mathsf{d}, h_\mathsf{d}) = S_2^T(f_\mathsf{d}\mathbf{1}, h_\mathsf{d}\mathbf{1}) \leq 3600\, C_2^T(\mathsf{d};R)\, \mathsf{b}^{-2}$, the suprema of the entries $f_\mathsf{d}\mathbf{1}$, $h_\mathsf{d}\mathbf{1}$ being 1; comparing with (a) gives the last bound.

Step 5: (d). Multiplying both entries by $c > 0$ keeps the pair separated, with the supports of Step 1, and multiplies S_2 by c^2 (Proposition 18.11(a)); for $c = \mathsf{d}^{5/4}$, Step 1 and (a) give the norms and the lower bound stated. Were Φ continuous at $(0,0)$, its values at these pairs would converge to the real number $\Phi(0,0)$ as $\mathsf{d} \to 0$; but they are values of S_2 and diverge. A bilinear form continuous for $\|\cdot\|_\sharp$ would be such a Φ. Finally, $(0,0)$ is a separated pair, the zero function being an allowed entry, and $S_2(0,0) = 0$ by Proposition 18.11(a). □

Proposition 18.13 (Two divergent local counterterms; an admissible extension)**.** Let g, σ', S_2, $\mathfrak{a}$, $\mathbf{s}$ and $\mathbf{c}_6$ be as in Proposition 18.11.

(a) Let f and h be real, continuous and compactly supported on $\mathbb{R}^3$. Then, as $\epsilon \downarrow 0$,
$$\epsilon^3 \iint_{|x-y|>\epsilon} f(x)h(y)\,\mathbf{s}(|x-y|)\,dx\,dy \longrightarrow \frac{4\pi}{3}\mathfrak{a}\int fh = \frac{3}{4\pi\mathsf{b}^2}\int fh.$$

(b) Set $\mathbf{A}_0(\epsilon) = 4\pi\int_\epsilon^1 \mathbf{s}(r)r^2\,dr$ and $\mathbf{A}_2(\epsilon) = \frac{2\pi}{3}\int_\epsilon^1 \mathbf{s}(r)r^4\,dr$ for $0 < \epsilon < 1$. As $\epsilon \downarrow 0$, $\epsilon^3\mathbf{A}_0(\epsilon) \to \frac{3}{4\pi\mathsf{b}^2}$ and $\epsilon\,\mathbf{A}_2(\epsilon) \to \frac{3}{8\pi\mathsf{b}^2}$.

(c) For each $\varphi \in \mathcal{D}$ the limit $\mathbf{T}_0(\varphi) := \lim_{\epsilon\downarrow 0}[\int_{|u|>\epsilon} \mathbf{s}(|u|)\varphi(u)\,du - \mathbf{A}_0(\epsilon)\varphi(0) - \mathbf{A}_2(\epsilon)\Delta\varphi(0)]$ is finite, equal to $4\pi\int_0^1 \mathbf{s}(r)r^2[\mathrm{av}_r\varphi - \varphi(0) - \frac{r^2}{6}\Delta\varphi(0)]\,dr + \int_{|u|\geq 1}\mathbf{s}(|u|)\varphi(u)\,du$, and bounded by $\frac{\pi}{6}\mathbf{c}_6\|\varphi\|_{(4)} + \mathbf{s}(1)\|\varphi\|_{L^1}$. $\mathbf{T}_0$ is a distribution, of order at most 4, which extends $\mathbf{s}$, satisfies $\mathbf{T}_0(\varphi\circ\mathsf{R}) = \mathbf{T}_0(\varphi)$ for $\mathsf{R} \in \mathrm{O}(3)$, and has $t^6(\mathbf{T}_0)_t(\varphi) \to \mathfrak{a}\,\mathrm{Pf}|u|^{-6}(\varphi)$ as $t \downarrow 0$ for each $\varphi \in \mathcal{D}$; hence its scaling degree is at most 6 and $\mathbf{T}_0$ is admissible. Its form is $\mathbf{S}_{\mathbf{T}_0}(f,h) = \lim_{\epsilon\downarrow 0}[\iint_{|x-y|>\epsilon} f(x)h(y)\,\mathbf{s}(|x-y|)\,dx\,dy - \mathbf{A}_0(\epsilon)\int fh + \mathbf{A}_2(\epsilon)\int \nabla f\cdot\nabla h]$ for $f, h \in \mathcal{D}$, and it agrees with $S_2(f,h)$ when $\mathrm{supp}\, f \cap \mathrm{supp}\, h = \emptyset$.

(d) Every extension of $\mathbf{s}$, admissible or not, has order larger than 3 near 0: there is no bound $|\mathbf{T}(\varphi)| \leq C\|\varphi\|_{C^N}$ with $N \leq 3$ for the φ supported in $\mathbb{B}(0,1)$; in particular no bound by $C\sup|\varphi|$, so no extension is given by a measure.

(e) For every extension $\mathbf{T}$ of $\mathbf{s}$ and every $\omega_0 < 6$, the scaling degree of $\mathbf{T}$ is not at most ω_0. ■

Proof. Step 1: Taylor's formula on spheres. Fix $\varphi \in C^4(\mathbb{R}^3)$, $r > 0$ and $\mathbf{n} \in \mathbb{S}^2$. Expanding $t \mapsto \varphi(t\mathbf{n})$ on $[0,r]$ to third order with Lagrange's remainder gives $\varphi(r\mathbf{n}) = \sum_{k=0}^3 \frac{r^k}{k!}(\mathbf{n}\cdot\nabla)^k\varphi(0) + \frac{r^4}{24}(\mathbf{n}\cdot\nabla)^4\varphi(t_0 r\mathbf{n})$ with some $t_0 \in (0,1)$. Averaging over $\mathbb{S}^2$ kills the terms with $k = 1$ and $k = 3$, which are odd in $\mathbf{n}$, and turns the term $k = 2$ into $\frac{r^2}{6}\Delta\varphi(0)$, by $\frac{1}{4\pi}\int_{\mathbb{S}^2} n_i n_j\,d\mathbf{n} = \frac{1}{3}\delta_{ij}$; the remainder depends continuously on $\mathbf{n}$, as a difference of continuous functions, and has modulus $\leq \frac{r^4}{24}\|\varphi\|_{(4)}$. So $|\mathrm{av}_r\varphi - \varphi(0) - \frac{r^2}{6}\Delta\varphi(0)| \leq \frac{r^4}{24}\|\varphi\|_{(4)}$.

Step 2: (a). The function $\varphi = \varphi_{f,h}$, given by the same formula, is continuous with compact support, and $\varphi(0) = \int fh$. On $[\epsilon,\infty)$ the kernel is bounded (Proposition 18.11(b)); so, changing variables to $x = y + u$ and using Fubini's theorem, $I_\epsilon := \iint_{|x-y|>\epsilon} f(x)h(y)\,\mathbf{s}(|x-y|)\,dx\,dy$ equals $\int_{|u|>\epsilon}\varphi(u)\,\mathbf{s}(|u|)\,du$. Given $\eta > 0$, pick $r_0 \in (0,1]$ so small that $|r^6\mathbf{s}(r) - \mathfrak{a}| \leq \eta$ on $(0,r_0]$ (Proposition 18.11(c)) and $|\varphi(u) - \varphi(0)| \leq \eta$ on $|u| \leq r_0$. As $\int_{\epsilon<|u|\leq r_0}|u|^{-6}du = \frac{4\pi}{3}(\epsilon^{-3} - r_0^{-3})$, for $\epsilon < r_0$ we may write $I_\epsilon - \frac{4\pi}{3}\mathfrak{a}\,\varphi(0)\,\epsilon^{-3} = \int_{\epsilon<|u|\leq r_0}[\varphi(u)|u|^6\mathbf{s}(|u|) - \mathfrak{a}\,\varphi(0)]\,|u|^{-6}du - \frac{4\pi}{3}\mathfrak{a}\,\varphi(0)\,r_0^{-3} +$

$\int_{|u|>r_0}\varphi(u)\,\mathbf{s}(|u|)\,du$. In modulus the expression in brackets does not exceed $|\varphi(u)-\varphi(0)|\,|u|^6\mathbf{s}(|u|)+|\varphi(0)|\,\big||u|^6\mathbf{s}(|u|)-\mathfrak{a}\big|\le\eta(\mathfrak{a}+\eta+|\varphi(0)|)$, and beyond r_0 the kernel is at most $\mathbf{s}(r_0)$. Therefore $|\epsilon^3 I_\epsilon-\frac{4\pi}{3}\mathfrak{a}\,\varphi(0)|\le\frac{4\pi}{3}\eta(\mathfrak{a}+\eta+|\varphi(0)|)+\epsilon^3[\frac{4\pi}{3}\mathfrak{a}\,|\varphi(0)|\,r_0^{-3}+\mathbf{s}(r_0)\|\varphi\|_{L^1}]$. First ϵ and then η go to 0; and $\frac{4\pi}{3}\mathsf{c}_2=\frac{3}{4\pi}$.

Step 3: (b). Given $\eta>0$, take $r_0\in(0,1]$ with $|r^6\mathbf{s}(r)-\mathfrak{a}|\le\eta$ on $(0,r_0]$, let $\epsilon<r_0$, and split $\mathbf{A}_0(\epsilon)$ and $\mathbf{A}_2(\epsilon)$ at r_0. Since $\mathbf{s}(r)r^2=r^{-4}\cdot r^6\mathbf{s}(r)$, $|\mathbf{A}_0(\epsilon)-4\pi\mathfrak{a}\int_\epsilon^{r_0}r^{-4}dr|\le 4\pi\eta\int_\epsilon^{r_0}r^{-4}dr+4\pi\int_{r_0}^1\mathbf{s}(r)r^2dr$, and $\int_\epsilon^{r_0}r^{-4}dr=\frac13(\epsilon^{-3}-r_0^{-3})$; multiplying by ϵ^3 and letting $\epsilon\to0$ leaves $\limsup|\epsilon^3\mathbf{A}_0(\epsilon)-\frac{4\pi}{3}\mathfrak{a}|\le\frac{4\pi}{3}\eta$. In the same way, from $\mathbf{s}(r)r^4=r^{-2}\cdot r^6\mathbf{s}(r)$ and $\int_\epsilon^{r_0}r^{-2}dr=\epsilon^{-1}-r_0^{-1}$, $\limsup|\epsilon\,\mathbf{A}_2(\epsilon)-\frac{2\pi}{3}\mathfrak{a}|\le\frac{2\pi}{3}\eta$. The constants are $\frac{4\pi}{3}\mathsf{c}_2=\frac{3}{4\pi}$ and $\frac{2\pi}{3}\mathsf{c}_2=\frac{3}{8\pi}$.

Step 4: (c). Passing to polar coordinates one finds, for $0<\epsilon<1$, $\int_{|u|>\epsilon}\mathbf{s}(|u|)\varphi(u)\,du-\mathbf{A}_0(\epsilon)\varphi(0)-\mathbf{A}_2(\epsilon)\Delta\varphi(0)=4\pi\int_\epsilon^1\mathbf{s}(r)r^2[\mathrm{av}_r\varphi-\varphi(0)-\frac{r^2}{6}\Delta\varphi(0)]\,dr+\int_{|u|\ge1}\mathbf{s}(|u|)\varphi(u)\,du$, because $\frac{2\pi}{3}r^4=4\pi r^2\cdot\frac{r^2}{6}$. Step 1 and $\mathbf{s}(r)\le\mathbf{c}_6r^{-6}$ on $(0,1]$ bound the function integrated in the first term by $\frac{\mathsf{c}_6}{24}\|\varphi\|_{(4)}$. So the limit exists and has the stated form, the expression at ϵ is within $\frac{\pi}{6}\mathbf{c}_6\|\varphi\|_{(4)}\,\epsilon$ of it, and $|\mathbf{T}_0(\varphi)|$ obeys the stated bound. Each of the 81 terms of $(e\cdot\nabla)^4=\sum e_ie_je_ke_l\partial_i\partial_j\partial_k\partial_l$ carries a coefficient of modulus ≤1, whence $\|\varphi\|_{(4)}\le81\|\varphi\|_{C^4}$; with $\|\varphi\|_{L^1}\le\frac{4\pi}{3}R^3\sup|\varphi|$ for $\mathrm{supp}\,\varphi\subset\mathbb{B}(0,R)$, $\mathbf{T}_0$ is a distribution of order at most 4. For φ vanishing near 0 both $\varphi(0)$ and $\Delta\varphi(0)$ are 0, and for small ϵ the expression reduces to $\int\mathbf{s}(|u|)\varphi(u)\,du$; thus $\mathbf{T}_0$ extends $\mathbf{s}$. Rotations and reflections $\mathsf{R}\in\mathrm{O}(3)$ preserve $|u|$, the spherical means and the value of the Laplacian at 0, so $\mathbf{T}_0(\varphi\circ\mathsf{R})=\mathbf{T}_0(\varphi)$. For the scaling, take φ supported in B_{R_0}, $0<t<1/R_0$ and $\varphi^t=\varphi(\cdot/t)$: then $\mathrm{av}_r\varphi^t=\mathrm{av}_{r/t}\varphi$, $\varphi^t(0)=\varphi(0)$ and $\Delta\varphi^t(0)=t^{-2}\Delta\varphi(0)$, while φ^t vanishes for $|u|\ge1$. Substituting $r=tv$ in the formula of (c), $t^6(\mathbf{T}_0)_t(\varphi)=t^3\mathbf{T}_0(\varphi^t)=4\pi\int_0^{1/t}(tv)^6\mathbf{s}(tv)\,v^{-4}[\mathrm{av}_v\varphi-\varphi(0)-\frac{v^2}{6}\Delta\varphi(0)]\,dv$. The factor $(tv)^6\mathbf{s}(tv)$ stays below $\mathbf{c}_6$ and converges to $\mathfrak{a}$ for each fixed v as $t\downarrow0$ (Proposition 18.11(c)); the remaining factor is bounded in modulus both by $\frac{1}{24}\|\varphi\|_{(4)}$ (Step 1) and by $2\sup|\varphi|\,v^{-4}+\frac16|\Delta\varphi(0)|\,v^{-2}$, so it has an integrable majorant on $(0,\infty)$. Dominated convergence gives $t^6(\mathbf{T}_0)_t(\varphi)\to\mathfrak{a}\,\mathrm{Pf}|u|^{-6}(\varphi)$; hence $t^\omega(\mathbf{T}_0)_t(\varphi)=t^{\omega-6}\cdot t^6(\mathbf{T}_0)_t(\varphi)\to0$ when $\omega>6$. The formula for $\mathbf{S}_{\mathbf{T}_0}$ is the definition of $\mathbf{T}_0$ evaluated at $\varphi_{f,h}$, using $\varphi_{f,h}(0)=\int fh$, $\Delta\varphi_{f,h}(0)=-\int\nabla f\cdot\nabla h$ and the identity of Step 2 between the two cut-off integrals; for disjoint supports, $\mathbf{T}_0$ being an extension, $\mathbf{S}_{\mathbf{T}_0}(f,h)=\iint f(x)h(y)\,\mathbf{s}(|x-y|)\,dx\,dy$, which is $S_2(f,h)$ by Proposition 18.11(a).

Step 5: (d). Let $\chi\in\mathcal{D}$ be non-negative with $\int\chi=1$ and support in $\mathbb{B}(e_3,\frac14)$, and $\chi_j(u)=2^{-3j}\chi(2^ju)$, $j\ge1$. Then χ_j is supported in the shell $\frac34 2^{-j}\le|u|\le\frac54 2^{-j}$; no two of these shells meet, since $\frac54 2^{-j-1}<\frac34 2^{-j}$, and all of them lie in $\mathbb{B}(0,1)\setminus\{0\}$. For $|\alpha|\le3$, $\sup|\partial^\alpha\chi_j|=2^{(|\alpha|-3)j}\sup|\partial^\alpha\chi|\le\sup|\partial^\alpha\chi|$; so each $\Phi_J=\sum_{j=1}^J\chi_j$ lies in $\mathcal{D}$, vanishes near 0, has support in $\mathbb{B}(0,1)$, and $\|\Phi_J\|_{C^3}\le\|\chi\|_{C^3}$. If $\mathbf{T}$ extends $\mathbf{s}$, then, $\mathbf{s}$ being non-increasing and $\int\chi_j=2^{-6j}$, $\mathbf{T}(\Phi_J)=\sum_{j\le J}\int\mathbf{s}(|u|)\chi_j(u)\,du\ge\sum_{j\le J}\mathbf{s}(\frac54 2^{-j})\,2^{-6j}$, and the summands $\mathbf{s}(\frac54 2^{-j})\,2^{-6j}=(\frac45)^6(\frac54 2^{-j})^6\mathbf{s}(\frac54 2^{-j})$ converge to $(\frac45)^6\mathfrak{a}>0$. Hence $\mathbf{T}(\Phi_J)$ is unbounded in J, although $\|\Phi_J\|_{C^N}\le\|\chi\|_{C^3}$ for $N\le3$, which excludes the bounds named in (d); $N=0$ is the bound by $C\sup|\varphi|$ that a measure would satisfy.

Step 6: (e). Take $\varphi\in\mathcal{D}$ non-negative, not identically 0, with support in the shell $\{\eta\le|u|\le R_0\}$, $0<\eta<R_0$. When $0<t<1/R_0$, $\varphi(\cdot/t)$ vanishes near 0, so for any extension $\mathbf{T}$ one has $t^6\mathbf{T}_t(\varphi)=t^3\int\mathbf{s}(|u|)\varphi(u/t)\,du=\int(t|v|)^6\mathbf{s}(t|v|)\,|v|^{-6}\varphi(v)\,dv$; dominated convergence, with the majorant $\mathbf{c}_6\eta^{-6}\varphi$, shows that this tends to $\mathfrak{a}\int|v|^{-6}\varphi(v)\,dv>0$. Hence $t^\omega\mathbf{T}_t(\varphi)$ has no limit 0 when $\omega\le6$; but scaling degree at most ω_0 for some $\omega_0<6$ would require that limit at $\omega=6$. □

Proposition 18.14 (The plane of admissible extensions and their common scaling limit)**.** Let g, σ', $\mathfrak{a}$, $\mathbf{s}$ and $\mathbf{T}_0$ be as in Propositions 18.11 and 18.13.

(a) Any two admissible extensions $\mathbf{T}$, $\mathbf{T}'$ of $\mathbf{s}$ satisfy $\mathbf{T}-\mathbf{T}'=c_0\delta+c_1\Delta\delta$ for some $(c_0,c_1)\in\mathbb{R}^2$, that is $\mathbf{S}_{\mathbf{T}}(f,h)-\mathbf{S}_{\mathbf{T}'}(f,h)=c_0\int fh-c_1\int\nabla f\cdot\nabla h$ for $f,h\in\mathcal{D}$; and for each $(c_0,c_1)\in\mathbb{R}^2$ the distribution $\mathbf{T}_0+c_0\delta+c_1\Delta\delta$ is an admissible extension. Thus the admissible extensions

of $\mathbf{s}$ form the plane $\{\mathbf{T}_0 + c_0\delta + c_1\Delta\delta : (c_0, c_1) \in \mathbb{R}^2\}$, and each of them has order exactly 4 near 0. Asking only for invariance under W_3, the group of the signed permutation matrices, yields this very plane; asking for no symmetry at all, two extensions of scaling degree at most 6 still differ only by a distribution $\varphi \mapsto \sum_{|\alpha|\le 3} c_\alpha \partial^\alpha\varphi(0)$, $c_\alpha \in \mathbb{R}$.

(b) Whichever admissible extension $\mathbf{T}$ is taken, $t^6\mathbf{T}_t(\varphi)$ tends to $\mathfrak{a}\,\mathrm{Pf}|u|^{-6}(\varphi)$ as $t \downarrow 0$, for each $\varphi \in \mathcal{D}$; the coordinates c_0, c_1 leave no trace in this limit. $\mathrm{Pf}|u|^{-6}$ is a distribution of order at most 4, homogeneous in the sense that $(\mathrm{Pf}|u|^{-6})_t = t^{-6}\,\mathrm{Pf}|u|^{-6}$ for $t > 0$, and $\mathrm{Pf}|u|^{-6}(\varphi) = \lim_{\epsilon\downarrow 0}[\int_{|u|>\epsilon} |u|^{-6}\varphi(u)\,du - \frac{4\pi}{3}\epsilon^{-3}\varphi(0) - \frac{2\pi}{3}\epsilon^{-1}\Delta\varphi(0)]$, the subtraction involving pure powers of ϵ only. On $\mathcal{S}(\mathbb{R}^3)$, $\mathrm{Pf}|u|^{-6}(\varphi) = \frac{\pi^2}{12}\int |p|^3\hat\varphi(p)\frac{dp}{(2\pi)^3}$; consequently $\mathfrak{a}\,\mathrm{Pf}|u|^{-6}(\varphi_{f,f}) = \frac{3}{64\,\mathfrak{b}^2}\int |p|^3|\hat f(p)|^2\frac{dp}{(2\pi)^3} \ge 0$ for every $f \in \mathcal{D}$.

■

Proof. Step 1: distributions carried by the origin. Let $\mathbf{D}$ be a distribution that annihilates every $\varphi \in \mathcal{D}$ vanishing near 0. Fix N and C such that $|\mathbf{D}(\varphi)| \le C\|\varphi\|_{C^N}$ whenever $\operatorname{supp}\varphi \subset \mathbb{B}(0,1)$, and a radial $\chi \in \mathcal{D}$, $0 \le \chi \le 1$, equal to 1 on $B_{1/2}$ and supported in B_1; for $0 < \eta \le 1$ write $\chi_\eta = \chi(\cdot/\eta)$, so that $\chi_1 = \chi$. Because $(1-\chi_\eta)\varphi$ vanishes near 0, $\mathbf{D}(\varphi) = \mathbf{D}(\chi_\eta\varphi)$ for all $\varphi \in \mathcal{D}$. Now let ψ be smooth with all derivatives of order $\le N$ vanishing at 0. Taylor's formula gives $|\partial^\beta\psi(u)| \le C_\psi|u|^{N+1-|\beta|}$ for $|u| \le 1$ and $|\beta| \le N$; with Leibniz' rule, for $|\alpha| \le N$ and $|u| \le \eta$, $|\partial^\alpha(\chi_\eta\psi)(u)| \le \sum_{\beta\le\alpha}\binom{\alpha}{\beta}\eta^{-|\alpha-\beta|}\sup|\partial^{\alpha-\beta}\chi|\,C_\psi\eta^{N+1-|\beta|} \le C'\eta$, and $\chi_\eta\psi$ is 0 for $|u| \ge \eta$. For $\eta \le \frac12$ the support of χ_η lies in $B_{1/2}$, where $\chi = 1$, so $\chi_\eta\chi = \chi_\eta$; applying the identity above to $\chi\psi \in \mathcal{D}$ we get $|\mathbf{D}(\chi\psi)| = |\mathbf{D}(\chi_\eta\chi\psi)| = |\mathbf{D}(\chi_\eta\psi)| \le CC'\eta$ for all $\eta \in (0, \frac12]$, so $\mathbf{D}(\chi\psi) = 0$. Applying this to $\psi = \varphi - P$, with $P(u) = \sum_{|\alpha|\le N}\frac{u^\alpha}{\alpha!}\partial^\alpha\varphi(0)$ the Taylor polynomial of $\varphi \in \mathcal{D}$, gives $\mathbf{D}(\varphi) = \mathbf{D}(\chi\varphi) = \mathbf{D}(\chi P) = \sum_{|\alpha|\le N} c_\alpha\partial^\alpha\varphi(0)$, where $c_\alpha = \mathbf{D}(\chi u^\alpha)/\alpha!$ is real.

Step 2: homogeneity bounds the order of the derivatives. Let $\mathbf{T}$, $\mathbf{T}'$ be extensions of $\mathbf{s}$ of scaling degree at most 6 and $\mathbf{D} = \mathbf{T} - \mathbf{T}'$. Then $\mathbf{D}$ annihilates the functions vanishing near 0, and $t^\omega\mathbf{D}_t(\varphi) \to 0$ for $\omega > 6$. By Step 1, $\mathbf{D}(\varphi) = \sum_{|\alpha|\le N} c_\alpha\partial^\alpha\varphi(0)$, and since $\partial^\alpha[\varphi(\cdot/t)](0) = t^{-|\alpha|}\partial^\alpha\varphi(0)$, $\mathbf{D}_t(\varphi) = \sum_\alpha c_\alpha t^{-3-|\alpha|}\partial^\alpha\varphi(0)$. Test with $\varphi = \chi u^{\alpha_0}$, χ as in Step 1: its derivative ∂^α at 0 is $\alpha_0!$ for $\alpha = \alpha_0$ and 0 for every other α, so $t^{13/2}\mathbf{D}_t(\varphi) = c_{\alpha_0}\alpha_0!\,t^{7/2-|\alpha_0|}$, which can tend to 0 for $|\alpha_0| \ge 4$ only if $c_{\alpha_0} = 0$. This is the statement of (a) without symmetry.

Step 3: symmetry leaves two coefficients. Suppose in addition that $\mathbf{T}$ and $\mathbf{T}'$ are invariant under W_3, as admissible extensions are. Then so is $\mathbf{D}$, and $c_\alpha = \mathbf{D}(\chi u^\alpha)/\alpha!$ with χ radial. The point reflection $u \mapsto -u$ sends χu^α to $(-1)^{|\alpha|}\chi u^\alpha$, which removes the coefficients with $|\alpha| = 1$ and $|\alpha| = 3$. For $i \ne j$, reversing the sign of the coordinate u_i reverses the sign of χu_iu_j, which removes the mixed second derivatives; interchanging u_i and u_j maps χu_i^2 to χu_j^2, which equalises the coefficients of ∂_i^2 and ∂_j^2. All three maps belong to $W_3 \subset \mathrm{O}(3)$. What is left is $\mathbf{D} = c_0\delta + c_1\Delta\delta$ with real $c_0 = \mathbf{D}(\chi)$ and $c_1 = \frac12\mathbf{D}(\chi u_1^2)$, and $\mathbf{D}(\varphi_{f,h}) = c_0\int fh - c_1\int\nabla f\cdot\nabla h$.

Step 4: every point of the plane occurs; orders. The distributions δ and $\Delta\delta$ annihilate the functions vanishing near 0, are invariant under $\mathrm{O}(3)$, and satisfy $\delta_t(\varphi) = t^{-3}\varphi(0)$ and $(\Delta\delta)_t(\varphi) = t^{-5}\Delta\varphi(0)$, which tend to 0 after multiplication by t^ω, $\omega > 6$. Together with Proposition 18.13(c), this makes each $\mathbf{T}_0 + c_0\delta + c_1\Delta\delta$ an admissible extension, and by Steps 2 and 3 there are no others, also when only invariance under W_3 is asked. As to the orders: $\mathbf{T}_0$ has order at most 4 near 0, δ and $\Delta\delta$ have orders 0 and 2, and by Proposition 18.13(d) no extension has order ≤ 3; so the order is exactly 4.

Step 5: the limit in (b). For $\mathbf{T}_0$ it was obtained in Step 4 of the proof of Proposition 18.13. For $\mathbf{T} = \mathbf{T}_0 + c_0\delta + c_1\Delta\delta$ the two extra terms contribute $t^6\delta_t(\varphi) = t^3\varphi(0)$ and $t^6(\Delta\delta)_t(\varphi) = t\,\Delta\varphi(0)$, both tending to 0.

Step 6: properties of $\mathrm{Pf}|u|^{-6}$. For φ in $\mathcal{D}$ or in $\mathcal{S}(\mathbb{R}^3)$, Step 1 of the proof of Proposition 18.13 bounds $r^{-4}|\mathrm{av}_r\varphi - \varphi(0) - \frac{r^2}{6}\Delta\varphi(0)|$ by $\frac{1}{24}\|\varphi\|_{(4)}$, and the same quantity is also at most $2\sup|\varphi|\,r^{-4} + \frac16|\Delta\varphi(0)|\,r^{-2}$; using the first bound on $(0,1]$ and the second on $[1,\infty)$, the integral converges

absolutely and $|\mathrm{Pf}|u|^{-6}(\varphi)| \le 4\pi[\frac{1}{24}\|\varphi\|_{(4)} + \frac{2}{3}\sup|\varphi| + \frac{1}{6}|\Delta\varphi(0)|]$, so $\mathrm{Pf}|u|^{-6}$ is a distribution of order at most 4. Substituting $r = tv$ shows $\mathrm{Pf}|u|^{-6}(\varphi(\cdot/t)) = t^{-3}\,\mathrm{Pf}|u|^{-6}(\varphi)$, i.e. $(\mathrm{Pf}|u|^{-6})_t = t^{-6}\,\mathrm{Pf}|u|^{-6}$. Polar coordinates give $\int_{|u|>\epsilon}|u|^{-6}\varphi(u)\,du = 4\pi\int_\epsilon^\infty r^{-4}[\mathrm{av}_r\varphi - \varphi(0) - \frac{r^2}{6}\Delta\varphi(0)]\,dr + \frac{4\pi}{3}\epsilon^{-3}\varphi(0) + \frac{2\pi}{3}\epsilon^{-1}\Delta\varphi(0)$, and letting $\epsilon\to 0$ gives the subtracted formula of (b).

Step 7: $\mathrm{Pf}|u|^{-6}$ *in Fourier variables.* Let $\varphi\in\mathcal{S}(\mathbb{R}^3)$ and $k = |p|$. Fourier inversion, $\varphi(u) = \int e^{ip\cdot u}\hat\varphi(p)\frac{dp}{(2\pi)^3}$, gives $\varphi(0) = \int\hat\varphi\frac{dp}{(2\pi)^3}$ and $\Delta\varphi(0) = -\int|p|^2\hat\varphi\frac{dp}{(2\pi)^3}$, and, with $\frac{1}{4\pi}\int_{\mathbb{S}^2}e^{irp\cdot\mathbf{n}}d\mathbf{n} = \frac{\sin kr}{kr}$ and Fubini's theorem, $\mathrm{av}_r\varphi - \varphi(0) - \frac{r^2}{6}\Delta\varphi(0) = \int[\frac{\sin kr}{kr} - 1 + \frac{k^2r^2}{6}]\hat\varphi(p)\frac{dp}{(2\pi)^3}$. For $x\ge 0$ one has $x - \frac{x^3}{6} \le \sin x \le \min\{x, x - \frac{x^3}{6} + \frac{x^5}{120}\}$, so $0 \le \frac{\sin x}{x} - 1 + \frac{x^2}{6} \le \min\{\frac{x^4}{120}, \frac{x^2}{6}\}$; the substitution $x = kr$ then gives $\int_0^\infty r^{-4}[\frac{\sin kr}{kr} - 1 + \frac{k^2r^2}{6}]\,dr = k^3 I$ with $I = \int_0^\infty x^{-5}(\sin x - x + \frac{x^3}{6})\,dx \in (0,\infty)$, and since $\int k^3|\hat\varphi|\,dp < \infty$ the order of integration may be exchanged: $\mathrm{Pf}|u|^{-6}(\varphi) = 4\pi I\int|p|^3\hat\varphi(p)\frac{dp}{(2\pi)^3}$. To evaluate I, put $F = \sin x - x + \frac{x^3}{6}$, so that $F' = \cos x - 1 + \frac{x^2}{2}$, $F'' = x - \sin x$ and $F''' = 1 - \cos x$; these behave like x^5, x^4, x^3, x^2 near 0 and like $x^3, x^2, x, 1$ near ∞, so integrating by parts three times, the boundary terms vanishing at both ends, yields $I = \frac{1}{4}\int_0^\infty F'x^{-4}dx = \frac{1}{12}\int_0^\infty F''x^{-3}dx = \frac{1}{24}\int_0^\infty(1-\cos x)\,x^{-2}dx = \frac{1}{24}\cdot\frac{\pi}{2} = \frac{\pi}{48}$, hence $4\pi I = \frac{\pi^2}{12}$. For $f\in\mathcal{D}$, $\hat\varphi_{f,f} = |\hat f|^2$, and $\frac{\pi^2}{12}\mathsf{c}_2 = \frac{3}{64}$. □

Remark. By Lemma 2.26(c), the contact terms of Lemma 2.26(b) at $n = 2$ on $\mathbb{R}^3$ that are invariant under translations, real, symmetric under the exchange of the two entries and covariant under O(3) make up a six-dimensional space, which the lemma spans by six forms written in Fourier space. Evaluated at the entries $f\mathbf{1}$ and $h\mathbf{1}$, these six forms become multiples of $\int fh$ (the two without p, as $\mathrm{tr}\,\mathbf{1} = 3$) and of $\int\nabla f\cdot\nabla h$ (the four with two factors p, as $p\cdot\mathbf{1}p = |p|^2$); so on the scalar entries the contact terms with these four properties are exactly the forms $c_0\int fh - c_1\int\nabla f\cdot\nabla h$ of Proposition 18.14(a).

Proposition 18.15 (Positive type does not select a point of the plane)**.** Let g, σ', $\mathbf{s}$, $\mathfrak{m}$, $\mathbf{c}_6$ and $\mathbf{T}_0$ be as in Propositions 18.11 and 18.13. For $p\in\mathbb{R}^3$ and $\psi\in\mathcal{D}$ let

$$\mathbf{w}(p) = \int_{(0,1]}\frac{8\pi E}{(E^2+|p|^2)^2}\,d\mathfrak{m}(E) + \int_{(1,\infty)}\frac{8\pi|p|^4(3E^2+2|p|^2)}{E^5(E^2+|p|^2)^2}\,d\mathfrak{m}(E) \in [0,\infty],$$

$$\mathbf{T}_+(\psi) = \mathfrak{m}(\{0\})\int\psi(u)\,du + \int\mathbf{w}(p)\hat\psi(p)\frac{dp}{(2\pi)^3}.$$

(a) The integral over $(0,1]$ in $\mathbf{w}$ is an integrable function of p, with integral $(2\pi)^3\mathfrak{m}((0,1])$ and finite values at all $p\ne 0$; the integral over $(1,\infty)$ is bounded by $264\pi\,\mathrm{e}\,\mathbf{c}_6|p|^3$.

(b) $\mathbf{T}_+$ takes real values on $\mathcal{D}$, is a distribution, extends $\mathbf{s}$, is admissible, and has positive type: $\mathbf{S}_{\mathbf{T}_+}(f,f) = \mathfrak{m}(\{0\})(\int f)^2 + \int\mathbf{w}(p)|\hat f(p)|^2\frac{dp}{(2\pi)^3} \ge 0$ for $f\in\mathcal{D}$.

(c) Let $\mathbf{Q}\subset\mathbb{R}^2$ consist of the (c_0,c_1) such that $\mathbf{T}_0 + c_0\delta + c_1\Delta\delta$ has positive type. Then $\mathbf{Q}\ne\emptyset$, $\mathbf{Q}$ is convex, and with (c_0,c_1) it contains $(c_0+\eta_0, c_1-\eta_1)$ for all $\eta_0,\eta_1\ge 0$. So the demand that the form be of positive type leaves admissible extensions and does not determine (c_0,c_1). ■

Proof. Step 1: Fourier transform of the exponential. For $E>0$ and $k = |p| > 0$, in polar coordinates $\int e^{-E|u|}e^{-ip\cdot u}\,du = 4\pi\int_0^\infty e^{-Er}\frac{\sin kr}{kr}r^2dr = \frac{4\pi}{k}\,\mathrm{Im}\int_0^\infty re^{-(E-ik)r}dr = \frac{4\pi}{k}\,\mathrm{Im}\frac{(E+ik)^2}{(E^2+k^2)^2} = \Upsilon_E(k) := \frac{8\pi E}{(E^2+k^2)^2}$, while for $p=0$ the integral is $8\pi E^{-3} = \Upsilon_E(0)$; replacing $e^{-ip\cdot u}$ by $e^{ip\cdot u}$ does not change the value. With $k = E\tan s$, $\int\Upsilon_E(|p|)\,dp = 32\pi^2E\int_0^\infty\frac{k^2\,dk}{(E^2+k^2)^2} = 32\pi^2\int_0^{\pi/2}\sin^2 s\,ds = 8\pi^3 = (2\pi)^3$.

Step 2: removing two Taylor terms. Put $x = k^2/E^2$. Then $\Upsilon_E(k) - \frac{8\pi}{E^3} + \frac{16\pi k^2}{E^5} = \frac{8\pi}{E^3}[(1+x)^{-2} - 1 + 2x] = \frac{8\pi}{E^3}\cdot\frac{x^2(3+2x)}{(1+x)^2} = \frac{8\pi k^4(3E^2+2k^2)}{E^5(E^2+k^2)^2}$, by the identity $1-(1-2x)(1+x)^2 = 3x^2+2x^3$. Hence the subtracted kernel is non-negative and bounded both by $\frac{8\pi}{E^3}3x^2 = 24\pi k^4 E^{-7}$, because $3+2x \le 3(1+x)^2$, and by $\frac{8\pi}{E^3}2x = 16\pi k^2 E^{-5}$, because $(1+x)^{-2} \le 1$.

Step 3: how fast $\mathfrak{m}$ grows. Write $\mathfrak{M}(v) = \mathfrak{m}([0,v])$. For $v \ge 1$ the weight $e^{-E/v}$ is at least e^{-1} on $[0,v]$, so $\mathfrak{M}(v) \le \mathrm{e}\int e^{-E/v}d\mathfrak{m}(E) = \mathrm{e}\,\mathbf{s}(1/v) \le \mathrm{e}\,\mathbf{c}_6 v^6$ (Proposition 18.11(b), (c)). For $k \ge 1$, writing $E^{-7} = \int_E^\infty 7v^{-8}dv$ and using Tonelli's theorem, $\int_{(k,\infty)} E^{-7}d\mathfrak{m}(E) = \int_k^\infty 7v^{-8}\mathfrak{m}((k,v])\,dv \le 7\mathrm{e}\,\mathbf{c}_6 k^{-1}$; writing $E^{-5} = k^{-5} + \int_E^k 5v^{-6}dv$ for $E \le k$, $\int_{(1,k]} E^{-5}d\mathfrak{m}(E) \le k^{-5}\mathfrak{M}(k) + \int_1^k 5v^{-6}\mathfrak{M}(v)\,dv \le 6\mathrm{e}\,\mathbf{c}_6 k$.

Step 4: (a), and the bound that makes $\mathbf{T}_+$ a distribution. Let $\mathbf{w}_1$ and $\mathbf{w}_2$ be the integrals over $(0,1]$ and over $(1,\infty)$ in $\mathbf{w}$. Tonelli's theorem and Step 1 give $\mathbf{w}_1 \ge 0$ and $\int \mathbf{w}_1 dp = (2\pi)^3\mathfrak{m}((0,1])$, and $\Upsilon_E(k) \le 8\pi k^{-4}$ for $E \le 1$ gives $\mathbf{w}_1(p) \le 8\pi|p|^{-4}\mathfrak{m}((0,1])$ for $p \ne 0$. By Step 2, $\mathbf{w}_2 \ge 0$; for $k = |p| \ge 1$, using the bound $24\pi k^4 E^{-7}$ on $E > k$ and the bound $16\pi k^2 E^{-5}$ on $1 < E \le k$, Step 3 gives $\mathbf{w}_2(p) \le 24\pi k^4\cdot 7\mathrm{e}\,\mathbf{c}_6 k^{-1} + 16\pi k^2\cdot 6\mathrm{e}\,\mathbf{c}_6 k = 264\pi\mathrm{e}\,\mathbf{c}_6 k^3$, and for $k < 1$ the first bound alone gives $\mathbf{w}_2(p) \le 24\pi k^4\cdot 7\mathrm{e}\,\mathbf{c}_6 \le 168\pi\mathrm{e}\,\mathbf{c}_6 k^3$. For $\psi \in \mathcal{D}$ supported in $\mathbb{B}(0,R)$, $(1+|p|^2)^4|\hat\psi(p)| = |\widehat{(1-\Delta)^4\psi}(p)| \le \|(1-\Delta)^4\psi\|_{L^1} \le C_R\|\psi\|_{C^8}$; therefore $|\mathbf{T}_+(\psi)| \le \mathfrak{m}(\{0\})\|\psi\|_{L^1} + (2\pi)^{-3}[\|\mathbf{w}_1\|_{L^1} + 264\pi\mathrm{e}\,\mathbf{c}_6\int|p|^3(1+|p|^2)^{-4}dp]\,C_R\|\psi\|_{C^8}$, and $\mathbf{T}_+$ is a linear functional with this bound.

Step 5: $\mathbf{T}_+$ agrees with $\mathbf{s}$ off the origin. Take $\psi \in \mathcal{D}$ with support avoiding a ball about 0. Inserting $\mathbf{s}(|u|) = \int e^{-E|u|}d\mathfrak{m}(E)$ (Proposition 18.11(b)) and interchanging the integrals, which is legitimate since $\iint e^{-E|u|}|\psi(u)|\,du\,d\mathfrak{m}(E) = \int \mathbf{s}(|u|)|\psi(u)|\,du < \infty$, one gets $\int \mathbf{s}(|u|)\psi(u)\,du = \int_{[0,\infty)}(\int e^{-E|u|}\psi(u)\,du)\,d\mathfrak{m}(E)$. The mass of $\mathfrak{m}$ at $E = 0$ contributes $\mathfrak{m}(\{0\})\int\psi$. For $E > 0$, by Fourier inversion, Fubini's theorem and Step 1, $\int e^{-E|u|}\psi(u)\,du = \int \Upsilon_E(|p|)\hat\psi(p)\frac{dp}{(2\pi)^3}$. Here $\int\hat\psi\,dp = (2\pi)^3\psi(0) = 0$ and $\int|p|^2\hat\psi\,dp = -(2\pi)^3\Delta\psi(0) = 0$, so that for $E > 1$ one may subtract $\frac{8\pi}{E^3} - \frac{16\pi|p|^2}{E^5}$ from Υ_E without changing the integral, which brings in the kernel of Step 2. Interchanging next the integrations over E and over p, as permitted by Tonelli's and Fubini's theorems because the kernels are non-negative and $\int(\mathbf{w}_1 + |p|^3)|\hat\psi|\,dp < \infty$ (Step 4), one arrives at $\mathbf{T}_+(\psi)$.

Step 6: (b). For real ψ, $\hat\psi(-p) = \overline{\hat\psi(p)}$, and $\mathbf{w}$ is a real function of $|p|$; the substitution $p \mapsto -p$ shows that $\int \mathbf{w}\hat\psi\,dp$ is real, so $\mathbf{T}_+$ is real-valued and, by Step 4, a distribution. For $\mathsf{R} \in \mathrm{O}(3)$, $\widehat{\psi\circ\mathsf{R}} = \hat\psi\circ\mathsf{R}$, and $\mathbf{w}$ depends on $|p|$ only, so $\mathbf{T}_+(\psi\circ\mathsf{R}) = \mathbf{T}_+(\psi)$. Since $\widehat{\psi(\cdot/t)}(p) = t^3\hat\psi(tp)$, $(\mathbf{T}_+)_t(\psi) = \mathfrak{m}(\{0\})\int\psi + \int\mathbf{w}(p)\hat\psi(tp)\frac{dp}{(2\pi)^3}$; here $|\int\mathbf{w}_1(p)\hat\psi(tp)\,dp| \le \|\mathbf{w}_1\|_{L^1}\sup|\hat\psi|$ and, by (a), $|\int\mathbf{w}_2(p)\hat\psi(tp)\,dp| \le 264\pi\mathrm{e}\,\mathbf{c}_6 t^{-6}\int|q|^3|\hat\psi(q)|\,dq$. Thus $t^\omega(\mathbf{T}_+)_t(\psi) \to 0$ for $\omega > 6$, and with Step 5, $\mathbf{T}_+$ is an admissible extension of $\mathbf{s}$. Lastly $\mathbf{T}_+(\varphi_{f,f}) = \mathfrak{m}(\{0\})\int\varphi_{f,f} + \int\mathbf{w}\,\hat\varphi_{f,f}\frac{dp}{(2\pi)^3} = \mathfrak{m}(\{0\})(\int f)^2 + \int\mathbf{w}|\hat f|^2\frac{dp}{(2\pi)^3}$, which is non-negative.

Step 7: (c). Proposition 18.14(a) writes $\mathbf{T}_+ = \mathbf{T}_0 + c_0^+\delta + c_1^+\Delta\delta$ with real (c_0^+, c_1^+), and by (b) this point lies in $\mathbf{Q}$. For each $f \in \mathcal{D}$ the value $(\mathbf{T}_0 + c_0\delta + c_1\Delta\delta)(\varphi_{f,f})$ is an affine function of (c_0, c_1); $\mathbf{Q}$ is the intersection, over $f \in \mathcal{D}$, of the sets where these affine functions are ≥ 0, hence convex. Finally $(\eta_0\delta - \eta_1\Delta\delta)(\varphi_{f,f}) = \eta_0\int f^2 + \eta_1\int|\nabla f|^2 \ge 0$ for $\eta_0, \eta_1 \ge 0$, so passing from $(c_0, c_1) \in \mathbf{Q}$ to $(c_0 + \eta_0, c_1 - \eta_1)$ keeps the form of positive type. □

18.3. **Energy and momentum as charges of a conserved tensor with a flux law; for data.** Over scalar reconstruction data with a unique vacuum we consider a tensor of the frame (M1)–(M5) of Definition 3.1 (3) and impose one further condition on its Euclidean kernels, the flux law of the translations (Definition 18.16): the inward flux of the kernel $\mathsf{s}_{ij}(\cdot\,; y)$ across the boundary of a region holding the first scalar point y_1 but none of the other scalar points is the derivative of the scalar kernel s_m in the j-th coordinate of y_1. At one scalar point every tensor of the frame satisfies this law, and the law for the full kernels is the same condition as the law for the connected

kernels (Lemma 18.20). The results are the following. Let α be a smooth function of the time with compact support and integral 1, g a smooth function of the space variables with compact support, equal to 1 on the disc of radius r_g about 0, and $g_R = g(\cdot/R)$. If the law holds in the direction e_3, respectively e_j with $j \in \{1,2\}$, then for every test function f of compact support the commutator of $T_{00}(\alpha \otimes g_R)$, respectively $T_{0j}(\alpha \otimes g_R)$, with $\phi(f)$ is $i\phi(\partial_\mu f)$, the commutator of the generator P_μ of the translations with $\phi(f)$, where $\mu = 0$, respectively $\mu = j$; this holds on the whole of $\mathcal{D}_\infty$ as soon as $R \geq R_0 = (r_O + t_* + 1)/r_g$, where I_α is a bounded interval containing the support of α, I_f a bounded open interval and $r_O > 0$ are such that $I_f \times \{|\vec{x}| < r_O\}$ contains the support of f, and $t_* = \sup\{|t - t'| : t \in I_\alpha,\ t' \in I_f\}$; conversely, these commutators for one μ imply the law in the corresponding direction (Proposition 18.23). If the tensor is besides covariant on the vacuum, (M5), the vacuum vectors $T_{00}(\alpha \otimes g_R)\Omega$ are of the order $R^{-1/2}$ in every graph norm of H; for every χ in the span $\mathcal{D}_0$ of the polynomial vectors, $T_{00}(\alpha \otimes g_R)\chi$ converges to $H\chi$ in the norm of $\mathcal{H}$ with the rate $R^{-1/2}$; the squared norms of $T_{0j}(\alpha \otimes g_R)\Omega$ converge to an explicit limit; and $T_{0j}(\alpha \otimes g_R)\chi$ converges weakly in $\mathcal{H}$ to $P_j\chi$ (Proposition 18.28). The commutators come from analytic continuation in two Euclidean heights. Between damping factors, the product of a smeared component and the scalar field in either order is the boundary value of a holomorphic function of the two heights, one function for each order. Conservation turns the derivative of each of them in the height of the component into the like function formed with the components whose first index is a direction of the plane, smeared with the derivative of the cut-off in that direction; these derivatives of the cut-off vanish near the support of the scalar test function, locality relative to ϕ gives the two functions so formed equal boundary values at nearby times, and so they are one holomorphic function on a domain that crosses the equal heights (Lemma 18.21). Hence each of the two original functions is a common primitive of that function, in the height of the component, plus a term that depends on the scalar height only; the difference of these two terms is, for real heights, the Euclidean kernel integrated against the gradient of a cut-off equal to 1 about the scalar point, and its values at imaginary heights give the commutator (Lemma 18.22). The limits rest on the form of the two-point measure of a conserved tensor covariant on the vacuum: two mass measures, finite near the mass 0, and a massless scalar part of weight $c_\partial \geq 0$ (Lemma 18.26). No decay at large distances is used. By Theorem F (d) and the uniqueness clause of Proposition YM3_I:110.1, the frame holds over every component of a tensor limit at a reference coupling not larger than γ_W^{sd}, and the results apply to it whenever its kernels obey the flux law (Remark 18.29).

Data. Throughout, σ' satisfies (Rec) of Section YM3_I:107 with numbers $C_\wp, \wp, c_0$ and unique vacuum, $\ker H = \mathbb{C}\Omega$. We call the latter property (Rec5). Let $\mathbb{E}_+ = \{x_3 > 0\}$. A tuple over $\mathbb{E}_+$ is a finite family of real $C^1_c(\mathbb{E}_+)$ functions with pairwise disjoint supports, including the empty tuple $\varnothing$. A tuple is smooth when all its entries are smooth. The classes $[F]$ of complex linear combinations of tuples form a dense subspace of the reflection Hilbert space $\mathcal{H} = \mathcal{H}(\sigma')$. Write $\Omega = [\varnothing]$ and take $H, \mathcal{U}(v)$ and the joint spectral measure $\mathcal{P}$ of the reflection translations as in YM3_I:(2031). Scalar products are antilinear in the first entry. Apart from the real tuple entries, the test-function spaces in this subsection are complex unless specified otherwise. For $X = (h_1, \dots, h_n)$ and $z = (z_1, \dots, z_n)$ put $X(z) = \prod_b h_b(z_b)$. Write $z + ae_3$ and $\theta(z + ae_3)$ for the tuples of translated and reflected points, where $\theta x = (\vec{x}, -x_3)$.

Let $R_H = (1 + H)^{-1}$ and $\mathcal{D}_\infty = \bigcap_{n \geq 1} \operatorname{dom} H^n$. The spectral projections onto $\{E \leq N\}$ have range in $\mathcal{D}_\infty$ and increase strongly to the identity, so $\mathcal{D}_\infty$ is dense. Spectral calculus gives $(1+H)^n\mathcal{D}_\infty = \mathcal{D}_\infty$, with inverse R_H^n on that subspace. For $\operatorname{Re}\tau > 0$, the operator $e^{-\tau H} = \int e^{-\tau E} d\mathcal{P}$ is norm holomorphic and maps $\mathcal{H}$ into $\mathcal{D}_\infty$, since $E^n e^{-\tau E}$ is bounded for every n. We fix an integer $l > \wp$. The scalar point insertion $\mathsf{B}_0(s, s')$ is the operator of Proposition YM3_I:107.2. Write A_l for the bounded operator in YM3_I:(2044), and q_0 for the form YM3_I:(2047) restricted to $\mathcal{D}_\infty$. Lemma YM3_I:107.3 gives

$$\mathsf{B}_0(s, s') = e^{-sH}(1 + H)^l \mathsf{A}_l (1 + H)^l e^{-s'H}, \qquad \mathsf{B}_0(s, s')^* = \mathsf{B}_0(s', s),$$

using YM3_I:(2046) for the first equality and the point-insertion adjoint relation for the second. The kernels s_n of σ' (Proposition YM3_I:108.3) are continuous and real-analytic on $(\mathbb{R}^3)^n_{\neq}$, symmetric and Euclidean invariant. In particular s_1 is constant and $\mathsf{s}_0 = 1$.

Real time and spectrum. Points of $\mathbb{R}^{1+2}$ are written $x = (t, \vec{x}) = (x^0, x^1, x^2)$; $x \cdot p = x^0 p^0 - \vec{x} \cdot \vec{p}$ and $\mathsf{g} = \mathrm{diag}(1, -1, -1)$, $p_\mu = \mathsf{g}_{\mu\mu} p^\mu$, $\partial_\mu = \partial/\partial x^\mu$ and $\partial_t = \partial_0$. Minkowski indices μ, ν, μ', ν' run through $\{0, 1, 2\}$ and are summed when repeated; Euclidean indices i, i', j, j' run through $\{1, 2, 3\}$, and k, k' through $\{1, 2\}$. $U(x) = e^{itH}\mathcal{U}(\vec{x})$; $P_0 = H$, and P_1, P_2 are the joint self-adjoint generators of $\mathcal{U}$, so that $U(x) = \exp i(x^0 P_0 + x^1 P_1 + x^2 P_2)$, and $\|P_k \psi\| \leq \|H\psi\|$ on $\mathrm{dom}\, H$ by (Rec3). E is the image of $\mathcal{P}$ under $(E, q) \mapsto (E, -q)$, so that $U(x) = \int e^{ix\cdot p}\, d\mathsf{E}(p)$. $V_+ = \{p^0 > |\vec{p}|\}$, and $\partial V_+ = \{p^0 = |\vec{p}| > 0\}$ is the cone without its apex. By the cone condition (Rec3), E is carried by $V_+ \cup \partial V_+ \cup \{0\}$, and as the range of $\mathsf{E}(\{0\})$ lies in $\ker H$ and contains the invariant vector Ω, (Rec5) gives $\mathsf{E}(\{0\}) = \langle \Omega, \cdot \rangle \Omega$. For $\psi \in \mathcal{H}$, $m_\psi = \langle \psi, \mathsf{E}(\cdot)\psi \rangle$, and for a bounded Borel function f, $\mathsf{f}(P) = \int \mathsf{f}\, d\mathsf{E}$. $\mathcal{S} = \mathcal{S}(\mathbb{R}^{1+2}; \mathbb{C})$; $\phi(f)$, $f \in \mathcal{S}$, is the field of Proposition YM3_I:109.1 on $\mathcal{D}_\infty$, and $\mathcal{D}_0$ is the span of Ω and of the vectors $\phi(f_1) \cdots \phi(f_n)\Omega$ (Theorem YM3_I:AO); $U(a, \Lambda) = U(a)U(\Lambda)$, $a \in \mathbb{R}^{1+2}$, $\Lambda \in \mathcal{L}$, is the representation of Proposition YM3_I:110.1, and $B(s)$ is the boost $B(s)(p^0, p^1, p^2) = (p^0 \cosh s + p^1 \sinh s, p^0 \sinh s + p^1 \cosh s, p^2)$. A *polynomial* is a finite linear combination Q of 1 and of products $\phi(h_1) \cdots \phi(h_n)$, $h_b \in \mathcal{S}$, acting on $\mathcal{D}_\infty$; its degree is the largest n that occurs, and $\mathsf{Q}^\dagger$ arises by reversing the order of the factors and conjugating the coefficients and the test functions, so that $\langle \psi', \mathsf{Q}\psi \rangle = \langle \mathsf{Q}^\dagger \psi', \psi \rangle$ on $\mathcal{D}_\infty$ by YM3_I:(2076); every vector of $\mathcal{D}_0$ is $\mathsf{Q}\Omega$ for a polynomial Q. For $F \in \mathcal{S}$, $\hat{F}(p) = \int F(x) e^{ix\cdot p}\, dx$; then $\int F(x)U(x)\, dx = \hat{F}(P)$ weakly, $\widehat{\partial_\mu F} = -ip_\mu \hat{F}$, $\widehat{F(\cdot - a)} = e^{ia\cdot p}\hat{F}$, and $\widehat{F \circ \Lambda^{-1}} = \hat{F} \circ \Lambda^{-1}$ for $\Lambda \in \mathcal{L}$. For $\alpha \in \mathcal{S}(\mathbb{R})$ and $g \in \mathcal{S}(\mathbb{R}^2)$ we write $(\alpha \otimes g)(t, \vec{x}) = \alpha(t) g(\vec{x})$, $\hat{\alpha}(E) = \int \alpha(t) e^{iEt}\, dt$ and $\hat{g}(\vec{k}) = \int g(\vec{x}) e^{-i\vec{k}\cdot\vec{x}}\, d^2x$, so that $\widehat{\alpha \otimes g}(p) = \hat{\alpha}(p^0)\hat{g}(\vec{p})$; for $R > 0$, $g_R = g(\cdot/R)$ has the transform $R^2 \hat{g}(R\,\cdot)$.

The frame. We use the frame (M1)–(M5) of Definition 3.1 (3) over σ', with its signs $\vartheta_1 = \vartheta_2 = 1$, $\vartheta_3 = -1$, its forms $\mathfrak{q}_{ij} = \mathfrak{q}_{ji}$ and its kernels s_{ij}, and with the real-time components $T_{00} = -T^E_{33}$, $T_{0k} = T_{k0} = -iT^E_{3k}$ and $T_{kk'} = T^E_{kk'}$; we read it as follows. The integer in the bound of (M1) is l, a bound with one integer giving the bound with every larger one, and $T^E_{ij}(F)$, $F \in \mathcal{S}$, is the operator $\mathfrak{q}_{ij}(F)$ of Lemma 18.17 (c). We put $\bar{c} = \max\{\|\mathsf{A}_l\|, c_T\}$ and $\mathsf{c}_N(f) = \bar{c} \sum_{n \leq N} \binom{N}{n} \|\partial_t^n f\|_{L^1}$ for $f \in \mathcal{S}$; this number is at least the number YM3_I:(2071), so that YM3_I:(2075) holds with it. In (M2), for every $m \geq 1$, $\mathsf{s}_{ij}(x; y_1, \ldots, y_m)$ is continuous on $(\mathbb{R}^3)^{1+m}_{\neq}$ and symmetric in $y_1, \ldots, y_m$, and $\mathsf{s}_{ij}(\mathsf{R}x + b; \mathsf{R}y_1 + b, \ldots, \mathsf{R}y_m + b) = \mathsf{R}_{ii'}\mathsf{R}_{jj'}\mathsf{s}_{i'j'}(x; y)$ for $\mathsf{R} \in \mathrm{O}(3)$ and $b \in \mathbb{R}^3$. For tuples X, X' over $\mathbb{E}_+$ with smooth entries, the empty tuple admitted, for $a > 0$ and for $x \neq y$ in $\{|x_3| < a\}$ we put $\mathsf{s}_{ij}^{X',X}(x, y) = \int X'(z') X(z)\, \mathsf{s}_{ij}(x; y, \theta(z' + ae_3), z + ae_3)\, dz'\, dz$, and the relation of the kernels to the forms is the product formula

$$\mathsf{s}_{ij}^{X',X}(x, y) = \begin{cases} \big\langle [X'], \mathcal{U}(\vec{x})\, \mathsf{B}_{ij}\big(a + x_3, \frac{y_3 - x_3}{2}\big)\, \mathcal{U}(\vec{y} - \vec{x})\, \mathsf{B}_0\big(\frac{y_3 - x_3}{2}, a - y_3\big)\, \mathcal{U}(-\vec{y})[X] \big\rangle & (x_3 < y_3), \\ \big\langle [X'], \mathcal{U}(\vec{y})\, \mathsf{B}_0\big(a + y_3, \frac{x_3 - y_3}{2}\big)\, \mathcal{U}(\vec{x} - \vec{y})\, \mathsf{B}_{ij}\big(\frac{x_3 - y_3}{2}, a - x_3\big)\, \mathcal{U}(-\vec{x})[X] \big\rangle & (y_3 < x_3), \end{cases} \tag{18.i}$$

where $\mathsf{B}_{ij} = \mathsf{B}_{\mathfrak{q}_{ij}}$ is the operator of Lemma 18.17 (b): the factor of the lower height stands on the left. The two lines are the relation $\mathsf{s}_{ij}^{F',G}(x, y) = \mathfrak{q}_{ij}(\psi'_x, \psi_x)$ to which (M2) of Definition 3.1 (3) refers, with the vectors ψ'_x, ψ_x that the proof of Lemma 3.5 (c) writes out for $x_3 < y_3$ and for $y_3 < x_3$, taken at the tuples $F' = X'$ and $G = X$, whose entries are real, so that the smeared kernel there is $\mathsf{s}_{ij}^{X',X}$, and at the intermediate height $h_* = \frac{1}{2}(x_3 + y_3)$: since the unitary group $\mathcal{U}$ commutes with the functions of H, the formula for the matrix elements in Lemma 18.17 (b) carries $\mathfrak{q}_{ij}(\psi'_x, \psi_x)$ into the first line when $x_3 < y_3$, and, with $\mathsf{B}_0(s, s')^* = \mathsf{B}_0(s', s)$, into the second line when $y_3 < x_3$. In (M3) the test functions F_1 and f lie in $C^\infty_c(\mathbb{R}^{1+2}; \mathbb{C})$ and their supports are spacelike separated: $|\vec{x} - \vec{x}'| > |t - t'|$ for $(t, \vec{x})$ in the one and $(t', \vec{x}')$ in the other. (M4) (a) reads $T_{0\nu}(\partial_0 F)\psi = \sum_{k=1,2} T_{k\nu}(\partial_k F)\psi$ for $F \in \mathcal{S}$, $\psi \in \mathcal{D}_0$ and $\nu = 0, 1, 2$. Let T be the space of the

symmetric complex tensors $t = (t^{\mu\nu})$, $T[t] = t^{\mu\nu}T_{\mu\nu}$, $e \vee e' = \frac{1}{2}(e \otimes e' + e' \otimes e)$ and $ee = e \vee e$ for $e, e' \in \mathbb{C}^3$, and $(\Lambda t)^{\mu\nu} = \Lambda^{\mu}{}_{\mu'}\Lambda^{\nu}{}_{\nu'}t^{\mu'\nu'}$; then $T[e \vee e'] = e^{\mu}e'^{\nu}T_{\mu\nu} = T[e, e']$, and (M5), extended by linearity, reads $U(\Lambda)T[t](F)\Omega = T[\Lambda t](F \circ \Lambda^{-1})\Omega$ for $\Lambda \in \mathcal{L}$, $F \in \mathcal{S}$ and $t \in \mathsf{T}$. We write $\mathfrak{M}^4$ for (M1), (M2), (M3) and (M4) (a), and $\mathfrak{M}^5$ for $\mathfrak{M}^4$ together with (M5).

Definition 18.16 (Flux laws of the translations)**.** Let kernels s_{ij} as in (M2) be given over σ'. A function $\eta \in C_c^\infty(\mathbb{R}^3)$ is *admitted at* $y \in (\mathbb{R}^3)^m_{\neq}$ if $\eta = 1$ on a neighbourhood of y_1 and $y_r \notin \operatorname{supp}\eta$ for $2 \le r \le m$. For $j \in \{1, 2, 3\}$ the *flux law* (FL_j) is the condition

$$\sum_{i=1}^{3} \int \partial_i\eta(x)\, \mathsf{s}_{ij}(x; y)\, dx = \partial_{y_1^j}\mathsf{s}_m(y) \qquad \text{for all } m \ge 1,\ y \in (\mathbb{R}^3)^m_{\neq} \text{ and } \eta \text{ admitted at } y, \tag{18.ii}$$

where $\partial_{y_1^j}$ is the derivative in the j-th coordinate of y_1. The *connected kernels* are given by recursion on m: $\mathsf{s}^{\mathrm{c}}_m$, $m \ge 1$, by $\mathsf{s}_m(y) = \sum_{A \ni 1} \mathsf{s}^{\mathrm{c}}_{|A|}(y_A)\, \mathsf{s}_{m-|A|}(y_{A^c})$, and $\mathsf{s}^{\mathrm{c}}_{ij}(x; y_1, \dots, y_m)$ by $\mathsf{s}_{ij}(x; y_1, \dots, y_m) = \sum_{A \neq \varnothing} \mathsf{s}^{\mathrm{c}}_{ij}(x; y_A)\, \mathsf{s}_{m-|A|}(y_{A^c})$; here A runs through the subsets of $\{1, \dots, m\}$, $y_A = (y_r)_{r \in A}$, A^c is the complement of A, and in each recursion the term $A = \{1, \dots, m\}$ carries the new function with the factor $\mathsf{s}_0 = 1$. The condition ($\mathrm{FL}^{\mathrm{c}}_j$) is eq. 18.ii for all $m \ge 2$, with $\mathsf{s}^{\mathrm{c}}_{ij}$ and $\mathsf{s}^{\mathrm{c}}_m$ in the places of s_{ij} and s_m. ■

The connected kernels are polynomials in the kernels s_n and s_{ij}; the scalar ones are real-analytic, so the right members are defined. Under (M1), (M2) and (M4) (a) the left member of eq. 18.ii is the same for all functions admitted at y (Lemma 18.20 (a)): the law fixes the flux of $\mathsf{s}_{ij}(\cdot\,; y)$ through the boundary of a neighbourhood of y_1 that avoids the other points, and with it the normalisation of the tensor relative to the generators of the translations of σ'. The real part of a function η admitted at y is again admitted at y, and $\eta - \operatorname{Re}\eta = i \operatorname{Im}\eta$ lies in $C_c^\infty(\mathbb{R}^3 \setminus \{y_1, \dots, y_m\})$, as $\operatorname{Im}\eta$ vanishes near y_1; so, under the same conditions, Lemma 18.18 (d) carries eq. 18.ii from the real functions admitted at y to all of them.

Lemma 18.17 (Forms, operators and boundary values)**.** Let $\mathfrak{q}$ be a sesquilinear form on $\mathcal{D}_\infty \times \mathcal{D}_\infty$, antilinear in the first entry, with $|\mathfrak{q}(\psi', \psi)| \le c\, \|(1 + H)^l\psi'\|\, \|(1 + H)^l\psi\|$.

(a) There is exactly one bounded operator $\mathsf{A}_\mathfrak{q}$ with $\mathfrak{q}(\psi', \psi) = \langle (1 + H)^l\psi', \mathsf{A}_\mathfrak{q}(1 + H)^l\psi\rangle$ for $\psi, \psi' \in \mathcal{D}_\infty$, and $\|\mathsf{A}_\mathfrak{q}\| \le c$. For $g \in L^1(\mathbb{R}^2)$, $\mathfrak{q}[g](\psi', \psi) = \int g(v)\, \mathfrak{q}(\mathcal{U}(-v)\psi', \mathcal{U}(-v)\psi)\, dv$ is a form of the same kind, with $c\|g\|_{L^1}$ in the place of c, and $\mathsf{A}_{\mathfrak{q}[g]} = \int g(v)\, \mathcal{U}(v)\mathsf{A}_\mathfrak{q}\mathcal{U}(-v)\, dv$ weakly.

(b) For $\operatorname{Re}\tau, \operatorname{Re}\tau' > 0$ the operator $\mathsf{B}_\mathfrak{q}(\tau, \tau') = e^{-\tau H}(1 + H)^l\mathsf{A}_\mathfrak{q}(1 + H)^l e^{-\tau' H}$ is bounded and holomorphic in norm; $\langle \xi', \mathsf{B}_\mathfrak{q}(\tau, \tau')\xi\rangle = \mathfrak{q}(e^{-\bar\tau H}\xi', e^{-\tau' H}\xi)$ for $\xi, \xi' \in \mathcal{H}$; $\|\mathsf{B}_\mathfrak{q}(\tau, \tau')\| \le c\, b_l(\operatorname{Re}\tau)\, b_l(\operatorname{Re}\tau')$ with $b_l(r) = \sup_{E \ge 0}(1 + E)^l e^{-rE} \le e^r(l/er)^l$; $e^{-zH}\mathsf{B}_\mathfrak{q}(\tau, \tau')e^{-z' H} = \mathsf{B}_\mathfrak{q}(\tau + z, \tau' + z')$ for $\operatorname{Re} z, \operatorname{Re} z' \ge 0$; and $\mathsf{B}_{\mathfrak{q}[g]} = \int g(v)\, \mathcal{U}(v)\mathsf{B}_\mathfrak{q}\mathcal{U}(-v)\, dv$. For $\mathfrak{q} = q_0$, $\mathsf{A}_{q_0} = \mathsf{A}_l$ and $\mathsf{B}_{q_0}(s, s') = \mathsf{B}_0(s, s')$.

(c) For $F \in \mathcal{S}$ there is exactly one operator $\mathfrak{q}(F) : \mathcal{D}_\infty \to \mathcal{D}_\infty$ with $\langle \psi', \mathfrak{q}(F)\psi\rangle = \int F(x)\, \mathfrak{q}(U(x)^{-1}\psi', U(x)^{-1}\psi)\, dx$ for $\psi, \psi' \in \mathcal{D}_\infty$. It satisfies $\|(1 + H)^n\mathfrak{q}(F)\psi\| \le c \sum_{n' \le l+n} \binom{l+n}{n'} \|\partial_t^{n'}F\|_{L^1}\, \|(1 + H)^{2l+n}\psi\|$, $[H, \mathfrak{q}(F)] = i\,\mathfrak{q}(\partial_t F)$ on $\mathcal{D}_\infty$, $U(a)\mathfrak{q}(F)U(a)^{-1} = \mathfrak{q}(F(\cdot - a))$, $\langle \psi', \mathfrak{q}(\alpha \otimes g)\psi\rangle = \int \alpha(t)\, \mathfrak{q}[g](e^{-itH}\psi', e^{-itH}\psi)\, dt$, $\mathfrak{q}(F)\Omega = (1 + H)^l\hat F(P)\mathsf{A}_\mathfrak{q}\Omega$ and $(1 + H)^N\mathfrak{q}(F)\Omega = \mathfrak{q}((1 + i\partial_t)^N F)\Omega$. If $\overline{\mathfrak{q}(\psi', \psi)} = \vartheta\, \mathfrak{q}(\psi, \psi')$ with $\vartheta = \pm 1$, then $\langle \psi', \mathfrak{q}(F)\psi\rangle = \vartheta\langle \mathfrak{q}(\bar F)\psi', \psi\rangle$; so $\langle \psi', T_{\mu\nu}(F)\psi\rangle = \langle T_{\mu\nu}(\bar F)\psi', \psi\rangle$. For $\mathfrak{q} = q_0$, $\mathfrak{q}(f) = \phi(f)$.

(d) Let $\mathfrak{q}_1, \mathfrak{q}_2$ be two such forms with the numbers c_1, c_2, let $g_1, g_2 \in C_c^\infty(\mathbb{R}^2)$, $\chi, \chi' \in \mathcal{H}$, $a > 0$, and $\mathcal{G}_< = \{(s, u) \in \mathbb{C}^2 : -a < \operatorname{Re} s < \operatorname{Re} u < a\}$. The function $\Gamma_<(s, u) = \langle \chi', \mathsf{B}_{\mathfrak{q}_1[g_1]}(a + s, \frac{u-s}{2})\, \mathsf{B}_{\mathfrak{q}_2[g_2]}(\frac{u-s}{2}, a - u)\chi\rangle$ is holomorphic on $\mathcal{G}_<$ and bounded by $c_1c_2\|g_1\|_{L^1}\|g_2\|_{L^1}\|\chi\|\|\chi'\|\, b_l(a + \operatorname{Re} s)\, b_l(\frac{1}{2}\operatorname{Re}(u - s))^2\, b_l(a - \operatorname{Re} u)$; and for

$r\in(-a,a)$, $\psi'=e^{-(a+r)H}\chi'$, $\psi=e^{-(a-r)H}\chi$ and $\alpha_1,\alpha_2\in C_c^\infty(\mathbb{R})$,

$$\lim_{\epsilon\downarrow0}\iint\alpha_1(t)\alpha_2(t')\,\Gamma_<(r-it,r+\epsilon-it')\,dt\,dt'=\langle\psi',\mathfrak{q}_1(\alpha_1\otimes g_1)\,\mathfrak{q}_2(\alpha_2\otimes g_2)\psi\rangle.$$

■

Proof. (a) $(1+H)^l$ maps $\mathcal{D}_\infty$ onto the dense subspace $\mathcal{D}_\infty$, so $(\xi',\xi)\mapsto\mathfrak{q}(R_H^l\xi',R_H^l\xi)$ is a sesquilinear form on a dense subspace bounded by $c\|\xi'\|\|\xi\|$, and the theorem of Riesz gives $\mathsf{A}_\mathfrak{q}$. $\mathcal{U}(-v)$ is unitary and commutes with $(1+H)^l$ on $\mathcal{D}_\infty$ by joint spectral calculus; hence $\mathfrak{q}(\mathcal{U}(-v)\psi',\mathcal{U}(-v)\psi)=\langle(1+H)^l\psi',\mathcal{U}(v)\mathsf{A}_\mathfrak{q}\mathcal{U}(-v)(1+H)^l\psi\rangle$ is continuous in v and bounded by $c\|(1+H)^l\psi'\|\|(1+H)^l\psi\|$, and its integral against g has the stated properties. (b) On the carrier of $\mathcal{P}$, $|e^{-\tau E}(1+E)^l|\le b_l(\operatorname{Re}\tau)$, and $(1+E)^le^{-rE}=e^ry^le^{-ry}$ at $y=1+E$, where $\sup_{y>0}y^le^{-ry}=(l/er)^l$; holomorphy in norm, the semigroup law and $(e^{-\tau H})^*=e^{-\bar\tau H}$ belong to the calculus of $\mathcal{P}$, and the matrix element is (a) at the vectors $e^{-\bar\tau H}\xi',e^{-\tau'H}\xi$ of $\mathcal{D}_\infty$. For q_0, YM3_I:(2047) gives $\mathsf{A}_{q_0}=\mathsf{A}_l$, and the point-insertion identity above gives $\mathsf{B}_{q_0}=\mathsf{B}_0$. (c) Let $\mathfrak{q}_F(\psi',\psi)$ denote the integral of the statement; as in (a) its integrand is continuous and bounded, and $|\mathfrak{q}_F(\psi',\psi)|\le c\|F\|_{L^1}\|(1+H)^l\psi'\|\|(1+H)^l\psi\|$. For $\psi\in\mathcal{D}_\infty$ the map $t\mapsto e^{-itH}(1+H)^l\psi$ is continuously differentiable in norm with the derivative $-iHe^{-itH}(1+H)^l\psi$ by the spectral theorem; as the form is antilinear in its first entry, $\partial_t\,\mathfrak{q}(U(x)^{-1}\psi',U(x)^{-1}\psi)=i\,\mathfrak{q}(U(x)^{-1}H\psi',U(x)^{-1}\psi)-i\,\mathfrak{q}(U(x)^{-1}\psi',U(x)^{-1}H\psi)$, and an integration by parts in t gives

$$\mathfrak{q}_F(H\psi',\psi)-\mathfrak{q}_F(\psi',H\psi)=i\,\mathfrak{q}_{\partial_tF}(\psi',\psi).$$

Hence $\mathfrak{q}_F((1+H)\chi',\psi)=\mathfrak{q}_F(\chi',(1+H)\psi)+i\,\mathfrak{q}_{\partial_tF}(\chi',\psi)$; the two operations commute, so $\mathfrak{q}_F((1+H)^N\chi',\psi)=\sum_{n'}\binom{N}{n'}i^{n'}\mathfrak{q}_{\partial_t^{n'}F}(\chi',(1+H)^{N-n'}\psi)$, and at $\chi'=R_H^l\psi'$, $N=l+n$, one obtains $|\mathfrak{q}_F((1+H)^n\psi',\psi)|\le c\sum_{n'}\binom{l+n}{n'}\|\partial_t^{n'}F\|_{L^1}\|\psi'\|\,\|(1+H)^{2l+n}\psi\|$. At $n=0$ the theorem of Riesz gives the vector $\mathfrak{q}(F)\psi$; for $n\ge1$, the graph-domain criterion YM3_I:(2073) puts it into $\operatorname{dom}H^n$ with the bound of the statement, so that $\mathfrak{q}(F)\mathcal{D}_\infty\subset\mathcal{D}_\infty$, and the last display is $[H,\mathfrak{q}(F)]=i\,\mathfrak{q}(\partial_tF)$. The covariance under $U(a)$ is a change of variables, and the formula for $\alpha\otimes g$ is the theorem of Fubini with $U(x)^{-1}=e^{-itH}\mathcal{U}(-\vec x)$. As $U(x)^{-1}\Omega=\Omega=(1+H)^l\Omega$, $\langle\psi',\mathfrak{q}(F)\Omega\rangle=\int F(x)\langle(1+H)^l\psi',U(x)\mathsf{A}_\mathfrak{q}\Omega\rangle\,dx=\langle(1+H)^l\psi',\hat F(P)\mathsf{A}_\mathfrak{q}\Omega\rangle$, and $(1+p^0)^l\hat F(p)$ is bounded; this is the formula on Ω, and the next one follows from $(1+p^0)^N\hat F=\widehat{(1+i\partial_t)^NF}$. The relation of adjoints follows by complex conjugation under the integral; for T_{00} and $T_{kk'}$ the sign is $\vartheta=1$, and for $T_{0k}=-iT^E_{3k}$ it is $\vartheta_3\vartheta_k=-1$, which the factor $-i$ compensates. For q_0 the defining relation is YM3_I:(2074). (d) On $\mathcal{G}_<$ all arguments of the factors have positive real parts, and (b) gives holomorphy and the bound. Let $0<\epsilon<a-r$, $s=r-it$, $u=r+\epsilon-it'$, $\psi_\epsilon=e^{-(a-r-\epsilon)H}\chi$ and $\mathsf{A}_b=\mathsf{A}_{\mathfrak{q}_b[g_b]}$. As $e^{-(a+s)H}=e^{-(a+r)H}e^{itH}$, $e^{-(u-s)H}=e^{-\epsilon H}e^{-itH}e^{it'H}$ and $e^{-(a-u)H}=e^{-it'H}e^{-(a-r-\epsilon)H}$,

$$\Gamma_<(s,u)=\langle\chi',\mathsf{Y}_t\,e^{-\frac{\epsilon}{2}H}e^{it'H}(1+H)^l\mathsf{A}_2(1+H)^le^{-it'H}\psi_\epsilon\rangle,\qquad\mathsf{Y}_t=e^{-(a+r)H}e^{itH}(1+H)^l\mathsf{A}_1(1+H)^le^{-itH}e^{-\frac{\epsilon}{2}H},$$

with Y_t bounded; the integrand of the double integral is continuous with compact support. For $\xi\in\mathcal{H}$, the bracket with ξ in the place of $\mathsf{Y}_t^*\chi'$ equals $\mathfrak{q}_2[g_2](e^{-it'H}e^{-\frac{\epsilon}{2}H}\xi,e^{-it'H}\psi_\epsilon)$, and its integral against $\alpha_2(t')$ is $\langle\xi,e^{-\frac{\epsilon}{2}H}\mathfrak{q}_2(\alpha_2\otimes g_2)\psi_\epsilon\rangle$ by (c); with $\xi=\mathsf{Y}_t^*\chi'$ and (c) for $\mathfrak{q}_1$ the double integral becomes $\langle\psi',\mathfrak{q}_1(\alpha_1\otimes g_1)\zeta_\epsilon\rangle$, $\zeta_\epsilon=e^{-\epsilon H}\mathfrak{q}_2(\alpha_2\otimes g_2)\psi_\epsilon\in\mathcal{D}_\infty$. Since $\|(1+H)^N(\psi_\epsilon-\psi)\|\le\sup_{E\ge0}(1+E)^Ne^{-(a-r)E}(e^{\epsilon E}-1)\,\|\chi\|\to0$, (c) gives $(1+H)^{2l}\zeta_\epsilon\to(1+H)^{2l}\mathfrak{q}_2(\alpha_2\otimes g_2)\psi$ as $\epsilon\downarrow0$, and (c) once more gives the limit. □

Lemma 18.18 (Generators, a core, local conservation)**.** (a) For $f\in\mathcal{S}$, $\psi\in\mathcal{D}_\infty$ and $\mu=0,1,2$, $[P_\mu,\phi(f)]\psi=i\,\phi(\partial_\mu f)\psi$; moreover $P_\mu\Omega=0$ and $P_\mu\phi(f_1)\cdots\phi(f_n)\Omega=i\sum_{b=1}^n\phi(f_1)\cdots\phi(\partial_\mu f_b)\cdots\phi(f_n)\Omega$.

(b) $\mathcal{D}_0$ is a core of $(1+H)^n$ for every integer $n\ge0$.

(c) Let (M1) and (M4) (a) hold. Then (M4) (a) holds for all $\psi \in \mathcal{D}_\infty$, and for $\psi', \psi \in \mathcal{D}_\infty$, $j = 1, 2, 3$ and $g' \in C_c^\infty(\mathbb{R}^2)$

$$\begin{aligned} \mathfrak{q}_{3j}(H\psi', \psi) - \mathfrak{q}_{3j}(\psi', H\psi) &= i \sum_{k\le 2} \big[\mathfrak{q}_{kj}(P_k\psi', \psi) - \mathfrak{q}_{kj}(\psi', P_k\psi)\big], \\ \mathfrak{q}_{3j}[g'](H\psi', \psi) - \mathfrak{q}_{3j}[g'](\psi', H\psi) &= -\sum_{k\le 2} \mathfrak{q}_{kj}[\partial_k g'](\psi', \psi). \end{aligned} \tag{18.iii}$$

If (M3) holds as well, it holds for all $\psi \in \mathcal{D}_\infty$.

(d) Let (M1), (M2) and (M4) (a) hold. For $m \ge 1$, $y \in (\mathbb{R}^3)^m_{\neq}$, $\zeta \in C_c^\infty(\mathbb{R}^3 \setminus \{y_1, \dots, y_m\})$ and $j = 1, 2, 3$, $\sum_i \int \partial_i \zeta(x)\, \mathsf{s}_{ij}(x; y)\, dx = 0$; the same holds for the connected kernels $\mathsf{s}^{\mathrm{c}}_{ij}$ of Definition 18.16.

■

Proof. (a) For $\mu = 0$ this is the last relation of YM3_I:(2076). For $\mu = k \le 2$, $U(se_k) = e^{isP_k}$, and the second relation of YM3_I:(2076) gives $\langle e^{isP_k}\psi', \phi(f) e^{isP_k}\psi\rangle = \langle \psi', \phi(f(\cdot + se_k))\psi\rangle$ for $\psi, \psi' \in \mathcal{D}_\infty$. Both members are differentiable at $s = 0$: on the left, $(1 + H)^{2l}\psi$ lies in $\operatorname{dom} P_k$, so $s \mapsto e^{isP_k}\psi$ is differentiable for the norm $\|(1 + H)^{2l} \cdot \|$, and YM3_I:(2075) applies; on the right, $s^{-1}(f(\cdot + se_k) - f) \to \partial_k f$ for every c_N. The derivatives give $-i\langle \psi', [P_k, \phi(f)]\psi\rangle = \langle \psi', \phi(\partial_k f)\psi\rangle$, as $\phi(f)\psi \in \mathcal{D}_\infty \subset \operatorname{dom} P_k$. $U(x)\Omega = \Omega$ gives $P_\mu \Omega = 0$, and moving P_μ to the right through the factors gives the last formula. (b) Let $\xi \in \operatorname{dom} H^n$ with $\langle (1 + H)^n \xi, (1 + H)^n \psi\rangle = 0$ for all $\psi \in \mathcal{D}_0$, and let $\zeta = (1 + H)^n \xi$. As $e^{itH} = U((t, \vec{0}))$ maps $\mathcal{D}_0$ onto itself (Theorem YM3_I: AO), $\int (1 + E)^n e^{itE}\, d\mu_\psi(E) = 0$ for all real t, where $\mu_\psi = \langle \zeta, \mathcal{P}_H(\cdot)\psi\rangle$ and $\mathcal{P}_H$ is the spectral measure of H; $(1 + E)^n \mu_\psi$ is a finite complex measure with vanishing Fourier transform, so it vanishes, and $\langle \zeta, \psi\rangle = \mu_\psi(\mathbb{R}) = 0$; $\mathcal{D}_0$ being dense, $\zeta = 0$ and $\xi = 0$. (c) By Lemma 18.17 (c) and YM3_I:(2075), both members of (M4) (a), and of (M3), are bounded by $C\|(1 + H)^{4l}\psi\|$; by (b) they extend from $\mathcal{D}_0$ to $\operatorname{dom} H^{4l} \supset \mathcal{D}_\infty$. In the Euclidean components, (M4) (a) at $\nu = k$ reads $-iT^E_{3k}(\partial_t F) = \sum_{k' \le 2} T^E_{k'k}(\partial_{k'} F)$, and at $\nu = 0$, multiplied by i and with $\mathfrak{q}_{k'3} = \mathfrak{q}_{3k'}$, it reads $-iT^E_{33}(\partial_t F) = \sum_{k' \le 2} T^E_{k'3}(\partial_{k'} F)$; so $-iT^E_{3j}(\partial_t F) - \sum_{k \le 2} T^E_{kj}(\partial_k F) = 0$ on $\mathcal{D}_\infty$ for $j = 1, 2, 3$. For $\psi', \psi \in \mathcal{D}_\infty$ the functions $\mathfrak{t}_{ij}(x) = \mathfrak{q}_{ij}(U(x)^{-1}\psi', U(x)^{-1}\psi)$ are continuously differentiable and bounded with their first derivatives, and an integration by parts against every $F \in \mathcal{S}$ gives $i\,\partial_t \mathfrak{t}_{3j} + \sum_{k \le 2} \partial_k \mathfrak{t}_{kj} = 0$. At $x = 0$, $\partial_t \mathfrak{t} = i\,\mathfrak{q}(H\psi', \psi) - i\,\mathfrak{q}(\psi', H\psi)$ by the proof of Lemma 18.17 (c), and $\partial_k \mathfrak{t} = i\,\mathfrak{q}(P_k\psi', \psi) - i\,\mathfrak{q}(\psi', P_k\psi)$, as $\mathcal{U}(-\vec{x}) = e^{-i\vec{x}\cdot P}$; this is the first identity of eq. 18.iii. As $\mathcal{U}(-v)$ commutes with H on $\mathcal{D}_\infty$, the first identity at the vectors $\mathcal{U}(-v)\psi', \mathcal{U}(-v)\psi$ has the right member $\sum_{k \le 2} \partial_{v_k} \mathfrak{q}_{kj}(\mathcal{U}(-v)\psi', \mathcal{U}(-v)\psi)$; multiplication by $g'(v)$ and an integration by parts in v give the second identity. (d) This is the last part of Lemma 3.5 (c). Its argument runs as follows. At a configuration with pairwise different heights in which a scalar point y_{r_0} is the lowest point above x, an open slab contains x and y_{r_0}, and its closure contains no other point; after a translation, under which (M2) and Proposition YM3_I:108.3 keep the kernels, it is $\{|x_3| < a\}$, and the other points, smeared by bumps, form a tuple X above the slab and, through their mirror images, a tuple X' below it. By the first line of eq. 18.i, the symmetry in the scalar points and the semigroup law of Lemma 18.17 (b), for x near the given point and $x_3 < h_* < y_{r_0,3}$, $\mathsf{s}^{X',X}_{ij}(x, y_{r_0}) = \mathfrak{q}_{ij}(\psi'_x, \psi_x)$ with $\psi'_x = \mathcal{U}(-\vec{x}) e^{-(a+x_3)H}[X']$ and $\psi_x = \mathcal{U}(-\vec{x}) e^{-(h_* - x_3)H} \mathcal{U}(\vec{y}_{r_0}) \mathsf{B}_0(y_{r_0,3} - h_*, a - y_{r_0,3}) \mathcal{U}(-\vec{y}_{r_0})[X]$. As $\partial_{x_3}\psi'_x = -H\psi'_x$, $\partial_{x_3}\psi_x = H\psi_x$, $\partial_{x_k}\psi'_x = -iP_k\psi'_x$ and $\partial_{x_k}\psi_x = -iP_k\psi_x$, the divergence $\sum_i \partial_{x_i} \mathsf{s}^{X',X}_{ij}(x, y_{r_0})$ is the difference of the two members of the first identity of eq. 18.iii with the sign changed, hence 0, and approximate units for the bumps give the identity for ζ carried near x. A rotation of SO(3), under which (M2) moves the indices as a tensor, brings every configuration of distinct points to pairwise different heights with y_1 above x, and a partition of unity gives every ζ. For the connected kernels, by induction on m: in the recursion of Definition 18.16 the terms with $A \neq \{1, \dots, m\}$ are connected kernels of fewer points times factors free of x, and ζ vanishes near the points of every y_A. □

Lemma 18.19 (One scalar insertion; smooth tuples; products). (a) For tuples X, X' over $\mathbb{E}_+$ with n and n' entries, $a > 0$ and $y \in \mathbb{R}^3$ with $|y_3| < a$,

$$\int X'(z')X(z)\,\mathsf{s}_{1+n'+n}(y, \theta(z' + ae_3), z + ae_3)\,dz'\,dz = \mathsf{n}^{X',X}(y),$$

$$\mathsf{n}^{X',X}(y) = \langle [X'], \mathcal{U}(\vec{y})\,\mathsf{B}_0(a + y_3, a - y_3)\,\mathcal{U}(-\vec{y})[X]\rangle.$$

For $\chi, \chi' \in \mathcal{H}$ the function $\mathsf{n}(y) = \langle \chi', \mathcal{U}(\vec{y})\mathsf{B}_0(a+y_3, a-y_3)\mathcal{U}(-\vec{y})\chi\rangle$, with $\mathsf{B}_0(a+y_3, a-y_3) = e^{-(a+y_3)H}(1+H)^l \mathsf{A}_l (1+H)^l e^{-(a-y_3)H}$, is defined for $\vec{y} \in \mathbb{R}^2$ and complex y_3 with $|\operatorname{Re} y_3| < a$; it is smooth there and holomorphic in y_3, and $\mathsf{n}(\vec{y}, -it') = q_0(U(y)^{-1}e^{-aH}\chi', U(y)^{-1}e^{-aH}\chi)$ at $y = (t', \vec{y}) \in \mathbb{R}^{1+2}$.

(b) The classes of the tuples over $\mathbb{E}_+$ with smooth entries span a dense subspace of $\mathcal{H}$.

(c) Let $I \subset \mathbb{R}^{n_1}$ and $B \subset \mathbb{R}^{n_2}$ be bounded open sets and $f \in C_c^\infty(I \times B; \mathbb{C})$. There are finite sums $f_M = \sum_b \beta_b \otimes \varkappa_b$ with $\beta_b \in C_c^\infty(I; \mathbb{C})$ and $\varkappa_b \in C_c^\infty(B; \mathbb{C})$, all carried by one compact subset of $I \times B$, such that $f_M \to f$ in every C^N.

■

Proof. (a) The right member is continuous in y by Proposition YM3_I:107.2 and the strong continuity of $\mathcal{U}$, the left member by the continuity of $\mathsf{s}_{1+n'+n}$ on the compact set of the points involved; so it suffices to integrate both against every $h \in C_c^1(\mathbb{R}^3)$ carried by $\{|y_3 - u_0| < c_0\eta\}$, where $|u_0| < a$ and $0 < \eta \le \min\{1, a - |u_0|\}$. By YM3_I:(2065) the integral of the left member against h is $\sigma'(\theta\tau_{ae_3}X' \cdot (h) \cdot \tau_{ae_3}X)$, and by (Rec1) for the translation by $-u_0e_3$, which turns $\theta\tau_{ae_3}$ into $\theta\tau_{(a+u_0)e_3}$ and τ_{ae_3} into $\tau_{(a-u_0)e_3}$, it equals $\sigma'(\theta\tau_{\eta e_3}Y' \cdot (h_0) \cdot \tau_{\eta e_3}Y)$ with $h_0 = h(\cdot + u_0e_3) \in C_c^1(\mathsf{Sl}_\eta)$ and the tuples $Y = \tau_{(a-u_0-\eta)e_3}X$, $Y' = \tau_{(a+u_0-\eta)e_3}X'$ over $\mathbb{E}_+$, the two shifts being ≥ 0. By YM3_I:(2037) and YM3_I:(2039) this is $\int h_0(x)\langle [Y'], \mathcal{U}(\vec{x})\mathsf{B}_0(\eta + x_3, \eta - x_3)\mathcal{U}(-\vec{x})[Y]\rangle\,dx$; $[Y] = e^{-(a-u_0-\eta)H}[X]$ and $[Y'] = e^{-(a+u_0-\eta)H}[X']$ by (Rec2), and the shift law YM3_I:(2038) turns the bracket into $\langle [X'], \mathcal{U}(\vec{x})\mathsf{B}_0(a + u_0 + x_3, a - u_0 - x_3)\mathcal{U}(-\vec{x})[X]\rangle$; the substitution $y = x + u_0e_3$ gives the right member integrated against h. Smoothness in $\vec{y}$ follows from $\mathcal{U}(\vec{y}) = e^{i\vec{y}\cdot P}$ and the boundedness of $P_k e^{-sH}$ for $s > 0$, holomorphy in y_3 from Lemma 18.17 (b); at $y_3 = -it'$, $e^{-(a\mp it')H} = e^{-aH}e^{\pm it'H}$ and $U(y)^{-1} = e^{-it'H}\mathcal{U}(-\vec{y})$ give the last formula by YM3_I:(2047). (b) The classes of the tuples are dense. For a tuple X with n entries let X^ε be the tuple of their mollifications, whose supports lie, for small ε, in fixed pairwise disjoint compact subsets of $\mathbb{E}_+$; by YM3_I:(2065), $\|[X] - [X^\varepsilon]\|^2 = \int \mathsf{s}_{2n}(\theta z', z)\,(X(z') - X^\varepsilon(z'))\,(X(z) - X^\varepsilon(z))\,dz'\,dz$, where the kernel is bounded on the compact set of the points involved and $X^\varepsilon \to X$ uniformly. (c) Choose $\chi_1 \in C_c^\infty(I)$ and $\chi_2 \in C_c^\infty(B)$ equal to 1 on the projections of $\operatorname{supp} f$, place $I \times B$ in an open cube, continue f periodically from it and expand it in its Fourier series, which converges in every C^N; the partial sums, multiplied by $\chi_1 \otimes \chi_2$, are the f_M. □

Lemma 18.20 (The flux law at one scalar point and for connected kernels). Let (M1), (M2) and (M4) (a) hold, and let $j \in \{1, 2, 3\}$.

(a) For $y \in (\mathbb{R}^3)^m_{\neq}$ the left member of eq. 18.ii is the same for all functions η admitted at y.

(b) For $y_1 \in \mathbb{R}^3$ and every η admitted at (y_1), $\sum_i \int \partial_i\eta(x)\,\mathsf{s}_{ij}(x; y_1)\,dx = 0 = \partial_{y_1^j}\mathsf{s}_1$; so eq. 18.ii holds at $m = 1$.

(c) (FL_j) holds if and only if $(\mathrm{FL}_j^{\mathrm{c}})$ holds.

■

Proof. (a) Two functions admitted at y differ by a function of $C_c^\infty(\mathbb{R}^3 \backslash \{y_1, \dots, y_m\})$; Lemma 18.18 (d). (b) By (M2) for the translations, $\mathsf{s}_{ij}(x; y_1) = \mathsf{t}_{ij}(x - y_1)$ with $\mathsf{t}_{ij}(\xi) = \mathsf{s}_{ij}(\xi; 0)$, and $\mathsf{t}_{ij}(\mathsf{R}\xi) = \mathsf{R}_{ii'}\mathsf{R}_{jj'}\mathsf{t}_{i'j'}(\xi)$ for $\mathsf{R} \in \mathrm{SO}(3)$. By (a) we may take $\eta(x) = \eta_0(|x - y_1|)$ with $\eta_0 \in C_c^\infty([0, \infty))$ equal to 1 near 0; the left member is then $\mathsf{V}_j = \sum_i \int \eta_0'(|\xi|)\,\xi_i|\xi|^{-1}\mathsf{t}_{ij}(\xi)\,d\xi$, and the substitution $\xi \mapsto \mathsf{R}\xi$ gives $\mathsf{V}_j = \mathsf{R}_{jj'}\mathsf{V}_{j'}$ for every $\mathsf{R} \in \mathrm{SO}(3)$, so $\mathsf{V} = 0$; s_1 is a constant. (c) Fix $y \in (\mathbb{R}^3)^m_{\neq}$ and η admitted

at y, and put $\mathsf{F}(A) = \sum_i \int \partial_i \eta(x)\, \mathsf{s}^{\mathrm{c}}_{ij}(x; y_A)\, dx$ for $\varnothing \neq A \subset \{1, \dots, m\}$. By the recursion, the left member of eq. 18.ii is $\sum_{A \neq \varnothing} \mathsf{F}(A)\, \mathsf{s}_{m-|A|}(y_{A^c})$. If $1 \notin A$, η vanishes near the points of y_A, and $\mathsf{F}(A) = 0$ by Lemma 18.18 (d) for the connected kernels; $\mathsf{s}^{\mathrm{c}}_{ij}(x; y_1) = \mathsf{s}_{ij}(x; y_1)$, so $\mathsf{F}(\{1\}) = 0$ by (b); if $1 \in A$ and $|A| \geq 2$, η is admitted at y_A. The right member is $\sum_{A \ni 1} \partial_{y_1^j} \mathsf{s}^{\mathrm{c}}_{|A|}(y_A)\, \mathsf{s}_{m-|A|}(y_{A^c})$, whose term $A = \{1\}$ vanishes, $\mathsf{s}^{\mathrm{c}}_1 = \mathsf{s}_1$ being a constant. Hence $(\mathrm{FL}^{\mathrm{c}}_j)$ gives (FL_j) term by term; conversely, by induction on m, (FL_j) at m together with $(\mathrm{FL}^{\mathrm{c}}_j)$ at the orders $2, \dots, m-1$ leaves $\mathsf{F}(\{1, \dots, m\}) = \partial_{y_1^j} \mathsf{s}^{\mathrm{c}}_m(y)$. □

Lemma 18.21 (An edge of the wedge in one complex variable, with a parameter)**.** Let $a, d_* > 0$, let $\mathcal{G}_<$ be as in Lemma 18.17 (d), $\mathcal{G}_> = \{(s,u) \in \mathbb{C}^2 : -a < \operatorname{Re} u < \operatorname{Re} s < a\}$ and $\mathcal{G}_{d_*} = \{(s,u) \in \mathbb{C}^2 : |\operatorname{Re} s| < a,\ |\operatorname{Re} u| < a,\ |\operatorname{Im}(s-u)| < d_*\}$. Let $\Gamma_<$ and $\Gamma_>$ be holomorphic on $\mathcal{G}_<$ and $\mathcal{G}_>$, and let there be an integer $p \geq 1$ and for every $\delta > 0$ a number C_δ with $|\Gamma_{\lessgtr}(s,u)| \leq C_\delta |\operatorname{Re}(u-s)|^{-p}$ wherever $|\operatorname{Re} s|, |\operatorname{Re} u| \leq a - \delta$. Suppose that for every $r \in (-a, a)$ and all $\alpha_1, \alpha_2 \in C^\infty_c(\mathbb{R})$ with $|t - t'| < d_*$ on $\operatorname{supp}\alpha_1 \times \operatorname{supp}\alpha_2$

$$\lim_{\epsilon \downarrow 0} \iint \alpha_1(t)\alpha_2(t') \big[\Gamma_<(r - it, r + \epsilon - it') - \Gamma_>(r + \epsilon - it, r - it')\big]\, dt\, dt' = 0.$$

Then there is exactly one holomorphic function Γ on $\mathcal{G}_{d_*}$ equal to $\Gamma_<$ on $\mathcal{G}_< \cap \mathcal{G}_{d_*}$ and to $\Gamma_>$ on $\mathcal{G}_> \cap \mathcal{G}_{d_*}$. ■

Proof. (1) Write $c = \frac{1}{2}(s+u)$ and $\varsigma = u - s$; then $\max\{|\operatorname{Re} s|, |\operatorname{Re} u|\} = |\operatorname{Re} c| + \frac{1}{2}|\operatorname{Re}\varsigma|$. Fix $0 < \delta < a/3$, put $\mathcal{C} = \{|\operatorname{Re} c| < a - 2\delta\}$ and $\mathcal{W}_\pm = \{0 < \pm \operatorname{Re}\varsigma < 2\delta\}$, and let $\Gamma_+(c,\varsigma)$ and $\Gamma_-(c,\varsigma)$ be $\Gamma_<$ and $\Gamma_>$ at $(s,u) = (c - \frac{\varsigma}{2}, c + \frac{\varsigma}{2})$: they are holomorphic on $\mathcal{C} \times \mathcal{W}_\pm$ and bounded there by $C_\delta |\operatorname{Re}\varsigma|^{-p}$. (2) Put $\Phi^0_\pm = \Gamma_\pm$ and $\Phi^{k+1}_\pm(c,\varsigma) = \int_{\pm\delta}^{\varsigma} \Phi^k_\pm(c,\varsigma')\, d\varsigma'$, the integral being taken in the convex strip $\mathcal{W}_\pm$; these functions are holomorphic in (c,ς). Integrating first along the segment from $\pm\delta$ to $\pm\delta + i\operatorname{Im}\varsigma$ and then parallel to the real axis, one finds on $\{|\operatorname{Im}\varsigma| \leq d_*\}$, with constants that do not depend on $c \in \mathcal{C}$, $|\Phi^k_\pm| \leq C_k |\operatorname{Re}\varsigma|^{k-p}$ for $k < p$, $|\Phi^p_\pm| \leq C_p(1 + |\log|\operatorname{Re}\varsigma||)$ and $|\Phi^{p+1}_\pm| \leq C_{p+1}$. So $\Phi_\pm = \Phi^{p+2}_\pm$ is Lipschitz in ς, uniformly in c; it extends continuously to $\operatorname{Re}\varsigma = 0$, its boundary values $\Psi_\pm(c,\tau) = \lim_{\epsilon\downarrow 0} \Phi_\pm(c, \pm\epsilon - i\tau)$ are uniform limits and therefore holomorphic in c (theorem of Weierstrass), and $\Gamma_\pm(c, \pm\epsilon - i\tau) = (i\partial_\tau)^{p+2}[\Phi_\pm(c, \pm\epsilon - i\tau)]$. (3) Put $N = p + 2$, $t_+ = \frac{1}{2}(t + t')$ and $t_- = t' - t$, a change of variables with Jacobian 1; the points $(r - it, r + \epsilon - it')$ and $(r + \epsilon - it, r - it')$ are $(c,\varsigma) = (r + \frac{\epsilon}{2} - it_+, \pm\epsilon - it_-)$. For $|r| < a - 2\delta$ and $\Upsilon \in C^\infty_c(\mathbb{R}^2)$, a function of (t_+, t_-) carried by $\{|t_-| < d_*\}$, N integrations by parts in t_- and the uniform convergence give $\iint \Upsilon\, \Gamma_\pm(r + \frac{\epsilon}{2} - it_+, \pm\epsilon - it_-)\, dt_+\, dt_- \to \iint ((-i\partial_{t_-})^N \Upsilon)\, \Psi_\pm(r - it_+, t_-)\, dt_+\, dt_-$. For $\Upsilon = \alpha_1(t)\alpha_2(t')$ the hypothesis says that the two limits are equal. With a partition of unity, a function Υ carried by $\{|t_-| < d_*\}$ is written as a sum of finitely many functions, each carried by a product of intervals in the variables (t,t') that lies inside $\{|t - t'| < d_*\}$; Lemma 18.19 (c) then shows that each of them is a limit in C^N of sums of such products, all carried by a single compact set. Hence the continuous function $\mathsf{d}(t_+, t_-) = (\Psi_+ - \Psi_-)(r - it_+, t_-)$ satisfies $\partial^N_{t_-} \mathsf{d} = 0$ as a distribution on $\mathbb{R} \times (-d_*, d_*)$; after a mollification it is a polynomial in t_- of degree $< N$, and so is d, with coefficients depending on t_+. Thus $(\Psi_+ - \Psi_-)(c,\tau) = \sum_{n<N} a_n(c)\tau^n$ for $c \in \mathcal{C}$ and $|\tau| < d_*$, and the values at N fixed points τ, through a Vandermonde system, show that the a_n are holomorphic on $\mathcal{C}$. (4) With $\mathsf{p}(c,\varsigma) = \sum_{n<N} a_n(c)(i\varsigma)^n$ put $\Phi = \Phi_+ - \mathsf{p}$ where $\operatorname{Re}\varsigma \geq 0$ and $\Phi = \Phi_-$ where $\operatorname{Re}\varsigma \leq 0$, on $\mathcal{C} \times \{|\operatorname{Re}\varsigma| < 2\delta,\ |\operatorname{Im}\varsigma| < d_*\}$. At $\operatorname{Re}\varsigma = 0$ the two definitions agree, as $\mathsf{p}(c, -i\tau) = \sum_n a_n(c)\tau^n$; Φ is continuous, holomorphic in ς for fixed c by the theorem of Morera, and holomorphic in c for fixed ς; by the theorem of Osgood it is holomorphic. $\Gamma = \partial^N_\varsigma \Phi$ equals $\Gamma_\pm$ on the two sides, p having degree $< N$ in ς. As $\delta \downarrow 0$, the sets so obtained, together with $\mathcal{G}_< \cap \mathcal{G}_{d_*}$ and $\mathcal{G}_> \cap \mathcal{G}_{d_*}$, cover $\mathcal{G}_{d_*}$; on overlaps the functions agree off $\{\operatorname{Re}(u-s) = 0\}$, hence everywhere by continuity. $\mathcal{G}_{d_*}$ is convex, so the identity theorem gives uniqueness. □

Lemma 18.22 (The commutator of a smeared component with the scalar field)**.** Let $\mathfrak{M}^4$ hold and $j \in \{1,2,3\}$. Put $\mathcal{J}_j(\alpha, g) = T^E_{3j}(\alpha \otimes g)$, $\mathfrak{L}_j f = \partial_j f$ for $j \le 2$ and $\mathfrak{L}_3 f = i\partial_t f$. Let $\alpha \in C^\infty_c(\mathbb{R})$, let $\varkappa, g \in C^\infty_c(\mathbb{R}^2)$ with $g = 1$ near $\operatorname{supp}\varkappa$, and let $0 < d_* < \operatorname{dist}(\operatorname{supp}\varkappa, \operatorname{supp}\nabla g)$.

(a) For tuples X, X' over $\mathbb{E}_+$ with smooth entries and $a > 0$ there is exactly one holomorphic function D on $\{u \in \mathbb{C} : |\operatorname{Re} u| < a\}$ such that $\sum_i \iint \partial_i\eta(x)\, h(y)\, \mathsf{s}^{X',X}_{ij}(x,y)\, dx\, dy = \int \beta_1(u)\, \mathsf{D}(u)\, du$ whenever $\beta_1, \chi_1 \in C^\infty_c((-a,a))$, $\chi_1 = 1$ near $\operatorname{supp}\beta_1$, $\eta(x) = \chi_1(x_3) g(\vec{x})$ and $h(y) = \beta_1(y_3)\varkappa(\vec{y})$.

(b) For $\beta \in C^\infty_c(\mathbb{R})$ with $|t - t'| < d_*$ on $\operatorname{supp}\alpha \times \operatorname{supp}\beta$, $\psi = e^{-aH}[X]$ and $\psi' = e^{-aH}[X']$: $\langle \psi', [\mathcal{J}_j(\alpha, g), \phi(\beta \otimes \varkappa)]\psi\rangle = (\int \alpha) \int \beta(t')\, \mathsf{D}(-it')\, dt'$.

(c) The function $\mathsf{N}(u) = \int \varkappa(\vec{y})\, (\partial_j \mathsf{n}^{X',X})(\vec{y}, u)\, d\vec{y}$, with $\mathsf{n}^{X',X}$ of Lemma 18.19 (a) and ∂_3 the derivative in y_3, is holomorphic on $\{|\operatorname{Re} u| < a\}$, and $\int \beta(t')\, \mathsf{N}(-it')\, dt' = -\langle \psi', \phi(\mathfrak{L}_j(\beta \otimes \varkappa))\psi\rangle$ for every $\beta \in C^\infty_c(\mathbb{R})$.

(d) If (FL_j) holds, then $\mathsf{D} = \mathsf{N}$. If moreover $f \in C^\infty_c(\mathbb{R}^{1+2}; \mathbb{C})$ is carried by $I_f \times B_f$, where I_f is a bounded open interval and B_f an open disc, $\operatorname{supp}\alpha$ lies in a bounded interval I_α, $t_* = \sup\{|t - t'| : t \in I_\alpha, t' \in I_f\}$, $g = 1$ near $\overline{B_f}$ and $\operatorname{dist}(B_f, \operatorname{supp}\nabla g) > t_*$, then $[\mathcal{J}_j(\alpha, g), \phi(f)]\psi = -(\int \alpha)\phi(\mathfrak{L}_j f)\psi$ for all $\psi \in \mathcal{D}_\infty$.

■

Proof. Fix $\chi, \chi' \in \mathcal{H}$ and $a > 0$, and let $\mathfrak{x} = \mathfrak{q}_{3j}[g]$, $\mathfrak{z} = \sum_{k\le 2} \mathfrak{q}_{kj}[\partial_k g]$ and $\mathfrak{y} = q_0[\varkappa]$ (Lemma 18.17 (a)); by the second identity of eq. 18.iii at $g' = g$, $\mathfrak{x}(H\psi', \psi) - \mathfrak{x}(\psi', H\psi) = -\mathfrak{z}(\psi', \psi)$ on $\mathcal{D}_\infty \times \mathcal{D}_\infty$. (1) On $\mathcal{G}_<$ and $\mathcal{G}_>$ (Lemma 18.21) put

$$G_<(s,u) = \langle \chi', \mathsf{B}_\mathfrak{x}(a+s, \tfrac{u-s}{2})\mathsf{B}_\mathfrak{y}(\tfrac{u-s}{2}, a-u)\chi\rangle, \qquad G_>(s,u) = \langle \chi', \mathsf{B}_\mathfrak{y}(a+u, \tfrac{s-u}{2})\mathsf{B}_\mathfrak{x}(\tfrac{s-u}{2}, a-s)\chi\rangle,$$

and let $Z_<, Z_>$ be the same with $\mathfrak{z}$ in the place of $\mathfrak{x}$; they are holomorphic by Lemma 18.17 (b). We have $\partial_s G_\lessgtr = Z_\lessgtr$. Indeed, by Lemma 18.17 (b), $G_<(s,u) = \mathfrak{x}(e^{-(a+\bar{s})H}\chi', \xi_s)$ with $\xi_s = \mathsf{B}_\mathfrak{y}(u - s, a - u)\chi \in \mathcal{D}_\infty$; as s moves, the factor $e^{-(a+s)H}(1+H)^l$ to the left of $\mathsf{A}_\mathfrak{x}$ acquires the derivative $-He^{-(a+s)H}(1+H)^l$ and $(1+H)^l\xi_s$ the derivative $(1+H)^l H\xi_s$, so that $\partial_s G_< = -\mathfrak{x}(He^{-(a+\bar{s})H}\chi', \xi_s) + \mathfrak{x}(e^{-(a+\bar{s})H}\chi', H\xi_s) = \mathfrak{z}(e^{-(a+\bar{s})H}\chi', \xi_s) = Z_<$; in the same way $G_>(s,u) = \mathfrak{x}(\mathsf{B}_\mathfrak{y}(a+u, s-u)^*\chi', e^{-(a-s)H}\chi)$, where again the factor to the left of $\mathsf{A}_\mathfrak{x}$ acquires $-H$ and the one to the right $+H$. (2) $Z_<$ and $Z_>$ satisfy the hypotheses of Lemma 18.21 with $p = 2l$. The bound follows from Lemma 18.17 (d), (b) and $b_l(r) \le e^{2a}(l/e)^l r^{-l}$ for $0 < r \le 2a$. By Lemma 18.17 (d), applied as it stands and with the two forms exchanged, the two smeared boundary values at $r \in (-a, a)$ are $\langle \psi'_r, \mathfrak{z}(\alpha_1)\phi(\alpha_2 \otimes \varkappa)\psi_r\rangle$ and $\langle \psi'_r, \phi(\alpha_2 \otimes \varkappa)\mathfrak{z}(\alpha_1)\psi_r\rangle$, where $\mathfrak{z}(\alpha_1) = \sum_{k\le 2} T^E_{kj}(\alpha_1 \otimes \partial_k g)$, the vectors $\psi'_r = e^{-(a+r)H}\chi'$ and $\psi_r = e^{-(a-r)H}\chi$ lie in $\mathcal{D}_\infty$, and $q_0(\alpha_2 \otimes \varkappa) = \phi(\alpha_2 \otimes \varkappa)$ by Lemma 18.17 (c). If $|t - t'| < d_*$ on $\operatorname{supp}\alpha_1 \times \operatorname{supp}\alpha_2$, the supports of $\alpha_1 \otimes \partial_k g$ and of $\alpha_2 \otimes \varkappa$ are spacelike separated, since $|\vec{x} - \vec{y}| \ge \operatorname{dist}(\operatorname{supp}\nabla g, \operatorname{supp}\varkappa) > d_* > |t - t'|$ on them, and (M3) on $\mathcal{D}_\infty$ (Lemma 18.18 (c)) makes the two boundary values equal. So there is one holomorphic function Z on $\mathcal{G}_{d_*}$ equal to $Z_\lessgtr$ on $\mathcal{G}_\lessgtr \cap \mathcal{G}_{d_*}$. (3) $\mathcal{Z}(s,u) = \int_u^s Z(w,u)\, dw$, along the segment from u to s, which keeps the point in $\mathcal{G}_{d_*}$, is holomorphic on $\mathcal{G}_{d_*}$, and $\partial_s\mathcal{Z} = Z$. On $\mathcal{G}_< \cap \mathcal{G}_{d_*}$, $\partial_s(G_< - \mathcal{Z}) = 0$, and for fixed u the set of the s with (s,u) in it is convex; so $G_< = \mathcal{Z} + c_<(u)$ there, and likewise $G_> = \mathcal{Z} + c_>(u)$ on $\mathcal{G}_> \cap \mathcal{G}_{d_*}$, with $c_<, c_>$ holomorphic on $\{|\operatorname{Re} u| < a\}$ (near u_0, $c_<(u) = (G_< - \mathcal{Z})(u - \epsilon_0, u)$ for a fixed small $\epsilon_0 > 0$). Put $\mathsf{D} = c_< - c_>$. (4) Let $\chi = [X]$ and $\chi' = [X']$. Integrating eq. 18.i against $g(\vec{x})\varkappa(\vec{y})$, respectively against $\partial_k g(\vec{x})\varkappa(\vec{y})$ summed over $k \le 2$, and using the last formula of Lemma 18.17 (b), one finds for real $s \ne u$ in $(-a, a)$

$$\iint g(\vec{x})\varkappa(\vec{y})\, \mathsf{s}^{X',X}_{3j}((\vec{x}, s), (\vec{y}, u))\, d\vec{x}\, d\vec{y} = G_\lessgtr(s,u),$$

$$\sum_{k\le 2} \iint \partial_k g(\vec{x})\varkappa(\vec{y})\, \mathsf{s}^{X',X}_{kj}((\vec{x}, s), (\vec{y}, u))\, d\vec{x}\, d\vec{y} = Z_\lessgtr(s,u) \quad (s \lessgtr u).$$

The second integrand stays continuous at $s=u$, as $\operatorname{supp}\nabla g$ and $\operatorname{supp}\varkappa$ are disjoint and the kernels are continuous; so the second integral equals Z on the whole of $(-a,a)^2$. With $\partial_3\eta=\chi_1'(x_3)g(\vec{x})$ and $\partial_k\eta=\chi_1(x_3)\partial_k g(\vec{x})$, the integrand of (a) is continuous with compact support, and the left member of (a) is $\int\beta_1(u)\big[\int\chi_1'(s)G(s,u)\,ds+\int\chi_1(s)Z(s,u)\,ds\big]du$, with $G=G_<$ for $s<u$ and $G=G_>$ for $s>u$. By (3), $\int\chi_1'(s)G(s,u)\,ds=-\int\chi_1(s)Z(s,u)\,ds+(c_<(u)-c_>(u))\chi_1(u)$, and $\chi_1=1$ on $\operatorname{supp}\beta_1$: this is (a), and, β_1 being arbitrary, D is fixed on $(-a,a)$, hence on the strip. (5) At $r=0$, Lemma 18.17 (d) gives $\iint\alpha(t)\beta(t')G_<(-it,\epsilon-it')\,dt\,dt'\to\langle\psi',\mathcal{J}_j(\alpha,g)\phi(\beta\otimes\varkappa)\psi\rangle$ and $\iint\alpha(t)\beta(t')G_>(\epsilon-it,-it')\,dt\,dt'\to\langle\psi',\phi(\beta\otimes\varkappa)\mathcal{J}_j(\alpha,g)\psi\rangle$ as $\epsilon\downarrow 0$. On the supports the points lie in $\mathcal{G}_{d_*}$, and by (3) the difference of the two integrals is $\iint\alpha\beta\,[\mathcal{Z}(-it,\epsilon-it')-\mathcal{Z}(\epsilon-it,-it')]+\iint\alpha\beta\,[c_<(\epsilon-it')-c_>(-it')]$, which tends to $(\int\alpha)\int\beta(t')\,\mathsf{D}(-it')\,dt'$ by the continuity of $\mathcal{Z}$ and of $c_<$: this is (b). (6) By Lemma 18.19 (a), $\mathsf{n}^{X',X}$ is holomorphic in y_3, and at $y_3=-it'$ it equals $\mathsf{w}(y)=q_0(U(y)^{-1}\psi',U(y)^{-1}\psi)$, $y=(t',\vec{y})$, with $(\partial_k\mathsf{n}^{X',X})(\vec{y},-it')=\partial_{y^k}\mathsf{w}(y)$ and $(\partial_3\mathsf{n}^{X',X})(\vec{y},-it')=i\partial_{t'}\mathsf{w}(y)$. So $\int\beta(t')\mathsf{N}(-it')\,dt'$ is $\int(\beta\otimes\varkappa)\,\partial_j\mathsf{w}\,dy$ for $j\le 2$ and $\int(\beta\otimes\varkappa)\,i\partial_{t'}\mathsf{w}\,dy$ for $j=3$, and an integration by parts and YM3_I:(2074) give (c). (7) If (FL_j) holds, multiply eq. 18.ii at the points $(y_1;\theta(z'+ae_3),z+ae_3)$ by $h(y_1)X'(z')X(z)$ and integrate: $\eta=\chi_1(x_3)g(\vec{x})$ is admitted at these points, the left member gives $\int\beta_1\mathsf{D}$ by (a), and the right member gives $\int h\,\partial_j\mathsf{n}^{X',X}=\int\beta_1\mathsf{N}$ by Lemma 18.19 (a); so $\mathsf{D}=\mathsf{N}$ on $(-a,a)$, and on the strip. With (b) and (c), $\langle\psi',[\mathcal{J}_j(\alpha,g),\phi(\beta\otimes\varkappa)]\psi\rangle=-(\int\alpha)\langle\psi',\phi(\mathfrak{L}_j(\beta\otimes\varkappa))\psi\rangle$. For fixed a both members are bounded sesquilinear forms of $([X'],[X])$, by Lemma 18.17 (c), YM3_I:(2075) and the boundedness of $(1+H)^Ne^{-aH}$; by Lemma 18.19 (b) the identity holds at $\psi'=e^{-aH}\chi'$, $\psi=e^{-aH}\chi$ for all $\chi,\chi'\in\mathcal{H}$, and as $e^{-aH}\psi\to\psi$ for $a\downarrow 0$ in every norm $\|(1+H)^N\cdot\|$, $\psi\in\mathcal{D}_\infty$, it is an identity of vectors on $\mathcal{D}_\infty$. Finally, by Lemma 18.19 (c), f is a limit in every C^N of sums of products $\beta_b\otimes\varkappa_b$ with $\operatorname{supp}\beta_b\subset I_f$ and $\operatorname{supp}\varkappa_b\subset B_f$, all carried by one compact set; each product satisfies the hypotheses above with any d_* strictly between t_* and $\operatorname{dist}(B_f,\operatorname{supp}\nabla g)$, and $\mathsf{c}_N(f-f_M)+\mathsf{c}_N(\mathfrak{L}_j(f-f_M))\to 0$; Lemma 18.17 (c) and YM3_I:(2075) carry the identity to f. □

Proposition 18.23 (The commutators of $T_{0\mu}(\alpha\otimes g_R)$ with the scalar field)**.** Let $\mathfrak{M}^4$ hold. Let $\alpha\in C_c^\infty(\mathbb{R})$ with $\int\alpha=1$ and $\operatorname{supp}\alpha$ in a bounded interval I_α, and let $g\in C_c^\infty(\mathbb{R}^2)$ with $g=1$ on $\{|\vec{x}|\le r_g\}$, $r_g>0$; α and g may be complex. For $f\in C_c^\infty(\mathbb{R}^{1+2};\mathbb{C})$ carried by $I_f\times\{|\vec{x}|<r_O\}$, where I_f is a bounded open interval and $r_O>0$, put $t_*=\sup\{|t-t'|:t\in I_\alpha,\,t'\in I_f\}$ and $R_0=(r_O+t_*+1)/r_g$. Let $j_0=3$, $j_1=1$ and $j_2=2$.

(a) Let $\mu\in\{0,1,2\}$ and let (FL_{j_μ}) hold. Then for every such f, every $R\ge R_0$ and every $\psi\in\mathcal{D}_\infty$

$$[T_{0\mu}(\alpha\otimes g_R),\phi(f)]\psi=i\,\phi(\partial_\mu f)\psi=[P_\mu,\phi(f)]\psi;\tag{18.iv}$$

in particular the commutator does not depend on α, on g and on $R\ge R_0$.

(b) Conversely, let $\mu\in\{0,1,2\}$, and let the first equality of eq. 18.iv hold, for the given α and g, for every f as above, every $R\ge R_0$ and every $\psi\in\mathcal{D}_0$. Then (FL_{j_μ}) holds.

■

Proof. (a) By the components of (M1), $\mathcal{J}_3(\alpha,g_R)=T_{33}^E(\alpha\otimes g_R)=-T_{00}(\alpha\otimes g_R)$ with $\mathfrak{L}_3=i\partial_t$, and $\mathcal{J}_k(\alpha,g_R)=T_{3k}^E(\alpha\otimes g_R)=iT_{0k}(\alpha\otimes g_R)$ with $\mathfrak{L}_k=\partial_k$. As $g_R=1$ on $\{|\vec{x}|\le Rr_g\}\supset\{|\vec{x}|\le r_O+t_*+1\}$ and $\operatorname{supp}\nabla g_R\subset\{|\vec{x}|\ge Rr_g\}$ for $R\ge R_0$, the disc $B_f=\{|\vec{x}|<r_O\}$ has $g_R=1$ near $\overline{B_f}$ and $\operatorname{dist}(B_f,\operatorname{supp}\nabla g_R)\ge t_*+1$. Lemma 18.22 (d) with $\int\alpha=1$ gives $[T_{00}(\alpha\otimes g_R),\phi(f)]\psi=i\phi(\partial_t f)\psi$ and $[T_{0k}(\alpha\otimes g_R),\phi(f)]\psi=i\phi(\partial_k f)\psi$ for $\psi\in\mathcal{D}_\infty$; Lemma 18.18 (a) gives the second equality. (b) Let $j=j_\mu$. Both members of the first equality are bounded by $C\|(1+H)^{4l}\psi\|$, so by Lemma 18.18 (b) the hypothesis holds on $\mathcal{D}_\infty$, and by the components listed in (a) it says $[\mathcal{J}_j(\alpha,g_R),\phi(f)]\psi=-\phi(\mathfrak{L}_j f)\psi$. Fix $\varkappa\in C_c^\infty(\mathbb{R}^2)$ carried by $\{|\vec{x}|<r_O\}$, tuples X,X' over $\mathbb{E}_+$ with smooth entries, $a>0$, and $R\ge R_0$ for the given I_f and r_O; let D and N be the functions of Lemma 18.22 (a), (c) for g_R and $d_*=t_*+\frac12$, which is admissible as $\operatorname{dist}(\operatorname{supp}\varkappa,\operatorname{supp}\nabla g_R)\ge t_*+1$. For $\beta\in C_c^\infty(I_f)$, Lemma 18.22 (b), (c) and the hypothesis at $f=\beta\otimes\varkappa$ give $\int\beta(t')(\mathsf{D}-\mathsf{N})(-it')\,dt'=0$; so $\mathsf{D}-\mathsf{N}$

vanishes on the segment $\{-it' : t' \in I_f\}$, hence on the strip (identity theorem), and at real u: by Lemma 18.22 (a) and Lemma 18.19 (a), $\sum_i \iint \partial_i\eta(x)\,h(y)\,\mathsf{s}_{ij}^{X',X}(x,y)\,dx\,dy = \int h\,\partial_j \mathsf{n}^{X',X}\,dy$ for $\eta = \chi_1(x_3)g_R(\vec{x})$ and $h = \beta_1 \otimes \varkappa$. Now let $y \in (\mathbb{R}^3)^m_{\neq}$ with $m \geq 2$ and $y_{r,3} \neq y_{1,3}$ for $r \geq 2$. The case $m = 1$ is Lemma 18.20 (b). Translate all points by $-y_1$, carrying the admitted functions by the same translation. Both members of eq. 18.ii are invariant under this operation by (M2) and Proposition YM3_I:108.3. In these coordinates $y_1 = 0$. Take $0 < a < \min_{r\geq 2}|y_{r,3}|$ and choose $\chi_1 = 1$ near 0. Let β_1, $\varkappa$ and the entries of X and X' run through real approximate units about 0, about $\vec{y}_1$, about the points $y_r - ae_3$ with $y_{r,3} > a$, and about the points $\theta y_r - ae_3$ with $y_{r,3} < -a$. By the continuity of the kernels and of $\partial_{y_1}\mathsf{s}_m$, the identity becomes eq. 18.ii at y for the function $\chi_1(x_3)g_R(\vec{x})$, which is admitted at y; by Lemma 18.20 (a) it holds for every function admitted at y. Such y are dense in $(\mathbb{R}^3)^m_{\neq}$, and for a fixed η both members of eq. 18.ii are continuous at every point at which η is admitted; so (FL_j) holds. □

Lemma 18.24 (Products of fields; from compact supports to Schwartz functions)**.** Let (M1) hold.

(a) For $f_1, \dots, f_n \in \mathcal{S}$, $\xi \in \mathcal{D}_\infty$ and $N \geq 0$,

$$\|(1+H)^N \phi(f_1)\cdots\phi(f_n)\xi\| \leq \prod_{b=1}^{n} \mathsf{c}_{(2b-1)l+N}(f_b)\,\|(1+H)^{2nl+N}\xi\|.$$

(b) Let $\kappa \in C_c^\infty(\mathbb{R}^{1+2})$ with $0 \leq \kappa \leq 1$, $\kappa = 1$ on $\{|x| \leq 1\}$ and $\kappa = 0$ off $\{|x| < 2\}$, $|x|$ the Euclidean norm of $x \in \mathbb{R}^{1+2}$; for $r \geq 1$ and $f \in \mathcal{S}$ put $f^{(r)} = \kappa(\cdot/r)f$, and put $\|f\|_{(N)} = \sum_{n\leq N}\int(1+|x|)^N|\partial_t^n f|\,dx$. There are numbers $C_{N,M}$, formed from N, M, κ and $\bar{c}$, with $\mathsf{c}_N(f) + \mathsf{c}_N(f^{(r)}) \leq C_{N,0}\|f\|_{(N)}$ and $\mathsf{c}_N(f - f^{(r)}) \leq C_{N,M}\,r^{-M}\|f\|_{(N+M)}$ for all $r \geq 1$.

(c) For $R \geq 1$ let $\mathsf{K}_R = \sum_a c_a\,\mathfrak{q}_a(F_{a,R})$ be a finite sum, with $c_a \in \mathbb{C}$, each $\mathfrak{q}_a$ one of the forms $\mathfrak{q}_{ij}$, and $F_{a,R} \in \mathcal{S}$ with $\mathsf{c}_N(F_{a,R}) \leq C_N R^3$ for every N. Let $\mathfrak{D}$ be a differential operator of the first order with polynomial coefficients and $c_1, r_1 > 0$, and suppose that $[\mathsf{K}_R, \phi(f)]\psi = \phi(\mathfrak{D}f)\psi$ for all $\psi \in \mathcal{D}_\infty$ whenever $f \in C_c^\infty(\mathbb{R}^{1+2};\mathbb{C})$ is carried by $\{|x| < r\}$ and $R \geq c_1(r + r_1)$. Then for $f_1, \dots, f_n \in \mathcal{S}$ and integers $N, M \geq 0$ there is a number C, formed from N, M, n, l, $\bar{c}$, c_1, r_1, κ, the c_a, the numbers $C_{N'}$ and the f_b, with

$$\Big\|(1+H)^N\Big[\mathsf{K}_R\phi(f_1)\cdots\phi(f_n)\Omega - \phi(f_1)\cdots\phi(f_n)\mathsf{K}_R\Omega - \sum_{b=1}^{n}\phi(f_1)\cdots\phi(\mathfrak{D}f_b)\cdots\phi(f_n)\Omega\Big]\Big\| \leq C\,R^{-M} \qquad (R \geq 1).$$

■

Proof. (a) Induction on n with YM3_I:(2075). (b) $\partial_t^n(\kappa(\cdot/r)f)$ is the sum of the terms $\binom{n}{n'}r^{-n'}(\partial_t^{n'}\kappa)(\cdot/r)\,\partial_t^{n-n'}f$, bounded by multiples of $|\partial_t^{n-n'}f|$ for $r \geq 1$; for $f - f^{(r)}$ the same terms, with $1-\kappa$ in the place of κ, vanish on $\{|x| < r\}$, and $\int_{|x|\geq r}|\partial_t^{n'}f| \leq r^{-M}\int|x|^M|\partial_t^{n'}f|$. (c) By Lemma 18.17 (c), $\|(1+H)^{N'}\mathsf{K}_R\xi\| \leq CR^3\|(1+H)^{2l+N'}\xi\|$ for $\xi \in \mathcal{D}_\infty$, in particular $\|(1+H)^{N'}\mathsf{K}_R\Omega\| \leq CR^3$. For $1 \leq R \leq R_1 = c_1(3+2r_1)$ the left member is bounded by these bounds and (a). For $R \geq R_1$ put $r = \frac{1}{3}(R/c_1 - r_1)$; then $r \geq 1$ and $r \geq R/(6c_1)$. The functions $f_b^{(r)}$ are carried by $\{|x| < 3r\}$ and $R = c_1(3r + r_1)$; moving K_R to the right through the factors, one commutator at a time on vectors of $\mathcal{D}_\infty$, gives the identity with the remainder 0 for the $f_b^{(r)}$ in the places of the f_b. Each of the three expressions formed with the f_b differs from the one formed with the $f_b^{(r)}$ by a sum of terms with one entry $f_b - f_b^{(r)}$ or $\mathfrak{D}(f_b - f_b^{(r)})$; the latter is $(1-\kappa(\cdot/r))\mathfrak{D}f_b - [\mathfrak{D},\kappa(\cdot/r)]f_b$, a Schwartz function times smooth factors bounded with their derivatives uniformly in $r \geq 1$ and vanishing on $\{|x| < r\}$, so that its numbers $\mathsf{c}_{N'}$ are at most $C_{M'}r^{-M'}$, as in (b). With (a) every term is at most $CR^3r^{-M'}$, and the choice $M' = M + 3$ gives the claim. □

Lemma 18.25 (The spectrum near zero momentum)**.** (a) $U(\Lambda)\mathsf{E}(\Delta)U(\Lambda)^{-1} = \mathsf{E}(\Lambda\Delta)$ for $\Lambda \in \mathcal{L}$ and Borel sets $\Delta \subset \mathbb{R}^3$, and $\mathsf{E}(\{p : \vec{p} = 0\}) = \mathsf{E}(\{0\})$.

(b) Let ξ_R, $R \geq 1$, be vectors orthogonal to Ω with $\sup_R \|\xi_R\| < \infty$ and $\|\mathsf{E}(\{|\vec{p}| > \delta\})\xi_R\| \to 0$ as $R \to \infty$ for every $\delta > 0$. Then $\xi_R \to 0$ weakly in $\mathcal{H}$.

■

Proof. (a) By YM3_I:(2087) and the invariance of the Minkowski product, $U(\Lambda)U(a)U(\Lambda)^{-1} = U(\Lambda a) = \int e^{ia\cdot\Lambda^{-1}p}\, d\mathsf{E}(p)$; the projection-valued measures $\Delta \mapsto U(\Lambda)\mathsf{E}(\Delta)U(\Lambda)^{-1}$ and $\Delta \mapsto \mathsf{E}(\Lambda\Delta)$ both have this Fourier transform, and such a measure is unique. Let $\ell = \{(E,0,0) : E > 0\}$. The rays $B(s)\ell = \{E(\cosh s, \sinh s, 0) : E > 0\}$, $s \in \mathbb{R}$, are pairwise disjoint, so the projections $\mathsf{E}(B(s)\ell) = U(B(s))\mathsf{E}(\ell)U(B(s))^{-1}$ are pairwise orthogonal and all unitarily equivalent to $\mathsf{E}(\ell)$; as $\mathcal{H}$ is separable, $\mathsf{E}(\ell) = 0$. The set $\{\vec{p} = 0\}$ meets $V_+ \cup \partial V_+ \cup \{0\}$, which carries E, in $\ell \cup \{0\}$. (b) Let $\psi \in \mathcal{H}$, $\delta > 0$ and $S_\delta = \{p \neq 0 : |\vec{p}| \leq \delta\}$. As $\mathsf{E}(\{0\})\xi_R = \langle\Omega, \xi_R\rangle\Omega = 0$, $|\langle\psi, \xi_R\rangle| \leq \|\mathsf{E}(S_\delta)\psi\| \sup_{R'} \|\xi_{R'}\| + \|\psi\|\, \|\mathsf{E}(\{|\vec{p}| > \delta\})\xi_R\|$; as $\delta \downarrow 0$, $\|\mathsf{E}(S_\delta)\psi\|$ tends to $\|\mathsf{E}(\{p \neq 0 : \vec{p} = 0\})\psi\|$, which is 0 by (a). □

Lemma 18.26 (The two-point measure of the tensor)**.** Let (M1), (M4) (a) and (M5) hold.

(a) For $t, t' \in \mathsf{T}$ there is exactly one complex Radon measure $\mathcal{M}_{t,t'}$ on $\mathbb{R}^3$ with $\langle T[t](F')\Omega, \mathsf{E}(\Delta)T[t'](F)\Omega\rangle = \int_\Delta \overline{\hat{F}'}\hat{F}\, d\mathcal{M}_{t,t'}$ for all $F, F' \in \mathcal{S}$ and Borel sets Δ. This measure depends antilinearly on t and linearly on t'; moreover $\mathcal{M}_{t,t} \geq 0$, it is concentrated on $V_+ \cup \partial V_+$, $\int (1+p^0)^{-2l}\, d|\mathcal{M}_{t,t'}| < \infty$, and $\mathcal{M}_{\Lambda t,\Lambda t'}(\Lambda\Delta) = \mathcal{M}_{t,t'}(\Delta)$ holds for each $\Lambda \in \mathcal{L}$.

(b) There are positive Radon measures ϱ_0, ϱ_2 on $(0,\infty)$ with $\int (3+2m)^{-2l}(\varrho_0 + \varrho_2)(dm) < \infty$, so finite on $(0,1]$ and polynomially bounded, and a number $c_\partial \geq 0$ such that, with $\omega_m(\vec{p}) = (m^2 + |\vec{p}|^2)^{1/2}$, the measures $\mathsf{v}_i = \varrho_i(dm)\, d^2p/\omega_m(\vec{p})$ on V_+, written in the coordinates $(m, \vec{p}) \mapsto (\omega_m(\vec{p}), \vec{p})$ $(i = 0, 2)$, the measure $\mathsf{v}_\partial = c_\partial\, d^2p/|\vec{p}|$ on ∂V_+, $\Pi_{\mu\nu} = p_\mu p_\nu - \mathsf{g}_{\mu\nu}\, p\cdot p$, $t\cdot\Pi = t^{\mu\nu}\Pi_{\mu\nu}$, $\langle t\Pi t\Pi\rangle = t^{\mu\nu}\Pi_{\nu\mu'}t^{\mu'\nu'}\Pi_{\nu'\mu}$ and $t\cdot pp = t^{\mu\nu}p_\mu p_\nu$,

$$\mathcal{M}_{t,t} = (t\cdot\Pi)^2\,\mathsf{v}_0 + \big[2\langle t\Pi t\Pi\rangle - (t\cdot\Pi)^2\big]\mathsf{v}_2 \ \text{ on } V_+ \text{ for real } t, \qquad \mathcal{M}_{t,t'} = \overline{(t\cdot pp)}\,(t'\cdot pp)\,\mathsf{v}_\partial \ \text{ on } \partial V_+.$$

In particular, with $\varrho = \varrho_0 + \varrho_2$, $T[e_0e_0] = T_{00}$, $T[e_0 \vee e_k] = T_{0k}$ and $n = (0,\vec{n})$, $\vec{n} \in \mathbb{R}^2$: $\mathcal{M}_{e_0e_0,e_0e_0} = |\vec{p}|^4\big[\varrho(dm)\, d^2p/\omega_m(\vec{p}) + c_\partial\, d^2p/|\vec{p}|\big]$ and $\mathcal{M}_{e_0\vee n,e_0\vee n} = (p^0)^2(\vec{n}\cdot\vec{p})^2(\mathsf{v}_0 + \mathsf{v}_\partial) + |\vec{p}|^2\big((\vec{n}\cdot\vec{p})^2 + |\vec{n}|^2\, p\cdot p\big)\mathsf{v}_2$.

■

Proof. (1) Put $\mathsf{A}_{00} = -\mathsf{A}_{\mathsf{q}_{33}}$, $\mathsf{A}_{0k} = \mathsf{A}_{k0} = -i\mathsf{A}_{\mathsf{q}_{3k}}$, $\mathsf{A}_{kk'} = \mathsf{A}_{\mathsf{q}_{kk'}}$ and $\mathsf{A}_t = t^{\mu\nu}\mathsf{A}_{\mu\nu}$; by Lemma 18.17 (c), $T[t](F)\Omega = (1+H)^l\hat{F}(P)\mathsf{A}_t\Omega$, and $\mathcal{M}_{t,t'}(\Delta) = \int_\Delta (1+p^0)^{2l}\, d\langle\mathsf{A}_t\Omega, \mathsf{E}(p)\mathsf{A}_{t'}\Omega\rangle$ for bounded Borel sets Δ has the property of (a) by the calculus of E. Every $\chi \in C_c^\infty(\mathbb{R}^3)$ is a product $\overline{\hat{F}'}\hat{F}$, with $\hat{F} = \chi$ and $\hat{F}' \in C_c^\infty(\mathbb{R}^3)$ equal to 1 on $\operatorname{supp}\chi$: this gives uniqueness. Sesquilinearity, positivity and the bound of the variation of $(1+p^0)^{-2l}\mathcal{M}_{t,t'}$ by $\|\mathsf{A}_t\Omega\|\|\mathsf{A}_{t'}\Omega\|$ can be read off; $\mathcal{M}_{t,t'}(\{0\}) = \overline{\langle\Omega, \mathsf{A}_t\Omega\rangle}\langle\Omega, \mathsf{A}_{t'}\Omega\rangle = 0$, as $\langle\Omega, \mathsf{A}_{\mathsf{q}_{ij}}\Omega\rangle = \mathsf{q}_{ij}(\Omega,\Omega) = 0$. (M5), the unitarity of $U(\Lambda)$, Lemma 18.25 (a) and $\widehat{F\circ\Lambda^{-1}} = \hat{F}\circ\Lambda^{-1}$ give

$$\int \chi(\Lambda^{-1}p)\, \mathcal{M}_{\Lambda t,\Lambda t'}(dp) = \int \chi\, d\mathcal{M}_{t,t'} \qquad (\chi \in C_c^\infty(\mathbb{R}^3),\ \Lambda \in \mathcal{L}). \tag{18.v}$$

(2) For every finite family $t_1, t_2, \ldots$ and Borel Δ the matrix $(\mathcal{M}_{t_a,t_b}(\Delta))$ is positive semi-definite, hence bounded by its trace; so every $\mathcal{M}_{t,t'}$ is absolutely continuous with respect to the positive Radon measure $\bar{\mathcal{M}} = \sum_{\mu\le\nu}\mathcal{M}_{e_\mu\vee e_\nu, e_\mu\vee e_\nu}$, and the theorem of Radon and Nikodym gives $\mathcal{M}_{t,t'} = \mathsf{M}_p(t,t')\,\bar{\mathcal{M}}(dp)$ with Borel densities; outside a null set, M_p is a positive semi-definite Hermitian form on T, and for such a form $\mathsf{M}_p(t,t) = 0$ implies $\mathsf{M}_p(t,\cdot) = 0$. (3) For real $\mathsf{u} \in \mathbb{R}^3$, (M4) (a) at $\psi = \Omega$, contracted with u^ν, is $\sum_{\mu,\nu}\mathsf{g}^{\mu\mu}\mathsf{u}^\nu T_{\mu\nu}(\partial_\mu F)\Omega = 0$, that is $-i(1+H)^l\sum_{\mu,\nu}(p^\mu\mathsf{u}^\nu\hat{F})(P)\,\mathsf{A}_{\mu\nu}\Omega = 0$; the square of its norm is $\int |\hat{F}|^2\,\mathsf{M}_p(p\vee\mathsf{u}, p\vee\mathsf{u})\, d\bar{\mathcal{M}}$, and a choice of F with $\hat{F} > 0$ gives, outside a null set and then for all $\mathsf{u} \in \mathbb{C}^3$,

$$\mathsf{M}_p(p\vee\mathsf{u}, \cdot) = 0. \tag{18.vi}$$

(4) Let J, N_1, N_2 be the matrices with $Jp = (0, -p^2, p^1)$, $N_1 p = (p^1, p^0, 0)$ and $N_2 p = (p^2, 0, p^0)$; $e^{sJ} = 1 \oplus \mathsf{R}_s$ is the rotation by the angle s, $e^{sN_1} = B(s)$, and e^{sN_2} is the boost in the plane of (x^0, x^2), the conjugate of $B(s)$ by a rotation, all in $\mathcal{L}$ by the displayed boost and rotation formulas. For a real matrix G put $(\mathsf{G}t)^{\mu\nu} = \mathsf{G}^{\mu}{}_{\mu'} t^{\mu'\nu} + \mathsf{G}^{\nu}{}_{\mu'} t^{\mu\mu'}$. Differentiating eq. 18.v at $\Lambda = e^{s\mathsf{G}}$, $s = 0$, for $\mathsf{G} \in \{J, N_1, N_2\}$ (the measure $\mathcal{M}_{\Lambda t, \Lambda t'}$ is a polynomial in the entries of Λ with fixed measures as coefficients) gives $-\int (\mathsf{G}p) \cdot \nabla\chi \, d\mathcal{M}_{t,t'} + \int \chi \, d(\mathcal{M}_{\mathsf{G}t,t'} + \mathcal{M}_{t,\mathsf{G}t'}) = 0$. With $\Xi_p = p^0 J + p^2 N_1 - p^1 N_2$ one has $\Xi_p p = 0$; adding these identities for $(J, p^0\chi)$, $(N_1, p^2\chi)$ and $(N_2, -p^1\chi)$, the terms with derivatives of χ cancel, because $\Xi_p p = 0$ and $(Jp)^0 = (N_1 p)^2 = (N_2 p)^1 = 0$, and what remains is $\int \chi(p) \, [\mathsf{M}_p(\Xi_p t, t') + \mathsf{M}_p(t, \Xi_p t')] \, \bar{\mathcal{M}}(dp) = 0$. So, outside a null set,

$$\mathsf{M}_p(e^{s\Xi_p} t, e^{s\Xi_p} t') = \mathsf{M}_p(t, t') \qquad (s \in \mathbb{R}, \ t, t' \in \mathsf{T}); \tag{18.vii}$$

Ξ_p is real, antisymmetric for the Minkowski product, like J, N_1, N_2, and not 0 for $p \neq 0$. (5) Let $p \in V_+$ lie outside the null sets. $W = \{w \in \mathbb{R}^3 : w \cdot p = 0\}$ is spacelike, so $\langle w, w' \rangle = -w \cdot w'$ is a scalar product on it; $\mathbb{C}^3 = W_{\mathbb{C}} \oplus \mathbb{C}p$, and by eq. 18.vi, $\mathsf{M}_p(t, t') = \mathsf{M}_p(t_\perp, t'_\perp)$, $t_\perp$ the image of t under $n \mapsto n - \frac{n \cdot p}{p \cdot p} p$ in both slots. Ξ_p maps W into itself, is antisymmetric for $\langle \cdot, \cdot \rangle$ and not 0 on W; in an orthonormal basis u_1, u_2 of W, $\Xi_p u_1 = \varpi u_2$ and $\Xi_p u_2 = -\varpi u_1$ with $\varpi \neq 0$, and $\mathsf{z}_\pm = u_1 \pm i u_2$ satisfy $e^{s\Xi_p} \mathsf{z}_\pm = e^{\mp i\varpi s} \mathsf{z}_\pm$. By eq. 18.vii the tensors $\mathsf{I} = u_1 u_1 + u_2 u_2 = \mathsf{z}_+ \vee \mathsf{z}_-$, $\mathsf{z}_+ \mathsf{z}_+$ and $\mathsf{z}_- \mathsf{z}_-$, which are multiplied by the different characters 1, $e^{-2i\varpi s}$, $e^{2i\varpi s}$, are pairwise orthogonal for M_p. With $\beta_0 = \frac{1}{4} \mathsf{M}_p(\mathsf{I}, \mathsf{I})$ and $\beta_2 = \frac{1}{16} [\mathsf{M}_p(\mathsf{z}_+ \mathsf{z}_+, \mathsf{z}_+ \mathsf{z}_+) + \mathsf{M}_p(\mathsf{z}_- \mathsf{z}_-, \mathsf{z}_- \mathsf{z}_-)]$, both ≥ 0, a real $\mathsf{s} \in \mathrm{Sym}^2(W)$ with the matrix (s_{ab}) in the basis is $\frac{1}{2}(\mathrm{tr}\, \mathsf{s})\mathsf{I} + \frac{1}{2}(c_3 - ic_1)\mathsf{z}_+ \mathsf{z}_+ + \frac{1}{2}(c_3 + ic_1)\mathsf{z}_- \mathsf{z}_-$, where $c_3 = \frac{1}{2}(\mathsf{s}_{11} - \mathsf{s}_{22})$ and $c_1 = \mathsf{s}_{12}$, and $\mathsf{M}_p(\mathsf{s}, \mathsf{s}) = (\mathrm{tr}\, \mathsf{s})^2 \beta_0 + 4(c_3^2 + c_1^2)\beta_2 = (\mathrm{tr}\, \mathsf{s})^2 \beta_0 + [2\, \mathrm{tr}\, \mathsf{s}^2 - (\mathrm{tr}\, \mathsf{s})^2]\beta_2$. For real t the matrix of $t_\perp$ is $\mathsf{s}_{ab} = t^{\mu\nu} (u_a)_\mu (u_b)_\nu$, and $\sum_a (u_a)_\mu (u_a)_\nu = \Pi_{\mu\nu}/(p \cdot p)$; so $\mathrm{tr}\, t_\perp = t \cdot \Pi/(p \cdot p)$ and $\mathrm{tr}\, t_\perp^2 = \langle t \Pi t \Pi \rangle / (p \cdot p)^2$, and, for all real t at once,

$$(p \cdot p)^2 \, \mathsf{M}_p(t, t) = (t \cdot \Pi)^2 \beta_0 + [2\langle t \Pi t \Pi \rangle - (t \cdot \Pi)^2] \beta_2. \tag{18.viii}$$

At $t = \mathsf{g}^{-1}$ the bracket is 0 and $t \cdot \Pi = -2\, p \cdot p$; at $t = e_1 e_1$ the bracket is $(t \cdot \Pi)^2 = ((p^1)^2 + p \cdot p)^2$; so β_0 and $\beta_0 + \beta_2$ are Borel functions. (6) Let $p \in \partial V_+$ lie outside the null sets, and choose real $e_\perp, n_*$ with $e_\perp \cdot e_\perp = -1$, $e_\perp \cdot p = 0$, $n_* \cdot n_* = 0$, $n_* \cdot p = 1$ and $n_* \cdot e_\perp = 0$; $(p, e_\perp, n_*)$ is a basis. The antisymmetry and $\Xi_p p = 0$ give $\Xi_p e_\perp = c_p p$ and $\Xi_p n_* = c_p e_\perp$ with a real c_p, which is $\neq 0$ as $\Xi_p \neq 0$; so $e^{s\Xi_p} n_* = n_* + s c_p e_\perp + \frac{1}{2} s^2 c_p^2 p$ and, modulo the tensors $p \vee \mathsf{u}$, $e^{s\Xi_p}(n_* n_*) \equiv n_* n_* + 2 s c_p \, e_\perp \vee n_* + s^2 c_p^2 \, e_\perp e_\perp$. By eq. 18.vii and eq. 18.vi, $\mathsf{M}_p(e^{s\Xi_p} n_* n_*, e^{s\Xi_p} n_* n_*)$ is a polynomial in s that does not depend on s: its coefficient of s^4, $c_p^4 \mathsf{M}_p(e_\perp e_\perp, e_\perp e_\perp)$, vanishes, and then its coefficient of s^2, $4 c_p^2 \mathsf{M}_p(e_\perp \vee n_*, e_\perp \vee n_*)$. So $e_\perp e_\perp$ and $e_\perp \vee n_*$ lie in the radical, with the $p \vee \mathsf{u}$; as $t \mapsto t \cdot pp$ is 1 at $n_* n_*$ and 0 at the other five basis tensors, every t equals $(t \cdot pp)\, n_* n_*$ modulo the radical, and $\mathsf{M}_p(t, t') = \overline{(t \cdot pp)} (t' \cdot pp) \beta_\partial(p)$ with $\beta_\partial = \mathsf{M}_p(n_* n_*, n_* n_*) = (p^0)^{-4} \mathsf{M}_p(e_0 e_0, e_0 e_0)$. (7) Put $\mathsf{v}_i = (p \cdot p)^{-2} \beta_i \bar{\mathcal{M}}$ on V_+ $(i = 0, 2)$ and $\mathsf{v}_\partial = \beta_\partial \bar{\mathcal{M}}$ on ∂V_+; these are Radon measures, as $\mathsf{v}_0 \leq \mathsf{v}_0 + \mathsf{v}_2 = ((p^1)^2 + p \cdot p)^{-2} \mathcal{M}_{e_1 e_1, e_1 e_1}$ on V_+ and $\mathsf{v}_\partial = (p^0)^{-4} \mathcal{M}_{e_0 e_0, e_0 e_0}$ on ∂V_+, and eq. 18.viii and (6) are the formulas of (b). They are invariant under $\mathcal{L}$, which keeps V_+ and ∂V_+: $\mathsf{v}_0 = \frac{1}{4}(p \cdot p)^{-2} \mathcal{M}_{\mathsf{g}^{-1}, \mathsf{g}^{-1}}$ with $\Lambda \mathsf{g}^{-1} = \mathsf{g}^{-1}$, so eq. 18.v applies; for real $w \in \mathbb{R}^3$, $\mathcal{M}_{ww,ww} = [(w \cdot p)^2 - (w \cdot w)(p \cdot p)]^2 (\mathsf{v}_0 + \mathsf{v}_2)$ on V_+ and $(w \cdot p)^4 \mathsf{v}_\partial$ on ∂V_+, the weights being unchanged under $(w, p) \mapsto (\Lambda w, \Lambda p)$, so eq. 18.v at $w = e_1$, with the weight $((p^1)^2 + p \cdot p)^2 > 0$ on V_+, gives the invariance of $\mathsf{v}_0 + \mathsf{v}_2$, hence of v_2, and at $w = e_0$, with the weight $(p^0)^4 > 0$ on ∂V_+, that of v_∂. (8) $(m, \vec{p}) \mapsto (\omega_m(\vec{p}), \vec{p})$ is a diffeomorphism of $(0, \infty) \times \mathbb{R}^2$ onto V_+, in which e^{sN_k} keeps m and moves $\vec{p}$ with the velocity $\omega_m(\vec{p}) e_k$ at $s = 0$. For an invariant Radon measure $\tilde{\mathsf{v}}$ the derivative at $s = 0$ gives $\int \omega_m(\vec{p}) \, \partial_{p_k} \chi \, d\tilde{\mathsf{v}} = 0$; so, for $0 \leq \chi_1 \in C_c^\infty((0, \infty))$, the positive distribution $\chi_2 \mapsto (\omega_m \tilde{\mathsf{v}})(\chi_1 \otimes \chi_2)$ on $\mathbb{R}^2$ has vanishing first derivatives and is a multiple $c(\chi_1)$ of the Lebesgue integral, $c(\chi_1) = \int \chi_1 \, d\varrho$ by the theorem of Riesz, and with Lemma 18.19 (c), $\tilde{\mathsf{v}} = \varrho(dm) \, d^2p / \omega_m(\vec{p})$. On ∂V_+, in the coordinate $\vec{p} \in \mathbb{R}^2 \setminus \{0\}$ moved with the velocity $|\vec{p}| e_k$, the measure $|\vec{p}| \tilde{\mathsf{v}}$ has vanishing first derivatives on a connected open set, so $\tilde{\mathsf{v}} = c_\partial \, d^2p / |\vec{p}|$. (9) By (a), $\infty > \int (1 + p^0)^{-2l} \, d\mathcal{M}_{e_0 e_0, e_0 e_0} \geq \int |\vec{p}|^4 (1 + p^0)^{-2l} \, \varrho(dm) \, d^2p / \omega_m(\vec{p})$; with $d^2p / \omega_m = 2\pi \, d\omega$ on $\omega \geq m$,

$|\vec{p}|^2 = \omega^2 - m^2$, and with $\omega^2 - m^2 \geq 1$ and $1 + \omega \leq 3 + 2m$ for $\omega \in [2m+1, 2m+2]$, the right member is at least $2\pi \int (3+2m)^{-2l} \varrho(dm)$. The two special formulas are (b) at $t = e_0 e_0$, where $t \cdot \Pi = |\vec{p}|^2$, $t \cdot pp = (p^0)^2$, which is $|\vec{p}|^2$ on ∂V_+, and the bracket is $|\vec{p}|^4$, and at $t = e_0 \vee n$, where $t \cdot \Pi = t \cdot pp = -p^0(\vec{n} \cdot \vec{p})$ and the bracket is $\Pi(e_0, e_0)\,\Pi(n,n) = |\vec{p}|^2((\vec{n} \cdot \vec{p})^2 + |\vec{n}|^2 p \cdot p)$. □

Lemma 18.27 (Norms of the vacuum vectors)**.** Let (M1), (M4) (a) and (M5) hold, and let $\varrho_0, \varrho_2, \varrho, c_\partial$ be as in Lemma 18.26. For $\alpha \in \mathcal{S}(\mathbb{R})$ put $\hat{\alpha}^*(m) = \sup_{E \geq m} |\hat{\alpha}(E)|$ and $\mathsf{a}(\alpha) = \int \hat{\alpha}^*(m)^2 \, \varrho(dm) + c_\partial \sup |\hat{\alpha}|^2$, which is finite. Let $g \in \mathcal{S}(\mathbb{R}^2)$ and $R \geq 1$.

(a) The vacuum norm satisfies

$$\|T_{00}(\alpha \otimes g_R)\Omega\|^2 \leq \mathsf{a}(\alpha)\, R^{-1} \int |\vec{k}|^3 |\hat{g}(\vec{k})|^2 \, d^2k,$$

and, as $R \to \infty$,

$$R\, \|T_{00}(\alpha \otimes g_R)\Omega\|^2 \to c_\partial\, |\hat{\alpha}(0)|^2 \int |\vec{k}|^3 |\hat{g}(\vec{k})|^2 \, d^2k.$$

(b) For $j \in \{1,2\}$, $\|T_{0j}(\alpha \otimes g_R)\Omega\|^2$ is bounded in $R \geq 1$ and tends, as $R \to \infty$, to

$$\mathsf{L}_j(\alpha, g) = \int m |\hat{\alpha}(m)|^2 \, \varrho_0(dm) \int k_j^2 |\hat{g}(\vec{k})|^2 \, d^2k + \int m |\hat{\alpha}(m)|^2 \, \varrho_2(dm) \int |\vec{k}|^2 |\hat{g}(\vec{k})|^2 \, d^2k.$$

(c) For every $\delta > 0$ and all μ, ν, $\|\mathsf{E}(\{|\vec{p}| > \delta\})\, T_{\mu\nu}(\alpha \otimes g_R)\Omega\| \to 0$ as $R \to \infty$.

■

Proof. By Lemma 18.26 (a) at $F' = F$ and $\Delta = \mathbb{R}^3$, $\|T[t](F)\Omega\|^2 = \int |\hat{F}|^2 \, d\mathcal{M}_{t,t}$, with $\hat{F}(p) = \hat{\alpha}(p^0) R^2 \hat{g}(R\vec{p})$ for $F = \alpha \otimes g_R$. We insert Lemma 18.26 (b) and substitute $\vec{p} = \vec{k}/R$; with $\omega = \omega_m(\vec{k}/R)$ one has $R\omega = (R^2 m^2 + |\vec{k}|^2)^{1/2} \geq |\vec{k}|$, $\omega \geq m$, and $\omega \to m$ as $R \to \infty$. $\mathsf{a}(\alpha)$ is finite because $\hat{\alpha}^*$ decreases faster than every power and $\int (3+2m)^{-2l} \varrho(dm) < \infty$. (a) At $t = e_0 e_0$ the powers of R give

$$\|T_{00}(\alpha \otimes g_R)\Omega\|^2 = \frac{1}{R} \int \varrho(dm) \int d^2k \, \frac{|\vec{k}|^4 |\hat{g}(\vec{k})|^2 |\hat{\alpha}(\omega)|^2}{R\omega} + \frac{c_\partial}{R} \int d^2k \, |\vec{k}|^3 |\hat{g}(\vec{k})|^2 |\hat{\alpha}(|\vec{k}|/R)|^2;$$

$R\omega \geq |\vec{k}|$ and $|\hat{\alpha}(\omega)| \leq \hat{\alpha}^*(m)$ give the bound. In the first integral the integrand is dominated by $|\vec{k}|^3 |\hat{g}|^2 \hat{\alpha}^*(m)^2$ and tends to 0 for every $m > 0$; in the second, $\hat{\alpha}(|\vec{k}|/R) \to \hat{\alpha}(0)$ boundedly. (b) At $t = e_0 \vee e_j$, that is $\vec{n} = e_j$ in Lemma 18.26 (b),

$$\begin{aligned} \|T_{0j}(\alpha \otimes g_R)\Omega\|^2 = {} & \int \varrho_0(dm) \int d^2k \, k_j^2 |\hat{g}|^2 \, \omega |\hat{\alpha}(\omega)|^2 \\ & + \int \varrho_2(dm) \int d^2k \, |\vec{k}|^2 |\hat{g}|^2 \, \frac{m^2 + k_j^2/R^2}{\omega} |\hat{\alpha}(\omega)|^2 \\ & + \frac{c_\partial}{R} \int d^2k \, |\vec{k}| \, k_j^2 |\hat{g}|^2 |\hat{\alpha}(|\vec{k}|/R)|^2; \end{aligned}$$

as $m^2 + k_j^2/R^2 \leq \omega^2$, both integrands over $m > 0$ are at most $|\vec{k}|^2 |\hat{g}(\vec{k})|^2 \sup_{E \geq m} E |\hat{\alpha}(E)|^2$, which is integrable for $\varrho(dm)\, d^2k$; this gives the bound, and dominated convergence with $\omega \to m$ gives the limit, the last term being $O(R^{-1})$. (c) The square is at most $R^4 \sup_{|\vec{k}| > R\delta} |\hat{g}(\vec{k})|^2 \int |\hat{\alpha}(p^0)|^2 \, d\mathcal{M}_{t,t}$ with $t = e_\mu \vee e_\nu$; the integral is finite by Lemma 18.26 (a), as $|\hat{\alpha}(p^0)|^2 \leq C(1+p^0)^{-2l}$, and $\sup_{|\vec{k}| > R\delta} |\hat{g}(\vec{k})|^2 \leq C(R\delta)^{-6}$. □

Proposition 18.28 (Energy and momentum as limits of smeared components)**.** Let (M1), (M4) (a) and (M5) hold; let α, I_α, g and r_g be as in Proposition 18.23, let ϱ and c_∂ be as in Lemma 18.26, a and L_j as in Lemma 18.27, and put $\alpha_N = (1 + i\partial_t)^N \alpha$.

(a) For all integers $N \geq 0$ and all $R \geq 1$,

$$\|(1+H)^N T_{00}(\alpha \otimes g_R)\Omega\| \leq \Big(\mathsf{a}(\alpha_N) \int |\vec{k}|^3 |\hat{g}(\vec{k})|^2 \, d^2k\Big)^{1/2} R^{-1/2},$$

$$R\, \|T_{00}(\alpha \otimes g_R)\Omega\|^2 \to c_\partial \int |\vec{k}|^3 |\hat{g}(\vec{k})|^2 \, d^2k \quad (R \to \infty).$$

If besides (M2), (M3) and (FL_3) hold, then for every $\chi \in \mathcal{D}_0$ there is a number C, formed from l, $\bar{c}$, ϱ, c_∂, α, I_α, g, r_g and a polynomial Q with $\chi = \mathsf{Q}\Omega$, such that

$$\|T_{00}(\alpha \otimes g_R)\chi - H\chi\| \leq C\, R^{-1/2} \qquad (R \geq 1);$$

in particular $\langle \psi, T_{00}(\alpha \otimes g_R)\chi\rangle \to \langle \psi, H\chi\rangle$ for every $\psi \in \mathcal{H}$.

(b) For $j \in \{1,2\}$, $\|T_{0j}(\alpha \otimes g_R)\Omega\|^2 \to \mathsf{L}_j(\alpha, g)$ as $R \to \infty$. If besides (M2), (M3) and (FL_j) hold, then $T_{0j}(\alpha \otimes g_R)\chi \to P_j\chi$ weakly in $\mathcal{H}$ as $R \to \infty$, for every $\chi \in \mathcal{D}_0$.

■

Proof. (1) Let $\mu \in \{0,1,2\}$, let $\mathfrak{M}^4$ and (FL_{j_μ}) hold, and let $t_\alpha = \sup_{t \in I_\alpha} |t|$. The operators $\mathsf{K}_R = T_{0\mu}(\alpha \otimes g_R)$ satisfy the hypotheses of Lemma 18.24 (c) with $\mathfrak{D} = i\partial_\mu$, $c_1 = 2/r_g$ and $r_1 = (t_\alpha + 1)/2$: $\mathsf{c}_N(\alpha \otimes g_R) = \bar{c} R^2 \|g\|_{L^1} \sum_n \binom{N}{n} \|\partial_t^n \alpha\|_{L^1}$, which is at most $C_N R^3$ for $R \geq 1$; and for f carried by $\{|x| < r\}$ one may take $I_f = (-r, r)$ and $r_O = r$ in Proposition 18.23, so that $t_* \leq r + t_\alpha$ and $R_0 \leq c_1(r + r_1)$, and Proposition 18.23 (a) gives the commutator. With Lemma 18.18 (a), Lemma 18.24 (c) gives, for a polynomial Q, $\chi = \mathsf{Q}\Omega$ and all N, M, a number C with

$$\|(1+H)^N [T_{0\mu}(\alpha \otimes g_R)\chi - P_\mu \chi - \mathsf{Q}\, T_{0\mu}(\alpha \otimes g_R)\Omega]\| \leq C\, R^{-M} \qquad (R \geq 1). \tag{18.ix}$$

(2) By Lemma 18.17 (c), $(1+H)^N T_{0\mu}(\alpha \otimes g_R)\Omega = T_{0\mu}(\alpha_N \otimes g_R)\Omega$, with $\alpha_N \in C_c^\infty(\mathbb{R})$. (a) The bound is Lemma 18.27 (a) for α_N, and the limit is Lemma 18.27 (a) for α, as $\hat{\alpha}(0) = \int \alpha = 1$. If Q has the degree n, Lemma 18.24 (a) and the bound at $2nl$ in the place of N give $\|\mathsf{Q}\, T_{00}(\alpha \otimes g_R)\Omega\| \leq C' \|(1+H)^{2nl} T_{00}(\alpha \otimes g_R)\Omega\| \leq C'' R^{-1/2}$, and eq. 18.ix at $\mu = 0$, $N = 0$ and $M = 1$ gives the claim, as $P_0 = H$. (b) The limit is Lemma 18.27 (b). The vector $\xi_R = T_{0j}(\alpha \otimes g_R)\Omega$ is orthogonal to Ω, since $\langle \Omega, T_{0j}(F)\Omega\rangle = -i \int F(x)\, \mathfrak{q}_{3j}(\Omega, \Omega)\, dx = 0$; it is bounded in R, and $\|\mathsf{E}(\{|\vec{p}| > \delta\})\xi_R\| \to 0$ (Lemma 18.27 (b), (c)); so $\xi_R \to 0$ weakly (Lemma 18.25 (b)). For a polynomial Q of degree n, $\|\mathsf{Q}\,\xi_R\| \leq C\|(1+H)^{2nl}\xi_R\| = C\|T_{0j}(\alpha_{2nl} \otimes g_R)\Omega\|$ is bounded in R (Lemma 18.24 (a), Lemma 18.27 (b)), and $\langle \psi, \mathsf{Q}\,\xi_R\rangle = \langle \mathsf{Q}^\dagger \psi, \xi_R\rangle \to 0$ for $\psi \in \mathcal{D}_\infty$; a bounded family that tends to 0 against the dense set $\mathcal{D}_\infty$ tends to 0 weakly, and eq. 18.ix at $\mu = j$ gives the claim. □

Remark 18.29 (Over the components of the tensor limits). Let σ_ξ^c be the recentred component of a tensor limit at a reference coupling not larger than γ_W^{sd}, as in Theorem F (b), (c). The functional $\sigma'(f_1, \dots, f_n) = \sigma_\xi^c(f_1\mathbf{1}, \dots, f_n\mathbf{1})$ on real tuples is scalar data (Rec) with (Rec5): by Theorem F (c), $(\mathrm{Rec1})_V$–$(\mathrm{Rec4})_V$ restrict to the entries in V_0, with the numbers $\sqrt{3}\, C_V$, p_V, $\frac{1}{2}$, as $|\mathbf{1}| = \sqrt{3}$ in the invariant norm; its space is the scalar subspace of $\mathcal{H}(\sigma_\xi^c)$, which reduces H, so that the kernel of H there is $\mathbb{C}\Omega$; and its field is the restriction of $T(f\mathbf{1})$. By Theorem F (d) the frame (M1)–(M5) holds over σ', with the forms $q_0(\cdot, \cdot; \mathsf{m}_{ij})$ at the label matrices m_{ij} of the stress tensor and the kernels $\mathsf{s}_{ij}(x; y) = \mathsf{s}_{1+m}(x, y; \mathsf{m}_{ij}, \mathbf{1}, \dots, \mathbf{1})$; on the vectors of $\mathcal{D}_\infty$ in the scalar subspace, the operators that these forms define are the compressions $T_{ij}^E(F) = \Pi_0 T(F\mathsf{m}_{ij})\Pi_0$, where Π_0 is the orthogonal projection of $\mathcal{H}(\sigma_\xi^c)$ onto the scalar subspace (Step 7 of the proof of Theorem F). In Theorem F (d), (M5) is formed with the restriction to the scalar subspace of the representation $U(a, \Lambda)$ of Theorem E (d) (ii) for σ_ξ^c. For $\Lambda \in \mathcal{L}$ the restricted operator $U(0, \Lambda)$ fixes Ω and satisfies $U(0,\Lambda)\phi(f)U(0,\Lambda)^{-1}\psi = \phi(f \circ \Lambda^{-1})\psi$ for $f \in \mathcal{S}$ and ψ in the span $\mathcal{D}_0$ of Ω and of the vectors $\phi(f_1) \cdots \phi(f_n)\Omega$ (Theorem F (d)); used on the factors one at a time, from the right, this gives $U(0,\Lambda)\phi(f_1) \cdots \phi(f_n)\Omega = \phi(f_1 \circ \Lambda^{-1}) \cdots \phi(f_n \circ \Lambda^{-1})\Omega$, so that $U(0, \Lambda)$ and

its inverse $U(0,\Lambda^{-1})$ map $\mathcal{D}_0$ into itself, and $U(0,\Lambda)\mathcal{D}_0 = \mathcal{D}_0$. Proposition YM3_I:110.1 allows only one unitary operator with these three properties, so the restricted $U(0,\Lambda)$ coincides with the $U(\Lambda)$ of σ' that enters (M5) in this subsection. Hence Lemmas 18.26 and 18.27 and the first statements of Proposition 18.28 (a), (b) hold for this tensor; Proposition 18.23 (a) and the second statements of Proposition 18.28 (a), (b) hold for it in every direction in which its kernels satisfy the flux law eq. 18.ii; and, by Proposition 18.23 (b), the commutator identity eq. 18.iv in one direction is equivalent to the flux law in that direction.

18.4. **The three-point function against the two-point functions: free rings, the value $\frac{4}{9}$, and the free template that the functions of two and three points single out.** For a triple $f = (f_1, f_2, f_3)$ of test functions of one scale with separated supports, the free ratio $\mathcal{R}(f) = \mathcal{K}^{(3)}_{\text{free}}(f)^2 / \prod_{i<j} \mathcal{K}^{(2)}_{\text{free}}(f_i, f_j)$, the square of the ring integral of three dipole kernels $\mathbb{K}_3$ divided by the three pair integrals, depends on the shapes and the positions of the three functions alone; for the free template with n photon fields and the label b the ratio $S_3^2/(S_2S_2S_2)$ equals $\mathcal{R}(f)/\mathsf{n}$, in which the label b does not enter. We show that at three distinct points x_1, x_2, x_3 the kernels satisfy $k_3(x)^2 / \prod_{i<j} k_2(x_i, x_j) = \frac{1}{3}(1 + 3\mathsf{q}_\triangle)^2$, where $\mathsf{q}_\triangle$ is the product of the three cosines of the angles of the triangle that the points span, so that this kernel quotient takes the value $\frac{4}{3}$ when the points lie on one line; that $0 \le \mathcal{R} < \frac{4}{3}$ on all test triples; that $\mathcal{R} \ge \frac{4}{3}(1 - 412w^2)$ for bumps of the radius $w\mathsf{d}$ about three points of a line, d being the scale, and $\mathcal{R} \to \frac{1}{3}(1 + 3\mathsf{q}_\triangle)^2$ for a family of bumps that shrink to the corners of a triangle whose three sides have lengths in $[\frac{9}{8}, 6]$; and that over the test triples of a fixed shape parameter ϑ the supremum of $\mathcal{R}$ lies below $\frac{4}{3}$ and tends to $\frac{4}{3}$ as $\vartheta \to 0$ (Propositions 18.32 to 18.37). For the limits $S_n^{(\ell,\mathsf{b})}$ of the connected functions of the action density on a torus, as the cutoff is removed at a fixed label, the law of two points $S_2^{(\ell,\mathsf{b})} = 3\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\text{free}}\,(1 + o(1))$ at short distance is valid on every side $\ell = 2L^m$ and at every real label $\mathsf{b} > 0$ (Proposition 18.38). Let g be a reference coupling with $g \le \gamma_W$, the ceiling YM3_I:(2346) of the law of two points of the main text, and let T_ℓ be the torus of a side ℓ at g. If on T_ℓ the law of three points $S_3^T \approx 3\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\text{free}}$ holds in the form of Definition 18.31, whose numbers are the same at all cutoffs, then the ratio $Q = S_3^2/(S_2S_2S_2)$ obeys $|3Q - \mathcal{R}| \le \Theta_{\text{Q}}$ at every large cutoff, where the bound sees the cutoff only through the quotient $a_K/(\vartheta\mathsf{d})$ and is uniform in β, in the label, in the triple and in its position, and Q obeys the same inequality in the limit, where the bound is free of the cutoff and tends to 0 with the scale; so $Q \to \frac{1}{3}\mathcal{R}$ along the dilates of one shape, $Q \to \frac{4}{9} = \frac{4}{3\dim \mathfrak{su}(2)}$ as the scale and then the width of bumps about three points of a line tend to 0, and the supremum of Q over the collinear triples of a shape parameter ϑ tends to a number below $\frac{4}{9}$ which increases to $\frac{4}{9}$ as $\vartheta \to 0$; besides, at every scale below a threshold that depends on ϑ, the function of three points is positive at the collinear triples of the shape parameter ϑ, and along the periodised dilates of the bumps of Proposition 18.36 about the corners of a triangle whose three sides have lengths in $[\frac{9}{8}, 6]$, $Q \to \frac{1}{9}(1 + 3\mathsf{q}_\triangle)^2$ as first the scale and then the width tend to 0, while in the case $1 + 3\mathsf{q}_\triangle \ne 0$ the function of three points at these dilates is not 0 and has the same sign as $-(1 + 3\mathsf{q}_\triangle)$ whenever the width is small enough and, for that width, the scale is small enough (Propositions 18.39 to 18.41). If the hypothesis is met on all sides at g for every small g, the conclusions on the limits are valid on all tori and at all real labels, and the ratios at the cutoffs converge to the ratio of the limits (Proposition 18.42). The function of two points of a free template depends on its data (n, b) through $\mathsf{n}\mathsf{b}^{-2}$ alone, so that, for instance, one photon field at the label $\mathsf{b}/\sqrt{3}$ and three at the label b share it; when the hypothesis holds on every side at g for all small g, the functions of two and of three points of $S^{(\ell,\mathsf{b})}$, divided by the free functionals along the periodised dilates of a collinear shape, tend at short distance to $3\mathsf{b}^{-2}$ and $3\mathsf{b}^{-3}$, and of all free templates only the one with three photon fields and the label b shows these two limits (Proposition 18.43). Conversely, given the law of two points, $3Q/\mathcal{R} \to 1$ is equivalent to the law of three points in modulus, and $Q \to \frac{4}{9}$ in the form with a width is equivalent to the law of three points in modulus in the limit of narrow bumps; an explicit

pair of functions of two and of three points has the law of two points and $Q \to \frac{4}{9}$, while along the dilates of a collinear shape its function of three points exceeds the free one by one fixed factor at every scale (Propositions 18.44 and 18.45). Under the ceiling (Γ) of Section 4.1, the uniform law follows by comparing each state with the cubic source jet on the least torus and estimating that jet (Remark 18.46). We use the setting and the signs of Section 4.1. For g under the ceiling (Γ) of that Section, its Theorem G bounds the function of three points at two scales against the lattice ring on the least torus (its clause (A.1)) and, through its clause (A.4)(i), for each state at a first-passage datum, the periodic extensions of the torus measures on all sides at g among them; taken at one scale and joined with Lemma 4.22(a), which passes from the lattice ring to the free ring, these bounds give the hypothesis on every side at g, for every such g (Remark 18.47).

Setting. We use the construction and the notation of Section 4.1 and its hypotheses where its estimates are invoked. From Section 4.1 we take the constants, among them the odd blocking factor $L \geq 13$, $M = L^{m'}$, $a_j = L^{-j}$, $B_\sharp \geq 0$ and $\bar B = B_\sharp L/(L-1)$, so that $LB_\sharp = (L-1)\bar B$, and $\gamma \in (0, \frac{1}{2}]$; the reference couplings $0 < g \leq \gamma$; the first-passage data (K, β) at g and their labels $\mathsf{b} = a_K\beta$, which satisfy $g^{-2} < \mathsf{b} \leq \bar{\mathsf{b}} = L(g^{-2} + \bar B)$ (Lemma 4.3(a)), so that every limit of such labels is a number $\geq g^{-2} > 0$; the interval $I(g) = (g^{-2} + \bar B, X_g - \bar B]$, $X_g = L(g^{-2} + B_\sharp)$, YM3_I: (1527), for whose points b every pair $(K, L^K\mathsf{b})$, $K \in \mathbb{N}$, is a first-passage datum at g with the label b; the tori $T_\ell = \mathbb{R}^3/\ell\mathbb{Z}^3$ of the sides $\ell = 2L^m$, $m \in \mathbb{N}$, with the lattices $a_K\mathbb{Z}^3/\ell\mathbb{Z}^3$; the sides at g, $\mathfrak{L}(g) = \{2L^m : m \in \mathbb{N},\ m \geq m_{\mathfrak{L}}(g)\}$ with $L^{m_{\mathfrak{L}}(g)} = LM \max\{R(L(g^{-2} + \bar B)), L^{\lceil \log_L C_{\mathrm{s}} \rceil}\}$, where for $x > 1$ the number $R(x)$ is the least power L^{u}, $\mathsf{u} \geq 0$ an integer, with $L^{\mathsf{u}} \geq (\log x)^r$, and $r \in \mathbb{N}$, $C_{\mathrm{s}} \geq 2$ are constants, and the least side ℓ_g; the torus measures $\mu_{K,\ell,\beta}$ and their periodic extensions $\tilde\mu_{K,\ell,\beta}$; the observable $\mathcal{O}(f) = a_K^{-1} \sum_p f(x(p))\, a_p$; the connected functions $S^T_{n;K,\ell,\beta}(f_1, \dots, f_n)$; the witness depth $s(\varrho)$ at g, an integer formed from the constants, g and the length ϱ, in which no cutoff enters; the periodisation $f^{\langle \ell \rangle}$ of a function f on $\mathbb{R}^3$; and the kernels $\mathbb{K}_3$ and k_3.

Free kernels and test classes. For a unit vector e put $D(e) = 3ee^{\mathsf{T}} - 1$, so that $\mathbb{K}_3(u) = (4\pi)^{-1}|u|^{-3}D(\hat u)$. For distinct $x_1, x_2, x_3 \in \mathbb{R}^3$, let a, b, c be the unit directions of $x_1 - x_2$, $x_2 - x_3$ and $x_3 - x_1$, and let $r_{ij} = |x_i - x_j|$. The product of the three angle cosines is $\mathsf{q}_\triangle = -(a \cdot b)(b \cdot c)(c \cdot a)$. Since the three vectors are coplanar, their Gram determinant gives

$$(a \cdot b)^2 + (b \cdot c)^2 + (c \cdot a)^2 = 1 - 2\mathsf{q}_\triangle .$$

Expanding the product of the three matrices then gives $\tau_\triangle = \operatorname{tr}(D(a)D(b)D(c)) = -3 - 9\mathsf{q}_\triangle$. On a line $\mathsf{q}_\triangle = -1$ and at an equilateral triangle $\mathsf{q}_\triangle = 1/8$. The two cyclic orders in the three-point ring have equal trace because D is even and symmetric. Thus

$$k_3(x) = \tau_\triangle(x)(4\pi)^{-3}(r_{12}r_{13}r_{23})^{-3}, \qquad k_2(x_1, x_2) = \tfrac{1}{2} \operatorname{tr} \mathbb{K}_3(x_1 - x_2)^2 = \tfrac{3}{16\pi^2} r_{12}^{-6}.$$

For bounded Borel functions with compact pairwise separated supports define $\mathcal{K}^{(n)}_{\mathrm{free}}(f) = \int k_n(x) \prod_i f_i(x_i)\, dx$ for $n = 2, 3$, taking the integrand to be zero where the product of the tests vanishes. These forms are symmetric and multilinear. The pair form is $\mathcal{K}^{(2)}_{\mathrm{free}} = \frac{3}{16\pi^2}\mathcal{K}_6$, where $\mathcal{K}_6(f, h) = \iint f(x)h(y)|x - y|^{-6}\, dx\, dy$. In the scalar two-point law, $\mathcal{K}_{\mathrm{free}} = \mathcal{K}_6$ and $\mathsf{c}_2 = 9/(16\pi^2)$, so $3\mathcal{K}^{(2)}_{\mathrm{free}} = \mathsf{c}_2\mathcal{K}_{\mathrm{free}}$.

The class $\mathfrak{T}_{\mathbb{E}}(\mathsf{d}; \vartheta)$, where $\mathbb{E} = \mathbb{R}^3$ or T_ℓ with $\ell \geq 20\mathsf{d}$, consists of pairs of nonzero nonnegative Lipschitz functions supported in closed balls of radius d, with support distance in $[\mathsf{d}, 6\mathsf{d}]$. Each entry u satisfies $\int u \geq \vartheta \|u\|_\infty \mathsf{d}^3$ and $\operatorname{Lip} u \leq \|u\|_\infty/(\vartheta\mathsf{d})$. The centers of any two such supports are at most $8\mathsf{d}$ apart by the triangle inequality. Write $\mathfrak{Q}^{(3)}_{\mathbb{E}}(\mathsf{d}; \vartheta)$ for the triples whose pairs all belong to this class, imposing $36\mathsf{d} < \ell$ on a torus. Let $\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{E}}(\mathsf{d}; \vartheta)$ be its subclass whose supports on $\mathbb{R}^3$ lie in balls of radius $\mathsf{d}/16$ with collinear centers, or on a torus have a common lift with that property.

To lift a triple from T_ℓ, fix a lift of the first center, and choose the lifts of the other centers within $8\mathsf{d}$ of it. The three lifted balls lie within $9\mathsf{d} < \ell/4$ of the first center. The covering map is an isometry on such a ball because every point difference there has length less than $\ell/2$. Each test is

pulled back there and extended by zero, preserving its supremum, integral and Lipschitz constant. For the latter, if one point lies outside the lifted ball, the test vanishes on the boundary and the segment to that point bounds the difference. The triple remains in its test class. Conversely a triple in the Euclidean test class periodises to a torus triple when $36\mathsf{d} < \ell$, by the same isometry. For a pair the midpoint of the two lifted centers gives a ball of radius $5\mathsf{d}$ containing both supports, and their mutual point distances are at most $10\mathsf{d} \le \ell/2$. The same conclusions hold for pairs. Any common lift of supports in a ball of radius less than $\ell/4$ gives the same relative positions, as every point difference is the unique shortest lift of that difference on the torus. All such lifts differ by a common period. Define the torus free forms at these lifts. They are independent of the lift by translation invariance. We write $\mathsf{N}(f) = \prod_a \|f_a\|_\infty$.

For $r > 0$ put $f_r(x) = f(x/r)$ and write Ψ_r for dilation of every entry. This preserves the test and width classes with d changed to $r\mathsf{d}$. Since k_n is homogeneous of degree $-3n$, $\mathcal{K}^{(n)}_{\mathrm{free}}(\Psi_r) = \mathcal{K}^{(n)}_{\mathrm{free}}(\Psi)$. Let $\psi_{i,r}^{\langle\ell\rangle} = ((\psi_i)_r)^{\langle\ell\rangle}$ and $\Psi_r^{\langle\ell\rangle} = (\Psi_r)^{\langle\ell\rangle}$ denote the periodised dilates, where $f^{\langle\ell\rangle}(x) = \sum_{z\in\ell\mathbb{Z}^3} f(x+z)$. For a periodically extended configuration the bare plaquette action is periodic. Grouping plaquettes by their images on T_ℓ therefore identifies the observable tested at f on the extended lattice with the observable tested at $f^{\langle\ell\rangle}$ on the torus, and identifies their joint cumulants. On $T_{L^s\ell}$ put $h^{(s)}(x) = h(L^{-s}x)$. The free template is $S_n^{\mathrm{fr}}[\mathsf{n},\mathsf{b}] = \mathsf{n}\mathsf{b}^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}$ for n photon fields and label b.

On the test pairs, point distances lie in $[\mathsf{d}, 10\mathsf{d}]$, and the test-integral and ball-volume bounds give

$$10^{-6}\vartheta^2\|f\|_\infty\|h\|_\infty \le \mathcal{K}_6(f,h) \le (4\pi/3)^2\|f\|_\infty\|h\|_\infty.$$

On the test triples, $|\tau_\triangle| \le 6$ by Proposition 18.32. The three support volumes then give $|\mathcal{K}^{(3)}_{\mathrm{free}}(f)| \le (2/9)\mathsf{N}(f) \le (4/9)\mathsf{N}(f)$. For collinear supports of radius at most $\mathsf{d}/16$, orient each of a, b, c toward the common line direction. Each perpendicular component has length at most $1/8$, so the mutual dot products are at least $1 - 2(1/8)^2$. Reversing a direction leaves both D and the product of the three dot products invariant. The formula for $\tau_\triangle$ then gives $\tau_\triangle \ge 6 - 216(1/16)^2 > 3.78$. The integral lower bounds and $r_{ij} \le 10\mathsf{d}$ give $\mathcal{K}^{(3)}_{\mathrm{free}}(f) \ge c_3^{\mathrm{col}}\vartheta^3\mathsf{N}(f)$ with $c_3^{\mathrm{col}} = 3.78(4\pi)^{-3}10^{-9}$.

Limits on a torus; the law of two points. Let $\ell = 2L^m$, $m \in \mathbb{N}$, let $\mathsf{b} > 0$ be real, and let $f_1, \dots, f_n$ be real Lipschitz functions on T_ℓ, none of them 0, whose supports have no common point. Then the limit $S_n^{(\ell,\mathsf{b})}(f_1,\dots,f_n) = \lim_{K\to\infty} S^T_{n;K,\ell,L^K\mathsf{b}}(f_1,\dots,f_n)$ exists (Theorem YM3_I:AS); for all pairs $(K_j,\beta_j) \in \mathbb{N}\times(0,\infty)$ with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}$ the numbers $S^T_{n;K_j,\ell,\beta_j}(f_1,\dots,f_n)$ tend to it along the whole sequence (YM3_I:(2216)), so that the limit along first-passage data of Section 4.1 is this limit; and $S_n^{(\ell,\mathsf{b})}(f_1,\dots,f_n) = L^{sn}S_n^{(L^s\ell,L^s\mathsf{b})}(f_1^{(s)},\dots,f_n^{(s)})$ for every integer $s \ge 0$, YM3_I:(2215). $\gamma_W \in (0,\gamma]$ is the ceiling YM3_I:(2346) of the law of two points of the main text; for $0 < g \le \gamma_W$ and $\vartheta \in (0,1)$, $\mathsf{d}_0(g,\vartheta) \in (0, \frac{1}{200}]$ is its threshold YM3_I:(2350), and $\bar\varepsilon_{g,\vartheta}$ its tolerance YM3_I:(2349), a function formed from the setting, g and ϑ. By Theorem YM3_I:AV: if $0 < g \le \gamma_W$, (K,β) is a first-passage datum at g with the label b, $0 < \mathsf{d} \le \mathsf{d}_0(g,\vartheta)$ and $s(\mathsf{d}) < K$, then for every $\ell \in \mathfrak{L}(g)$ and every $(f,h) \in \mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$

$$S^T_{2;K,\ell,\beta}(f,h) = \mathsf{c}_2\,\mathsf{b}^{-2}\,\mathcal{K}_{\mathrm{free}}(f,h)\,(1+\varepsilon'), \qquad |\varepsilon'| \le \bar\varepsilon_{g,\vartheta}(\mathsf{d}),$$

where the same function $\bar\varepsilon_{g,\vartheta}$ serves every first-passage datum at g, every pair and every position; it is non-decreasing, $\bar\varepsilon_{g,\vartheta}(\mathsf{d}) \to 0$ as $\mathsf{d} \to 0$, and $\bar\varepsilon_{g,\vartheta} \le \frac{1}{3}$ on $(0,\mathsf{d}_0(g,\vartheta)]$.

What is used where. Propositions 18.32 to 18.37, parts (a) and (b) of Proposition 18.43, part (a) of Proposition 18.44 and parts (b) and (c) of Proposition 18.45 concern the free kernels alone. Proposition 18.38, parts (b) and (c) of Proposition 18.44 and part (a) of Proposition 18.45 rest besides on the limits on a torus and on the law of two points recalled above; though the last three speak of the function of three points and of the ratio Q, they ask no bound on that function. Propositions 18.39 to 18.42 and part (c) of Proposition 18.43 rest, beyond these, on the hypothesis of Definition 18.31.

Definition 18.30 (Width classes; the two ratios; four numbers)**.** (1) *Width classes.* Let $0 < w \le \frac{1}{16}$, $\mathsf{d} > 0$ and $\vartheta \in (0,1)$. $\mathfrak{T}^{\mathrm{col}}_{\mathbb{R}^3}(\mathsf{d};\vartheta;w)$ is the set of the triples $f \in \mathfrak{Q}^{(3)}_{\mathbb{R}^3}(\mathsf{d};\vartheta)$ for which there are points c_1, c_2, c_3 on one line with $\operatorname{supp} f_i \subset \mathbb{B}(c_i, w\mathsf{d})$ for $i = 1,2,3$; for a side ℓ with $36\mathsf{d} < \ell$, $\mathfrak{T}^{\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta;w)$ is the set of the triples of $\mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$ one lift of which lies in $\mathfrak{T}^{\mathrm{col}}_{\mathbb{R}^3}(\mathsf{d};\vartheta;w)$; then all lifts lie in it, since any two lifts are translates of each other and a translation takes a line to a line and a ball to a ball of equal radius. The width classes increase with w, and at $w = \frac{1}{16}$ they are the classes $\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{E}}(\mathsf{d};\vartheta)$.

(2) *The free ratio.* For bounded Borel functions $f_1, f_2, f_3 \ge 0$ on $\mathbb{R}^3$ with compact supports at pairwise positive distance and with $\mathcal{K}^{(2)}_{\mathrm{free}}(f_i, f_j) > 0$ for $i < j$,

$$\mathcal{R}(f) = \frac{\mathcal{K}^{(3)}_{\mathrm{free}}(f_1,f_2,f_3)^2}{\mathcal{K}^{(2)}_{\mathrm{free}}(f_1,f_2)\,\mathcal{K}^{(2)}_{\mathrm{free}}(f_1,f_3)\,\mathcal{K}^{(2)}_{\mathrm{free}}(f_2,f_3)};$$

for a triple of $\mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$, $\mathcal{R}$ is formed at a lift, at which the four functionals have the values that they have on the torus. On the test classes the denominator is positive, by the lower bound of $\mathcal{K}^{(2)}_{\mathrm{free}}$ recalled above. For $0 < \vartheta \le \frac{\pi}{13440}$ we put $\bar{\mathcal{R}}(\vartheta) = \sup\{\mathcal{R}(f) : f \in \mathfrak{Q}^{(3)}_{\mathbb{R}^3}(1;\vartheta)\}$, $\bar{\mathcal{R}}^{\mathrm{col}}(\vartheta) = \sup\{\mathcal{R}(f) : f \in \mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{R}^3}(1;\vartheta)\}$ and $w_\vartheta = (\frac{105\,\vartheta}{32\pi})^{1/3}$, so that $w_\vartheta \le \frac{1}{16}$; both classes have elements (Proposition 18.35(b)).

(3) *The ratio of the connected functions.* For a triple f of real Lipschitz functions on T_ℓ, none of them 0, with pairwise disjoint supports,

$$Q_{K,\ell,\beta}(f) = \frac{S^T_{3;K,\ell,\beta}(f_1,f_2,f_3)^2}{\prod_{i<j} S^T_{2;K,\ell,\beta}(f_i,f_j)}, \qquad Q^{(\ell,\mathsf{b})}(f) = \frac{S^{(\ell,\mathsf{b})}_3(f_1,f_2,f_3)^2}{\prod_{i<j} S^{(\ell,\mathsf{b})}_2(f_i,f_j)},$$

each where the three factors below the line are positive. For the free template with the data (n,b) the same quotient is $(\mathsf{n}\mathsf{b}^{-3})^2\mathcal{K}^{(3)}_{\mathrm{free}}(f)^2/((\mathsf{n}\mathsf{b}^{-2})^3\prod_{i<j}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j)) = \mathcal{R}(f)/\mathsf{n}$.

(4) *Numbers.* $\mathsf{C}_{\mathrm{P}} = (\frac{16\pi^2}{3})^3\,10^{18}$; for $\vartheta \in (0,1)$ and real $t, e \ge 0$,

$$\Theta_{\mathrm{Q}}(\vartheta;t,e) = \tfrac{27}{8}\,\mathsf{C}_{\mathrm{P}}\,\vartheta^{-6}(\tfrac{8}{9}\,t + t^2) + \tfrac{37}{2}\,e;$$

and for $0 < w \le \frac{1}{16}$, $\mathsf{t}_w = 1 - 90w^2 - 72w^3$ and $\varkappa_w = \log\frac{1+2w}{1-2w}$. ■

Definition 18.31 (The uniform law of three points)**.** Let $0 < g \le \gamma$ and $\ell \in \mathfrak{L}(g)$. We say that the uniform law of three points holds at (g,ℓ), and write $\mathrm{UL}_3(g,\ell)$, if to each $\vartheta \in (0,1)$ one can find $\mathsf{d}_{\mathrm{III}} \in (0, \frac{1}{200}]$, $C_{\mathrm{III}} \ge 0$, integers $K_{\mathrm{III}}(\mathsf{d})$ for $0 < \mathsf{d} \le \mathsf{d}_{\mathrm{III}}$, and a function ϵ_{III} on $(0,\mathsf{d}_{\mathrm{III}}]$ with values in $[0,\infty)$ and the limit 0 at 0, depending on the setting, on g, ℓ, ϑ and, for K_{III} and ϵ_{III}, on d, but on none of K, β, the triple and the place of the triple, with the following property: whenever (K,β) is a first-passage datum at g, $\mathsf{b} = a_K\beta$ its label, $0 < \mathsf{d} \le \mathsf{d}_{\mathrm{III}}$, $K \ge K_{\mathrm{III}}(\mathsf{d})$ and $f \in \mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$, then

$$\left|S^T_{3;K,\ell,\beta}(f_1,f_2,f_3) - 3\,\mathsf{b}^{-3}\,\mathcal{K}^{(3)}_{\mathrm{free}}(f_1,f_2,f_3)\right| \le \left[\epsilon_{\mathrm{III}}(\mathsf{d}) + C_{\mathrm{III}}\,\frac{a_K}{\vartheta\,\mathsf{d}}\right]\mathsf{b}^{-3}\,\mathsf{N}(f).$$

By UL^*_3 we mean: for some $\gamma_{\mathrm{III}} \in (0,\gamma]$, $\mathrm{UL}_3(g,\ell)$ is true whenever $0 < g \le \gamma_{\mathrm{III}}$ and $\ell \in \mathfrak{L}(g)$. ■

The free ratio.

Proposition 18.32 (Three points)**.** Let $x_1, x_2, x_3 \in \mathbb{R}^3$ be pairwise different.

(a) $-1 \le \mathsf{q}_\triangle(x) \le \frac{1}{8}$ and $-\frac{33}{8} \le \tau_\triangle(x) \le 6$; $\mathsf{q}_\triangle(x) = -1$, and equally $\tau_\triangle(x) = 6$, if and only if the three points lie on one line.

(b) $k_3(x) = \frac{\tau_\triangle(x)}{3\sqrt{3}}\prod_{i<j} k_2(x_i,x_j)^{1/2}$, and

$$\frac{k_3(x)^2}{k_2(x_1,x_2)\,k_2(x_1,x_3)\,k_2(x_2,x_3)} = \frac{\tau_\triangle(x)^2}{27} = \frac{(1+3\,\mathsf{q}_\triangle(x))^2}{3}.$$

(c) For the template with the data (n,b) the quotient of its kernels is

$$(\mathsf{n}\mathsf{b}^{-3}k_3(x))^2/\prod_{i<j}\mathsf{n}\mathsf{b}^{-2}k_2(x_i,x_j)=(1+3\mathsf{q}_\triangle(x))^2/(3\mathsf{n}).$$

It depends neither on b nor on the size of the triangle. At three points of a line it is $\frac{4}{3\mathsf{n}}$ for all distances between the points, so $\frac{4}{9}$ for $\mathsf{n}=3=\dim\mathfrak{su}(2)$; at the corners of an equilateral triangle it is $\frac{121}{192\,\mathsf{n}}$, and there $k_3<0$. At $(x_1,x_2,x_3)=(0,e_3,2e_3)$, $(4\pi)^3k_3=6\cdot 2^{-3}=\frac{3}{4}$. ■

Proposition 18.33 (The free ratio stays below $\frac{4}{3}$)**.** (a) For bounded Borel functions $f_1,f_2,f_3\ge 0$ on $\mathbb{R}^3$ whose supports are compact and at pairwise positive distance,

$$\mathcal{K}^{(3)}_{\mathrm{free}}(f_1,f_2,f_3)^2\le\tfrac{4}{3}\,\mathcal{K}^{(2)}_{\mathrm{free}}(f_1,f_2)\,\mathcal{K}^{(2)}_{\mathrm{free}}(f_1,f_3)\,\mathcal{K}^{(2)}_{\mathrm{free}}(f_2,f_3).$$

(b) If moreover each f_i is continuous and not the zero function, then $\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j)>0$ for $i<j$, and strict inequality is valid in (a): $0\le\mathcal{R}(f)<\frac{4}{3}$.

(c) For every $\mathsf{d}>0$, $\vartheta\in(0,1)$ and $f\in\mathfrak{Q}^{(3)}_{\mathbb{E}}(\mathsf{d};\vartheta)$, on $\mathbb{E}=\mathbb{R}^3$ and on $\mathbb{E}=T_\ell$ with $36\mathsf{d}<\ell$, $0\le\mathcal{R}(f)<\frac{4}{3}$; so the quotient $\mathcal{R}(f)/\mathsf{n}$ of the template with the data (n,b) lies in $[0,\frac{4}{3\mathsf{n}})$. ■

Proposition 18.34 (Narrow bumps about three points of a line)**.** Let $\mathbb{E}=\mathbb{R}^3$, or $\mathbb{E}=T_\ell$ and $36\mathsf{d}<\ell$; let $\mathsf{d}>0$, $\vartheta\in(0,1)$, $0<w\le\frac{1}{16}$ and $f\in\mathfrak{T}^{\mathrm{col}}_{\mathbb{E}}(\mathsf{d};\vartheta;w)$. Then $\mathsf{t}_w>0$, $\mathcal{K}^{(3)}_{\mathrm{free}}(f)>0$, and

$$\tfrac{4}{3}\,(1-412\,w^2)\le\tfrac{4}{3}\,\mathsf{t}_w^2\,e^{-\frac{27}{2}\varkappa_w^2}\le\mathcal{R}(f)<\tfrac{4}{3}.$$

So $0<\frac{4}{3}-\mathcal{R}(f)\le\frac{1648}{3}\,w^2$, a bound quadratic in w that is uniform in the scale d and in the shape parameter ϑ. ■

Proposition 18.35 (The collinear classes and the suprema of the free ratio)**.** Let $\mathbb{E}$, d, ϑ and w be as in Proposition 18.34.

(a) A width class $\mathfrak{T}^{\mathrm{col}}_{\mathbb{E}}(\mathsf{d};\vartheta;w)$ that has an element has $\vartheta\le\frac{4\pi}{3}w^3$.

(b) For $\vartheta\le\frac{32\pi}{105}w^3$ the width class $\mathfrak{T}^{\mathrm{col}}_{\mathbb{E}}(\mathsf{d};\vartheta;w)$ has elements: for a unit vector e and $c_j=2(j-1)\mathsf{d}\,e$, the functions $u_j(x)=(1-|x-c_j|^2/(w\mathsf{d})^2)^2$ for $|x-c_j|\le w\mathsf{d}$ and $u_j(x)=0$ otherwise, $j=1,2,3$, form a triple of it on $\mathbb{R}^3$, and their periodisations one on T_ℓ.

(c) Let $0<\vartheta\le\frac{\pi}{13440}$. For every d and on both spaces, $\sup\{\mathcal{R}(f):f\in\mathfrak{Q}^{(3)}_{\mathbb{E}}(\mathsf{d};\vartheta)\}=\bar{\mathcal{R}}(\vartheta)$ and $\sup\{\mathcal{R}(f):f\in\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{E}}(\mathsf{d};\vartheta)\}=\bar{\mathcal{R}}^{\mathrm{col}}(\vartheta)$; both are non-increasing functions of ϑ; and

$$\tfrac{4}{3}\,(1-412\,w_\vartheta^2)\le\bar{\mathcal{R}}^{\mathrm{col}}(\vartheta)\le\bar{\mathcal{R}}(\vartheta)\le\tfrac{4}{3},$$

so that both tend to $\frac{4}{3}$ as $\vartheta\to 0$. ■

Proposition 18.36 (Bumps at the corners of a triangle)**.** Let $c_1,c_2,c_3\in\mathbb{R}^3$ with $\frac{9}{8}\le|c_i-c_j|\le 6$ for $i\ne j$, let $0<w\le\frac{1}{16}$, let $u_j(x)=(1-|x-c_j|^2/w^2)^2$ for $|x-c_j|\le w$ and $u_j(x)=0$ otherwise, and $\Psi^{c,w}=(u_1,u_2,u_3)$. Then $\Psi^{c,w}\in\mathfrak{Q}^{(3)}_{\mathbb{R}^3}(1;\vartheta)$ for $0<\vartheta\le\frac{32\pi}{105}w^3$; as $w\to 0$, $\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi^{c,w})/\prod_j\int u_j\to k_3(c)$ and

$$\mathcal{R}(\Psi^{c,w})\to\tfrac{1}{3}\,(1+3\,\mathsf{q}_\triangle(c))^2.$$

■

Proposition 18.37 (A fixed shape parameter keeps the free ratio away from $\frac{4}{3}$)**.** For every $0<\vartheta\le\frac{\pi}{13440}$, $\bar{\mathcal{R}}^{\mathrm{col}}(\vartheta)\le\bar{\mathcal{R}}(\vartheta)<\frac{4}{3}$. Consequently, if for $k\in\mathbb{N}$ the space $\mathbb{E}_k$ is $\mathbb{R}^3$ or a torus, $\mathsf{d}_k>0$, $\vartheta_k\in(0,1)$, $f^{(k)}\in\mathfrak{Q}^{(3)}_{\mathbb{E}_k}(\mathsf{d}_k;\vartheta_k)$, and $\mathcal{R}(f^{(k)})\to\frac{4}{3}$, then $\vartheta_k\to 0$. ■

The law of two points for the limits on all tori.

Proposition 18.38 (The law of two points on all sides and at all labels)**.** (a) Let $0 < g \le \gamma_W$, $\ell \in \mathfrak{L}(g)$ and $\vartheta \in (0,1)$, and let b be the limit of the labels $a_{K_j}\beta_j$ of first-passage data (K_j,β_j) at g with $K_j \to \infty$, for instance any $\mathsf{b} \in I(g)$. Then for every $0 < \mathsf{d} \le \mathsf{d}_0(g,\vartheta)$ and every $(f,h) \in \mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$

$$S_2^{(\ell,\mathsf{b})}(f,h) = 3\,\mathsf{b}^{-2}\,\mathcal{K}^{(2)}_{\mathrm{free}}(f,h)\,(1+\eta), \qquad |\eta| \le \bar\varepsilon_{g,\vartheta}(\mathsf{d}).$$

(b) Let $\ell = 2L^m$, $m \in \mathbb{N}$, be any side, $\mathsf{b} > 0$ any real number and $\vartheta \in (0,1)$. One can choose a number $\mathsf{d}_{\mathrm{II}} = \mathsf{d}_{\mathrm{II}}(\ell,\mathsf{b},\vartheta) \in (0, \frac{1}{200}]$ and a non-decreasing function ϵ_{II} from $(0,\mathsf{d}_{\mathrm{II}}]$ to $[0,\frac13]$ with $\epsilon_{\mathrm{II}}(\mathsf{d}) \to 0$ as $\mathsf{d} \to 0$, both depending on the setting, ℓ, b and ϑ only, such that for every $0 < \mathsf{d} \le \mathsf{d}_{\mathrm{II}}$ and every $(f,h) \in \mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ the display of (a) holds with $\epsilon_{\mathrm{II}}(\mathsf{d})$ in the place of $\bar\varepsilon_{g,\vartheta}(\mathsf{d})$.

(c) In (a) and in (b), $S_2^{(\ell,\mathsf{b})}(f,h) \ge 2\,\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}(f,h) > 0$.

■

Three points, under the uniform law.

Proposition 18.39 (The ratio at a cutoff and in the limit)**.** Let $0 < g \le \gamma_W$ and $\ell \in \mathfrak{L}(g)$, and suppose $\mathrm{UL}_3(g,\ell)$. Let $\vartheta \in (0,1)$, let $\mathsf{d}_{\mathrm{III}}$, C_{III}, ϵ_{III}, K_{III} be the numbers of Definition 18.31 at ϑ, and $0 < \mathsf{d} \le \min\{\mathsf{d}_0(g,\vartheta), \mathsf{d}_{\mathrm{III}}\}$.

(a) For every first-passage datum (K,β) at g with $K > s(\mathsf{d})$ and $K \ge K_{\mathrm{III}}(\mathsf{d})$ and every $f \in \mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$, the three numbers $S^T_{2;K,\ell,\beta}(f_i,f_j)$ are positive, and

$$|3\,Q_{K,\ell,\beta}(f) - \mathcal{R}(f)| \le \Theta_{\mathrm{Q}}\Big(\vartheta;\ \tfrac13\Big[\epsilon_{\mathrm{III}}(\mathsf{d}) + C_{\mathrm{III}}\frac{a_K}{\vartheta\,\mathsf{d}}\Big],\ \bar\varepsilon_{g,\vartheta}(\mathsf{d})\Big);$$

this bound involves only the setting, g, ℓ, ϑ, d and a_K.

(b) Let (K_j,β_j) be first-passage data at g with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}$. Then for every $f \in \mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$, $Q_{K_j,\ell,\beta_j}(f) \to Q^{(\ell,\mathsf{b})}(f)$ along the whole sequence, and

$$|S_3^{(\ell,\mathsf{b})}(f) - 3\,\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f)| \le \epsilon_{\mathrm{III}}(\mathsf{d})\,\mathsf{b}^{-3}\,\mathsf{N}(f), \qquad |3\,Q^{(\ell,\mathsf{b})}(f) - \mathcal{R}(f)| \le \Theta_{\mathrm{Q}}(\vartheta;\tfrac13\epsilon_{\mathrm{III}}(\mathsf{d}),\bar\varepsilon_{g,\vartheta}(\mathsf{d}));$$

the last right member tends to 0 as $\mathsf{d} \to 0$.

■

Proposition 18.40 (Short distance: along one shape, at a small width, and for the supremum)**.** Let $0 < g \le \gamma_W$ and $\ell \in \mathfrak{L}(g)$, suppose $\mathrm{UL}_3(g,\ell)$, and let (K_j,β_j) be first-passage data at g with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}$. For $\vartheta \in (0,1)$ the numbers $\mathsf{d}_{\mathrm{III}}$, ϵ_{III} are those of Definition 18.31 at ϑ.

(a) *Along one shape.* For every $\vartheta \in (0,1)$ and every $\Psi \in \mathfrak{Q}^{(3)}_{\mathbb{R}^3}(1;\vartheta)$, $\lim_{r\to0} Q^{(\ell,\mathsf{b})}(\Psi_r^{\langle\ell\rangle}) = \frac13\mathcal{R}(\Psi)$, which is smaller than $\frac49$.

(b) *At a small width.* Let $\vartheta \in (0,1)$ and $0 < w \le \frac{1}{16}$. For $0 < \mathsf{d} \le \min\{\mathsf{d}_0(g,\vartheta), \mathsf{d}_{\mathrm{III}}\}$ and $f \in \mathfrak{T}^{\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta;w)$,

$$|Q^{(\ell,\mathsf{b})}(f) - \tfrac49| \le 184\,w^2 + \tfrac13\,\Theta_{\mathrm{Q}}(\vartheta;\tfrac13\epsilon_{\mathrm{III}}(\mathsf{d}),\bar\varepsilon_{g,\vartheta}(\mathsf{d})).$$

Consequently, for every function $w \mapsto \vartheta(w)$ on $(0,\frac{1}{16}]$ with $0 < \vartheta(w) \le \frac{32\pi}{105}w^3$,

$$\lim_{w\to0}\ \limsup_{\mathsf{d}\to0}\ \sup_{f\in\mathfrak{T}^{\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta(w);w)}\ \limsup_{j\to\infty}\ |Q_{K_j,\ell,\beta_j}(f) - \tfrac49| = 0;$$

the classes that occur are not empty, and $\vartheta(w) \to 0$ as $w \to 0$.

(c) *For the supremum.* For $0<\vartheta\le\frac{\pi}{13440}$,

$$\lim_{\mathsf{d}\to0}\sup_{f\in\mathfrak{T}^{(3),\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta)}Q^{(\ell,\mathsf{b})}(f)=\tfrac{1}{3}\,\bar{\mathcal{R}}^{\mathrm{col}}(\vartheta),\qquad \lim_{\mathsf{d}\to0}\sup_{f\in\mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)}Q^{(\ell,\mathsf{b})}(f)=\tfrac{1}{3}\,\bar{\mathcal{R}}(\vartheta);$$

both limits lie in $[\frac{4}{9}(1-412\,w_\vartheta^2),\frac{4}{9})$, both are non-increasing in ϑ, and both tend to $\frac{4}{9}$ as $\vartheta\to0$.

■

Proposition 18.41 (Positivity at the collinear triples; the corners of a triangle)**.** Let g, ℓ, (K_j,β_j) and b be as in Proposition 18.40, under $\mathrm{UL}_3(g,\ell)$.

(a) Let $\vartheta\in(0,1)$, $0<\mathsf{d}\le\min\{\mathsf{d}_0(g,\vartheta),\mathsf{d}_{\mathrm{III}}\}$ and $\epsilon_{\mathrm{III}}(\mathsf{d})<3c_3^{\mathrm{col}}\vartheta^3$. Then for every $f\in\mathfrak{T}^{(3),\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta)$, $S_3^{(\ell,\mathsf{b})}(f)\ge(3c_3^{\mathrm{col}}\vartheta^3-\epsilon_{\mathrm{III}}(\mathsf{d}))\,\mathsf{b}^{-3}\mathsf{N}(f)>0$.

(b) For c and $\Psi^{c,w}$ as in Proposition 18.36,

$$\lim_{w\to0}\lim_{r\to0}Q^{(\ell,\mathsf{b})}((\Psi^{c,w})_r^{\langle\ell\rangle})=\tfrac{1}{9}\,(1+3\,\mathsf{q}_\triangle(c))^2.$$

If $1+3\mathsf{q}_\triangle(c)\neq0$, there is $w_0>0$ such that for every $0<w\le w_0$ there is $r_0(w)>0$ with the following property: for $0<r\le r_0(w)$ the number $S_3^{(\ell,\mathsf{b})}((\Psi^{c,w})_r^{\langle\ell\rangle})$ is not 0, and its sign is that of $-(1+3\mathsf{q}_\triangle(c))$. When the c_i lie on one line this sign is $+$; for an equilateral triangle it is $-$, and the iterated limit equals $\frac{121}{576}$.

■

Proposition 18.42 (All sides and all real labels)**.** Suppose UL_3^*. Let $\ell=2L^m$, $m\in\mathbb{N}$, be any side, $\mathsf{b}>0$ any real number and $\vartheta\in(0,1)$. There are a number $\mathsf{d}_\sharp>0$ and functions $\epsilon_\sharp,e_\sharp$ on $(0,\mathsf{d}_\sharp]$, formed from the setting, ℓ, b, ϑ and the numbers of UL_3^*, with $\epsilon_\sharp(\mathsf{d})\to0$, $0\le e_\sharp\le\frac{1}{3}$ and $e_\sharp(\mathsf{d})\to0$ as $\mathsf{d}\to0$, such that for $0<\mathsf{d}\le\mathsf{d}_\sharp$, $f\in\mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$ and $i<j$

$$|S_3^{(\ell,\mathsf{b})}(f)-3\,\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f)|\le\epsilon_\sharp(\mathsf{d})\,\mathsf{b}^{-3}\mathsf{N}(f),\qquad |S_2^{(\ell,\mathsf{b})}(f_i,f_j)-3\,\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j)|\le e_\sharp(\mathsf{d})\,3\,\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j),$$

and $|3Q^{(\ell,\mathsf{b})}(f)-\mathcal{R}(f)|\le\Theta_\sharp(\mathsf{d}):=\Theta_{\mathrm{Q}}(\vartheta;\frac{1}{3}\epsilon_\sharp(\mathsf{d}),e_\sharp(\mathsf{d}))$, which tends to 0 as $\mathsf{d}\to0$. The assertions of Propositions 18.40 and 18.41 hold on T_ℓ at the label b, with $\mathsf{d}_\sharp$, $\epsilon_\sharp$ and $\Theta_\sharp$ in the places of $\min\{\mathsf{d}_0(g,\vartheta),\mathsf{d}_{\mathrm{III}}\}$, ϵ_{III} and $\Theta_{\mathrm{Q}}(\vartheta;\frac{1}{3}\epsilon_{\mathrm{III}}(\cdot),\bar\varepsilon_{g,\vartheta}(\cdot))$, all at the shape parameter at hand, and, in the display of Proposition 18.40(b), with any pairs $(K_j,\beta_j)\in\mathbb{N}\times(0,\infty)$ such that $K_j\to\infty$ and $a_{K_j}\beta_j\to\mathsf{b}$ in the place of the first-passage data; for such pairs and every f as above, $Q_{K_j,\ell,\beta_j}(f)$ is formed for all large j and tends to $Q^{(\ell,\mathsf{b})}(f)$. ■

The number of photon fields and the label.

Proposition 18.43. *Within the free templates, the function of two points fixes one number, and the functions of two and three points fix both.*

(a) Let $\mathsf{n},\mathsf{n}'\in\mathbb{N}$ and $\mathsf{b},\mathsf{b}'>0$. The functions $S_2^{\mathrm{fr}}[\mathsf{n},\mathsf{b}]$ and $S_2^{\mathrm{fr}}[\mathsf{n}',\mathsf{b}']$ agree at one test pair if and only if $\mathsf{n}'\mathsf{b}'^{-2}=\mathsf{n}\,\mathsf{b}^{-2}$, and then they agree at every pair at which they are defined. The templates whose function of two points is $3\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}$, the leading term of Proposition 18.38, are exactly the $S^{\mathrm{fr}}[\mathsf{n}',\mathsf{b}(\mathsf{n}'/3)^{1/2}]$, $\mathsf{n}'\in\mathbb{N}$; among them are $S^{\mathrm{fr}}[1,\mathsf{b}/\sqrt{3}]$, $S^{\mathrm{fr}}[3,\mathsf{b}]$ and $S^{\mathrm{fr}}[12,2\mathsf{b}]$.

(b) The map $(\mathsf{n},\mathsf{b})\mapsto(A_2,A_3)=(\mathsf{n}\,\mathsf{b}^{-2},\mathsf{n}\,\mathsf{b}^{-3})$ of $(0,\infty)^2$ into itself is injective, with the inverse $(A_2,A_3)\mapsto(A_2^3/A_3^2,\ A_2/A_3)$.

(c) Suppose UL_3^*. Let $\ell=2L^m$, $m\in\mathbb{N}$, $\mathsf{b}>0$, $\vartheta\in(0,1)$ and $\Psi=(\psi_1,\psi_2,\psi_3)\in\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{R}^3}(1;\vartheta)$. Then the limits

$$A_2=\lim_{r\to0}\frac{S_2^{(\ell,\mathsf{b})}(\psi_{i,r}^{\langle\ell\rangle},\psi_{j,r}^{\langle\ell\rangle})}{\mathcal{K}^{(2)}_{\mathrm{free}}(\psi_i,\psi_j)}\quad(i<j),\qquad A_3=\lim_{r\to0}\frac{S_3^{(\ell,\mathsf{b})}(\Psi_r^{\langle\ell\rangle})}{\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi)}$$

exist, with $A_2 = 3\,\mathsf{b}^{-2}$ for each of the three pairs and $A_3 = 3\,\mathsf{b}^{-3}$; the first of them exists, with this value, without UL_3^*. Hence $\lim_{r\to 0}\mathcal{R}(\Psi)/Q^{(\ell,\mathsf{b})}(\Psi_r^{\langle\ell\rangle}) = A_2^3/A_3^2 = 3$ and $A_2/A_3 = \mathsf{b}$; and the only template $S^{\mathrm{fr}}[\mathsf{n}',\mathsf{b}']$, $\mathsf{n}' \in \mathbb{N}$, $\mathsf{b}' > 0$, with these two limits at the periodised dilates of Ψ is $S^{\mathrm{fr}}[3,\mathsf{b}]$, where $3 = \dim \mathfrak{su}(2)$.

■

How the ratio stands to the law of three points.

Proposition 18.44 (The ratio and the law of three points in modulus)**.** (a) Let $\mathbb{E} = \mathbb{R}^3$, or $\mathbb{E} = T_\ell$ with $36\mathsf{d} < \ell$, $f \in \mathfrak{Q}^{(3)}_{\mathbb{E}}(\mathsf{d};\vartheta)$ with $\mathcal{K}^{(3)}_{\mathrm{free}}(f) \neq 0$, $\mathsf{b} > 0$, $y_3 \in \mathbb{R}$, and $y_{ij} = 3\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j)(1+e_{ij})$ with $|e_{ij}| < 1$ for $i < j$. Then

$$\Big(\frac{y_3}{3\,\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f)}\Big)^2 = \frac{3\,y_3^2/(y_{12}y_{13}y_{23})}{\mathcal{R}(f)}\ \prod_{i<j}(1+e_{ij}).$$

(b) Let $\ell = 2L^m$, $m \in \mathbb{N}$, $\mathsf{b} > 0$, $\vartheta \in (0,1)$, and for $k \in \mathbb{N}$ let $f^{(k)} \in \mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d}_k;\vartheta)$ with $\mathcal{K}^{(3)}_{\mathrm{free}}(f^{(k)}) \neq 0$ and $\mathsf{d}_k \to 0$. Then $3Q^{(\ell,\mathsf{b})}(f^{(k)})/\mathcal{R}(f^{(k)}) \to 1$ if and only if $|S_3^{(\ell,\mathsf{b})}(f^{(k)})|/(3\mathsf{b}^{-3}|\mathcal{K}^{(3)}_{\mathrm{free}}(f^{(k)})|) \to 1$.

(c) On the collinear classes $27\,(c_3^{\mathrm{col}})^2\vartheta^6 \le \mathcal{R}(f) < \frac{4}{3}$. For every side $\ell = 2L^m$, $m \in \mathbb{N}$, every $\mathsf{b} > 0$ and every $\vartheta \in (0,1)$, the supremum over the empty set being taken as 0,

$$\lim_{\mathsf{d}\to 0}\ \sup_{f\in\mathfrak{T}^{(3),\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta)} \big|3\,Q^{(\ell,\mathsf{b})}(f) - \mathcal{R}(f)\big| = 0 \quad\Longleftrightarrow\quad \lim_{\mathsf{d}\to 0}\ \sup_{f\in\mathfrak{T}^{(3),\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta)} \Big|\frac{|S_3^{(\ell,\mathsf{b})}(f)|}{3\,\mathsf{b}^{-3}\,\mathcal{K}^{(3)}_{\mathrm{free}}(f)} - 1\Big| = 0.$$

■

Proposition 18.45. *The value $\frac{4}{9}$ and the law in modulus for narrow bumps; an explicit pair.*

(a) Let $\ell = 2L^m$, $m \in \mathbb{N}$, $\mathsf{b} > 0$, $0 < w \le \frac{1}{16}$, $\vartheta \in (0,1)$, $0 < \mathsf{d} \le \mathsf{d}_{\mathrm{II}}(\ell,\mathsf{b},\vartheta)$ with ϵ_{II} as in Proposition 18.38(b), $f \in \mathfrak{T}^{\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta;w)$, and $\mathsf{v}(f) = |S_3^{(\ell,\mathsf{b})}(f)|/(3\,\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f))$, the denominator being positive. Then $\frac{9}{4}\,Q^{(\ell,\mathsf{b})}(f) = \mathsf{A}(f)\,\mathsf{v}(f)^2$, where the number $\mathsf{A}(f)$ satisfies

$$\frac{1-412\,w^2}{(1+\epsilon_{\mathrm{II}}(\mathsf{d}))^3} \le \mathsf{A}(f) \le \frac{1}{(1-\epsilon_{\mathrm{II}}(\mathsf{d}))^3}.$$

Consequently, for every function $w \mapsto \vartheta(w)$ on $(0,\frac{1}{16}]$ with $0 < \vartheta(w) \le \frac{32\pi}{105}w^3$ and every sequence of pairs $(K_j,\beta_j) \in \mathbb{N}\times(0,\infty)$ with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}$, the display of Proposition 18.40(b) holds if and only if

$$\lim_{w\to 0}\ \limsup_{\mathsf{d}\to 0}\ \sup_{f\in\mathfrak{T}^{\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta(w);w)} \big|\mathsf{v}(f) - 1\big| = 0.$$

(b) For bounded Borel functions $f_1,f_2,f_3 \ge 0$ on $\mathbb{R}^3$ with compact supports at pairwise positive distance put $\hat{S}_2 = S_2^{\mathrm{fr}}[3,\mathsf{b}]$ and

$$\hat{S}_3(f) = 18\,\mathsf{b}^{-3}(4\pi)^{-3}\int \prod_i f_i(x_i)\,(r_{12}r_{13}r_{23})^{-3}\,dx,$$

and, if each f_i is positive on a set of positive measure, $\hat{Q}(f) = \hat{S}_3(f)^2/\prod_{i<j}\hat{S}_2(f_i,f_j)$; on a torus both are formed at a lift, which is possible as $\hat{S}_3$ does not change under a common translation of the entries. Let Ψ° be the triple of Proposition 18.35(b) at $\mathsf{d} = 1$, $w = \frac{1}{16}$ and $e = e_3$. Then: (i) $\hat{S}_2$ satisfies the display of Proposition 18.38(a) with $\eta = 0$. (ii) $\hat{Q}(f) \le \frac{4}{9}$; for $f \in \mathfrak{T}^{\mathrm{col}}_{\mathbb{E}}(\mathsf{d};\vartheta;w)$, at every d and ϑ, $\hat{Q}(f) \ge \frac{4}{9}\,e^{-\frac{27}{2}\varkappa_w^2} \ge \frac{4}{9}\,(1-223\,w^2)$, so that $|\hat{Q}(f) - \frac{4}{9}| \le 100\,w^2$; and for $0 < \vartheta \le \frac{\pi}{13440}$ the supremum of $\hat{Q}$ over $\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{E}}(\mathsf{d};\vartheta)$ lies

in $[\frac{4}{9}(1-223\,w_\vartheta^2),\frac{4}{9}]$ at every d, and so tends to $\frac{4}{9}$ as $\vartheta\to 0$. (iii) For $f\in\mathfrak{T}^{\mathrm{col}}_{\mathbb{E}}(\mathsf{d};\vartheta;w)$, $1<\hat S_3(f)/(3\,\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f))\le \mathsf{t}_w^{-1}$; for $\Psi\in\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{R}^3}(1;\vartheta)$ the quotient takes the same value $1+\hat\delta(\Psi)$, with $\hat\delta(\Psi)>0$, at all the dilates Ψ_r, $r>0$, and $3\hat Q(\Psi_r)=\mathcal{R}(\Psi)\,(1+\hat\delta(\Psi))^2>\mathcal{R}(\Psi)$; for every $0<\vartheta\le\frac{\pi}{13440}$ and every $\mathsf{d}>0$ (on T_ℓ, $36\mathsf{d}<\ell$)

$$\sup_{f\in\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{E}}(\mathsf{d};\vartheta)}\Big(\frac{\hat S_3(f)}{3\,\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f)}-1\Big)\ge\hat\delta(\Psi^\circ)>0,$$

and $|\hat S_3(\Psi_r^\circ)-3\,\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi_r^\circ)|=3\,\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi^\circ)\,\hat\delta(\Psi^\circ)$ for every $r>0$, while $\mathsf{N}(\Psi_r^\circ)=1$.

(c) So the pair $(\hat S_2,\hat S_3)$ has the law of two points with $\eta=0$, the bound $|\hat Q-\frac{4}{9}|\le 100\,w^2$ on the width classes and suprema over the collinear classes that tend to $\frac{4}{9}$ as $\vartheta\to0$, while at the collinear triples of every shape parameter $\vartheta\le\frac{\pi}{13440}$ its function of three points exceeds $3\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}$ by the factor $1+\hat\delta(\Psi^\circ)$ along the dilates of Ψ°, at every scale.

■

Remark 18.46 (Comparison to the cubic source jet). Let g satisfy (Γ) of Definition 4.1(1). Take $\mathsf{d}_{\mathrm{III}}=\min\{\mathsf{d}_4(g),1/200\}$ and let $K_{\mathrm{III}}(\mathsf{d})$ be the least integer $K\ge\max\{2,s(\mathsf{d})\}$ with $4a_K\le\mathsf{d}$ and $\sqrt{3}\,a_K<2\vartheta\mathsf{d}$. For $\ell\in\mathfrak{L}(g)$, lift $f\in\mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$ to a triple $\hat f$ in the same class on $\mathbb{R}^3$. Its three supports lie in a ball of radius $9\mathsf{d}<\ell_g/8-1$, so periodisation on the least torus preserves the suprema and gives weights $w_a=\hat f_a^{\langle\ell_g\rangle}\circ x$ placed at $(\mathsf{d},\mathsf{d},\mathsf{d})$. Each $\hat f_a$ is positive on the open ball of radius $\vartheta\mathsf{d}$ about a point at which it attains its maximum. The barycentres of plaquettes of a fixed orientation form a translate of $a_K\mathbb{Z}^3$, which meets every closed ball of radius $\sqrt{3}\,a_K/2$. Thus the sampled weights on T_{ℓ_g} are nonzero.

Let J_3 be the cubic jet on T_{ℓ_g} at these weights used in Proposition 4.19(a). By the finite-cutoff identity for periodic extensions, $S^T_{3;K,\ell,\beta}(f)=S^T_3[\tilde\mu_{K,\ell,\beta}](\hat f)$. Theorem G(A.4)(i) compares this cumulant to the one on T_{ℓ_g}, and Lemma 4.21 compares the least-torus cumulant to J_3. Here $s(\mathsf{d})\le K$ and $\mathsf{d}\le\mathsf{d}_4(g)\le r_1(\bar{\mathsf{b}})\le r_1(\mathsf{b})$. Adding the estimates and using $\mathsf{b}\le\bar{\mathsf{b}}$ yields

$$|S^T_{3;K,\ell,\beta}(f)-\mathsf{J}_3|\le[C_3^{\mathrm{tr3}}(g)+13\Lambda_3^3(\bar{\mathsf{M}}^{(24)})^3]\bar{\mathsf{b}}^3\mathsf{d}^{3/2}\mathsf{b}^{-3}\mathsf{N}(f).$$

Proposition 4.19(a) compares J_3 to the lattice ring. Lemma 4.22(a), applied at $\rho=r=\mathsf{d}$ and $\mathsf{d}^+=18\mathsf{d}$ with $4a_K\le\mathsf{d}$ and $72\mathsf{d}<\ell_g$, compares the lattice ring to the free integral. Together they give

$$|\mathsf{J}_3-3\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f)|\le\left[\epsilon^{\mathrm{nar}}(g,\mathsf{d})+3C^{(3)}\left(\frac{a_K}{\vartheta\mathsf{d}}+\left(\frac{18\mathsf{d}}{\ell_g}\right)^3\right)\right]\mathsf{b}^{-3}\mathsf{N}(f).$$

The triangle inequality proves Definition 18.31 with $C_{\mathrm{III}}=3C^{(3)}$. The remaining error tends to zero uniformly in the cutoff, label, triple and position. Thus UL^*_3 holds with γ_{III} the least of γ and the coupling bounds in (Γ). The conclusions of Propositions 18.39 to 18.43 then apply for $0<g\le\min\{\gamma_W,\gamma_{\mathrm{III}}\}$ and, by the change of units in Proposition 18.42, on all tori at all labels.

Remark 18.47 (The hypothesis from the law of three points of Section 4.1). Let g be a reference coupling under the ceiling (Γ) of Definition 4.1(1); let $r_1(\cdot)$ and $\mathsf{d}_4(g)$ be the function and the number of Definition 4.1(2), $\bar{\mathsf{M}}^{(24)}$, Λ_3, $C^{(3)}$ and $C_3^{\mathrm{tr3}}(g)$ the numbers of its item (3), and $\epsilon^{\mathrm{nar}}(g,\cdot)$ the function of its item (4). Then $\mathrm{UL}_3(g,\ell)$ holds for every $\ell\in\mathfrak{L}(g)$: at every $\vartheta\in(0,1)$ one may take $C_{\mathrm{III}}=3C^{(3)}$, $\mathsf{d}_{\mathrm{III}}=\min\{\mathsf{d}_4(g),\frac{1}{200}\}$, $\epsilon_{\mathrm{III}}(\mathsf{d})=\epsilon^{\mathrm{nar}}(g,\mathsf{d})+(13\Lambda_3^3(\bar{\mathsf{M}}^{(24)})^3+C_3^{\mathrm{tr3}}(g))\bar{\mathsf{b}}^3\mathsf{d}^{3/2}+3C^{(3)}(18\mathsf{d}/\ell_g)^3$, and for $K_{\mathrm{III}}(\mathsf{d})$ the least integer $K\ge\max\{1,s(\mathsf{d})\}$ with $4a_K\le\mathsf{d}$. Indeed, let (K,β) be a first-passage datum at g with the label b, $0<\mathsf{d}\le\mathsf{d}_{\mathrm{III}}$, $K\ge K_{\mathrm{III}}(\mathsf{d})$ and $f\in\mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$. By the lifting argument above, f has a lift $\hat f$ whose entries form test pairs on $\mathbb{R}^3$, with $\operatorname{supp}\hat f_a\subset\mathbb{B}(\hat x_a,\mathsf{d})$, $|\hat x_a-\hat x_1|\le8\mathsf{d}$ and all three supports inside $\mathbb{B}(\hat x_1,9\mathsf{d})$; by the periodic extension identity $S^T_{3;K,\ell,\beta}(f)=S^T_3[\tilde\mu_{K,\ell,\beta}](\hat f)$,

and $\tilde{\mu}_{K,\ell,\beta}$ is a state at (K,β) in the sense of Section 4.1. We read Theorem G at $\rho = r = \mathsf{d}$, where the natural size of Section 4.1 is $\mathrm{nat}_3 = \mathsf{b}^{-3}\mathsf{N}(f)$. Its hypotheses hold: $s(\mathsf{d}) \le K$; $\mathsf{d} \le \mathsf{d}_4(g) \le r_1(\bar{\mathsf{b}}) \le r_1(\mathsf{b})$, as $\mathsf{b} \le \bar{\mathsf{b}}$ and r_1 does not increase; $9\mathsf{d} < \frac{1}{8}\ell_g - 1$, as $\ell_g \ge 2LM \ge 26$; and on T_{ℓ_g}, where the covering map is isometric on every ball of a radius $< \ell_g/4$, the weights $w_a = \hat{f}_a^{\langle \ell_g \rangle} \circ x$ are placed at $(\mathsf{d},\mathsf{d},\mathsf{d})$, in the sense of Section 4.1, about the images of the points $\hat{x}_a$. Clause (A.4)(i) bounds $|S_3^T[\tilde{\mu}_{K,\ell,\beta}](\hat{f}) - S_{3;K,\ell_g,\beta}^T(w_1,w_2,w_3)|$ by $C_3^{\mathrm{tr}3}(g)\mathsf{b}^3\mathsf{d}^{3/2}\,\mathsf{b}^{-3}\mathsf{N}(f)$; clause (A.1), whose number M' is at most $\bar{\mathsf{M}}^{(24)}$, bounds the distance of $S_{3;K,\ell_g,\beta}^T(w_1,w_2,w_3)$ from the lattice ring $3\mathsf{b}^{-3}\,\mathrm{Tr}\prod_a(w_a C_K^{\mathrm{free}})$ by $[\epsilon^{\mathrm{nar}}(g,\mathsf{d}) + 13\Lambda_3^3(\bar{\mathsf{M}}^{(24)})^3\mathsf{b}^3\mathsf{d}^{3/2}]\,\mathsf{b}^{-3}\mathsf{N}(f)$; and Lemma 4.22(a) on T_{ℓ_g}, at $\rho = r = \mathsf{d}$ and $\mathsf{d}^+ = 18\mathsf{d}$, applicable as $4a_K \le \mathsf{d}$, $72\mathsf{d} < \ell_g$ and the periodisations $\hat{f}_a^{\langle \ell_g \rangle}$ form test pairs on T_{ℓ_g} with the sup norms of the f_a, bounds the distance of that trace from $\int k_3 \prod_a \hat{f}_a = \mathcal{K}_{\mathrm{free}}^{(3)}(f)$ by $C^{(3)}[a_K/(\vartheta\mathsf{d}) + (18\mathsf{d}/\ell_g)^3]\,\mathsf{N}(f)$, the least lifts of the differences of points of one ball of a radius $< \ell_g/4$ being the differences of their lifts in one ball. The three bounds together, with $\mathsf{b} \le \bar{\mathsf{b}}$, give the inequality of Definition 18.31 with the numbers above, none of which depends on K, β, the triple or its place, and $\epsilon_{\mathrm{III}}(\mathsf{d}) \to 0$ as $\mathsf{d} \to 0$. Each member of (Γ) bounds g from above by a number formed from the constants (Definition 4.1(1)); with γ_{III} the least of these numbers and of γ, UL_3^* therefore holds, and the conclusions of Propositions 18.39 to 18.43 hold for $0 < g \le \min\{\gamma_W, \gamma_{\mathrm{III}}\}$, and on all tori at all labels.

The argument.

Lemma 18.48 (A Cauchy inequality for three kernels)**.** Let μ_1,μ_2,μ_3 be finite Borel measures on $\mathbb{R}^3$ and $F_{12},F_{13},F_{23} \ge 0$ bounded Borel functions on $\mathbb{R}^3 \times \mathbb{R}^3$. Then

$$\int F_{12}(x_1,x_2)F_{13}(x_1,x_3)F_{23}(x_2,x_3)\,d\mu_1(x_1)\,d\mu_2(x_2)\,d\mu_3(x_3) \le \prod_{i<j}\Big(\int F_{ij}^2\,d\mu_i\,d\mu_j\Big)^{1/2}.$$

■

Proof. Integrate first in x_3: the function $G(x_1,x_2) = \int F_{13}(x_1,x_3)F_{23}(x_2,x_3)\,d\mu_3(x_3)$ is bounded and Borel, and by Tonelli's theorem the integral to be bounded equals $\int F_{12}\,G\,d\mu_1 d\mu_2$. The Cauchy–Schwarz inequality for $\mu_1 \otimes \mu_2$ bounds this by $(\int F_{12}^2\,d\mu_1 d\mu_2)^{1/2}(\int G^2\,d\mu_1 d\mu_2)^{1/2}$. For fixed x_1,x_2 the same inequality for μ_3 gives $G(x_1,x_2)^2 \le (\int F_{13}(x_1,\cdot)^2\,d\mu_3)(\int F_{23}(x_2,\cdot)^2\,d\mu_3)$; integrating in x_1 and x_2 separates the two factors, and $\int G^2\,d\mu_1 d\mu_2 \le \int F_{13}^2\,d\mu_1 d\mu_3 \cdot \int F_{23}^2\,d\mu_2 d\mu_3$. □

Lemma 18.49 (Jensen's inequality and a bound for $\langle e^{2Y}\rangle$)**.** Let ν be a probability measure, $\langle\cdot\rangle$ the mean for ν, and Y a bounded real measurable function. (J) $\langle e^Y\rangle \ge e^{\langle Y\rangle}$. (V) If the values of Y lie in an interval of the length ω, then $\langle e^{2Y}\rangle \le e^{2\langle Y\rangle + \omega^2/2}$. ■

Proof. (J) Since $e^u \ge 1 + u$ for real u, averaging at $u = Y - \langle Y\rangle$ gives $\langle e^Y\rangle\, e^{-\langle Y\rangle} \ge 1$. (V) Let $\psi(\sigma) = \log\langle e^{\sigma Y}\rangle$ for real σ. As Y is bounded, one may differentiate under the average; ψ is twice continuously differentiable, $\psi(0) = 0$ and $\psi'(0) = \langle Y\rangle$. With $\langle\cdot\rangle_\sigma$ the average for the probability measure $e^{\sigma Y}\nu/\langle e^{\sigma Y}\rangle$, $\psi''(\sigma) = \langle Y^2\rangle_\sigma - \langle Y\rangle_\sigma^2 = \min_{c\in\mathbb{R}}\langle (Y-c)^2\rangle_\sigma$; choosing for c the centre of an interval of the length ω that holds the values of Y gives $\psi''(\sigma) \le \frac{\omega^2}{4}$. Taylor's formula at 0 with the remainder in Lagrange's form then yields $\psi(2) \le 2\psi'(0) + 2\sup\psi'' \le 2\langle Y\rangle + \frac{\omega^2}{2}$. □

Proof of Proposition 18.32. (a) The three numbers $u = (a\cdot b)^2$, $v = (b\cdot c)^2$, $z = (c\cdot a)^2$ lie in $[0,1]$, and $\mathsf{q}_\triangle^2 = uvz \le 1$. The value $\mathsf{q}_\triangle = -1$ forces $uvz = 1$, hence $u = v = z = 1$; then $b = \pm a$, so $x_1 - x_2$ is a multiple of $x_2 - x_3$, and x_1,x_2,x_3 are collinear. Collinear points give $\mathsf{q}_\triangle = -1$. Suppose $\mathsf{q} = \mathsf{q}_\triangle > 0$. From $u + v + z = 1 - 2\mathsf{q} \ge 0$ we get $\mathsf{q} \le \frac{1}{2}$, and as a geometric mean does not exceed the arithmetic mean of the same numbers, $\mathsf{q}^2 = uvz \le (\frac{u+v+z}{3})^3 = (\frac{1-2\mathsf{q}}{3})^3$, i.e. $27\mathsf{q}^2 \le (1-2\mathsf{q})^3$. The function $\mathsf{q} \mapsto 27\mathsf{q}^2 - (1-2\mathsf{q})^3$ is increasing on $(0,\frac{1}{2}]$ and vanishes at $\mathsf{q} = \frac{1}{8}$,

where $27\mathsf{q}^2 = (1-2\mathsf{q})^3 = \frac{27}{64}$; hence $\mathsf{q} \le \frac{1}{8}$. The bounds for $\tau_\triangle$ follow, $\tau_\triangle = -3 - 9\mathsf{q}_\triangle$ being a decreasing affine function of $\mathsf{q}_\triangle$ with the values 6 and $-\frac{33}{8}$ at $\mathsf{q}_\triangle = -1$ and at $\mathsf{q}_\triangle = \frac{1}{8}$.

(b) By the formula for k_2, $k_2(x_i,x_j)^{1/2} = \frac{\sqrt{3}}{4\pi} r_{ij}^{-3}$, so $\prod_{i<j} k_2(x_i,x_j)^{1/2} = 3\sqrt{3}\,(4\pi)^{-3}(r_{12}r_{13}r_{23})^{-3}$, while $k_3(x) = \tau_\triangle(x)(4\pi)^{-3}(r_{12}r_{13}r_{23})^{-3}$; the quotient is $\tau_\triangle(x)/(3\sqrt{3})$. Its square is $\tau_\triangle^2/27 = 9(1+3\mathsf{q}_\triangle)^2/27$.

(c) In the quotient of the kernels of the template the factors n and b give $\mathsf{n}^2\mathsf{b}^{-6}/(\mathsf{n}^3\mathsf{b}^{-6}) = \mathsf{n}^{-1}$; the rest is (b), with $(1-3)^2/3 = \frac{4}{3}$ at $\mathsf{q}_\triangle = -1$, and with $(\frac{11}{8})^2/3 = \frac{121}{192}$ and $\tau_\triangle = -\frac{33}{8} < 0$ at $\mathsf{q}_\triangle = \frac{1}{8}$. At $(0, e_3, 2e_3)$ the points lie on a line, so $\tau_\triangle = 6$, and $r_{12}r_{13}r_{23} = 1\cdot 2\cdot 1$. □

Proof of Proposition 18.33. (a) Put $\mu_i = f_i\,dx$, finite Borel measures, and define $F_{ij}(x,y) = k_2(x,y)^{1/2}$ when $x \in \operatorname{supp} f_i$ and $y \in \operatorname{supp} f_j$, and $F_{ij}(x,y) = 0$ otherwise; F_{ij} is bounded and Borel, since $|x-y|$ is at least the positive distance of the two supports wherever $F_{ij} \ne 0$, and $\int F_{ij}^2\,d\mu_i d\mu_j = \mathcal{K}^{(2)}_{\text{free}}(f_i,f_j)$. On $\prod_i \operatorname{supp} f_i$, Proposition 18.32(a), (b) give $|k_3| = \frac{|\tau_\triangle|}{3\sqrt{3}} \prod_{i<j} F_{ij}$ with $|\tau_\triangle| \le 6$, so that $|k_3| \le \frac{2}{\sqrt{3}} \prod_{i<j} F_{ij} = \sqrt{\frac{4}{3}} \prod_{i<j} F_{ij}$. Writing I for $\int F_{12}F_{13}F_{23}\,d\mu_1 d\mu_2 d\mu_3$ and using Lemma 18.48,

$$|\mathcal{K}^{(3)}_{\text{free}}(f)| \le \int |k_3|\,d\mu_1 d\mu_2 d\mu_3 \le \sqrt{\tfrac{4}{3}}\,\mathsf{I} \le \sqrt{\tfrac{4}{3}} \prod_{i<j} \Big(\int F_{ij}^2\,d\mu_i d\mu_j \Big)^{1/2} = \sqrt{\tfrac{4}{3}} \prod_{i<j} \mathcal{K}^{(2)}_{\text{free}}(f_i,f_j)^{1/2}.$$

(b) Let $G_i = \{f_i > 0\}$, an open set that is not empty. The integrand $k_2(x,y)f_i(x)f_j(y)$ of $\mathcal{K}^{(2)}_{\text{free}}(f_i,f_j)$ is non-negative, and continuous and positive on $G_i \times G_j$; so $\mathcal{K}^{(2)}_{\text{free}}(f_i,f_j) > 0$. Pick $x_1 \in G_1$ and $x_2 \in G_2$, and, as a non-empty open subset of $\mathbb{R}^3$ is contained in no line, a point $x_3 \in G_3$ outside the line through x_1 and x_2. These points are distinct, and Proposition 18.32(a) gives $-1 < \mathsf{q}_\triangle(x) \le \frac{1}{8}$, hence $|\tau_\triangle(x)| < 6$. By the continuity of $\mathsf{q}_\triangle$ on the distinct triples there is an open set $U \ni x$ inside $G_1 \times G_2 \times G_3$ on which $|\tau_\triangle| < 6$. The function $\sqrt{4/3}\prod_{i<j} F_{ij} - |k_3| = \frac{6-|\tau_\triangle|}{3\sqrt{3}} \prod_{i<j} F_{ij}$, non-negative on $\prod_i \operatorname{supp} f_i$, is positive on U, and U carries positive mass for $\mu_1 \otimes \mu_2 \otimes \mu_3$, the density $\prod_i f_i(x_i)$ being positive there; so $\int |k_3|\,d\mu_1 d\mu_2 d\mu_3 < \sqrt{4/3}\,\mathsf{I}$, and the inequality of (a) is strict.

(c) A triple of $\mathfrak{Q}^{(3)}_{\mathbb{R}^3}(\mathsf{d};\vartheta)$ consists of Lipschitz functions ≥ 0, none of them zero, whose supports are compact and at least d apart; on T_ℓ one passes to a lift in $\mathfrak{Q}^{(3)}_{\mathbb{R}^3}(\mathsf{d};\vartheta)$, at which $\mathcal{R}$ is formed. So (b) applies. □

Proof of Proposition 18.34. Since $\mathcal{K}^{(3)}_{\text{free}}$ and $\mathcal{R}$ of a triple on T_ℓ are their values at a lift, and a lift of a triple of the width class on T_ℓ lies in the width class on $\mathbb{R}^3$ (Definition 18.30(1), (2)), we may take $\mathbb{E} = \mathbb{R}^3$. Fix points c_i on a line $y + \mathbb{R}e$, $|e| = 1$, with $\operatorname{supp} f_i \subset \mathbb{B}(c_i, w\mathsf{d})$, put $m_i = \int f_i > 0$ and $\nu_i = m_i^{-1} f_i\,dx$, and write $\langle\cdot\rangle$ for averages with respect to $\nu_1 \otimes \nu_2 \otimes \nu_3$.

Step 1: distances. For $x_i \in \operatorname{supp} f_i$ and $x_j \in \operatorname{supp} f_j$, $r_{ij} = |x_i - x_j| \ge \mathsf{d}$, the supports being at least d apart. The difference $x_i - x_j$ is $c_i - c_j$ plus the vector $u_{ij} = (x_i - c_i) - (x_j - c_j)$, whose length is at most $2w\mathsf{d} \le 2w\,r_{ij}$; hence $|c_i - c_j|$ lies between $(1-2w)r_{ij}$ and $(1+2w)r_{ij}$, so that $|c_i - c_j| > 0$, and $\log r_{ij}$ ranges in the interval from $\log|c_i - c_j| - \log(1+2w)$ to $\log|c_i - c_j| - \log(1-2w)$, of the length $\varkappa_w$.

Step 2: directions. The vector $c_i - c_j$ is a multiple of e, so the part of $x_i - x_j$ perpendicular to e is the part of u_{ij} perpendicular to e, of a length at most $2w\,r_{ij}$. Dividing by r_{ij}: the unit vector along $x_i - x_j$ makes with $\mathbb{R}e$ an angle whose sine is at most $2w \le \frac{1}{8}$. Orient the three unit vectors toward e. Their projections on e are at least $\sqrt{1-4w^2}$ and their perpendicular components have norm at most $2w$. Thus each mutual dot product is at least $1 - 8w^2$. The trace identity gives $\tau_\triangle \ge -3 + 9(1-8w^2)^3 \ge 6 - 216w^2 \ge 6\,\mathsf{t}_w$. Also $\mathsf{t}_w \ge \mathsf{t}_{1/16} = 1 - \frac{90}{256} - \frac{72}{4096} > 0$, t_w decreasing in w.

Step 3: the bound. On $\operatorname{supp} f_i \times \operatorname{supp} f_j$ put $\lambda_{ij} = \log k_2(x_i,x_j)^{1/2} = \log\frac{\sqrt3}{4\pi} - 3\log r_{ij}$; by Step 1 it takes its values in an interval of the length $3\varkappa_w$. Proposition 18.32(b) writes $k_3 = \frac{\tau_\triangle}{3\sqrt3}\exp(\lambda_{12}+\lambda_{13}+\lambda_{23})$ on the product of the three supports; so by Step 2 and Lemma 18.49(J)

$$\mathcal{K}^{(3)}_{\text{free}}(f) = m_1m_2m_3\,\langle k_3\rangle \ge m_1m_2m_3\,\frac{6\,\mathsf{t}_w}{3\sqrt3}\,e^{\langle\lambda_{12}\rangle+\langle\lambda_{13}\rangle+\langle\lambda_{23}\rangle} > 0,$$

while Lemma 18.49(V), for $Y=\lambda_{ij}$ and $\omega = 3\varkappa_w$, gives

$$\mathcal{K}^{(2)}_{\text{free}}(f_i,f_j) = m_im_j\,\langle e^{2\lambda_{ij}}\rangle \le m_im_j\,e^{2\langle\lambda_{ij}\rangle+\frac92\varkappa_w^2}.$$

The numbers m_i enter $\mathcal{K}^{(3)}_{\text{free}}(f)^2$ and $\prod_{i<j}\mathcal{K}^{(2)}_{\text{free}}(f_i,f_j)$ through one and the same factor $(m_1m_2m_3)^2$, and the averages $\langle\lambda_{ij}\rangle$ through one and the same factor $\exp(2\sum_{i<j}\langle\lambda_{ij}\rangle)$; dividing, $\mathcal{R}(f) \ge \frac{36}{27}\,\mathsf{t}_w^2\exp(-3\cdot\frac92\varkappa_w^2) = \frac43\,\mathsf{t}_w^2\,e^{-\frac{27}{2}\varkappa_w^2}$.

Step 4: a polynomial lower bound. For $0\le x<1$ the series $\log\frac{1+x}{1-x} = 2\sum_{k\ge0}\frac{x^{2k+1}}{2k+1}$ is at most $2x\sum_{k\ge0}x^{2k} = \frac{2x}{1-x^2}$; with $x = 2w \le \frac18$ this gives $\varkappa_w \le \frac{4w}{1-1/64} = \frac{256}{63}w$, and $\frac{27}{2}(\frac{256}{63})^2 = \frac{884736}{3969} < 223$. Hence $e^{-\frac{27}{2}\varkappa_w^2} \ge e^{-223w^2} \ge 1-223w^2$, a positive number as $w^2 \le \frac{1}{256}$; also $\mathsf{t}_w^2 \ge 1-2(90w^2+72w^3) \ge 1-189w^2 > 0$, using $144w \le 9$. The product of these two positive lower bounds is at least $1-412w^2$. The upper bound $\mathcal{R}(f) < \frac43$ is Proposition 18.33(c), and $\frac43\cdot412 = \frac{1648}{3}$. □

Proof of Proposition 18.35. (a) Passing to a lift changes neither $\|f_1\|_\infty$ nor $\int f_1$. As f_1 vanishes off a ball of the radius $w\mathsf{d}$, $\int f_1 \le \frac{4\pi}{3}(w\mathsf{d})^3\|f_1\|_\infty$; together with $\int f_1 \ge \vartheta\|f_1\|_\infty\mathsf{d}^3$ and $\|f_1\|_\infty > 0$ this gives $\vartheta \le \frac{4\pi}{3}w^3$.

(b) The bump formula in the subsection on the scalar two-point function gives $u_j \in C^1$, $\operatorname{supp}u_j = \mathbb{B}(c_j,w\mathsf{d}) \subset \mathbb{B}(c_j,\mathsf{d})$, $\|u_j\|_\infty = 1$, $\int u_j = \frac{32\pi}{105}w^3\mathsf{d}^3 \ge \vartheta\mathsf{d}^3$ and $\operatorname{Lip}u_j = \frac{8}{3\sqrt3\,w\mathsf{d}}$; the last number is at most $\frac{1}{\vartheta\mathsf{d}}$, as $\vartheta \le \frac{32\pi}{105}w^3 \le \frac{32\pi}{105\cdot256}w < \frac{3\sqrt3}{8}w$. If the centres of two balls of the radius $w\mathsf{d}$ are $D > 2w\mathsf{d}$ apart, the balls themselves are $D-2w\mathsf{d}$ apart; here $D = 2\mathsf{d}$ or $D = 4\mathsf{d}$, so the supports are between $\frac{15}{8}\mathsf{d}$ and $4\mathsf{d}$ apart, inside $[\mathsf{d},6\mathsf{d}]$. Hence each pair (u_i,u_j) is a test pair with the centres c_i,c_j, the triple belongs to $\mathfrak{Q}^{(3)}_{\mathbb{R}^3}(\mathsf{d};\vartheta)$, and, the centres being on $\mathbb{R}e$, to $\mathfrak{T}^{\text{col}}_{\mathbb{R}^3}(\mathsf{d};\vartheta;w)$. On T_ℓ, by the lifting argument above, the periodisations form a triple of $\mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$ having (u_1,u_2,u_3) as a lift.

(c) The dilations $\Psi\mapsto\Psi_{\mathsf{d}}$ and $\Psi\mapsto\Psi_{1/\mathsf{d}}$ are mutually inverse maps between the classes on $\mathbb{R}^3$ at the scale 1 and at the scale d, both for $\mathfrak{Q}^{(3)}$ and for $\mathfrak{T}^{(3),\text{col}}$, and they leave $\mathcal{K}^{(3)}_{\text{free}}$ and $\mathcal{K}^{(2)}_{\text{free}}$, hence $\mathcal{R}$, unchanged. On T_ℓ with $36\mathsf{d} < \ell$, every triple of a torus class has a lift in the matching class on $\mathbb{R}^3$ with the same value of $\mathcal{R}$; conversely, the periodisations of a triple of a class on $\mathbb{R}^3$ form a triple of the matching torus class that has the given triple as a lift. So on both spaces and at every scale the suprema equal those on $\mathbb{R}^3$ at the scale 1. When ϑ decreases the classes can only become larger by the test inequalities, the requirement $\operatorname{supp}f_i \subset \mathbb{B}(c_i,\mathsf{d}/16)$ being free of ϑ; so the suprema are non-increasing in ϑ. Proposition 18.33(c) gives the upper bound $\frac43$. For the lower bound note that $\frac{\pi}{13440} = \frac{32\pi}{105}16^{-3}$; so $w_\vartheta \le \frac{1}{16}$ and $\vartheta = \frac{32\pi}{105}w_\vartheta^3$, by (b) the width class $\mathfrak{T}^{\text{col}}_{\mathbb{R}^3}(1;\vartheta;w_\vartheta)$ has elements, it is contained in $\mathfrak{T}^{(3),\text{col}}_{\mathbb{R}^3}(1;\vartheta) \subset \mathfrak{Q}^{(3)}_{\mathbb{R}^3}(1;\vartheta)$, and on it $\mathcal{R} \ge \frac43(1-412w_\vartheta^2)$ by Proposition 18.34. Since $w_\vartheta \to 0$ as $\vartheta\to0$, both suprema tend to $\frac43$. □

Proof of Proposition 18.36. The argument of Proposition 18.35(b) at the scale 1, with the centres c_j, gives the membership: $\operatorname{supp}u_j = \mathbb{B}(c_j,w) \subset \mathbb{B}(c_j,1)$, and two supports are $|c_i-c_j|-2w$ apart, a number in $[1,6]$ as $\frac98-\frac18 = 1$. After normalisation, $\nu_j^w = u_j\,dx/\int u_j$ is a probability measure carried by $\mathbb{B}(c_j,w)$, and $\mathcal{K}^{(3)}_{\text{free}}(\Psi^{c,w})/\prod_j\int u_j = \int k_3\,d\nu_1^w d\nu_2^w d\nu_3^w$. Its distance from $k_3(c)$ is bounded by the oscillation $\sup\{|k_3(x)-k_3(c)| : |x_j-c_j| \le w \text{ for } j=1,2,3\}$, which goes to 0 with w because k_3 is continuous at the triple c of distinct points; likewise $\mathcal{K}^{(2)}_{\text{free}}(u_i,u_j)/(\int u_i\int u_j) \to k_2(c_i,c_j) > 0$.

In $\mathcal{R}(\Psi^{c,w})$ the factors $\int u_j$ drop out, so it tends to $k_3(c)^2/\prod_{i<j}k_2(c_i,c_j)$, which is $\frac{1}{3}(1+3\mathsf{q}_\triangle(c))^2$ by Proposition 18.32(b). □

Proof of Proposition 18.37. Fix $\vartheta\in(0,\frac{\pi}{13440}]$.

Step 1: an auxiliary family. Let $\mathcal{C}_\vartheta$ consist of the triples $h=(h_1,h_2,h_3)$ of functions from $\mathbb{R}^3$ to $[0,1]$ for which one can find $x_1=0$ and points $x_2,x_3\in\mathbb{B}(0,8)$ with: (i) $\sup h_i=1$; (ii) $|h_i(x)-h_i(y)|\le|x-y|/\vartheta$ for all x,y; (iii) $h_i(x)=0$ whenever $|x-x_i|>1$; (iv) for $i\ne j$, $h_i(x)h_j(y)>0$ implies $|x-y|\ge1$. Every such h_i is continuous, non-negative, not the zero function and zero outside $\mathbb{B}(0,9)$, and by (iv) two of the supports, the closures of the sets where the functions are positive, are at least 1 apart; so $\mathcal{R}(h)$ is formed and $\mathcal{R}(h)<\frac{4}{3}$ (Proposition 18.33(b)).

Step 2: reduction to the family. Take $f\in\mathfrak{Q}^{(3)}_{\mathbb{R}^3}(1;\vartheta)$ and points x_i with $\operatorname{supp}f_i\subset\mathbb{B}(x_i,1)$. Any two of these points serve as centres of a test pair, so $|x_i-x_j|\le8$. Multiplying each f_i by some $c_i>0$ multiplies both $\mathcal{K}^{(3)}_{\mathrm{free}}(f)^2$ and $\prod_{i<j}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j)$ by $(c_1c_2c_3)^2$, and a common translation of the three functions changes neither; so $\mathcal{R}$ takes the same value at f and at $h=(f_i(\cdot+x_1)/\|f_i\|_\infty)_{i=1,2,3}$. This h belongs to $\mathcal{C}_\vartheta$ with the points x_i-x_1: (i) and (iii) are immediate, (ii) is the Lipschitz condition of a test pair at the scale 1, on which the normalisation has no effect, and (iv) restates that the supports of f_i and f_j are at least 1 apart. Hence $\bar{\mathcal{R}}(\vartheta)\le R^*:=\sup_{\mathcal{C}_\vartheta}\mathcal{R}$.

Step 3: a maximising triple. Choose $h^{(k)}\in\mathcal{C}_\vartheta$, with points $x_i^{(k)}$, such that $\mathcal{R}(h^{(k)})\to R^*$. On the compact ball $\mathbb{B}(0,9)$ the functions $h_i^{(k)}$ are bounded by 1 and ϑ^{-1}-Lipschitz, so by the Arzelà–Ascoli theorem a subsequence converges uniformly on that ball, hence on $\mathbb{R}^3$, as all of them vanish outside it; after a further subsequence, $x_i^{(k)}\to x_i$, where $x_1=0$ and $|x_i|\le8$. Call the limit h. It lies in $\mathcal{C}_\vartheta$: its values are in $[0,1]$; $\sup h_i=\lim_k\sup h_i^{(k)}=1$ by the uniform convergence; the bound (ii) passes to pointwise limits; a point y with $|y-x_i|>1$ has $|y-x_i^{(k)}|>1$ for all large k, so $h_i(y)=0$; and $h_i(x)h_j(y)>0$ with $i\ne j$ gives $h_i^{(k)}(x)h_j^{(k)}(y)>0$ for all large k, hence $|x-y|\ge1$.

Step 4: passage to the limit in $\mathcal{R}$. Define $\tilde k_3(x)=k_3(x)$ if $r_{12},r_{13},r_{23}\ge1$ and $\tilde k_3(x)=0$ otherwise, and $\tilde k_2(x,y)=k_2(x,y)$ if $|x-y|\ge1$ and $\tilde k_2(x,y)=0$ otherwise; these Borel functions satisfy $|\tilde k_3|\le6(4\pi)^{-3}$, by Proposition 18.32(a), (b), and $0\le\tilde k_2\le\frac{3}{16\pi^2}$. For $h\in\mathcal{C}_\vartheta$ property (iv) allows one to replace k_3 and k_2 by $\tilde k_3$ and $\tilde k_2$ in $\mathcal{K}^{(3)}_{\mathrm{free}}(h)$ and $\mathcal{K}^{(2)}_{\mathrm{free}}(h_i,h_j)$, and to integrate over $\mathbb{B}(0,9)^3$ and $\mathbb{B}(0,9)^2$ only. As $|\alpha_1\alpha_2\alpha_3-\alpha_1'\alpha_2'\alpha_3'|\le\sum_i|\alpha_i-\alpha_i'|$ for numbers in $[0,1]$, we get, with $V=\frac{4\pi}{3}9^3$, $|\mathcal{K}^{(3)}_{\mathrm{free}}(h^{(k)})-\mathcal{K}^{(3)}_{\mathrm{free}}(h)|\le6(4\pi)^{-3}V^3\sum_i\|h_i^{(k)}-h_i\|_\infty\to0$ and $|\mathcal{K}^{(2)}_{\mathrm{free}}(h_i^{(k)},h_j^{(k)})-\mathcal{K}^{(2)}_{\mathrm{free}}(h_i,h_j)|\le\frac{3}{16\pi^2}V^2(\|h_i^{(k)}-h_i\|_\infty+\|h_j^{(k)}-h_j\|_\infty)\to0$. The numbers $\mathcal{K}^{(2)}_{\mathrm{free}}(h_i,h_j)$ are positive (Proposition 18.33(b)); hence $\mathcal{R}(h^{(k)})\to\mathcal{R}(h)$, so $R^*=\mathcal{R}(h)<\frac{4}{3}$ by Step 1, and with Step 2, $\bar{\mathcal{R}}^{\mathrm{col}}(\vartheta)\le\bar{\mathcal{R}}(\vartheta)<\frac{4}{3}$.

The consequence. Suppose that ϑ_k does not tend to 0. Then some $\vartheta_0\in(0,\frac{\pi}{13440}]$ satisfies $\vartheta_k\ge\vartheta_0$ for infinitely many k. For each such k, by the test inequalities, $f^{(k)}$ lies in $\mathfrak{Q}^{(3)}_{\mathbb{E}_k}(\mathsf{d}_k;\vartheta_0)$ as well, and Proposition 18.35(c) gives $\mathcal{R}(f^{(k)})\le\bar{\mathcal{R}}(\vartheta_0)$, a number below $\frac{4}{3}$; so $\mathcal{R}(f^{(k)})$ does not tend to $\frac{4}{3}$. □

Lemma 18.50 (The ratio near the free one)**.** Let $\mathbb{E}=\mathbb{R}^3$, or $\mathbb{E}=T_\ell$ with $36\mathsf{d}<\ell$, let $f\in\mathfrak{Q}^{(3)}_{\mathbb{E}}(\mathsf{d};\vartheta)$, let $\mathsf{n}>0$, $\mathsf{b}>0$, $t\ge0$ and $0\le e\le\frac{1}{3}$ be real numbers, and let y_3 and y_{ij}, $i<j$, be real numbers with

$$|y_3-\mathsf{n}\,\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f)|\le t\,\mathsf{n}\,\mathsf{b}^{-3}\,\mathsf{N}(f),\qquad |y_{ij}-\mathsf{n}\,\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j)|\le e\,\mathsf{n}\,\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j).$$

Then $y_{ij}>0$, and $\bigl|\mathsf{n}\,y_3^2/(y_{12}y_{13}y_{23})-\mathcal{R}(f)\bigr|\le\Theta_{\mathrm{Q}}(\vartheta;t,e)$. ■

Proof. Set $\kappa=\mathcal{K}^{(3)}_{\mathrm{free}}(f)/\mathsf{N}(f)$ and $P=\prod_{i<j}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j)/\mathsf{N}(f)^2$; each $\|f_a\|_\infty$ occurs in two of the three pairs, so $\mathcal{R}(f)=\kappa^2/P$. The hypotheses say that $y_3=\mathsf{n}\mathsf{b}^{-3}\mathsf{N}(f)(\kappa+\delta)$ with $|\delta|\le t$ and $y_{ij}=\mathsf{n}\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j)(1+e_{ij})$ with $|e_{ij}|\le e<1$; so $y_{ij}>0$, as $\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j)>0$. With

$\Pi = \prod_{i<j}(1+e_{ij})$,

$$\mathsf{n}\,\frac{y_3^2}{y_{12}y_{13}y_{23}} = \frac{\mathsf{n}^3\mathsf{b}^{-6}\mathsf{N}(f)^2(\kappa+\delta)^2}{\mathsf{n}^3\mathsf{b}^{-6}\mathsf{N}(f)^2 P\,\Pi} = \frac{(\kappa+\delta)^2}{P\,\Pi}, \qquad \frac{(\kappa+\delta)^2}{P\,\Pi} - \frac{\kappa^2}{P} = \frac{\delta\,(2\kappa+\delta)}{P\,\Pi} + \mathcal{R}(f)\,\frac{1-\Pi}{\Pi}.$$

We bound the pieces. $|\kappa| \le \frac{4}{9}$ gives $|\delta(2\kappa+\delta)| \le \frac{8}{9}t + t^2$; $\Pi \ge (1-e)^3 \ge \frac{8}{27}$; the lower bound for $\mathcal{K}^{(2)}_{\mathrm{free}}$ at the test pairs gives $P \ge (\frac{3}{16\pi^2}10^{-6}\vartheta^2)^3 = \vartheta^6/\mathsf{C}_{\mathrm{P}}$; Π lies between $(1-e)^3$ and $(1+e)^3$, and $(1+e)^3 + (1-e)^3 = 2+6e^2 \ge 2$ shows $1-(1-e)^3 \le (1+e)^3 - 1$, so that $|1-\Pi| \le (1+e)^3 - 1 = e(3+3e+e^2) \le \frac{37}{9}e$ for $e \le \frac{1}{3}$; finally $\mathcal{R}(f) \le \frac{4}{3}$ by Proposition 18.33(c). Adding up, $|\mathsf{n}\,y_3^2/(y_{12}y_{13}y_{23}) - \mathcal{R}(f)| \le \frac{27}{8}\mathsf{C}_{\mathrm{P}}\vartheta^{-6}(\frac{8}{9}t+t^2) + \frac{4}{3}\cdot\frac{27}{8}\cdot\frac{37}{9}\,e$, and the last coefficient equals $\frac{37}{2}$. □

Lemma 18.51 (From any side and any label to a reference coupling)**.** Let $m \in \mathbb{N}$, $\mathsf{b} > 0$ and $\gamma_* \in (0,\gamma]$, and for an integer $s \ge 0$ put $g_s = (\frac{1}{2}L^s\mathsf{b})^{-1/2}$. There is an integer $s_0 \ge 0$ such that for every integer $s \ge s_0$: $g_s \le \gamma_*$, $L^s\mathsf{b} \in I(g_s)$ and $2L^{m+s} \in \mathfrak{L}(g_s)$; and for such s the pairs $(K, L^{K+s}\mathsf{b})$, $K \in \mathbb{N}$, are first-passage data at g_s with the label $L^s\mathsf{b}$. ■

Proof. Since $g_s^{-2} = \frac{1}{2}L^s\mathsf{b}$ grows without bound, both $g_s \le \gamma_*$ and $g_s^{-2} > \bar{B}$ are true for all large s. Write $\mathsf{b}' = L^s\mathsf{b}$, so that $\mathsf{b}' = 2g_s^{-2}$. *Membership in $I(g_s)$.* On the left, $g_s^{-2} + \bar{B} < 2g_s^{-2} = \mathsf{b}'$ because $g_s^{-2} > \bar{B}$. On the right, $X_{g_s} - \bar{B} = Lg_s^{-2} + LB_\sharp - \bar{B} = Lg_s^{-2} + (L-2)\bar{B}$ by $LB_\sharp = (L-1)\bar{B}$, and this equals $\frac{L}{2}\mathsf{b}' + (L-2)\bar{B} \ge \mathsf{b}'$. *The side.* $\mathfrak{L}(g_s)$ is defined, as $g_s \le \gamma \le \frac{1}{2}$. Put $x_s = L(g_s^{-2} + \bar{B})$; then $x_s \ge 4L > e$, so $(\log x_s)^r > 1$, and $R(x_s) = L^{\mathsf{u}}$ with an integer $\mathsf{u} \ge 1$ for which $L^{\mathsf{u}-1} < (\log x_s)^r$; thus $R(x_s) < L(\log x_s)^r$. From $x_s \le L^{s+1}(\mathsf{b}+\bar{B})$ we get $\log x_s \le (s+1)\log L + |\log(\mathsf{b}+\bar{B})|$, whence $L^{m_{\mathfrak{L}}(g_s)} = LM\max\{R(x_s), L^{\lceil \log_L C_{\mathrm{s}}\rceil}\} \le L^2M\,[(s+1)\log L + |\log(\mathsf{b}+\bar{B})|]^r + LM\,L^{\lceil\log_L C_{\mathrm{s}}\rceil}$. This bound grows polynomially in s and L^{m+s} exponentially, so $m+s \ge m_{\mathfrak{L}}(g_s)$, that is $2L^{m+s} \in \mathfrak{L}(g_s)$, for all large s. The statement on the pairs $(K, L^K\mathsf{b}')$ is the property of the points of $I(g_s)$ recalled in the setting, at the coupling $g_s \le \gamma$. □

Lemma 18.52 (Dilating a triple of a torus by L^s)**.** Let $\ell = 2L^m$, $m \in \mathbb{N}$, $s \ge 0$ an integer, $\mathsf{d} > 0$ with $36\mathsf{d} < \ell$, $\vartheta \in (0,1)$ and $f \in \mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$, and let $f^{(s)} = (f_1^{(s)}, f_2^{(s)}, f_3^{(s)})$. Then $f^{(s)} \in \mathfrak{Q}^{(3)}_{T_{L^s\ell}}(L^s\mathsf{d};\vartheta)$; $\|f_a^{(s)}\|_\infty = \|f_a\|_\infty$; $\mathcal{K}^{(3)}_{\mathrm{free}}(f^{(s)}) = \mathcal{K}^{(3)}_{\mathrm{free}}(f)$, $\mathcal{K}^{(2)}_{\mathrm{free}}(f_i^{(s)}, f_j^{(s)}) = \mathcal{K}^{(2)}_{\mathrm{free}}(f_i, f_j)$ and $\mathcal{R}(f^{(s)}) = \mathcal{R}(f)$; if $f \in \mathfrak{T}^{\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta;w)$, then $f^{(s)} \in \mathfrak{T}^{\mathrm{col}}_{T_{L^s\ell}}(L^s\mathsf{d};\vartheta;w)$; and for every $\mathsf{b} > 0$, $S_n^{(\ell,\mathsf{b})} = L^{sn}S_n^{(L^s\ell, L^s\mathsf{b})}$ at the triple and at its pairs and their dilates ($n = 3, 2$), so that $Q^{(\ell,\mathsf{b})}(f) = Q^{(L^s\ell, L^s\mathsf{b})}(f^{(s)})$ whenever one of the two is formed. ■

Proof. The map $x \mapsto L^s x$ from T_ℓ onto $T_{L^s\ell}$ multiplies distances by L^s. It preserves the supremum of every transformed test $f^{(s)}$, multiplies its integral by L^{3s} and divides its Lipschitz constant by L^s. Therefore the image triple is in the test class at scale $L^s\mathsf{d}$. If $\hat{f}$ is a common lift inside a ball of radius $\rho < \ell/4$, the lifted transformed triple in the dilated ball is $(\hat{f})_{L^s}$, since the covering maps commute with $x \mapsto L^s x$. Thus both free forms are invariant by homogeneity. The centers of narrow collinear supports are carried to collinear centers, and their widths multiply by L^s just as the scale does. The identity for the limits is YM3_I:(2215), and in the quotient Q the powers of L cancel, as $(L^{3s})^2 = (L^{2s})^3$. □

Proof of Proposition 18.38. (a) $\mathsf{b} \ge g^{-2} > 0$, as recalled in the setting. Let $0 < \mathsf{d} \le \mathsf{d}_0(g,\vartheta)$ and $(f,h) \in \mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$. Both supports lie in one ball of the radius $5\mathsf{d} \le \frac{1}{40} < \frac{\ell}{4}$; so $\mathcal{K}^{(2)}_{\mathrm{free}}(f,h)$ is formed on T_ℓ, and $\mathsf{c}_2\mathcal{K}_{\mathrm{free}}(f,h) = 3\mathcal{K}^{(2)}_{\mathrm{free}}(f,h)$. The witness depth $s(\mathsf{d})$ is one integer, in which no cutoff enters, so $s(\mathsf{d}) < K_j$ once j is large. For such j, Theorem YM3_I:AV gives $|S^T_{2;K_j,\ell,\beta_j}(f,h) - 3\mathsf{b}_j^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}(f,h)| \le \bar{\varepsilon}_{g,\vartheta}(\mathsf{d})\,3\mathsf{b}_j^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}(f,h)$, where $\mathsf{b}_j = a_{K_j}\beta_j$. As $j \to \infty$, YM3_I:(2216), applicable as f, h are real, Lipschitz, not 0 and have disjoint supports, gives $S^T_{2;K_j,\ell,\beta_j}(f,h) \to S_2^{(\ell,\mathsf{b})}(f,h)$, and $\mathsf{b}_j^{-2} \to \mathsf{b}^{-2}$; a

non-strict inequality between convergent sequences persists for the limits. For $\mathsf{b} \in I(g)$ take $K_j = j$ and $\beta_j = L^j\mathsf{b}$.

(b) Take for s the smallest s_0 allowed by Lemma 18.51 at $(m, \mathsf{b}, \gamma_* = \gamma_W)$; then $g' = g_s$, $\ell' = L^s\ell \in \mathfrak{L}(g')$ and $\mathsf{b}' = L^s\mathsf{b} \in I(g')$. Put $\mathsf{d}_{\mathrm{II}} = L^{-s}\mathsf{d}_0(g', \vartheta)$ and $\epsilon_{\mathrm{II}}(\mathsf{d}) = \bar\varepsilon_{g',\vartheta}(L^s\mathsf{d})$; these have the properties stated, by YM3_I:(2349). For $0 < \mathsf{d} \le \mathsf{d}_{\mathrm{II}}$ and $(f, h) \in \mathfrak{T}_{T_\ell}(\mathsf{d}; \vartheta)$, the same dilation gives $(f^{(s)}, h^{(s)}) \in \mathfrak{T}_{T_{\ell'}}(L^s\mathsf{d}; \vartheta)$ with $\mathcal{K}^{(2)}_{\mathrm{free}}(f^{(s)}, h^{(s)}) = \mathcal{K}^{(2)}_{\mathrm{free}}(f, h)$. By YM3_I:(2215) and by (a) on $T_{\ell'}$ at the label b', which is the label of the first-passage data $(K, L^K\mathsf{b}')$ at g',

$$S_2^{(\ell,\mathsf{b})}(f, h) = L^{2s} S_2^{(\ell',\mathsf{b}')}(f^{(s)}, h^{(s)}) = L^{2s}\, 3\,(L^s\mathsf{b})^{-2}\,\mathcal{K}^{(2)}_{\mathrm{free}}(f, h)\,(1 + \eta) = 3\,\mathsf{b}^{-2}\,\mathcal{K}^{(2)}_{\mathrm{free}}(f, h)\,(1 + \eta), \qquad |\eta| \le \bar\varepsilon_{g',\vartheta}(L^s\mathsf{d}).$$

(c) $|\eta| \le \frac{1}{3}$, and $\mathcal{K}^{(2)}_{\mathrm{free}}(f, h) > 0$ at a test pair. □

Proof of Proposition 18.39. (a) $36\mathsf{d} \le \frac{36}{200} < \ell$, so the class is formed, and every pair (f_i, f_j) of the triple lies in $\mathfrak{T}_{T_\ell}(\mathsf{d}; \vartheta)$. The hypotheses of Theorem YM3_I:AV hold ($g \le \gamma_W$, $\mathsf{d} \le \mathsf{d}_0(g, \vartheta)$, $s(\mathsf{d}) < K$); with $\mathsf{c}_2\mathcal{K}_{\mathrm{free}} = 3\mathcal{K}^{(2)}_{\mathrm{free}}$, its torus estimate says that $y_{ij} = S^T_{2;K,\ell,\beta}(f_i, f_j)$ satisfies the second hypothesis of Lemma 18.50 with $\mathsf{n} = 3$ and $e = \bar\varepsilon_{g,\vartheta}(\mathsf{d}) \le \frac{1}{3}$. By $\mathrm{UL}_3(g, \ell)$ ($\mathsf{d} \le \mathsf{d}_{\mathrm{III}}$, $K \ge K_{\mathrm{III}}(\mathsf{d})$), $y_3 = S^T_{3;K,\ell,\beta}(f)$ satisfies the first with $\mathsf{n} = 3$ and $t = \frac{1}{3}[\epsilon_{\mathrm{III}}(\mathsf{d}) + C_{\mathrm{III}}\frac{a_K}{\vartheta\mathsf{d}}]$, since the bound in Definition 18.31 equals $t \cdot 3\,\mathsf{b}^{-3}\mathsf{N}(f)$. Lemma 18.50 now gives the claim. The bound contains ϵ_{III} and C_{III}, which depend on the setting, g, ℓ and ϑ, the tolerance $\bar\varepsilon_{g,\vartheta}$, and d and a_K; nothing else enters.

(b) For $j \ge j_1$, $K_j > s(\mathsf{d})$ and $K_j \ge K_{\mathrm{III}}(\mathsf{d})$. By YM3_I:(2216) at $n = 3$ and at $n = 2$, the entries of f being real Lipschitz functions, none of them 0, with pairwise disjoint supports, $S^T_{3;K_j,\ell,\beta_j}(f) \to S_3^{(\ell,\mathsf{b})}(f)$ and $S^T_{2;K_j,\ell,\beta_j}(f_i, f_j) \to S_2^{(\ell,\mathsf{b})}(f_i, f_j)$, and the latter limits are positive by Proposition 18.38(a), (c); hence $Q_{K_j,\ell,\beta_j}(f) \to Q^{(\ell,\mathsf{b})}(f)$. In the inequality of Definition 18.31 at (K_j, β_j) let $j \to \infty$: $a_{K_j} \to 0$ and $a_{K_j}\beta_j \to \mathsf{b}$, which gives the first display. With it and Proposition 18.38(a), Lemma 18.50 at $\mathsf{n} = 3$, $t = \frac{1}{3}\epsilon_{\mathrm{III}}(\mathsf{d})$, $e = \bar\varepsilon_{g,\vartheta}(\mathsf{d})$, $y_3 = S_3^{(\ell,\mathsf{b})}(f)$ and $y_{ij} = S_2^{(\ell,\mathsf{b})}(f_i, f_j)$ gives the second. For fixed ϑ the function $\Theta_{\mathrm{Q}}(\vartheta; t, e)$ is continuous in (t, e) and vanishes at $(0, 0)$. □

Proof of Proposition 18.40. (a) For $36r < \ell$, $\Psi_r \in \mathfrak{Q}^{(3)}_{\mathbb{R}^3}(r; \vartheta)$, and $\Psi_r^{\langle\ell\rangle} \in \mathfrak{Q}^{(3)}_{T_\ell}(r; \vartheta)$ has the lift Ψ_r; so $\mathcal{R}(\Psi_r^{\langle\ell\rangle}) = \mathcal{R}(\Psi_r) = \mathcal{R}(\Psi)$. Proposition 18.39(b) at $\mathsf{d} = r$ gives $|3Q^{(\ell,\mathsf{b})}(\Psi_r^{\langle\ell\rangle}) - \mathcal{R}(\Psi)| \le \Theta_{\mathrm{Q}}(\vartheta; \frac{1}{3}\epsilon_{\mathrm{III}}(r), \bar\varepsilon_{g,\vartheta}(r)) \to 0$ as $r \to 0$; and $\mathcal{R}(\Psi) < \frac{4}{3}$ by Proposition 18.33(c).

(b) $|Q - \frac{4}{9}| \le \frac{1}{3}|3Q - \mathcal{R}(f)| + \frac{1}{3}|\mathcal{R}(f) - \frac{4}{3}|$; the first term is bounded by Proposition 18.39(b), and by Proposition 18.34 the second is at most $\frac{1}{3} \cdot \frac{1648}{3}w^2 = \frac{1648}{9}w^2 < 184\,w^2$. For the display fix w and $\vartheta = \vartheta(w)$; by Proposition 18.35(b) the classes $\mathfrak{T}^{\mathrm{col}}_{T_\ell}(\mathsf{d}; \vartheta(w); w)$ with $36\mathsf{d} < \ell$ are not empty. For $\mathsf{d} \le \min\{\mathsf{d}_0(g, \vartheta(w)), \mathsf{d}_{\mathrm{III}}\}$, with $\mathsf{d}_{\mathrm{III}}$ at $\vartheta(w)$, Proposition 18.39(b) gives $\limsup_j |Q_{K_j,\ell,\beta_j}(f) - \frac{4}{9}| = |Q^{(\ell,\mathsf{b})}(f) - \frac{4}{9}|$ for every f of the class; so the supremum over the class is at most $184w^2 + \frac{1}{3}\Theta_{\mathrm{Q}}(\vartheta(w); \frac{1}{3}\epsilon_{\mathrm{III}}(\mathsf{d}), \bar\varepsilon_{g,\vartheta(w)}(\mathsf{d}))$, its upper limit as $\mathsf{d} \to 0$ is at most $184w^2$, and $184w^2 \to 0$ as $w \to 0$. Finally $\vartheta(w) \le \frac{32\pi}{105}w^3 \to 0$.

(c) For real-valued bounded F, G defined on the same non-empty set, $|\sup F - \sup G| \le \sup|F - G|$. On the class, which is not empty (Proposition 18.35(b)), take $F = Q^{(\ell,\mathsf{b})}$ and $G = \frac{1}{3}\mathcal{R}$, both bounded by Propositions 18.33(c) and 18.39(b); so the difference of the two suprema is at most $\frac{1}{3}\Theta_{\mathrm{Q}}(\vartheta; \frac{1}{3}\epsilon_{\mathrm{III}}(\mathsf{d}), \bar\varepsilon_{g,\vartheta}(\mathsf{d}))$, a number that goes to 0 as $\mathsf{d} \to 0$. The suprema of $\mathcal{R}$ over the two torus classes are $\bar{\mathcal{R}}^{\mathrm{col}}(\vartheta)$ and $\bar{\mathcal{R}}(\vartheta)$ at every d, with the lower bound, the monotonicity and the limit of Proposition 18.35(c); and they are $< \frac{4}{3}$ by Proposition 18.37. □

Proof of Proposition 18.41. (a) By the first display of Proposition 18.39(b) and the lower bound $\mathcal{K}^{(3)}_{\mathrm{free}}(f) \ge c_3^{\mathrm{col}}\vartheta^3\mathsf{N}(f)$ on the collinear class, $S_3^{(\ell,\mathsf{b})}(f) \ge 3\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f) - \epsilon_{\mathrm{III}}(\mathsf{d})\mathsf{b}^{-3}\mathsf{N}(f) \ge (3c_3^{\mathrm{col}}\vartheta^3 - \epsilon_{\mathrm{III}}(\mathsf{d}))\mathsf{b}^{-3}\mathsf{N}(f)$.

(b) Fix $w \in (0, \frac{1}{16}]$ and $\vartheta_w = \frac{32\pi}{105} w^3$. By Proposition 18.36, $\Psi^{c,w} \in \mathfrak{Q}^{(3)}_{\mathbb{R}^3}(1; \vartheta_w)$, and Proposition 18.40(a) at ϑ_w gives $\lim_{r\to 0} Q^{(\ell,\mathsf{b})}((\Psi^{c,w})^{\langle\ell\rangle}_r) = \frac{1}{3}\mathcal{R}(\Psi^{c,w})$; as $w \to 0$ this tends to $\frac{1}{9}(1+3\mathsf{q}_\triangle(c))^2$ by Proposition 18.36. *The sign.* By Proposition 18.36, $\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi^{c,w})/\prod_j \int u_j \to k_3(c)$, whose sign, by Proposition 18.32(b), is that of $\tau_\triangle(c) = -3(1+3\mathsf{q}_\triangle(c)) \neq 0$; so for all w up to some $w_0 > 0$ the number $\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi^{c,w})$ is non-zero with that sign. By homogeneity and the lift, it is the value of $\mathcal{K}^{(3)}_{\mathrm{free}}$ at $(\Psi^{c,w})^{\langle\ell\rangle}_r$, where $\mathsf{N} = 1$, the u_j having the sup norm 1. By Proposition 18.39(b) at ϑ_w and $\mathsf{d} = r$, $|S^{(\ell,\mathsf{b})}_3((\Psi^{c,w})^{\langle\ell\rangle}_r) - 3\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi^{c,w})| \le \epsilon_{\mathrm{III}}(r)\mathsf{b}^{-3}$, which is $< 3\mathsf{b}^{-3}|\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi^{c,w})|$ for all small r. On a line $\mathsf{q}_\triangle = -1$ and $-(1+3\mathsf{q}_\triangle) = 2 > 0$; at the corners of an equilateral triangle with a side in $[\frac{9}{8}, 6]$, $\mathsf{q}_\triangle = \frac{1}{8}$, $-(1+3\mathsf{q}_\triangle) < 0$, and $\frac{1}{9}(\frac{11}{8})^2 = \frac{121}{576}$. □

Proof of Proposition 18.42. Take for s the smallest s_0 allowed by Lemma 18.51 at $(m, \mathsf{b}, \gamma_* = \min\{\gamma_W, \gamma_{\mathrm{III}}\})$, and let $g' = g_s$, $\ell' = L^s\ell \in \mathfrak{L}(g')$ and $\mathsf{b}' = L^s\mathsf{b} \in I(g')$. By UL^*_3, $\mathrm{UL}_3(g', \ell')$ holds; let $\mathsf{d}'_{\mathrm{III}}$, ϵ'_{III} be its numbers at ϑ. The pairs $(K, L^K\mathsf{b}')$, $K \in \mathbb{N}$, are first-passage data at g' with the label b'. Put $\mathsf{d}_\sharp = L^{-s}\min\{\mathsf{d}_0(g', \vartheta), \mathsf{d}'_{\mathrm{III}}\}$, $\epsilon_\sharp(\mathsf{d}) = \epsilon'_{\mathrm{III}}(L^s\mathsf{d})$ and $e_\sharp(\mathsf{d}) = \bar\varepsilon_{g',\vartheta}(L^s\mathsf{d})$. For $0 < \mathsf{d} \le \mathsf{d}_\sharp$ and $f \in \mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d}; \vartheta)$, Lemma 18.52 gives $f^{(s)} \in \mathfrak{Q}^{(3)}_{T_{\ell'}}(L^s\mathsf{d}; \vartheta)$ with the same sup norms, the same values of $\mathcal{K}^{(3)}_{\mathrm{free}}$, $\mathcal{K}^{(2)}_{\mathrm{free}}$ and $\mathcal{R}$, and $S^{(\ell,\mathsf{b})}_n = L^{sn}S^{(\ell',\mathsf{b}')}_n$ at the triple and its pairs. The first display of Proposition 18.39(b) on $T_{\ell'}$ at g', b' and $L^s\mathsf{d}$, multiplied by L^{3s}, with $L^{3s}(L^s\mathsf{b})^{-3} = \mathsf{b}^{-3}$, gives the first bound; Proposition 18.38(a) on $T_{\ell'}$, multiplied by L^{2s}, gives the second, with $e_\sharp \le \frac{1}{3}$ by YM3_I:(2349); and Lemma 18.50 with $\mathsf{n} = 3$, $t = \frac{1}{3}\epsilon_\sharp(\mathsf{d})$, $e = e_\sharp(\mathsf{d})$ gives the third. In the proofs of Propositions 18.40 and 18.41, Proposition 18.39 enters only through the two inequalities of its part (b), used at all small scales and uniformly on the classes, and through the convergence of the ratios at the cutoffs; all three are now available on T_ℓ at the label b. For the pairs (K_j, β_j) with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}$, YM3_I:(2216) at $n = 3$ and $n = 2$, which needs no further property of the pairs, gives the convergence of the connected functions at the triple and its pairs; by the second bound the limits at the pairs are at least $2\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i, f_j) > 0$; so $Q_{K_j,\ell,\beta_j}(f)$ is formed for all large j and tends to $Q^{(\ell,\mathsf{b})}(f)$. □

Proof of Proposition 18.43. (a) $S^{\mathrm{fr}}_2[\mathsf{n}, \mathsf{b}] = \mathsf{n}\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}$, and $\mathcal{K}^{(2)}_{\mathrm{free}} > 0$ at a test pair; so agreement at one test pair forces $\mathsf{n}'\mathsf{b}'^{-2} = \mathsf{n}\mathsf{b}^{-2}$, which in turn gives agreement wherever both are defined. $\mathsf{n}'\mathsf{b}'^{-2} = 3\mathsf{b}^{-2}$ holds exactly for $\mathsf{b}' = \mathsf{b}(\mathsf{n}'/3)^{1/2}$: at $\mathsf{n}' = 1$, $(\mathsf{b}/\sqrt{3})^{-2} = 3\mathsf{b}^{-2}$, and at $\mathsf{n}' = 12$, $12(2\mathsf{b})^{-2} = 3\mathsf{b}^{-2}$.

(b) $A_2/A_3 = \mathsf{b}$ and $A_2^3/A_3^2 = \mathsf{n}^3\mathsf{b}^{-6}/(\mathsf{n}^2\mathsf{b}^{-6}) = \mathsf{n}$.

(c) For $36r < \ell$, $(\psi^{\langle\ell\rangle}_{i,r}, \psi^{\langle\ell\rangle}_{j,r}) \in \mathfrak{T}_{T_\ell}(r; \vartheta)$, with the lift $((\psi_i)_r, (\psi_j)_r)$ and the value $\mathcal{K}^{(2)}_{\mathrm{free}}(\psi_i, \psi_j)$ of $\mathcal{K}^{(2)}_{\mathrm{free}}$; so by Proposition 18.38(b) the first quotient is $3\mathsf{b}^{-2}(1+\eta)$ with $|\eta| \le \epsilon_{\mathrm{II}}(r) \to 0$, for $r \le \mathsf{d}_{\mathrm{II}}(\ell, \mathsf{b}, \vartheta)$. The first bound of Proposition 18.42 at $\mathsf{d} = r$, at the triple $\Psi^{\langle\ell\rangle}_r$, whose lift is Ψ_r and whose value of $\mathcal{K}^{(3)}_{\mathrm{free}}$ and of N are those of Ψ, divided by $\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi) \ge c_3^{\mathrm{col}}\vartheta^3\mathsf{N}(\Psi) > 0$, gives $|S^{(\ell,\mathsf{b})}_3(\Psi^{\langle\ell\rangle}_r)/\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi) - 3\mathsf{b}^{-3}| \le \epsilon_\sharp(r)\mathsf{b}^{-3}/(c_3^{\mathrm{col}}\vartheta^3) \to 0$. So, for small r, $Q^{(\ell,\mathsf{b})}(\Psi^{\langle\ell\rangle}_r)$ is formed, and

$$\frac{\mathcal{R}(\Psi)}{Q^{(\ell,\mathsf{b})}(\Psi^{\langle\ell\rangle}_r)} = \frac{\prod_{i<j} S^{(\ell,\mathsf{b})}_2(\psi^{\langle\ell\rangle}_{i,r}, \psi^{\langle\ell\rangle}_{j,r})/\mathcal{K}^{(2)}_{\mathrm{free}}(\psi_i, \psi_j)}{\big(S^{(\ell,\mathsf{b})}_3(\Psi^{\langle\ell\rangle}_r)/\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi)\big)^2} \to \frac{A_2^3}{A_3^2} = \frac{27\,\mathsf{b}^{-6}}{9\,\mathsf{b}^{-6}} = 3.$$

For a template $S^{\mathrm{fr}}[\mathsf{n}', \mathsf{b}']$ the two quotients, formed at the periodised dilates of Ψ and evaluated at the lift Ψ_r, are $\mathsf{n}'\mathsf{b}'^{-2}$ and $\mathsf{n}'\mathsf{b}'^{-3}$ at every r; by (b) they are $(3\mathsf{b}^{-2}, 3\mathsf{b}^{-3})$ exactly when $(\mathsf{n}', \mathsf{b}') = (3, \mathsf{b})$. □

Proof of Proposition 18.44. (a) Inserting the y_{ij}, $3y_3^2/(y_{12}y_{13}y_{23}) = 3y_3^2/(27\mathsf{b}^{-6}\prod_{i<j}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i, f_j)\prod_{i<j}(1+e_{ij}))$. Dividing by $\mathcal{R}(f)$, which is positive as $\mathcal{K}^{(3)}_{\mathrm{free}}(f) \neq 0$, puts $\mathcal{K}^{(3)}_{\mathrm{free}}(f)^2$ in the place of $\prod_{i<j}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i, f_j)$, and multiplying by $\prod_{i<j}(1+e_{ij})$ leaves $y_3^2/(9\mathsf{b}^{-6}\mathcal{K}^{(3)}_{\mathrm{free}}(f)^2)$.

(b) For $\mathsf{d}_k \le \mathsf{d}_{\mathrm{II}}(\ell,\mathsf{b},\vartheta)$, Proposition 18.38(b), (c) shows that the numbers $y_{ij} = S_2^{(\ell,\mathsf{b})}(f_i^{(k)}, f_j^{(k)})$ are positive and of the form of (a) with $|e_{ij}| \le \epsilon_{\mathrm{II}}(\mathsf{d}_k) \to 0$; so $Q^{(\ell,\mathsf{b})}(f^{(k)})$ is formed, and (a) at $y_3 = S_3^{(\ell,\mathsf{b})}(f^{(k)})$ says $\mathsf{v}_k^2 = (3Q^{(\ell,\mathsf{b})}(f^{(k)})/\mathcal{R}(f^{(k)}))\,\Pi_k$, with $\mathsf{v}_k = |S_3^{(\ell,\mathsf{b})}(f^{(k)})|/(3\mathsf{b}^{-3}|\mathcal{K}^{(3)}_{\mathrm{free}}(f^{(k)})|) \ge 0$ and $\Pi_k = \prod_{i<j}(1+e_{ij}) \to 1$. So $3Q/\mathcal{R} \to 1$ if and only if $\mathsf{v}_k^2 \to 1$, that is $\mathsf{v}_k \to 1$.

(c) By the bounds recalled in the setting, $\mathcal{K}^{(3)}_{\mathrm{free}}(f) \ge c_3^{\mathrm{col}}\vartheta^3\mathsf{N}(f)$ and $\prod_{i<j}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j) \le \frac{1}{27}\mathsf{N}(f)^2$; so $\mathcal{R}(f) \ge 27(c_3^{\mathrm{col}})^2\vartheta^6 =: \mathcal{R}_\vartheta > 0$, and $\mathcal{R}(f) < \frac{4}{3}$ by Proposition 18.33(c). Let $\mathsf{d} \le \mathsf{d}_{\mathrm{II}}(\ell,\mathsf{b},\vartheta)$ and f in the collinear class; with v the quotient of the right display, $\Pi = \prod_{i<j}(1+e_{ij})$ formed as in (b), $\pi(\mathsf{d}) = (1+\epsilon_{\mathrm{II}}(\mathsf{d}))^3 - 1$, which bounds $|\Pi - 1|$ as in the proof of Lemma 18.50 and tends to 0, and with $\mathsf{X}(\mathsf{d})$, $\mathsf{Y}(\mathsf{d})$ the two suprema of the display at d, (a) says $\mathsf{v}^2 = (3Q/\mathcal{R})\Pi$. ($\Rightarrow$) $\mathsf{v}^2 - 1 = \frac{3Q-\mathcal{R}}{\mathcal{R}}\Pi + (\Pi - 1)$, so $|\mathsf{v}^2-1| \le \frac{\mathsf{X}}{\mathcal{R}_\vartheta}(1+\pi) + \pi$, and $|\mathsf{v}-1| = |\mathsf{v}^2-1|/(\mathsf{v}+1) \le |\mathsf{v}^2-1|$. ($\Leftarrow$) $3Q - \mathcal{R} = \mathcal{R}\,\frac{(\mathsf{v}^2-1)+(1-\Pi)}{\Pi}$, $|\mathsf{v}^2-1| \le \mathsf{Y}(2+\mathsf{Y})$ and $\Pi \ge \frac{8}{27}$, so $\mathsf{X} \le \frac{4}{3}\cdot\frac{27}{8}\,[\mathsf{Y}(2+\mathsf{Y}) + \pi]$. Where the class is empty both suprema are 0. □

Proof of Proposition 18.45. (a) f lies in $\mathfrak{T}^{(3),\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta)$, as $w \le \frac{1}{16}$; so $\mathcal{K}^{(3)}_{\mathrm{free}}(f) \ge c_3^{\mathrm{col}}\vartheta^3\mathsf{N}(f) > 0$. By Proposition 18.38(b) the numbers $y_{ij} = S_2^{(\ell,\mathsf{b})}(f_i,f_j)$ are as in Proposition 18.44(a), with $|e_{ij}| \le \epsilon_{\mathrm{II}}(\mathsf{d}) \le \frac{1}{3}$, and Proposition 18.44(a) at $y_3 = S_3^{(\ell,\mathsf{b})}(f)$ gives $\mathsf{v}^2 = (3Q/\mathcal{R})\,\Pi$, $\Pi = \prod_{i<j}(1+e_{ij})$. So $\frac{9}{4}Q = \mathsf{A}\mathsf{v}^2$ with $\mathsf{A} = \frac{3}{4}\mathcal{R}(f)/\Pi$, and $1 - 412w^2 \le \frac{3}{4}\mathcal{R}(f) < 1$ (Proposition 18.34), $(1-\epsilon_{\mathrm{II}}(\mathsf{d}))^3 \le \Pi \le (1+\epsilon_{\mathrm{II}}(\mathsf{d}))^3$. *The equivalence.* Fix the function $\vartheta(\cdot)$; for each w, d_{II} and ϵ_{II} are taken at $(\ell,\mathsf{b},\vartheta(w))$. For $\mathsf{d} \le \mathsf{d}_{\mathrm{II}}$ let $\mathsf{X}(w,\mathsf{d}) = \sup_f |\frac{9}{4}Q^{(\ell,\mathsf{b})}(f) - 1|$ and $\mathsf{Y}(w,\mathsf{d}) = \sup_f |\mathsf{v}(f) - 1|$, the suprema over $\mathfrak{T}^{\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta(w);w)$, which is not empty (Proposition 18.35(b)), and $\alpha(w,\mathsf{d}) = \max\{1 - (1-412w^2)(1+\epsilon_{\mathrm{II}}(\mathsf{d}))^{-3},\ (1-\epsilon_{\mathrm{II}}(\mathsf{d}))^{-3} - 1\}$, which bounds $|\mathsf{A}(f) - 1|$ on the class; as $\epsilon_{\mathrm{II}}(\mathsf{d}) \to 0$, $\alpha(w,\mathsf{d}) \to 412w^2$. By YM3_I:(2216) at $n=3$, $n=2$ and Proposition 18.38(c), $Q_{K_j,\ell,\beta_j}(f) \to Q^{(\ell,\mathsf{b})}(f)$; so the display of Proposition 18.40(b) says $\lim_{w\to 0}\limsup_{\mathsf{d}\to 0}\frac{4}{9}\mathsf{X}(w,\mathsf{d}) = 0$. From $\frac{9}{4}Q - 1 = \mathsf{A}(\mathsf{v}^2-1) + (\mathsf{A}-1)$ and $|\mathsf{v}^2-1| \le |\mathsf{v}-1|(2+|\mathsf{v}-1|)$, $\mathsf{X} \le (1+\alpha)\mathsf{Y}(2+\mathsf{Y}) + \alpha$. From $\mathsf{v}^2 - 1 = [(\frac{9}{4}Q - 1) - (\mathsf{A}-1)]/\mathsf{A}$, $\mathsf{A} \ge 1-\alpha$ and $|\mathsf{v}-1| \le |\mathsf{v}^2-1|$, $\mathsf{Y} \le (\mathsf{X}+\alpha)/(1-\alpha)$ wherever $\alpha < 1$, that is for $412w^2 < 1$ and small d. Taking the upper limit as $\mathsf{d} \to 0$ in each inequality, the right members being increasing continuous functions of Y, α, respectively X, α, and then letting $w \to 0$, each of the two iterated limits is 0 if the other one is.

(b) Let $\mu_i = f_i\,dx$, F_{ij} and I be as in the proof of Proposition 18.33. As $\prod_{i<j}F_{ij} = 3\sqrt{3}\,(4\pi)^{-3}(r_{12}r_{13}r_{23})^{-3}$ on $\prod_i \operatorname{supp} f_i$, $\hat{S}_3(f) = \frac{18}{3\sqrt{3}}\mathsf{b}^{-3}\mathsf{I} = 2\sqrt{3}\,\mathsf{b}^{-3}\mathsf{I}$. (i) $\hat{S}_2 = 3\mathsf{b}^{-2}\mathcal{K}^{(2)}_{\mathrm{free}}$. (ii) $\hat{Q}(f) = \frac{12\,\mathsf{b}^{-6}\mathsf{I}^2}{27\,\mathsf{b}^{-6}\prod_{i<j}\mathcal{K}^{(2)}_{\mathrm{free}}(f_i,f_j)} = \frac{4}{9}\,\mathsf{I}^2/\prod_{i<j}\int F_{ij}^2\,d\mu_i d\mu_j \le \frac{4}{9}$ by Lemma 18.48. On a width class, at a lift on $\mathbb{R}^3$ and in the signs of the proof of Proposition 18.34: by Lemma 18.49(J), $\mathsf{I} = m_1m_2m_3\langle e^{\lambda_{12}+\lambda_{13}+\lambda_{23}}\rangle \ge m_1m_2m_3\,e^{\sum_{i<j}\langle\lambda_{ij}\rangle}$, and by Lemma 18.49(V), $\int F_{ij}^2\,d\mu_i d\mu_j = m_im_j\langle e^{2\lambda_{ij}}\rangle \le m_im_j\,e^{2\langle\lambda_{ij}\rangle + \frac{9}{2}\varkappa_w^2}$; so $\mathsf{I}^2/\prod_{i<j}\int F_{ij}^2 \ge e^{-\frac{27}{2}\varkappa_w^2} \ge 1 - 223w^2$ (Step 4 of that proof), and $\frac{4}{9}\cdot 223 < 100$. For $0 < \vartheta \le \frac{\pi}{13440}$ the width class at w_ϑ is not empty and lies in $\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{E}}(\mathsf{d};\vartheta)$ (Proposition 18.35(b)), which gives the bounds of the supremum. (iii) By Proposition 18.32(b), $3\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f) = \frac{\mathsf{b}^{-3}}{\sqrt{3}}\int \tau_\triangle \prod_{i<j}F_{ij}\,d\mu_1d\mu_2d\mu_3$, while $\hat{S}_3(f) = \frac{\mathsf{b}^{-3}}{\sqrt{3}}\,6\,\mathsf{I}$; so

$$\frac{\hat{S}_3(f)}{3\,\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f)} = \frac{\int 6\prod_{i<j}F_{ij}\,d\mu_1d\mu_2d\mu_3}{\int \tau_\triangle\prod_{i<j}F_{ij}\,d\mu_1d\mu_2d\mu_3}.$$

On a width class $6\mathsf{t}_w \le \tau_\triangle \le 6$ on $\prod_i \operatorname{supp} f_i$ (Step 2 of the proof of Proposition 18.34, and Proposition 18.32(a)), which gives the upper bound t_w^{-1}; and $\tau_\triangle < 6$ on an open set on which $\prod_i f_i \prod_{i<j}F_{ij} > 0$ (proof of Proposition 18.33(b)), which makes the quotient larger than 1. For the dilates Ψ_r the substitution $x_i = rx_i'$ multiplies dx by r^9 and $\prod_{i<j}F_{ij}$ by r^{-9}, and does not change

$\tau_\triangle$, which depends only on the directions of x_1-x_2, x_2-x_3, x_3-x_1; so neither integral depends on r, and the quotient takes one value, $1+\hat\delta(\Psi)$, for all r; $\hat\delta(\Psi)>0$ by what was just shown, as Ψ_r lies in $\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{R}^3}(r;\vartheta)$, the width class at $w=\frac{1}{16}$. Proposition 18.44(a), with $y_3=\hat S_3(\Psi_r)$ and $e_{ij}=0$, gives $(1+\hat\delta(\Psi))^2=3\hat Q(\Psi_r)/\mathcal{R}(\Psi_r)$, and $\mathcal{R}(\Psi_r)=\mathcal{R}(\Psi)>0$. For $0<\vartheta\le\frac{\pi}{13440}$, $\Psi^\circ\in\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{R}^3}(1;\vartheta)$ by Proposition 18.35(b); so Ψ°_{d} lies in $\mathfrak{T}^{(3),\mathrm{col}}_{\mathbb{R}^3}(\mathsf{d};\vartheta)$, and its periodisation in $\mathfrak{T}^{(3),\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta)$ with the lift Ψ°_{d}; the quotient there is $1+\hat\delta(\Psi^\circ)$, which gives the display. As $\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi^\circ_r)=\mathcal{K}^{(3)}_{\mathrm{free}}(\Psi^\circ)$, the last identity is the same fact, and $\mathsf{N}(\Psi^\circ_r)=1$ as the entries of Ψ° have the sup norm 1.

(c) This collects (i)–(iii). □

18.5. **The dilation bulk term with one constant in every periodic Gibbs state and on all tori above one side; the flux alone in the limits.** This subsection bounds the bulk term of the dilation Ward identity, whose cubic member is bounded on one torus in Theorem O(d), by CK^pL^{-cK} for every $c<\frac{1}{14}$, with one constant C in every periodic Gibbs state and on all the tori whose sides are at least one fixed side, and it takes the identity, with the flux alone beside the term of the label, to every volume-first limit at g and, for $0<g\le\gamma^{\mathrm{ref}}_W$, to the components of the limits of Gibbs sequences at g; for $\gamma^{\mathrm{ref}}_W<g\le\gamma$ it reaches these components for the flux and the term of the label taken together, and for the flux alone along the subsequences on which the term of the label converges. The bulk term is a sum of hard combinations of local insertions with the sources (Proposition 18.53); a hard combination is an algebraic function of means of functions of one cell (Lemma 18.54); the chessboard bound of Lemma 5.8 carries such a mean, in every law at hand, to the eighth root of the mean on one torus of the product of its eight mirror copies (Lemma 18.55); on that torus the eight copies enter the exponent of the small-field chain, where copies in different cells and sources far apart decouple, and each copy is read off at one source at a time (Lemmas 18.56, 18.57 and Proposition 18.58). Theorem BD is the resulting transfer, Theorem BE the bound of the bulk term, and Corollary 18.60 the identity in the limits.

Setting. We keep the setting and the signs of Section 5.1, with $0<g\le\gamma$ throughout: the lattice $\mathbb{L}_K=a\mathbb{Z}^3$, $a=a_K=L^{-K}$, the tori T_ℓ, $\ell=2L^m$, the label $\mathsf{b}=a\beta$, the set $\mathfrak{d}(g)$ of the first-passage data at g (the set $\mathfrak{D}(g)$ of Section 5.1), the set $\mathfrak{L}(g)$ of the sides at g, the number G_g, $\mathsf{b}_+=X_g+\bar B$, and the lattice calculus with $\mathfrak{d}_{b,p,\rho}$, $\mathfrak{s}_{l\rho}$, Ψ_ρ, $\mathfrak{r}^\sharp_\rho$, $G_\rho(b)$, Θ_v, $\mathfrak{K}^{\mathrm{v}}$, $\mathfrak{K}^\sharp$, div^s, e^η, ∇^+_ρ, ∇^c_ρ, the derivations v_η and the null terms $N_\beta[\eta]$. Every label of $\mathfrak{d}(g)$ lies in $[\gamma^{-2},\mathsf{b}_+]$, and $MR(\mathsf{b}_+)\le L^m$ on every side $2L^m\in\mathfrak{L}(g)$ ([7, Lemma 3.12](a)). A *law* at (K,β) is a Borel probability measure on the configurations of $\mathbb{L}_K$; $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ is the set of the periodic Gibbs states at (a_K,β), and $\mathcal{G}^{\mathrm{tor}}_{K,\beta}$ the set of the weak limit points, as $m\to\infty$, of the laws $\tilde\mu_{K,2L^m,\beta}$ of the tori, a subset of $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ by Proposition YM3_I:91.2; the law $\tilde\mu_{K,\ell,\beta}$ is the measure of T_ℓ at (K,β) carried to $\mathbb{L}_K$ by the periodic extension of the configurations, so that the mean under it of a bounded Borel function of the bonds inside the chart $(-\frac{\ell}{2},\frac{\ell}{2})^3$ equals the mean on T_ℓ of that function read in the chart, and joint cumulants of such functions agree in the same way; for action densities $\mathcal{O}(f)$ with supports anywhere, the periodised weights give the same observables by grouping bare plaquettes in each period class, and hence the same cumulants. For a law ν, $\langle Y_1;\dots;Y_q\rangle_\nu$ is the joint cumulant, $\mathcal{O}(h)=a^{-1}\sum_p h(p)a_p$ for a weight h of the plaquettes or a function h read at the barycentres, and $S^T_q[\nu](h_1,\dots,h_q)=\langle\mathcal{O}(h_1);\dots;\mathcal{O}(h_q)\rangle_\nu$. As in Section 5.1, a distance is Euclidean unless it is called a sup distance, Lip_∞ is the Lipschitz constant for the sup distance and Lip the Euclidean one, and $\|h\|_{C^{1,1}}=\max\{\sup|h|,\sup|\nabla h|,\mathrm{Lip}\,\nabla h\}$; $\mathsf{A}_r=\{y\in\mathbb{R}^3:|y|_\infty\le r\}$, and $\|h\|_\sharp=\max\{\sup|h|,40M\,\mathrm{Lip}\,h\}$. Since $\mathrm{Lip}\,h\le\sup|\nabla h|$ and $|y|\le\sqrt{3}|y|_\infty$, one has $\max_\rho\sup|\partial_\rho h|\le\|h\|_{C^{1,1}}$, $\max_\rho\mathrm{Lip}_\infty\partial_\rho h\le\sqrt{3}\|h\|_{C^{1,1}}$, $\mathrm{Lip}_\infty h\le\sqrt{3}\|h\|_{C^{1,1}}$ and $\|h\|_\sharp\le40M\|h\|_{C^{1,1}}$. For a function h of the class C^3, $\|h\|_{C^3}$ is the sum of the suprema of $|h|$, $|\nabla h|$, $|\nabla^2h|$ and $|\nabla^3h|$. The numbers $\mathsf{op}_q=\sum_\pi(\#\pi-1)!$ and Bl_q, the number of the partitions π of q points, are those of [7, § 3]; by the moment–cumulant formula a joint cumulant of q bounded functions is at most op_q times the product of their suprema.

The dilation objects. For a real function φ on $\mathbb{R}^3$, and on a torus for a function in the chart $(-\frac{\ell}{2},\frac{\ell}{2})^3$ that vanishes within the sup distance $2a$ of its boundary, put $\nabla^s_{\mathrm{dil}}\varphi(y)=\sum_\rho y_\rho(2a)^{-1}[\varphi(y+ae_\rho)-\varphi(y-ae_\rho)]$ and $\delta^2_\rho\varphi(y)=\varphi(y+ae_\rho)+\varphi(y-ae_\rho)-2\varphi(y)$, and for a plaquette p

$$(\mathsf{L}\varphi)(p)=-\tfrac14\sum_{\nu\in P(p)}\delta^2_\nu\varphi(x(p))-\tfrac12\delta^2_{\lambda(p)}\varphi(x(p)),\qquad \varphi^{\square}(p)=\tfrac14\sum_{b\subset\partial p}\varphi(x_b),\qquad v^{\mathrm{dil}}_\varphi(p)=\sum_{\rho\in P(p)}x(p)_\rho\,\nabla^c_\rho\varphi(x(p)),$$

$$h^{\mathrm{dil}}_\varphi(p)=a^{-1}\sum_{b\subset\partial p}\sum_\rho[\varphi(x_b)-\varphi(x(p))](x_b)_\rho\,\mathfrak{d}_{b,p,\rho},\qquad \psi(p)=\tfrac12\sum_{\nu\in P(p)}\big[\Psi_\nu(p)+\Psi_\nu(p-ae_\nu)\big],$$

the last one the in-plane orbital potential of p. With the identity field $\mathsf{y}(y)=y$ and real functions χ and f, the *dilation flux insertion* and the two *bulk insertions* are

$$\mathfrak{B}^{\mathrm{dil}}_\chi=\mathsf{b}\,\mathcal{O}(\nabla^s_{\mathrm{dil}}\chi)-\beta\sum_p h^{\mathrm{dil}}_\chi(p)-\tfrac32 a\,\mathcal{O}(v^{\mathrm{dil}}_\chi),\qquad \mathfrak{X}^{(0)}_\chi=\mathfrak{K}^{\mathrm{v}}[\beta\chi\mathsf{y}]+\beta\sum_p\chi(x(p))(\psi(p)-a_p^2)+\mathsf{b}\,\mathcal{O}(\mathsf{L}\chi)+3a\,\mathcal{O}(\chi^{\square}),$$

$$\mathfrak{X}^{(f)}=-a^{-1}\mathfrak{K}^{\mathrm{v}}[f\mathsf{y}]-a^{-1}\sum_p f(x(p))(\psi(p)-a_p^2)-\mathcal{O}(\mathsf{L}f),$$

and for a law ν and $\underline{f}=(f_1,\dots,f_n)$ the *flux* and the *bulk term* are

$$\mathsf{Fl}_K[\nu](\underline{f})[\chi]=-\langle\mathfrak{B}^{\mathrm{dil}}_\chi;\mathcal{O}(f_1);\dots;\mathcal{O}(f_n)\rangle_\nu,\qquad \mathfrak{U}^{\mathrm{dil}}_K[\nu](\underline{f})[\chi]=\langle\mathfrak{X}^{(0)}_\chi;\mathcal{O}(f_1);\dots;\mathcal{O}(f_n)\rangle_\nu+\sum_{i=1}^n\langle\mathfrak{X}^{(f_i)};(\mathcal{O}(f_l))_{l\neq i}\rangle_\nu.$$

The flux insertion depends on the configuration only near the closed set $\mathrm{Var}(\chi)$ of the points near which χ is not constant, and $\nabla^s_{\mathrm{dil}}\varphi$ tends to $y\cdot\nabla\varphi=\sum_\rho y_\rho\partial_\rho\varphi$ as $a\to0$.

Insertion tuples and hard combinations. An *insertion tuple* over real functions $g_1,\dots,g_n$, the *sources*, is a tuple $\mathbb{J}=(\mathfrak{J}_0,\mathfrak{J}_1,\dots,\mathfrak{J}_n)$ of bounded functions of finitely many bonds; for a law ν and $B\subset\{1,\dots,n\}$ its *hard combination* is

$$\mathsf{T}_\nu[\mathbb{J}](B)=\big\langle\mathfrak{J}_0;(\mathcal{O}(g_i))_{i\in B}\big\rangle_\nu+\sum_{i\in B}\big\langle\mathfrak{J}_i;(\mathcal{O}(g_l))_{l\in B\setminus\{i\}}\big\rangle_\nu,\qquad \mathsf{T}_\nu[\mathbb{J}](\emptyset)=\nu(\mathfrak{J}_0).$$

Thus $\mathfrak{U}^{\mathrm{dil}}_K[\nu](\underline{f})[\chi]=\mathsf{T}_\nu[\mathbb{X}](\{1,\dots,n\})$ for $\mathbb{X}=(\mathfrak{X}^{(0)}_\chi,\mathfrak{X}^{(f_1)},\dots,\mathfrak{X}^{(f_n)})$ over the sources f_i. A *local observable* is one of [7, Definition 5.19], with its order $m_{\mathfrak{J}}$, its type $(m_{\mathfrak{J}},c,\hat c,N)$, its weights $\varkappa$, the number $|\varkappa|_\infty$, its boxes and its carrier; an insertion in the sense of [7, Definition 3.2](1), and an entry in the sense of Lemma 5.10, of a given type is a local observable of that type, as the three definitions ask the same of the boxes, of the densities with their heights and orders, and of the number of the boxes that have one lowest site; an insertion tuple is *local* if its members are local observables of orders ≥2 with real weights and with densities that are real on the configurations with values in SU(2).

Data of the transfer. Let $n\geq1$, $R\geq1$ and $0<\mathsf{d}\leq1$. Let m_1 be the least integer with $2L^{m_1}\in\mathfrak{L}(g)$ and $L^{m_1}\geq32n(R+1)$, $\mathsf{l}=L^{m_1}$, and $\ell'=\ell'(g,n,R)=2\mathsf{l}$. The board of cubic cells of side l whose cell $\square_0=[-\frac{\mathsf{l}}{2},\frac{\mathsf{l}}{2}]^3$ is centred at 0 lies on $\mathbb{L}_K$, on $T_{\ell'}$ and on every T_ℓ with $\ell\geq\ell'$ in $\mathfrak{L}(g)$, as l divides $\frac{\ell'}{2}$; $\square_0$ holds A_{R+2} at sup distance $\geq\frac{\mathsf{l}}{2}-R-2\geq16$ from its walls. $\mathsf{Z}=(\mathbb{Z}/2)^3$ numbers the eight cells of $T_{\ell'}$, and r_κ is the diagonal isometry of the lattice of $T_{\ell'}$ that carries $\square_0$ onto the cell $\kappa\in\mathsf{Z}$ by reflections in walls; for a real bounded Borel function F of the bonds inside $\square_0$ its mirror copy $F^{[\kappa]}=F\circ\mathsf{r}_\kappa^{-1}$ is a function of the cell κ, and $F\mapsto F^{[\kappa]}$ is real linear, multiplicative and the identity on constants by its definition as composition. The measure of $T_{\ell'}$ at (K,β), whose means and cumulants we write $\langle\cdot\rangle'$, is invariant under every r_κ by relabelling plaquettes and Haar variables. We put $\mathsf{Q}=e^{G_g\mathsf{l}^3}$, and the *laws of the transfer* at $(K,\beta)\in\mathfrak{d}(g)$ are those of $\mathfrak{S}_{K,\beta}=\mathcal{G}^{\mathrm{per}}_{K,\beta}\cup\{\tilde\mu_{K,\ell,\beta}:\ell\in\mathfrak{L}(g),\ \ell\geq\ell'\}$. The *sources of the transfer* are real Lipschitz functions $g_1,\dots,g_n\neq0$ on $\mathbb{R}^3$ that vanish outside A_R, with supports at pairwise sup distances $\geq\mathsf{d}$; $O_i=\mathcal{O}(g_i)$, and on $T_{\ell'}$, $g_i^\kappa=g_i\circ\mathsf{r}_\kappa^{-1}$, so that $O_i^{[\kappa]}=\mathcal{O}(g_i^\kappa)$ and $\|g_i^\kappa\|_\sharp=\|g_i\|_\sharp$ by relabelling the plaquettes. *The chain on $T_{\ell'}$.* For $0<\phi\leq\frac{1}{84}$, $K\geq\max\{K_\phi,5\}$ with the number K_ϕ of [7, Lemma 3.12](b), $u=\lceil\phi K\rceil$ and $t=K-u$, the setting (Th) of §2.3.1 holds on $T_{\ell'}$ with (K,b,m_1,t)

([7, Lemma 3.12](b)); we use its cuts Cut_k, its inner ball $\mathsf{In}_t \subset \mathsf{Cut}_t$, the backgrounds U over $V \in \mathsf{Cut}_k$, the weights p_k and $\mathfrak{w}_t^{\mathrm{sf}}$ of [7, Definition 3.2](3), the discarded-mass bound R_t of Proposition YM3_I:115.2, the source class $\mathsf{Src} = \mathsf{Src}_{\mathsf{Bc}}(2\varrho, 2\varrho)$ of the calibrated construction, and $\rho_0^w = \rho_0 e^{\mathcal{O}(w)}$, the numbers $N_k = (\ell' L^{K-k})^3$, $\mathsf{m}_t^S = C_{\mathrm{old}} L E_0^{\mathrm{s}} N_t/(L-1)$ and $\mathsf{M}_t^{\mathrm{rd}} = \max\{\varrho^{-1}, \frac{3}{2}(\mathsf{e}_t^{\mathrm{c}})^2 L^{K-t} N_t, \varrho^{-1}\mathsf{m}_t^S\}$, the source-action bound and read-out radius of Section YM3_I:114 and Lemma YM3_I:114.5, so that $\mathsf{M}_t^{\mathrm{rd}} \geq \varrho^{-1}\mathsf{m}_t^S$, $\mathsf{M} = \max\{1, 8\mathsf{M}_t^{\mathrm{rd}}\}$, the small-field functional $\Lambda'(F) = \int F\, \mathfrak{w}_t^{\mathrm{sf}} \rho_0\, dU$, $Z = Z_{K,\ell',\beta}$, and for the sources the radii $r_i = (8\mathsf{M}_t^{\mathrm{rd}} \|g_i\|_\sharp)^{-1}$; by Lemma 5.10(b), $\mathsf{M} \leq C K^{2\mathfrak{p}_0} \ell'^3 L^{3u}$ with C a function of the constants and b_+. *The numbers of an observable.* [7, Lemma 5.20] applies on $T_{\ell'}$ with $m = m_1$, $\mathsf{b}_- = \gamma^{-2}$ and $\mathsf{b}' = \mathsf{b}$ ([7, Lemma 3.12](a)), as $\phi < \frac{1}{42}$ and as every $K \geq K_\phi$ meets the two conditions with which that Lemma fixes its own threshold, both of them among the conditions on K_ϕ in [7, Lemma 3.12](b). For a local observable $\mathfrak{J}$ of an order ≥ 2 on $T_{\ell'}$, m_j, $\mathsf{n}_{\mathfrak{J}}^{\mathrm{f}}$, d_i, n_j and $r_{\mathfrak{J}}$ are the numbers of [7, Lemma 5.20](a), and $\mathsf{o}_t(\mathfrak{J})$ is the number of [7, Lemma 5.20](b); in the bounds below, C is a function of the constants, m_1, b_+ and the type of $\mathfrak{J}$, and does not read ϕ. [7, Lemma 5.20](a) bounds $\mathsf{o}_t(\mathfrak{J})$ by $CK^{2\mathfrak{p}_0} L^{4u-K} |\varkappa|_\infty$ at the order 2 and by $CK^{3\mathfrak{p}_0} L^{4u-\frac{3}{2}K} |\varkappa|_\infty$ at the orders ≥ 3, and [7, Lemma 5.20](c) gives $1/r_{\mathfrak{J}} \leq C|\varkappa|_\infty$ and $\sup|\mathfrak{J}| \leq N\hat{c}\,\ell'^3 L^{3K} |\varkappa|_\infty$ at real configurations. The numbers m_j, n_j and d_i are given by the formulas of [7, Proposition 3.13], except $\mathsf{d}_1 = K^{\mathrm{d}} \mathsf{n}_{\mathfrak{J}}^{\mathrm{f}}$, with $K^{\mathrm{d}} = (351/2) L^3 K_\Pi$, as in the construction preceding Proposition YM3_I:114.3. As [7, Lemma 5.20](a) gives $\mathsf{n}_{\mathfrak{J}}^{\mathrm{f}} \leq C_{\mathrm{hz}} N \hat{c}\, x_0^{-1/2} (\log x_0)^{\mathfrak{p}_0} |\varkappa|_\infty$, where C_{hz} is formed from the constants alone and $x_0 = \beta = L^K \mathsf{b} \in [\gamma^{-2} L^K, \mathsf{b}_+ L^K]$, one has $\mathsf{d}_1 \leq C K^{\mathfrak{p}_0} L^{-K/2} |\varkappa|_\infty$. The proof of [7, Lemma 3.14](c) uses d_1 only through a bound of this form, with constants that do not read ϕ when $\phi \leq \frac{1}{84}$ and $K \geq \max\{K_\phi, 5\}$; carried out for the present numbers, it gives $\max_i \mathsf{d}_i \leq C|\varkappa|_\infty$ and, at the order 2, $\sum_{i \leq k} L^i \mathsf{d}_i \leq C K^{\mathfrak{p}_0} L^{-(K-k)/2} |\varkappa|_\infty$ for $1 \leq k \leq t$.

Proposition 18.53 (The dilation identity; the bulk term as a sum of hard combinations)**.** Let $K \in \mathbb{N}$, $\beta > 0$, $n \geq 1$, and let $\chi, f_1, \dots, f_n$ be bounded real functions on $\mathbb{R}^3$ of bounded supports such that χ *covers* the f_i: $\chi = 1$ at $x(p)$ and at the four x_b, $b \subset \partial p$, wherever $f_i(x(p)) \neq 0$ for some i. Let ν be a Gibbs state at (a_K, β), or the measure of a torus T_ℓ when all the supports lie in $(-\frac{\ell}{2} + 2a, \frac{\ell}{2} - 2a)^3$.

(a) *(The identity.)* $\sum_{i=1}^n S_n^T[\nu](f_1, \dots, f_i - \nabla_{\mathrm{dil}}^s f_i, \dots, f_n) = \mathsf{b}\, S_{n+1}^T[\nu](\chi, f_1, \dots, f_n) + \mathsf{Fl}_K[\nu](\underline{f})[\chi] + \mathfrak{U}_K^{\mathrm{dil}}[\nu](\underline{f})[\chi]$.

(b) *(The pieces.)* For complex vector fields k and complex functions f, f_l, w on $\mathbb{R}^3$ that vanish outside bounded sets, read on $\mathbb{L}_K$, the relations (N1) and (N4) of Lemma 5.9(f) hold as they are written there, (N2) holds with the mean under ν in the place of the integral against $e^{-\beta A} dU$, and (N3) holds with the joint cumulants under ν in the place of $\langle\cdot\rangle_{K,\ell,\beta}$; for the measure of a torus and functions read in its chart these are the relations of that Lemma. Let besides $n \geq 2$, let the supports of the f_i lie at pairwise sup distances $> 4a$, and let $\chi = 1$ at every point within sup distance $2a$ of $\bigcup_i \operatorname{supp} f_i$. For a real function φ let k^φ be the vector field with $\mathsf{k}^{\varphi,\rho}(z) = \nabla_\rho^+(\varphi\, y_\rho)(z) = \varphi(z + a e_\rho) + z_\rho \nabla_\rho^+ \varphi(z)$; let $\mathfrak{J}_v[\mathsf{k}]$, $1 \leq v \leq 5$, be the five sums of Lemma 5.9(c); and, with the constant field $\mathbf{1} = (1,1,1)$ and the notation of Lemma 5.9(f), let $\mathfrak{R}^\circ[f] = \mathfrak{R}[\mathbf{1}; f] - \mathsf{b}^{-1} c_{f\mathbf{1}} = -3\mathsf{b}^{-1} \sum_p a_p\, \mathsf{e}^{f\mathbf{1}}(p) + \mathfrak{C}'[\mathbf{1}; f]$. Then $\mathfrak{U}_K^{\mathrm{dil}}[\nu](\underline{f})[\chi] = \sum_\pi \mathsf{T}_\nu[\mathbb{J}^\pi](\{1, \dots, n\})$, over the sources $f_1, \dots, f_n$ and the ten insertion tuples

$$\mathbb{J}^\sharp = (\beta \mathfrak{K}^\sharp[\chi \mathsf{y}],\ (-a^{-1} \mathfrak{K}^\sharp[f_i \mathsf{y}])_i),$$

$$\mathbb{J}^\psi = \Big(\beta \sum_p \chi(x(p)) \psi(p),\ (-a^{-1} \sum_p f_i(x(p)) \psi(p))_i\Big),$$

$$\mathbb{J}^{a^2} = \Big(-\beta \sum_p \chi(x(p)) a_p^2,\ (a^{-1} \sum_p f_i(x(p)) a_p^2)_i\Big),$$

$$\mathbb{J}^v = \big(-\mathfrak{J}_v[\mathsf{k}^\chi],\, (\mathsf{b}^{-1}\mathfrak{J}_v[\mathsf{k}^{f_i}])_i\big)\ (1 \le v \le 5),$$
$$\mathbb{J}^{\mathfrak{R}} = \big(0,\, (\tfrac{1}{4}\mathfrak{R}^\circ[f_i])_i\big),$$
$$\mathbb{J}^{\mathrm{s}} = \big(\mathsf{b}\,\mathcal{O}(\mathsf{L}\chi) + 3a\,\mathcal{O}(\chi^\square),\, (-\mathcal{O}(\mathsf{L}f_i))_i\big).$$

(c) *(Carriers, orders, weights.)* In each of these tuples $\mathfrak{J}_0$ is a sum over plaquettes and boxes within sup distance $4a$ of $\operatorname{supp}\chi$, and $\mathfrak{J}_i$ a sum over plaquettes and boxes within the sup distance $4a$ of $\operatorname{supp} f_i$. Let besides $(K,\beta) \in \mathfrak{d}(g)$ and $a \le \frac{1}{4}$, and let χ and the f_i belong to $C^{1,1}(\mathbb{R}^3)$ and vanish outside A_R; write $\|\cdot\| = \|\cdot\|_{C^{1,1}}$, and let C_R be a function of R. All the members are local observables of types formed with pure numbers. In $\mathbb{J}^\psi$ and $\mathbb{J}^{a^2}$ the densities are the in-plane orbital potentials of $\psi(p)$, of the order 2, each on the box of a planar 1×2 rectangle, and a_p^2, of the order 4, with weights at most $\beta \sup|\chi|$ in $\mathfrak{J}_0$ and $a^{-1}\sup|f_i|$ in $\mathfrak{J}_i$. In $\mathbb{J}^v$ the orders are $2,2,2,3,4$ for $v = 1,\dots,5$, and the weights are at most $C_R(1+\mathsf{b})\|\chi\|$ and $C_R\|f_i\|$ for $v \le 3$, and $C_R\beta\|\chi\|$ and $C_R a^{-1}\|f_i\|_\sharp$ for $v = 4,5$. In $\mathbb{J}^{\mathfrak{R}}$ the densities a_p and $\langle G_\rho(b), \mathbf{w}(W_{b,p})\rangle$ have the order 2 and weights at most $\|f_i\|_\sharp$. In $\mathbb{J}^{\mathrm{s}}$ the density a_p has weights at most $3\sup|\chi| + 2\mathsf{b}a\|\chi\|$ in $\mathfrak{J}_0$ and $2a\|f_i\|$ in $\mathfrak{J}_i$. And $\mathbb{J}^\sharp = (\beta\mathfrak{K}^\sharp[\Xi], (-a^{-1}\mathfrak{K}^\sharp[f_i\Xi])_i)$ for the field $\Xi = \chi\mathsf{y}$, as $f_i\chi = f_i$, with $\mathsf{H}(\Xi) \le C_R\|\chi\|$: its members are weighted sums of the cubic density $\mathfrak{r}^\sharp_{\lambda(p)}(p)$, with weights at most $L^{2K}\mathsf{b}_+\mathsf{H}(\Xi)$ and $L^{2K}\sup|f_i|\,\mathsf{H}(\Xi)$, and in the sense of [7, Definition 5.19] this density has the order 3: the paragraph that follows that Definition presents it on a box of $2\times2\times3$ sites with the type $(3, 2^{36}\hat{c}_\sharp, \hat{c}_\sharp, N)$, $\hat{c}_\sharp$ and N pure numbers. Here the order measures a bound by a constant times δ^3 where the plaquette variables lie within δ of $\mathbf{1}$; it is not the least order 2 of the monomials with which Lemma 5.9(b) writes $\mathfrak{r}^\sharp$ as a block form.

■

Sketch. Null terms with sources. Let $\mathbf{X}$ be a polynomial field of directions that vanishes off a finite set Λ of bonds, as in Lemma 5.9(a), and w a complex weight of finite support. In a Gibbs state the conditional law of the bonds of Λ, given the other bonds, is $e^{-\beta\sum_{p\cap\Lambda\neq\emptyset} a_p}$ times the Haar measure of these bonds, normalised by a function of the other bonds; the integration by parts of Lemma 5.9(a) in the bonds of Λ, applied to $e^{\mathcal{O}(w)}$, gives $\nu((\beta v_{\mathbf{X}}A - \operatorname{div} v_{\mathbf{X}})e^{\mathcal{O}(w)}) = \nu((v_{\mathbf{X}}\mathcal{O}(w))e^{\mathcal{O}(w)})$, and on a torus this is the integration by parts against its measure. At $w = \sum_i z_i f_i$ we divide by $\nu(e^{\mathcal{O}(w)})$, which is 1 at $z=0$, and differentiate once in each z_i at $z=0$: the means under the measure with the source become joint cumulants, and $v_{\mathbf{X}}\mathcal{O}(w) = \sum_i z_i v_{\mathbf{X}}\mathcal{O}(f_i)$ is linear in z, so that

$$\langle \beta v_{\mathbf{X}}A - \operatorname{div} v_{\mathbf{X}}; \mathcal{O}(f_1); \dots; \mathcal{O}(f_n)\rangle_\nu = \sum_i \langle v_{\mathbf{X}}\mathcal{O}(f_i); (\mathcal{O}(f_l))_{l\neq i}\rangle_\nu.$$

For the field $\mathbf{X}^{\mathsf{k}}$ of Lemma 5.9(c), k of bounded support, the identity before the derivatives is (N2) in ν; (N1) and (N4) are identities in U whose terms read k, f and the configuration near the supports, so they hold on $\mathbb{L}_K$ as on T_ℓ; and (N1), inserted into the right member of the display, gives (N3) in ν by induction on the number of sources.

The identity (a). The field $\eta = \chi\mathsf{y}$ has bounded support, and for the field of directions of v_η the left member of the display is $\langle N_\beta[\eta]; \mathcal{O}(f_1); \dots; \mathcal{O}(f_n)\rangle_\nu$, while $v_\eta\mathcal{O}(f) = -\mathrm{Ct}[f;\eta]$ (Lemma 5.9(a) and the identities recalled in Section 5.1). Write $\eta^\rho(x_b) - \eta^\rho(x(p)) = [\chi(x_b) - \chi(x(p))](x_b)_\rho + \chi(x(p))(x_b - x(p))_\rho$; then $\Theta_v[\chi\mathsf{y}] = \sum_p v(p)h^{\mathrm{dil}}_\chi(p) + \sum_p v(p)\chi(x(p))\operatorname{tr}\mathfrak{s}(p)$ with $\operatorname{tr}\mathfrak{s} = \sum_\rho \mathfrak{s}_{\rho\rho}$, and the formulas for $\mathfrak{s}$ in Lemma 5.9(e) ($\mathfrak{s}_{\lambda\rho}(p) = 0$ for $\lambda = \lambda(p)$, and the value of $\mathfrak{s}_{\nu\nu}(p)$ for $\nu \in P(p)$) give $\operatorname{tr}\mathfrak{s}(p) = 4a_p - a_p^2 + \frac{1}{4}\sum_{\nu\in P(p)}(a_{p+ae_\nu} + a_{p-ae_\nu} - 2a_p) + \psi(p)$. Moved onto the weight, the shifted plaquette terms give $\sum_p \varphi(x(p))(a_{p+ae_\nu} + a_{p-ae_\nu} - 2a_p) = \sum_p a_p\,\delta^2_\nu\varphi(x(p))$, both sums over the plaquettes with $\nu \in P(p)$. Moreover $\operatorname{div}^s(\chi\mathsf{y}) = \nabla^s_{\mathrm{dil}}\chi + 3\chi + \frac{1}{2}\sum_\rho \delta^2_\rho\chi$, and $e^{\chi\mathsf{y}}(p) = v^{\mathrm{dil}}_\chi(p) + 2\chi^\square(p)$, since the two bonds of p normal to $\rho \in P(p)$ have their midpoints at $x(p) \pm \frac{a}{2}e_\rho$. Inserted at $v \equiv \beta$ into $N_\beta[\eta] = \Theta_\beta[\eta] + \mathfrak{K}^{\mathrm{v}}[\beta\eta] - \mathsf{b}\,\mathcal{O}(\operatorname{div}^s\eta) + \frac{3}{2}a\,\mathcal{O}(e^\eta)$, these formulas give $N_\beta[\chi\mathsf{y}] = -\mathfrak{B}^{\mathrm{dil}}_\chi + \mathsf{b}\,\mathcal{O}(\chi) + \mathfrak{X}^{(0)}_\chi$.

At $v = f$: as χ covers f, the terms of a plaquette with $f(x(p)) \neq 0$ see $\chi = 1$ at all their points, and $f\chi = f$ at every barycentre; so $\Theta_f[\chi\mathsf{y}] = \sum_p f(x(p)) \operatorname{tr} \mathfrak{s}(p)$, $\operatorname{div}^s(f\chi\mathsf{y}) = \operatorname{div}^s(f\mathsf{y})$ at the barycentres, $\mathfrak{K}^{\mathrm{v}}[f\chi\mathsf{y}] = \mathfrak{K}^{\mathrm{v}}[f\mathsf{y}]$, and $\mathrm{Ct}[f;\chi\mathsf{y}] = \mathcal{O}(\operatorname{div}^s(f\mathsf{y})) - a^{-1}\Theta_f[\chi\mathsf{y}] - a^{-1}\mathfrak{K}^{\mathrm{v}}[f\mathsf{y}] = -\mathcal{O}(f - \nabla^s_{\mathrm{dil}} f) + \mathfrak{X}^{(f)}$. The display, with these two expansions and the multilinearity of the cumulants, is (a).

The pieces (b). Lemma 5.9(b) at the vector weights $\beta\chi\mathsf{y}$ and $f\mathsf{y}$, with $\nabla^+_\rho(\varphi y_\rho) = \mathsf{k}^{\varphi,\rho}$, gives

$$\mathfrak{K}^{\mathrm{v}}[\beta\chi\mathsf{y}] = -\mathfrak{J}^{\mathrm{II}}[\mathsf{k}^\chi] + \beta\mathfrak{K}^\sharp[\chi\mathsf{y}], \qquad -a^{-1}\mathfrak{K}^{\mathrm{v}}[f\mathsf{y}] = \mathsf{b}^{-1}\mathfrak{J}^{\mathrm{II}}[\mathsf{k}^f] - a^{-1}\mathfrak{K}^\sharp[f\mathsf{y}], \qquad \mathfrak{J}^{\mathrm{II}}[\mathsf{k}] = \beta\sum_{p,\rho} \mathsf{k}^\rho(x(p))\Psi_\rho(p),$$

and Lemma 5.9(c) gives $\mathfrak{J}^{\mathrm{II}}[\mathsf{k}] = -\frac{1}{4}\mathfrak{N}[\mathsf{k}] + \sum_v \mathfrak{J}_v[\mathsf{k}] - \frac{1}{4}c_{\mathsf{k}}$. Numbers drop from joint cumulants of order ≥ 2, and as $n \geq 2$ every cumulant of the bulk term has at least two entries. The field of directions of $\mathfrak{N}[\mathsf{k}^{f_i}]$ vanishes off the bonds whose midpoints lie within the sup distance a of $\operatorname{supp} f_i$, and no $\mathcal{O}(f_l)$, $l \neq i$, reads these bonds, the supports lying at sup distances $> 4a$; so $\langle \mathfrak{N}[\mathsf{k}^{f_i}]; (\mathcal{O}(f_l))_{l\neq i}\rangle_\nu = 0$ (Lemma 5.9(a)). In (N3) for $\langle \mathfrak{N}[\mathsf{k}^\chi]; \mathcal{O}(f_1); \dots; \mathcal{O}(f_n)\rangle_\nu$ every term with $j \geq 2$ holds $\mathfrak{R}[f_{q_1}\cdots f_{q_{j-1}}\mathsf{k}^\chi; f_{q_j}]$ with $q_1 \neq q_j$, whose weights and whose number vanish by (N4), as the supports of f_{q_1} and f_{q_j} lie at a sup distance $> 2a$; the terms with $j = 1$ are $\langle \mathfrak{R}[\mathsf{k}^\chi; f_q]; (\mathcal{O}(f_l))_{l\neq q}\rangle_\nu$, and $\mathfrak{R}[\mathsf{k}^\chi; f_q]$ reads k^χ at bond midpoints within the sup distance $\frac{a}{2}$ of $\operatorname{supp} f_q$, where $\mathsf{k}^\chi = \mathbf{1}$ because $\chi = 1$ within the sup distance $2a$ of that support; so it is $\mathfrak{R}[\mathbf{1}; f_q]$, whose number drops. Grouping the members of $\mathfrak{X}^{(0)}_\chi$ and of the $\mathfrak{X}^{(f_i)}$ by their kind gives the ten tuples.

Carriers and weights (c). The weights of the $\mathfrak{J}_v[\mathsf{k}]$ and of $\mathfrak{R}[\mathbf{1}; f]$ are those listed in Lemma 5.9(c) and in (N4), the latter multiplied by $\frac{1}{4}$; with $|\mathsf{k}^\varphi|_\infty \leq \sup|\varphi| + (R+1)\max_\rho \sup|\partial_\rho\varphi|$ and $\mathrm{Lip}_\infty \mathsf{k}^\varphi \leq 2\,\mathrm{Lip}_\infty\varphi + (R+1)\max_\rho \mathrm{Lip}_\infty \partial_\rho\varphi$ for φ that vanish outside A_R, with $|\mathsf{L}\varphi| \leq a^2 \max_\rho \mathrm{Lip}_\infty \partial_\rho\varphi$, $|\chi^\square| \leq \sup|\chi|$, with the comparisons of the Setting between these numbers and $\|\varphi\|$, and with $4 \leq \mathsf{b} \leq \mathsf{b}_+$ at first-passage data ([7, Lemma 3.12](a)), they give the bounds. The orders are those of Lemma 5.9(c) for $\Psi_\rho(p)$, a_p, $\langle G_\rho(b), \mathbf{w}(W_{b,p})\rangle$, $\mathfrak{e}_{\lambda(p)}(p)$ and a_p^2, and the order and the type of the cubic density $\mathfrak{r}^\sharp_{\lambda(p)}(p)$ are those of the paragraph that follows [7, Definition 5.19]. Every density sits on a box within the sup distance $2a$ of its plaquette, and k^{f_i} vanishes beyond the sup distance a of $\operatorname{supp} f_i$, which gives the carriers. □

Lemma 18.54 (Moments for hard combinations)**.** Let ν be a probability measure, $\mathfrak{J}_0, \dots, \mathfrak{J}_n, O_1, \dots, O_n$ bounded real measurable functions, and $\bar o_1, \dots, \bar o_n, \alpha_\emptyset, \alpha_1, \dots, \alpha_n$ real numbers; put $\hat O_i = O_i - \bar o_i$, $\alpha_{\{i\}} = \alpha_i$, $\alpha_A = 0$ for $\#A \geq 2$, $\mathsf{T}_\nu(A) = \langle \mathfrak{J}_0; (O_i)_{i\in A}\rangle_\nu + \sum_{i\in A}\langle \mathfrak{J}_i; (O_l)_{l\in A\setminus\{i\}}\rangle_\nu$ with $\mathsf{T}_\nu(\emptyset) = \nu(\mathfrak{J}_0)$, $P_\nu(C) = \nu(\prod_{i\in C}\hat O_i)$ with $P_\nu(\emptyset) = 1$, and

$$H_B = (\mathfrak{J}_0 - \alpha_\emptyset)\prod_{i\in B}\hat O_i + \sum_{i\in B}(\mathfrak{J}_i - \alpha_i)\prod_{l\in B\setminus\{i\}}\hat O_l.$$

Then $\nu(H_B) = \sum_{A\subset B}(\mathsf{T}_\nu(A) - \alpha_A)P_\nu(B\setminus A)$ for every $B \subset \{1,\dots,n\}$. Consequently, if $|\nu(H_A)| \leq \eta\prod_{i\in A}\gamma_i$ for all $A \subset B$ and $|P_\nu(C)| \leq \bar P\prod_{i\in C}\gamma_i$ for all non-empty $C \subset B$, with numbers $\eta, \bar P \geq 0$ and $\gamma_i > 0$, then $|\mathsf{T}_\nu(B) - \alpha_B| \leq \mathsf{c}_{\#B}\,\eta\prod_{i\in B}\gamma_i$, where $\mathsf{c}_0 = 1$ and $\mathsf{c}_k = 1 + \bar P\sum_{j<k}\binom{k}{j}\mathsf{c}_j$. ■

Sketch. For $z \in \mathbb{C}^n$ put $Y_z = \mathfrak{J}_0 + \sum_i z_i\mathfrak{J}_i$, $\mathsf{a}_\circ(z) = \alpha_\emptyset + \sum_i \alpha_i z_i$, $\Gamma(z) = \nu(e^{\sum_i z_i\hat O_i})$ and $\mathcal{N}(z) = \nu(Y_z e^{\sum_i z_i\hat O_i})$, entire functions with $\Gamma(0) = 1$, and near 0 let $\mathcal{X} = \mathcal{N}/\Gamma$, the mean of Y_z under the measure with the source $\sum_i z_i O_i$, from which the numbers $\bar o_i$ drop. Let ∂_A be the derivative once in each z_i, $i \in A$, at $z = 0$. The derivatives of a mean under a source are joint cumulants, and Y_z is affine in z; so $\partial_A\mathcal{X} = \mathsf{T}_\nu(A)$, while $\partial_A\mathsf{a}_\circ = \alpha_A$ and $\partial_C\Gamma = P_\nu(C)$. As a function of the configuration, by the rule of Leibniz for a derivative in which each variable stands once and as $Y_z - \mathsf{a}_\circ(z)$ is affine, $\partial_B[(Y_z - \mathsf{a}_\circ(z))e^{\sum_i z_i\hat O_i}] = H_B$. The functions are bounded, so ν and ∂_B commute, and $\nu(H_B) = \partial_B[(\mathcal{X} - \mathsf{a}_\circ)\Gamma] = \sum_{A\subset B}(\mathsf{T}_\nu(A) - \alpha_A)P_\nu(B\setminus A)$. For the bound let $\delta_A = \mathsf{T}_\nu(A) - \alpha_A$; then $\delta_B = \nu(H_B) - \sum_{A\subsetneq B}\delta_A P_\nu(B\setminus A)$, and induction on $\#B$ gives $|\delta_B| \leq \eta\prod_B\gamma_i + \bar P\sum_{j<\#B}\binom{\#B}{j}\mathsf{c}_j\,\eta\prod_B\gamma_i$. □

Lemma 18.55 (Domination at one side; moments of the sources)**.** In the data of the transfer let $(K,\beta)\in\mathfrak{d}(g)$.

(a) For every $\rho\in\mathfrak{S}_{K,\beta}$ and every bounded real Borel function F of the bonds inside $\square_0$, $|\rho(F)|\le \mathsf{Q}\,|\langle\prod_{\kappa\in\mathsf{Z}}F^{[\kappa]}\rangle'|^{1/8}$.

(b) Let $\bar o_i=\langle O_i\rangle'$. There is a number $\bar P$, a function of g, n, R and d, such that $|\rho(\prod_{i\in C}(O_i-\bar o_i))|\le \bar P\prod_{i\in C}\|g_i\|_\sharp$ for every $\rho\in\mathfrak{S}_{K,\beta}$ and every non-empty $C\subset\{1,\dots,n\}$.

■

Sketch. (a) is Lemma 5.8 for the board of the side $\mathsf{l}'=\mathsf{l}$, which divides $\frac{\ell'}{2}$, with $N'=8$: the law ρ is a periodic Gibbs state at (K,β) or the measure of a torus T_ℓ, $\ell\ge\ell'$ in $\mathfrak{L}(g)$, lifted to $\mathbb{L}_K$, and F is a function of the bonds inside one cell. (b) A moment of the centred functions $O_i-\bar o_i$ is the sum, over the partitions of C, of the products of the joint cumulants under ρ of the blocks. A block $\{i\}$ gives $\rho(O_i)-\langle O_i\rangle'$, the difference of the means of $\mathcal{O}(g_i)$ under two laws of $\mathfrak{S}_{K,\beta}$; the support of g_i lies in the Euclidean ball of radius $2R$ about 0, every pair of $\mathfrak{d}(g)$ has the property (Nr1) on $\mathfrak{L}(g)$ (Theorem YM3_I:91.12), and the one-point comparison in Proposition YM3_I:91.13 bounds the difference by $C_1(2R)\|g_i\|_\sharp$. A block of $N\ge2$ sources, whose supports lie at pairwise Euclidean distances $\ge\mathsf{d}$, has a joint cumulant at most $C_N^{\mathrm{per}}(\mathsf{d};2R)\prod\|g_i\|_\sharp$ in a periodic Gibbs state (Proposition YM3_I:91.13) and at most $C_N^{g}(\mathsf{d};2R)\prod\|g_i\|_\sharp$ on a torus T_ℓ, $\ell\ge\ell'\ge16N(2R+1)$, the supports lying in $(-\frac{\ell}{4},\frac{\ell}{4})^3$ (Proposition YM3_I:91.13). So $\bar P=\mathsf{Bl}_n\max\{1,C_1(2R),\max_{2\le N\le n}C_N^{\mathrm{per}}(\mathsf{d};2R),\max_{2\le N\le n}C_N^{g}(\mathsf{d};2R)\}^n$ serves. □

Lemma 18.56 (The chain on $T_{\ell'}$ with observables in the exponent; read-outs)**.** In the data of the transfer let $(K,\beta)\in\mathfrak{d}(g)$, $0<\phi\le\frac{1}{84}$ and $K\ge\max\{K_\phi,5\}$, and let $\mathfrak{J}_\iota$, $\iota\in\mathcal{A}_0$, finitely many, be local observables of orders ≥2 on $T_{\ell'}$ with complex weights $\varkappa_\iota$ and with the radii $r_{\mathfrak{J}_\iota}$ of [7, Lemma 5.20](a), so that $1/r_{\mathfrak{J}_\iota}\le C_r|\varkappa_\iota|_\infty$ with C_r a function of ℓ', b_+ and the type ([7, Lemma 5.20](c)).

(a) For $w\in\mathsf{Src}$ and $\mathbf{s}\in\mathbb{C}^{\mathcal{A}_0}$ with $\sum_\iota|s_\iota|/r_{\mathfrak{J}_\iota}<1$ let $\mathcal{L}(\mathbf{s},w;V)=\sum_{i\le t}\mathsf{c}_i(w,\mathbf{s})+\Phi_t^{w,\mathbf{s}}(V)$, $V\in\mathsf{Cut}_t$, with the numbers and the exponent of [7, Lemma 5.20](a) formed for $\sum_\iota s_\iota\mathfrak{J}_\iota$. Then

$$(\mathcal{M}^t)_*(\mathsf{p}_t e^{\sum_\iota s_\iota\mathfrak{J}_\iota}\rho_0^w dU)=\mathbf{1}_{\mathsf{Cut}_t}e^{\mathcal{L}(\mathbf{s},w;\cdot)}dV,\qquad (\mathcal{M}^t)_*(\mathfrak{w}_t^{\mathrm{sf}}e^{\sum_\iota s_\iota\mathfrak{J}_\iota}\rho_0^w dU)=\mathbf{1}_{\mathsf{In}_t}e^{\mathcal{L}(\mathbf{s},w;\cdot)}dV;$$

$\mathcal{L}(\mathbf{s},w;V)$ is holomorphic in $(\mathbf{s},w)$, and for every background U over V

$$\mathcal{L}(\mathbf{s},w;V)=\mathsf{c}_\circ+\sum_{i\le t}\sum_{X,z}E^{(i)}[w,\mathbf{s}](X,U,z)-A^{\eta_t}(x_t^w,U)+\sum_\iota s_\iota\mathfrak{J}_\iota(U),$$

with the families $E^{(i)}[w,\mathbf{s}]$ of that Lemma and a number $\mathsf{c}_\circ$ that reads neither $\mathbf{s}$ nor w nor V.

(b) *(Mixed derivatives across a gap.)* Let $\Theta\subset\mathbb{C}^{\mathcal{V}}$ be a polydisc about 0 with the radii ρ_v, and $\theta\mapsto(\mathbf{s}(\theta),w(\theta))$ a polynomial map of Θ into the domain of (a) with $w(\theta)$ linear in θ; for each variable v let $S(v)\subset T_{\ell'}$ be a closed set such that $w(\theta)(p)$ reads θ_v only if $x(p)\in S(v)$, and $s_\iota(\theta)$ reads θ_v only if the boxes of $\mathfrak{J}_\iota$ lie in $S(v)$. Let $b\subset\mathcal{V}$, $\#b\ge2$, hold two variables v,v' whose sets $S(v)$, $S(v')$ lie at sup distance $\ge\mathsf{d}_*>2a$. Then at every $V\in\mathsf{Cut}_t$, with a background U over V,

$$\Big|\prod_{v\in b}\partial_{\theta_v}\Big[\mathcal{L}(\mathbf{s}(\theta),w(\theta);V)-\sum_\iota s_\iota(\theta)\mathfrak{J}_\iota(U)\Big]_{\theta=0}\Big|\le\tau_t(\mathsf{d}_*)\prod_{v\in b}\rho_v^{-1},\qquad \tau_t(\mathsf{d}_*)=e^2E_0C_{\mathrm{E},0}\sum_{i\le t}N_ie^{-(\mathsf{d}_*-2a)L^{K-i}/M},$$

with E_0 of (Th1) and $C_{\mathrm{E},0}$ of Proposition YM3_I:45.1(a4).

(c) *(Read-outs.)* For one local observable $\mathfrak{J}$ of an order ≥2 and $w\in\mathsf{Src}$ put $\dot F[\mathfrak{J};w](V)=\partial_s\mathcal{L}(s,w;V)|_{s=0}$, $V\in\mathsf{Cut}_t$. Then $(\mathcal{M}^t)_*(\mathsf{p}_t\mathfrak{J}\rho_0^w dU)=\dot F[\mathfrak{J};w]\,\mathbf{1}_{\mathsf{Cut}_t}e^{\mathcal{L}(0,w;\cdot)}dV$. At a real source w the measure $\nu_t^w=(\mathcal{M}^t)_*(\mathsf{p}_t\rho_0^w dU)=\mathbf{1}_{\mathsf{Cut}_t}e^{\mathcal{L}(0,w;\cdot)}dV$ is positive and has the null sets of the Haar measure on Cut_t, and $\dot F[\mathfrak{J};w]$ is, almost everywhere on Cut_t, the

conditional mean $\mathsf{Q}^w_{t\leftarrow 0}\mathfrak{J}$ of $\mathfrak{J}$ given the block field of the level t under $\mathsf{p}_t\rho_0^w dU$, that is, the density of $(\mathcal{M}^t)_*(\mathsf{p}_t\mathfrak{J}\rho_0^w dU)$ against ν_t^w. For two observables, $\dot F[\mathfrak{J}_1+\zeta\mathfrak{J}_2;w]=[\partial_{s_1}+\zeta\partial_{s_2}]\mathcal{L}((s_1,s_2),w;\cdot)|_{s=0}$; $\dot F[\mathfrak{J};w](V)$ is holomorphic in w; and at every $V\in\mathsf{Cut}_t$ and every $w\in\mathsf{Src}$, $|\dot F[\mathfrak{J};w](V)|\le C_B L^{3K}|\varkappa|_\infty$, C_B a function of ℓ', b_+ and the type of $\mathfrak{J}$.

(d) *(One source.)* For a real Lipschitz function $h\neq 0$ on $T_{\ell'}$ and $|\zeta|<(8\mathsf{M}_t^{\mathrm{rd}}\|h\|_\sharp)^{-1}$, $\zeta h\in\mathsf{Src}$ and $\mathcal{L}(0,\zeta h;V)-\mathcal{L}(0,0;V)=\mathsf{k}(\zeta)+\Delta\Phi(\zeta,V)$, where k is holomorphic with $\mathsf{k}(0)=0$ and reads no V, and $\Delta\Phi=\Phi_t^{\zeta h}-\Phi_t^0$, formed with the field-dependent exponents of the chain at the two sources, is holomorphic in ζ and at most $\frac14$ in modulus on Cut_t.

■

Sketch. (a) [7, Lemma 5.20](a), for several observables and at every source, complex sources included, gives at the level t the display $(\mathcal{M}^t)_*(\mathsf{p}_t e^{\sum_\iota s_\iota\mathfrak{J}_\iota}\rho_0^w dU)=\exp[\sum_{i\le t}\mathsf{c}_i(w,\mathbf{s})]\mathbf{1}_{\mathsf{Cut}_t}e^{\Phi_t^{w,\mathbf{s}}}dV$, with families $E^{(i)}[w,\mathbf{s}]$ that are holomorphic in $(w,\mathbf{s})$ and in the fields, local in w and in the observables, and of norms below E_0 on the domain; multiplied by $\mathbf{1}_{\mathsf{In}_t}\circ\mathcal{M}^t$ it gives the second display, as $\mathfrak{w}_t^{\mathrm{sf}}=(\mathbf{1}_{\mathsf{In}_t}\circ\mathcal{M}^t)\mathsf{p}_t$ and $\mathsf{In}_t\subset\mathsf{Cut}_t$. The number $\mathsf{c}_i(w,\mathbf{s})$ is $\log(\mathsf{pf}_{i-1}(x_{i-1})\mathsf{Z}^{(i-1)}[(\mathbf{1},0,0)])$, which reads neither w nor $\mathbf{s}$, plus the sum of the members of $E^{(i)}[w,\mathbf{s}]$ at the trivial configuration (Proposition YM3_I:114.2 and [7, Lemma 5.20(a)]), while $\Phi_t^{w,\mathbf{s}}(V)$ is $-A^{\eta_t}(x_t^w,U)$ plus the sums of the same members at U less their values at $\mathbf{1}$, plus $\sum_\iota s_\iota\mathfrak{J}_\iota(U)$; adding them gives the formula, $\mathsf{c}_\circ$ being the sum of the logarithms.

(b) In the bracket the term $\mathsf{c}_\circ$ reads no variable, and $-A^{\eta_t}(x_t^{w(\theta)},U)$ is affine in w, so affine in θ; the derivative in the $\#b\ge 2$ variables of b kills both. The member of $E^{(i)}$ at (X,z), taken at U, reads w on the plaquettes of X alone and s_ι only if $\mathfrak{J}_\iota$ meets X ([7, Lemma 5.20](a), whose families are local in w and in the observables); so it reads θ_v only if X meets $S(v)$, and its derivative in the variables of b vanishes unless X meets both $S(v)$ and $S(v')$. Such a domain of the level i holds two points at sup distance $\ge\mathsf{d}_*-2a$, so that $d_i(X)\ge(\mathsf{d}_*-2a)L^{K-i}/M-2$ (Proposition YM3_I:45.1(b3)). On Θ the member is at most $E_0e^{-(\kappa+1)d_i(X)}$, where κ is the rate of decay in the norms of the families of the main text, and Cauchy's estimate bounds its mixed derivative by this number times $\prod_{v\in b}\rho_v^{-1}$; the sum over the domains through each of the N_i sites of the level i, with Proposition YM3_I:45.1(a4) as in the proof of [7, Proposition 3.15](b), and over $i\le t$ gives $\tau_t(\mathsf{d}_*)$.

(c) The densities in (a) are bounded on a disc of s uniformly in V, the members having norms below E_0; so (a), integrated against a bounded Borel function of V, may be differentiated in s at 0 under the integrals, which gives the display, and at a real source the measures are images of positive measures, the density $e^{\mathcal{L}(0,w;\cdot)}$ has no zero on Cut_t, and the conditional mean is the quotient of the two densities. The rule for two observables holds because the recursion of [7, Lemma 5.20](a) reads the observables through $\sum_\iota s_\iota\mathfrak{J}_\iota$ alone, and holomorphy in w comes from (a). For the bound, by (a), $\dot F[\mathfrak{J};w](V)=\sum_{i\le t}\mathrm{Sum}[\mathsf{g}_i](U)+\mathfrak{J}(U)$ with the pointed families $\mathsf{g}_i=\partial_s E^{(i)}[w,s]|_{s=0}$, of norms at most the numbers d_i of the Lipschitz bound of [7, Lemma 5.20](a), which holds at every source; Proposition YM3_I:45.1(a4) at $D=0$ bounds $|\mathrm{Sum}[\mathsf{g}_i](U)|$ by $C_{\mathrm{E},0}N_i\mathsf{d}_i$, $\max_i\mathsf{d}_i\le C|\varkappa|_\infty$ (the numbers of an observable, in the data of the transfer), $\sum_{i\ge1}N_i\le 2\ell'^3L^{3K}$, and $|\mathfrak{J}(U)|\le N\hat c\,\ell'^3L^{3K}|\varkappa|_\infty$ at the real configuration U ([7, Lemma 5.20](c)).

(d) This is Lemma YM3_I:114.5 for the single function h, with $\|h\|_{\flat;T_{\ell'}}\le\|h\|_\sharp$: below the radius $(8\mathsf{M}_t^{\mathrm{rd}}\|h\|_\sharp)^{-1}$ the source ζh lies in Src and $|\Phi_t^{\zeta h}-\Phi_t^0|\le\frac14$ on Cut_t. At $s=0$ the families of [7, Lemma 5.20](a) are those of the chain at the source, so $\mathcal{L}(0,\zeta h;V)=\sum_i\mathsf{c}_i(\zeta h)+\Phi_t^{\zeta h}(V)$, and $\mathsf{k}(\zeta)=\sum_i(\mathsf{c}_i(\zeta h)-\mathsf{c}_i(0))$ is holomorphic by Proposition YM3_I:114.2. □

Lemma 18.57 (Oscillations of read-outs)**.** In the setting of Lemma 18.56:

(a) *(Power counting, at every source.)* For a local observable $\mathfrak{J}$ of the order $m_{\mathfrak{J}}\ge2$ and every $w\in\mathsf{Src}$, real or complex, $\dot F[\mathfrak{J};w]$ differs at every point of Cut_t from one number by at

most $\mathsf{o}_t(\mathfrak{J})$, the number of [7, Lemma 5.20](b); and $\mathsf{o}_t(\mathfrak{J}) \le CK^{2\mathfrak{p}_0}L^{4u-K}|\varkappa|_\infty$ if $m_{\mathfrak{J}} = 2$, $\mathsf{o}_t(\mathfrak{J}) \le CK^{3\mathfrak{p}_0}L^{4u-\frac{3}{2}K}|\varkappa|_\infty$ if $m_{\mathfrak{J}} \ge 3$, C a function of ℓ', b_+ and the type.

(b) *(In-plane orbital potentials, at a real source.)* Let $0 < \kappa_{\mathrm{H}} < 1$, $\phi < \psi_{\mathrm{c}} < 1$ and $n_0 = K - \lceil \psi_{\mathrm{c}} K \rceil$. There are K_ψ and C_ψ, functions of ℓ', b_+, κ_{H}, ψ_{c} and ϕ, such that for $K \ge K_\psi$, every real weight $\varkappa$ of the plaquettes and every real source $w \in \mathsf{Src}$ there is a number a with $|\dot F[\mathfrak{J}_\varkappa; w] - \mathsf{a}| \le \epsilon_\psi |\varkappa|_\infty$ almost everywhere on Cut_t, where $\mathfrak{J}_\varkappa = \sum_p \varkappa(p)\psi(p)$ and

$$\epsilon_\psi = C_\psi K^{3\mathfrak{p}_0} L^{-K} \big[L^{-(2\kappa_{\mathrm{H}} - (3+2\kappa_{\mathrm{H}})\psi_{\mathrm{c}})K} + L^{3u - \frac{1}{2}\psi_{\mathrm{c}} K} \big].$$

(c) *(The cubic insertion, at a real source.)* Let $0 < \tau \le \frac{1}{4}$, $\phi < \frac{1}{42}$, $c_0' = \min\{\frac{1}{14} - \frac{\tau}{7}, \frac{1}{14} - 3\phi\}$, and let K_2, C_2, p_2 be the numbers of Lemma 5.10(b) on $T_{\ell'}$ for $\mathsf{b}_- = \gamma^{-2}$ and b_+. For $K \ge K_2$, every field Ξ on $T_{\ell'}$, every real Lipschitz $h \ne 0$ on $T_{\ell'}$ and every real x with $|x| < (8\mathsf{M}_t^{\mathrm{rd}} \|h\|_\sharp)^{-1}$ there is a number $\mathsf{a}(x)$ with $|\dot F[\mathfrak{K}^\sharp[(\beta - a^{-1}xh)\Xi]; xh] - \mathsf{a}(x)| \le C_2 \mathsf{H}(\Xi) K^{p_2} L^{-c_0' K}$ almost everywhere on Cut_t.

■

Sketch. (a) At a background U over $V \in \mathsf{Cut}_t$ the formula of Lemma 18.56(a) gives $\Phi_t^{w,s}(V) - \Phi_t^{w,s'}(V) = (s - s')\mathfrak{J}(U) + \sum_{i \le t}(\mathrm{Sum}[\delta E_i](U) - \mathrm{Sum}[\delta E_i](\mathbf{1}))$ with $\delta E_i = E^{(i)}[w, s] - E^{(i)}[w, s']$, of norms at most $|s - s'|\mathsf{d}_i$ at every source ([7, Lemma 5.20](a)). The sum is the action at U of a bare array with vanishing counterterms and an empty slot, at most $C_{\mathrm{old}} N_t \sum_i L^{-(t-i)}|s - s'|\mathsf{d}_i$ by Proposition YM3_I:113.13, which reads no source, and $|\mathfrak{J}(U)| \le N_t N c(\mathsf{e}_t^{\mathrm{c}})^{m_{\mathfrak{J}}} |\varkappa|_\infty L^{-(2m_{\mathfrak{J}}-3)t}$, the plaquette variables of U lying within $\mathsf{e}_t^{\mathrm{c}} L^{-2t}$ of $\mathbf{1}$; this is the computation of the proof of [7, Lemma 5.20](a), and it gives $|\partial_s \Phi_t^{w,s}|_{s=0}| \le \mathsf{o}_t(\mathfrak{J})$ at every point of Cut_t. The difference $\dot F[\mathfrak{J}; w] - \partial_s \Phi_t^{w,s}|_{s=0} = \sum_i \partial_s \mathsf{c}_i(w, s)|_{s=0}$ reads no V, and the bounds of o_t are those of [7, Lemma 5.20](a).

(b) Let w be a real source and $\mathfrak{J} = \mathfrak{J}_\varkappa$, an observable of the order 2. We follow the proof of [7, Lemma 3.18](a) at the source w. The chain measures $\nu_k^w = (\mathcal{M}^k)_*(\mathsf{p}_k \rho_0^w dU)$ are positive and obey $\nu_{k+1}^w = \mathbf{1}_{\mathsf{Cut}_{k+1}} \mathbf{T}(\mathfrak{G}_k[x_k] \chi_{x_k}^{\mathrm{sf}} \nu_k^w)$, by the recursion of the weights p_k ([7, Definition 3.2](3)); so the conditional mean $\mathsf{Q}_k^w h$, the density of $\mathbf{1}_{\mathsf{Cut}_{k+1}} \mathbf{T}(\mathfrak{G}_k[x_k] \chi_{x_k}^{\mathrm{sf}} h\, \nu_k^w)$ against ν_{k+1}^w, averages h against a positive kernel, $|\mathsf{Q}_k^w h - \mathsf{a}_0| \le \|h - \mathsf{a}_0\|_{L^\infty(\nu_k^w)}$ for real h and numbers a_0, and $\mathsf{Q}_{t \leftarrow 0}^w = \mathsf{Q}_{t \leftarrow n_0}^w \mathsf{Q}_{n_0 \leftarrow 0}^w$ with $\mathsf{Q}_{t \leftarrow n_0}^w = \mathsf{Q}_{t-1}^w \cdots \mathsf{Q}_{n_0}^w$. The display of [7, Lemma 5.20](a) at the level n_0, differentiated in s as in Lemma 18.56(c), gives $\mathsf{Q}_{n_0 \leftarrow 0}^w \mathfrak{J} = \dot c + \mathfrak{J}(U_{n_0}) + \sum_{i \le n_0}(\mathrm{Sum}[\mathsf{g}_i](U_{n_0}) - \mathrm{Sum}[\mathsf{g}_i](\mathbf{1}))$ almost everywhere on Cut_{n_0}, with a number $\dot c$ and the pointed families $\mathsf{g}_i = \partial_s E^{(i)}[w, s]|_{s=0}$, of norms $\le \mathsf{d}_i$. A pointed family g of a level $i' \le k$ is carried by one conditional mean as $\mathsf{Q}_k^w \Sigma_k[\mathsf{g}] = \Sigma_{k+1}[\mathsf{g} + \mathsf{S}_k^w \mathsf{g}]$, $\Sigma_k[\mathsf{g}] = \mathrm{Sum}[\mathsf{g}] \circ U_k$, with $\|\mathsf{S}_k^w \mathsf{g}\| \le \theta_k L^{-(k-i')}\|\mathsf{g}\|$: the derivation of [7, Lemma 3.14](a), which perturbs an early member of the run by $\mu\mathsf{g}$ and differentiates the identity of the step in μ, rests on the step identity of Proposition YM3_I:114.2 and on the loss of memory of Proposition YM3_I:114.3, both of them stated at one source, and so holds at w. Hence, as in the proof of [7, Lemma 3.18](a), the families carried from the level n_0 to the level t differ at every point of Cut_t from a number by at most $e\mathsf{B}_0' L^{3u-K} \sum_{i \le n_0} L^i \mathsf{d}_i \le CK^{3\mathfrak{p}_0} L^{3u-K-(K-n_0)/2}|\varkappa|_\infty$ ([7, Lemma 3.16](b), and the bound of $\sum_{i \le k} L^i \mathsf{d}_i$ at the order 2 and $k = n_0$ among the numbers of an observable), while $|\mathsf{Q}_{t \leftarrow n_0}^w(\mathfrak{J} \circ U_{n_0})| \le \epsilon_X$, the supremum of $|\mathfrak{J}|$ over the backgrounds over Cut_{n_0}. To bound ϵ_X we use Lemma 5.9(e), which writes at every real configuration

$$\psi(p) = -\tfrac{1}{8} \sum_{b \subset \partial p} |G_{\nu(p,b)}(b)|^2 - \tfrac{1}{8} \sum_{\nu \in P(p)} (2a_p^2 + a_{p+ae_\nu}^2 + a_{p-ae_\nu}^2),$$

$\nu(p, b)$ the direction of $P(p)$ normal to b; and $G_\rho(b)$ is the vector $\mathbf{y}_{b,\rho}$ of [7, § 3]. A background U over $V \in \mathsf{Cut}_{n_0}$ is regular of level n_0 at the radius ε_{n_0}, with $\varepsilon_{n_0}^2 \le \bar{\mathsf{c}}_\varepsilon (K \log L + \log \mathsf{b}_+)^{2\mathfrak{p}_0} L^{-(K-n_0)}$ ([7, Lemma 3.16](a)); so $a_q(U) = \frac{1}{2}|\partial U(q) - \mathbf{1}|^2 < \frac{1}{2}\varepsilon_{n_0}^2 L^{-4n_0}$, and for $K \ge K_\psi$, which brings the data of [7, Lemma 3.16](c) at $n = n_0$ and $\varepsilon = \varepsilon_{n_0}$ together with the thresholds of [7, Lemma 3.18], $|\mathbf{y}_{b,\rho}(U)| \le 48\, \mathsf{c}_{\mathrm{g}}(\kappa_{\mathrm{H}}) \rho_{\mathrm{H}} \varepsilon_{n_0} L^{-(2+\kappa_{\mathrm{H}})n_0}$. With $3\ell'^3 L^{3K}$ plaquettes this gives $\epsilon_X \le CK^{2\mathfrak{p}_0} L^{2K-(3+2\kappa_{\mathrm{H}})n_0}|\varkappa|_\infty$. By

Lemma 18.56(c) the read-out is $\mathsf{Q}^{w}_{t\leftarrow 0}\mathfrak{J}$ almost everywhere on Cut_t; with $n_0 \ge (1-\psi_{\rm c})K-1$ and $K-n_0 \ge \psi_{\rm c}K$ the two bounds give ϵ_ψ.

(c) Lemma 5.10(b), on $T_{\ell'}$ with $\mathsf{b}_- = \gamma^{-2}$ and b_+ ([7, Lemma 3.12](a)), with $n=1$ and the function h, gives at real x in its polydisc, whose radius is $(8\mathsf{M}_t^{\rm rd}\|h\|_\sharp)^{-1}$, a number $\mathsf{a}(x)$ with $|\mathsf{Q}^{xh}_{t\leftarrow 0}\mathfrak{K}^\sharp[(\beta-a^{-1}xh)\Xi]-\mathsf{a}(x)| \le C_2\mathsf{H}(\Xi)K^{p_2}L^{-c_0'K}$ almost everywhere for ν_t^{xh} on Cut_t; by Lemma 18.56(c) the read-out is that conditional mean almost everywhere, and ν_t^{xh} has the null sets of the Haar measure on Cut_t. □

Proposition 18.58 (The mean of the eight mirror copies)**.** In the data of the transfer, with $\|g_i\|_\sharp = 1$ for every i, let $\mathbb{J} = (\mathfrak{J}_0,\dots,\mathfrak{J}_n)$ be a local insertion tuple over the sources, of types with constants at most $(c,\hat c,N)$, with $\mathfrak{J}_0$ carried by A_{R+1} and $\mathfrak{J}_i$ within sup distance $4a$ of $\operatorname{supp} g_i$, and with $\varkappa^* = |\varkappa_0|_\infty + \max_i|\varkappa_i|_\infty = 1$, $\varkappa_i$ the weights of $\mathfrak{J}_i$, $0\le i\le n$. Let $(K,\beta)\in\mathfrak{d}(g)$, $0<\phi\le\frac{1}{84}$, $K\ge\max\{K_\phi,5\}$ and $16a\le\mathsf{d}$. Put $\alpha_\emptyset = \langle\mathfrak{J}_0\rangle'$, $\alpha_i = \langle\mathfrak{J}_0;O_i\rangle' + \langle\mathfrak{J}_i\rangle'$, $\bar o_i = \langle O_i\rangle'$, let H_B be the functions of Lemma 18.54, and for $\kappa\in\mathsf{Z}$, $1\le i\le n$ and $|\zeta|<r_i$ let $\dot F_i^\kappa(\zeta,\cdot) = \dot F[\mathfrak{J}_0^{[\kappa]} + \zeta\mathfrak{J}_i^{[\kappa]};\zeta g_i^\kappa]$, the read-out of Lemma 18.56(c), which applies as each of the mirror copies $\mathfrak{J}_0^{[\kappa]},\dots,\mathfrak{J}_n^{[\kappa]}$ is a local observable on $T_{\ell'}$ of the order of the member that it copies, of a type formed from the type of that member alone, and with weights of the same moduli ([7, Lemma 5.20](d)). Suppose that for numbers $0<\epsilon_1\le B_1$ and all κ and i:

(OI-C) $|\dot F_i^\kappa(\zeta,V)|\le B_1$ for $|\zeta|<r_i$ and $V\in\mathsf{Cut}_t$;

(OI-R) for every real $x\in(-r_i,r_i)$ there is a number a with $|\dot F_i^\kappa(x,V)-\mathsf{a}|\le\epsilon_1$ for almost every $V\in\mathsf{In}_t$.

Then there are $K_\star$, a function of g, n, R, d, ϕ and $(c,\hat c,N)$, an integer q_n and a number C of the same data, such that for $K\ge K_\star$, every $B\subset\{1,\dots,n\}$, $k=\#B$, and every $0<\sigma\le 1$

$$\Big|\Big\langle\prod_{\kappa\in\mathsf{Z}}H_B^{[\kappa]}\Big\rangle'\Big|^{1/8} \le [(1+k)\epsilon_2+\vartheta_K]\mathsf{M}^k, \qquad \epsilon_2 = \frac{4}{\pi\sigma}(2\epsilon_1)^{1-\sigma}(2B_1)^\sigma + 2\epsilon_1, \qquad \vartheta_K \le (CL^K)^{q_n}[\tau_t(\tfrac12\mathsf{d})^{1/8} + \mathsf{R}_t^{1/8}],$$

with τ_t of Lemma 18.56(b). For $B=\emptyset$ only the read-outs at $\zeta=0$ enter. ■

Sketch. 1. The identity. Let $\mathcal{A} = \{\mu_\kappa : \kappa\in\mathsf{Z}\}\cup\{z_i^\kappa : \kappa\in\mathsf{Z},\ i\in B\}$, $8(1+k)$ variables, and let Θ be the polydisc $|\mu_\kappa|<\mu^\sharp$, $|z_i^\kappa|<\zeta_\circ$, with $\zeta_\circ = \min\{1,\varrho/(8n)\}$ and $\mu^\sharp = [16(1+n)C_r]^{-1}$, C_r the number of Lemma 18.56 for the types of the copies. On Θ put $w(\theta) = \sum_{\kappa,i} z_i^\kappa g_i^\kappa$, which lies in Src by Lemma YM3_I:114.5(b), as $\sum_{\kappa,i}|z_i^\kappa|\,\|g_i^\kappa\|_{\flat;T_{\ell'}} < 8k\zeta_\circ \le \varrho$, and give the observables $\mathfrak{J}_0^{[\kappa]}$ and $\mathfrak{J}_i^{[\kappa]}$ the coefficients μ_κ and $\mu_\kappa z_i^\kappa$, which keeps $\sum_\iota |s_\iota|/r_{\mathfrak{J}_\iota}<1$. Then $\sum_\iota s_\iota\mathfrak{J}_\iota + \mathcal{O}(w) = \sum_\kappa[\mu_\kappa Y^\kappa_{z^\kappa} + \sum_i z_i^\kappa O_i^\kappa]$ with $Y_z^\kappa = \mathfrak{J}_0^{[\kappa]} + \sum_{i\in B} z_i\mathfrak{J}_i^{[\kappa]}$ and $O_i^\kappa = O_i^{[\kappa]}$, and Lemma 18.56(a) gives $\Lambda'(\exp\sum_\kappa[\mu_\kappa Y^\kappa_{z^\kappa} + \sum_i z_i^\kappa O_i^\kappa]) = \int_{\mathsf{In}_t} e^{\mathcal{L}(\theta;V)}dV$, $\mathcal{L}(\theta;V) = \mathcal{L}(\mathbf{s}(\theta),w(\theta);V)$. We multiply by $\exp[-\sum_\kappa\mu_\kappa\mathsf{a}_\circ(z^\kappa) - \sum_{\kappa,i}\bar o_i z_i^\kappa]$, $\mathsf{a}_\circ(z) = \alpha_\emptyset + \sum_i\alpha_i z_i$, and differentiate once in each variable of $\mathcal{A}$ at $\theta=0$, under the integrals, the integrands being holomorphic on Θ and bounded there uniformly in the point. As the copies are multiplicative and fix constants, the left member becomes $\Lambda'(\prod_\kappa H_B^{[\kappa]})$ by the rule of Leibniz of the proof of Lemma 18.54, and the right member becomes $\int D\,d\tilde\nu$, with the positive measure $\tilde\nu = \mathbf{1}_{\mathsf{In}_t}e^{\mathcal{L}(0;\cdot)}dV = (\mathcal{M}^t)_*(\mathfrak{w}_t^{\rm sf}\rho_0 dU)$ and

$$D(V) = \prod_{v\in\mathcal{A}}\partial_v\, e^{\bar{\mathcal{E}}(\theta;V)}\Big|_{\theta=0} = \sum_\pi\prod_{b\in\pi}\partial^b\bar{\mathcal{E}}(0;V), \qquad \bar{\mathcal{E}}(\theta;V) = \mathcal{L}(\theta;V) - \mathcal{L}(0;V) - \sum_\kappa\mu_\kappa\mathsf{a}_\circ(z^\kappa) - \sum_{\kappa,i}\bar o_i z_i^\kappa,$$

the sum over the partitions π of $\mathcal{A}$, ∂^b the derivative once in each variable of b.

2. Discarding. For a bounded real gauge invariant Borel function F, Proposition YM3_I:115.2, applied to its positive and to its negative part, give $|Z\langle F\rangle' - \Lambda'(F)| \le \sup|F|\,\mathsf{R}_tZ$, and $0\le Z-\Lambda'(1)\le\mathsf{R}_tZ$. With $\tilde\nu(\mathsf{In}_t) = \Lambda'(1)\le Z$ this gives $|\langle\prod_\kappa H_B^{[\kappa]}\rangle'| \le \operatorname{ess\,sup}_{\mathsf{In}_t}|D| + \mathsf{R}_tS_H^8$, $S_H\ge\sup|H_B|$; and, with $\langle F\rangle_{\Lambda'} = \Lambda'(F)/\Lambda'(1)$, $|\langle F\rangle' - \langle F\rangle_{\Lambda'}| \le 2\mathsf{R}_t\sup|F|$ once $\mathsf{R}_t\le\frac12$.

3. Blocks across a gap. Let $S(\mu_\kappa)$ be the union of the boxes of $\mathfrak{J}_0^{[\kappa]},\dots,\mathfrak{J}_n^{[\kappa]}$, and $S(z_i^\kappa)$ the union of $\{x(p): g_i^\kappa(x(p))\neq 0\}$ with the boxes of $\mathfrak{J}_i^{[\kappa]}$. They are as Lemma 18.56(b) asks. The sets of one cell lie in the copy of A_{R+2}, at sup distance ≥ 16 from the walls, so sets of two different cells lie at sup distance ≥ 32; and $S(z_i^\kappa)$, $S(z_l^\kappa)$, $i\neq l$, lie at sup distance $\geq \mathsf{d}-8a\geq \frac12\mathsf{d}$. So every block b with $\#b\geq 2$ that is not of the form $\{\mu_\kappa,z_i^\kappa\}$ holds two variables whose sets lie at sup distance $\geq \frac12\mathsf{d}>2a$. The subtracted terms of $\bar{\mathcal{E}}$ and the sum $\sum_\iota s_\iota(\theta)\mathfrak{J}_\iota(U)$ are sums of the monomials μ_κ, $\mu_\kappa z_i^\kappa$, z_i^κ, which ∂^b kills; Lemma 18.56(b) gives $|\partial^b\bar{\mathcal{E}}(0;V)|\leq \tau_t(\frac12\mathsf{d})\prod_{v\in b}\rho_v^{-1}$ at every $V\in\mathsf{Cut}_t$.

4. Read-outs. For $K\geq K_\star$, $r_i\leq\zeta_\circ$, and $\dot F_i^\kappa(\zeta,V)$ is $\partial_{\mu_\kappa}\mathcal{L}(\theta;V)$ at $\mu=0$, $z_i^\kappa=\zeta$ and the other z equal to 0 (the rule for two observables of Lemma 18.56(c)); it is holomorphic in ζ at every V. Let $\mathsf{In}^\circ\subset\mathsf{In}_t$ be the set of the V at which (OI-R) holds for all κ, i and all x of a countable dense subset of $(-r_i,r_i)$; its complement in In_t is a Haar null set, and by continuity in x, $|\dot F_i^\kappa(x,V)-\dot F_i^\kappa(x,V')|\leq 2\epsilon_1$ for all real $x\in(-r_i,r_i)$ and $V,V'\in\mathsf{In}^\circ$. The one-variable estimate in the proof of Lemma YM3_I: 116.2, applied to $\zeta\mapsto \dot F_i^\kappa(\zeta,V)-\dot F_i^\kappa(\zeta,V')$, bounded by $2B_1$ on the disc and by $2\epsilon_1$ on the real interval, gives $|\partial_\zeta\dot F_i^\kappa(0,V)-\partial_\zeta\dot F_i^\kappa(0,V')|\leq\omega/r_i$ with $\omega=\frac{4}{\pi\sigma}(2\epsilon_1)^{1-\sigma}(2B_1)^\sigma$.

5. The blocks $\{\mu_\kappa\}$, $\{z_i^\kappa\}$, $\{\mu_\kappa,z_i^\kappa\}$, at $V\in\mathsf{In}^\circ$, with the probability measure $\hat\nu=\tilde\nu/\tilde\nu(\mathsf{In}_t)$, which charges no Haar null set, and with the invariance of $\langle\cdot\rangle'$ under the r_κ. $\{\mu_\kappa\}$: $\partial_{\mu_\kappa}\bar{\mathcal{E}}(0;V)=\dot F_i^\kappa(0,V)-\alpha_\emptyset$; the identity of Step 1 differentiated in μ_κ alone gives $\langle\mathfrak{J}_0^{[\kappa]}\rangle_{\Lambda'}=\int\dot F_i^\kappa(0,\cdot)\,d\hat\nu$, while $\alpha_\emptyset=\langle\mathfrak{J}_0^{[\kappa]}\rangle'$, and by (OI-R) at $x=0$, $|\dot F_i^\kappa(0,V)-\int\dot F_i^\kappa(0,\cdot)\,d\hat\nu|\leq 2\epsilon_1$; so $|\partial_{\mu_\kappa}\bar{\mathcal{E}}(0;V)|\leq 2\epsilon_1+2\mathsf{R}_tS_0$, $S_0\geq\sup|\mathfrak{J}_0|$. $\{z_i^\kappa\}$: by Lemma 18.56(d) for $h=g_i^\kappa$, $\partial_{z_i^\kappa}\bar{\mathcal{E}}(0;V)=\mathsf{k}'(0)+\varphi(V)-\bar o_i$ with $\varphi=\partial_\zeta\Delta\Phi(0,\cdot)$, $|\varphi|\leq\frac{1}{4r_i}$ by Cauchy's estimate; $T(\zeta)=\Lambda'(e^{\zeta O_i^\kappa})=e^{\mathsf{k}(\zeta)}\int e^{\Delta\Phi(\zeta,\cdot)}d\tilde\nu$ gives $\mathsf{k}'(0)+\int\varphi\,d\hat\nu=\langle O_i^\kappa\rangle_{\Lambda'}$, while $\bar o_i=\langle O_i^\kappa\rangle'$; so $|\partial_{z_i^\kappa}\bar{\mathcal{E}}(0;V)|\leq\frac{1}{2r_i}+2\mathsf{R}_tS_O$, $S_O\geq\max_i\sup|O_i|$. $\{\mu_\kappa,z_i^\kappa\}$: $\partial_{\mu_\kappa}\partial_{z_i^\kappa}\bar{\mathcal{E}}(0;V)=\partial_\zeta\dot F_i^\kappa(0,V)-\alpha_i$. The function $N(\zeta)=\Lambda'(Y_\zeta^\kappa e^{\zeta O_i^\kappa})$, $Y_\zeta^\kappa=\mathfrak{J}_0^{[\kappa]}+\zeta\mathfrak{J}_i^{[\kappa]}$, is $e^{\mathsf{k}(\zeta)}\int\dot F_i^\kappa(\zeta,\cdot)e^{\Delta\Phi(\zeta,\cdot)}d\tilde\nu$, by Step 1 differentiated in μ_κ alone at the source ζg_i^κ; so $(N/T)'(0)=\int\partial_\zeta\dot F_i^\kappa(0,\cdot)\,d\hat\nu+\int(\dot F_i^\kappa(0,\cdot)-\mathsf{a})(\varphi-\int\varphi\,d\hat\nu)\,d\hat\nu$, a the number of (OI-R) at $x=0$, and the second integral has modulus at most $\frac{\epsilon_1}{2r_i}$. On the other hand $(N/T)'(0)=\langle\mathfrak{J}_0^{[\kappa]}O_i^\kappa\rangle_{\Lambda'}-\langle\mathfrak{J}_0^{[\kappa]}\rangle_{\Lambda'}\langle O_i^\kappa\rangle_{\Lambda'}+\langle\mathfrak{J}_i^{[\kappa]}\rangle_{\Lambda'}$, and α_i is the same expression under $\langle\cdot\rangle'$; by Step 2 they differ by at most $6\mathsf{R}_tS_0S_O+2\mathsf{R}_tS_*$, $S_*\geq\max_i\sup|\mathfrak{J}_i|$. With Step 4: $|\partial_{\mu_\kappa}\partial_{z_i^\kappa}\bar{\mathcal{E}}(0;V)|\leq(\omega+\frac12\epsilon_1)r_i^{-1}+6\mathsf{R}_tS_0S_O+2\mathsf{R}_tS_*$.

6. The sum over the partitions. Let $K_\star$ be such that for $K\geq K_\star$: $\mathsf{R}_t\leq\frac12$, $2\mathsf{R}_tS_O\leq\frac{1}{2r_i}$, $r_i\leq\zeta_\circ$; this is possible, as R_t lies below every power of L^{-K} ([7, Lemma 3.14](d)), $S_O\leq 6\ell'^3L^{4K}$ and $r_i^{-1}=8\mathsf{M}_t^{\mathrm{rd}}\geq 8\varrho^{-1}\mathsf{m}_t^S$. Then $|\partial_{z_i^\kappa}\bar{\mathcal{E}}(0;V)|\leq r_i^{-1}$. Call a partition good if its blocks are of the forms $\{\mu_\kappa\}$, $\{z_i^\kappa\}$, $\{\mu_\kappa,z_i^\kappa\}$: in a cell κ it has either $\{\mu_\kappa\}$ and all the $\{z_i^\kappa\}$, or one $\{\mu_\kappa,z_{i_0}^\kappa\}$ and the $\{z_i^\kappa\}$, $i\neq i_0$; so the good partitions add up to the product over κ of $\partial_{\mu_\kappa}\bar{\mathcal{E}}\prod_i\partial_{z_i^\kappa}\bar{\mathcal{E}}+\sum_{i_0}\partial_{\mu_\kappa}\partial_{z_{i_0}^\kappa}\bar{\mathcal{E}}\prod_{i\neq i_0}\partial_{z_i^\kappa}\bar{\mathcal{E}}$, each factor of modulus at most $[(1+k)\epsilon_2+\delta_{\mathsf{R}}]\prod_{i\in B}r_i^{-1}$, with $\delta_{\mathsf{R}}=2\mathsf{R}_tS_0+k(6\mathsf{R}_tS_0S_O+2\mathsf{R}_tS_*)$, as $r_i\leq 1$ and $2\epsilon_1+k(\omega+\frac12\epsilon_1)\leq(1+k)\epsilon_2$. Every other partition holds a block across a gap (Step 3), and every block obeys $|\partial^b\bar{\mathcal{E}}(0;V)|\leq G_*\prod_{v\in b}\rho_v^{-1}$ with $G_*=\sup_{\Theta\times\mathsf{Cut}_t}|\bar{\mathcal{E}}|$, by Cauchy's estimate; there are $\mathsf{Bl}_{8(1+k)}$ partitions. So on In°

$$|D|\leq\Big([(1+k)\epsilon_2+\delta_{\mathsf{R}}]\prod_{i\in B}r_i^{-1}\Big)^8+\mathsf{Bl}_{8(1+k)}\,\tau_t(\tfrac12\mathsf{d})\max\{1,G_*\}^{8(1+k)}(\mu^\sharp)^{-8}\zeta_\circ^{-8k},$$

and Step 2, $(x^8+y+y')^{1/8}\leq x+y^{1/8}+y'^{1/8}$ and $r_i^{-1}\leq\mathsf{M}$ give the claim with $\vartheta_K=\delta_{\mathsf{R}}+\mathsf{Bl}_{8(1+n)}^{1/8}\tau_t(\frac12\mathsf{d})^{1/8}\max\{1,G_*\}^{1+n}(\mu^\sharp)^{-1}\zeta_\circ^{-n}+\mathsf{R}_t^{1/8}S_H$. As $\varkappa^*=1$, the suprema S_0, S_* are at most $N\hat c\,\ell'^3L^{3K}$ ([7, Lemma 5.20](c)); with $|\mathfrak{J}_0-\alpha_\emptyset|\leq 2S_0$, $|\mathfrak{J}_i-\alpha_i|\leq 2S_*+2S_0S_O$ and $|O_i-\bar o_i|\leq 2S_O$ one may take $S_H=(n+1)(2+2S_O)^n(2S_0+2S_*+2S_0S_O)$, a power of L^K times a number; and G_*, which holds the members of the families (of norms below E_0, summed with Proposition YM3_I: 45.1(a4)), the source term A^{η_t} and the polynomial terms on Θ, is a power of L^K times a number; this gives the bound of ϑ_K. □

Theorem BD (Hard combinations in every law of the transfer)**.** In the data of the transfer let $\mathbb{J}$ be a local insertion tuple over the sources g_i as in Proposition 18.58, but with sources of any norms and with $\varkappa^* = |\varkappa_0|_\infty + \max_i |\varkappa_i|_\infty / \|g_i\|_\sharp$, and let its read-outs satisfy (OI-C) and (OI-R) of that Proposition, with the radii $r_i = (8\mathsf{M}_t^{\mathrm{rd}}\|g_i\|_\sharp)^{-1}$ and numbers $0 < \epsilon_1 \le B_1$. Then for $(K,\beta) \in \mathfrak{d}(g)$ with $K \ge K_\star$ and $16a \le \mathsf{d}$, every law $\rho \in \mathfrak{S}_{K,\beta}$, every $B \subset \{1,\dots,n\}$ with $\#B \ge 2$ and every $0 < \sigma \le 1$,

$$|\mathsf{T}_\rho[\mathbb{J}](B)| \le \mathsf{c}_{\#B}\,\mathsf{Q}\,[(1+n)\epsilon_2 + \varkappa^*\vartheta_K]\,\mathsf{M}^{\#B}\prod_{i\in B}\|g_i\|_\sharp,$$

with ϵ_2, ϑ_K and $K_\star$ of Proposition 18.58 and the numbers c_k of Lemma 18.54 at the number $\bar{P}$ of Lemma 18.55(b). The numbers c_k and Q read g, n, R and d, and no K, no β, no side and no law. ■□

Sketch. Normalisation. Replacing $(g_i, \mathfrak{J}_i)$ by $(g_i/\|g_i\|_\sharp, \mathfrak{J}_i/\|g_i\|_\sharp)$ divides $\mathsf{T}_\rho[\mathbb{J}](B)$ by $\prod_{i\in B}\|g_i\|_\sharp$ and leaves $\varkappa^*$, (OI-C) and (OI-R) as they are: the new read-out at ζ is the old one at $\zeta/\|g_i\|_\sharp$, and the radius r_i is multiplied by $\|g_i\|_\sharp$. Dividing the tuple by $\varkappa^*$ divides $\mathsf{T}_\rho[\mathbb{J}](B)$, ϵ_1, B_1 and ϵ_2 by $\varkappa^*$. So we may take $\|g_i\|_\sharp = 1$ and $\varkappa^* = 1$.

The moments. Let $\alpha_\emptyset$, α_i, $\bar{o}_i$ and H_A be those of Proposition 18.58. Every H_A, $A \subset B$, is a bounded real Borel function of the bonds inside $\square_0$, all the carriers lying in A_{R+2}; Lemma 18.55(a) and Proposition 18.58 give $|\rho(H_A)| \le \eta\prod_{i\in A}\gamma_i$ with $\eta = \mathsf{Q}[(1+n)\epsilon_2 + \vartheta_K]$ and $\gamma_i = \mathsf{M}$, and Lemma 18.55(b) gives $|\rho(\prod_{i\in C}(O_i - \bar{o}_i))| \le \bar{P} \le \bar{P}\prod_{i\in C}\gamma_i$, as $\mathsf{M} \ge 1$. Lemma 18.54, applied in the law ρ with these numbers, gives $|\mathsf{T}_\rho[\mathbb{J}](B) - \alpha_B| \le \mathsf{c}_{\#B}\,\eta\,\mathsf{M}^{\#B}$, and $\alpha_B = 0$ for $\#B \ge 2$. □

Theorem BE (The dilation bulk term with one constant in every periodic Gibbs state and on all tori above one side)**.** Let $0 < g \le \gamma$, $n \ge 2$, $R \ge 1$, $0 < \mathsf{d} \le 1$, $\delta_1 > 0$ and $c < \frac{1}{14}$, and let $\ell' = \ell'(g,n,R)$ be the side of the data of the transfer. There are p, C and K_1, functions of g, n, R, d, δ_1 and c, such that for every first-passage datum $(K,\beta) \in \mathfrak{d}(g)$ with $K \ge K_1$, all real $\chi, f_1, \dots, f_n \in C^{1,1}(\mathbb{R}^3)$ that vanish outside A_R, with the supports of the f_i at pairwise sup distances $\ge \mathsf{d}$ and $\chi = 1$ on the closed sup δ_1-neighbourhood of $\bigcup_i \operatorname{supp} f_i$, and every law ν that is a periodic Gibbs state at (a_K, β) or the measure of a torus T_ℓ with $\ell \in \mathfrak{L}(g)$, $\ell \ge \ell'$ (the functions read in its chart):

$$|\mathfrak{U}_K^{\mathrm{dil}}[\nu](\underline{f})[\chi]| \le CK^pL^{-cK}\|\chi\|_{C^{1,1}}\prod_{i=1}^n\|f_i\|_{C^{1,1}},$$

$$\begin{aligned}&\Big|\mathsf{FI}_K[\nu](\underline{f})[\chi]\\ &\quad - \sum_{i=1}^n S_n^T[\nu](f_1,\dots,f_i - \nabla_{\mathrm{dil}}^s f_i,\dots,f_n)\\ &\quad + \mathsf{b}\,S_{n+1}^T[\nu](\chi,\underline{f})\Big|\\ &\quad \le CK^pL^{-cK}\|\chi\|_{C^{1,1}}\prod_{i=1}^n\|f_i\|_{C^{1,1}}.\end{aligned}$$

On these tori the part of the bulk term that comes from the tuple $\mathbb{J}^{\mathrm{s}}$ of Proposition 18.53(b), the soft combination $\mathsf{T}_\nu[\mathbb{J}^{\mathrm{s}}](\{1,\dots,n\})$, is moreover at most $Ca_K\|\chi\|_{C^{1,1}}\prod_{i=1}^n\|f_i\|_{C^{1,1}}$. With a larger C the first bound holds at every $(K,\beta) \in \mathfrak{d}(g)$, and the second at every one with $a_K \le \delta_1$. One C serves for all these tori and all these states at once. ■□

Sketch. Vanishing sources. Let first $f_{i_0} = 0$ for some i_0. Then $\mathcal{O}(f_{i_0}) = 0$, and $\mathfrak{X}^{(f_{i_0})}$, $\mathcal{O}(\mathsf{L}f_{i_0})$ and $\mathcal{O}(f_{i_0} - \nabla_{\mathrm{dil}}^s f_{i_0})$ are 0 too, all three being linear in f_{i_0}. Every joint cumulant in the bulk term, in the flux, in the sums S_n^T and S_{n+1}^T of the second display and in the soft combination has one of these four as an entry: $\mathcal{O}(f_{i_0})$ wherever it stands, and in the remaining terms, those of the index i_0, one of the other three. So all these cumulants vanish, and with them both members of each

bound of the statement, the right ones through the factor $\|f_{i_0}\|_{C^{1,1}} = 0$. In what follows every f_i is non-zero; then $\bigcup_i \operatorname{supp} f_i$ is not empty, $\chi = 1$ on it, and $\|\chi\|_{C^{1,1}} \geq \sup|\chi| \geq 1$.

Choices. We may take $0 < c < \frac{1}{14}$. Let $\delta = \frac{1}{14} - c$, $\tau = \delta$, $\phi = \delta/(30(n+1))$, $\sigma = \delta/30$, $\kappa_{\mathrm{H}} = \frac{3}{4}$ and $\psi_{\mathrm{c}} = \frac{1}{4}$, and let $K_1 \geq \max\{K_\phi, 5\}$ be so large that $16a_{K_1} \leq \min\{\mathsf{d}, \delta_1\}$, $8\mathsf{M}_t^{\mathrm{rd}} \geq 1$, and that the thresholds $K_\star$ of Theorem BD for the ten tuples below and K_ψ, K_2 of Lemma 18.57 are reached. Let $K \geq K_1$; the sources of the transfer are the f_i.

The tuples. As $2a \leq \delta_1$ and $4a < \mathsf{d}$, Proposition 18.53(b) writes the bulk term in ν as the sum of the ten hard combinations $\mathsf{T}_\nu[\mathbb{J}^\pi](\{1,\dots,n\})$, and the laws ν of the statement are laws of the transfer. By Proposition 18.53(c) every tuple is local, with $\mathfrak{J}_0$ carried by A_{R+1} and $\mathfrak{J}_i$ within the sup distance $4a$ of $\operatorname{supp} f_i$; with $\|\cdot\| = \|\cdot\|_{C^{1,1}}$, $\mathsf{N} = \|\chi\| + \max_i \|f_i\|/\|f_i\|_\sharp$, and C_R now a function of R and g (it absorbs $\mathsf{b} \leq \mathsf{b}_+$), its number $\varkappa^*$ is at most $C_R\mathsf{N}$ for $\mathbb{J}^1$, $\mathbb{J}^2$, $\mathbb{J}^3$, $\mathbb{J}^{\mathfrak{R}}$, $\mathbb{J}^{\mathrm{s}}$, at most $C_R L^K \mathsf{N}$ for $\mathbb{J}^\psi$, $\mathbb{J}^{a^2}$, $\mathbb{J}^4$, $\mathbb{J}^5$, and at most $C_R L^{2K}\mathsf{N}$ for $\mathbb{J}^\sharp$.

The read-outs. The read-out of the cell κ and the source i is that of $\mathfrak{J}_0^{[\kappa]} + \zeta\mathfrak{J}_i^{[\kappa]}$ at the source ζf_i^κ. The copies of a local observable are local observables of a type formed from its type alone, with weights of the same moduli ([7, Lemma 5.20](d)). The copy of $\sum_p \varkappa(p)\psi(p)$ is $\sum_p \varkappa(\mathsf{r}_\kappa^{-1}p)\psi(p)$: a diagonal isometry r maps bonds to bonds with $(\mathsf{r}U)(\mathsf{r}b) = U(b)$, so the holonomy of $\mathsf{r}U$ along the image of a closed path is that of U along the path; around the image of a plaquette or of a planar 1×2 rectangle this image path may start at another corner and run in the other sense, which changes the holonomy by a conjugation or an inversion and leaves its trace, and so the plaquette or rectangle term, as it is; hence r carries the plaquette terms and the terms of the planar 1×2 rectangles to those of the image plaquettes and rectangles, and $\psi(p)$ is symmetric in the two pairs of neighbours of p in each direction of its plane. The copies of $\beta\mathfrak{K}^\sharp[\Xi]$ and of $a^{-1}\mathfrak{K}^\sharp[f_i\Xi]$ are $\beta\mathfrak{K}^\sharp[\Xi^\kappa]$ and $a^{-1}\mathfrak{K}^\sharp[f_i^\kappa\Xi^\kappa]$, $\Xi^\kappa_\rho = s_\rho\,\Xi_\rho \circ \mathsf{r}_\kappa^{-1}$ with the signs s_ρ of r_κ, and $\mathsf{H}(\Xi^\kappa) = \mathsf{H}(\Xi)$, as $\mathfrak{r}^\sharp$ transforms as a vector under the coordinate mirrors (Lemma 5.9(b)); so the cubic read-out is that of $\mathfrak{K}^\sharp[(\beta - a^{-1}\zeta f_i^\kappa)\Xi^\kappa]$ at the source ζf_i^κ. For $|\zeta| < r_i$ the weights of $\mathfrak{J}_0^{[\kappa]} + \zeta\mathfrak{J}_i^{[\kappa]}$ are at most $\varkappa^*$. Hence (OI-C) holds with $B_1 = C_B L^{3K}\varkappa^*$ (Lemma 18.56(c)), and (OI-R) holds with $\epsilon_1 = \mathsf{o}_t$ for $\mathbb{J}^{a^2}$, $\mathbb{J}^v$, $\mathbb{J}^{\mathfrak{R}}$, $\mathbb{J}^{\mathrm{s}}$ (Lemma 18.57(a)), with $\epsilon_1 = \epsilon_\psi\varkappa^*$ for $\mathbb{J}^\psi$ (Lemma 18.57(b)), and with $\epsilon_1 = C_2\mathsf{H}(\Xi)K^{p_2}L^{-c_0'K}$, $c_0' = \frac{1}{14} - \frac{\delta}{7}$, for $\mathbb{J}^\sharp$ (Lemma 18.57(c)), where $3\phi < \frac{\delta}{7}$. A tuple with $\varkappa^* = 0$ has only vanishing members, so that its hard combinations vanish; we leave it out. For the others $B_1 > 0$, and (OI-C) gives (OI-R) with the number $\mathsf{a} = 0$ and with B_1 in the place of ϵ_1; as (OI-R) persists when its number grows, it holds with every number of $(0, B_1]$ that is not below $\min\{\epsilon_1, B_1\}$. Theorem BD applies with each of these numbers in the place of ϵ_1; since ϵ_2 is continuous and increasing in ϵ_1, its bound then holds with ϵ_2 formed from the numbers ϵ_1 listed above.

The rates. With $\epsilon_2 \leq \frac{C}{\sigma}\epsilon_1^{1-\sigma}B_1^\sigma + 2\epsilon_1$, $u \leq \phi K + 1$, $\mathsf{M}^n \leq CK^{2n\mathfrak{p}_0}L^{3n\phi K}$, and the bounds of o_t and of ϵ_ψ, in which $2\kappa_{\mathrm{H}} - (3+2\kappa_{\mathrm{H}})\psi_{\mathrm{c}} = \frac{3}{8}$ and $\frac{1}{2}\psi_{\mathrm{c}} = \frac{1}{8}$, the number $\epsilon_2\mathsf{M}^n$ is at most $CK^p\mathsf{N}$ times L^{-rK} with $r = (1-\sigma)(1-4\phi) - 3\sigma - 3n\phi$ for $\mathbb{J}^1$, $\mathbb{J}^2$, $\mathbb{J}^3$, $\mathbb{J}^{\mathfrak{R}}$, $\mathbb{J}^{\mathrm{s}}$; $r = (1-\sigma)(\frac{1}{2} - 4\phi) - 4\sigma - 3n\phi$ for $\mathbb{J}^{a^2}$, $\mathbb{J}^4$, $\mathbb{J}^5$; $r = (1-\sigma)(\frac{1}{8} - 3\phi) - 4\sigma - 3n\phi$ for $\mathbb{J}^\psi$; and $r = (1-\sigma)c_0' - 5\sigma - 3n\phi$ for $\mathbb{J}^\sharp$. As $3n\phi \leq \frac{\delta}{10}$ and $\sigma = \frac{\delta}{30}$, the last is at least $\frac{1}{14} - \frac{\delta}{7} - \frac{71}{14}\sigma - \frac{\delta}{10} = \frac{1}{14} - \frac{173}{420}\delta > c$, and the other three exceed $\frac{1}{14}$, as $\delta < \frac{1}{14}$. The term $\varkappa^*\vartheta_K\mathsf{M}^n$ lies below every power of L^{-K} times N, as $\mathsf{R}_t \leq C_{\mathrm{R}}L^{3u}e^{-c'A_0^2(\phi K\log L)^{2\mathfrak{p}_0}}$ ([7, Lemma 3.14](d)) and $\tau_t(\frac{1}{2}\mathsf{d}) \leq e^2E_0C_{\mathrm{E},0}tN_1e^{-(\frac{1}{2}\mathsf{d}-2a)L^u/M}$. Theorem BD at $B = \{1,\dots,n\}$ bounds each of the ten hard combinations by $CK^pL^{-cK}\mathsf{N}\prod_i\|f_i\|_\sharp$, in every law of the transfer, and $\mathsf{N}\prod_i\|f_i\|_\sharp \leq (n+1)(40M)^n\|\chi\|\prod_i\|f_i\|$, because $\|\chi\| \geq \sup|\chi| \geq 1$.

The soft combination on the tori. Let ν be the measure of T_ℓ, $\ell \in \mathfrak{L}(g)$, $\ell \geq \ell'$, so that $\ell \geq 128(R+1)$; then $\mathsf{T}_\nu[\mathbb{J}^{\mathrm{s}}](\{1,\dots,n\})$ equals $\mathsf{b}\langle\mathcal{O}(\mathsf{L}\chi);\mathcal{O}(f_1);\dots;\mathcal{O}(f_n)\rangle_\nu + 3a\langle\mathcal{O}(\chi^\square);\mathcal{O}(f_1);\dots;\mathcal{O}(f_n)\rangle_\nu - \sum_i\langle\mathcal{O}(\mathsf{L}f_i);(\mathcal{O}(f_l))_{l\neq i}\rangle_\nu$, a sum of joint cumulants on T_ℓ of action densities of weights of the plaquettes. To use Lemma 18.59, write each weight as a Lipschitz function on T_ℓ. Two distinct barycentres of plaquettes are at least $a/\sqrt{2}$ apart, since two of their coordinates differ by at least $\frac{a}{2}$ when their planes differ; so for a real weight v with $|v| \leq s_0$ and $\Lambda = 2\sqrt{2}s_0/a$ the function

$\tilde v = \max_p[v^+(p) - \Lambda\,\mathrm{dist}(\cdot, x(p))]_+ - \max_p[v^-(p) - \Lambda\,\mathrm{dist}(\cdot, x(p))]_+$, with the distance of T_ℓ, takes the value $v(q)$ at every $x(q)$, as every other term there is at most $s_0 - \Lambda a/\sqrt{2} = -s_0$; each of its two maxima is Λ-Lipschitz with values in $[0, s_0]$, so that $\|\tilde v\|_\sharp \le \max\{s_0, 80M\Lambda\} \le 227 M s_0/a$; $\tilde v$ vanishes beyond the distance $\frac{a}{2}$ of the barycentres at which $v \ne 0$; and $\mathcal{O}(v) = \mathcal{O}(\tilde v)$. Second differences give $|\mathsf{L}\varphi| \le a^2 \max_\rho \mathrm{Lip}_\infty \partial_\rho\varphi \le \sqrt{3}a^2\|\varphi\|$ and, the midpoints of the four bonds of p being $x(p) \pm \frac{a}{2}e_\lambda$, $\lambda \in P(p)$, $\chi^\square(p) = \chi(x(p)) + r(p)$ with $|r(p)| \le \frac{1}{8}a^2 \mathrm{Lip}\,\nabla\chi$. So the entries other than the sources are $\mathcal{O}(\widetilde{\mathsf{L}\chi})$, $\mathcal{O}(\chi) + \mathcal{O}(\tilde r)$ and $\mathcal{O}(\widetilde{\mathsf{L}f_i})$, with $\|\widetilde{\mathsf{L}\chi}\|_\sharp \le 400Ma\|\chi\|$, $\|\tilde r\|_\sharp \le 29Ma\|\chi\|$, $\|\chi\|_\sharp \le 40M\|\chi\|$ and $\|\widetilde{\mathsf{L}f_i}\|_\sharp \le 400Ma\|f_i\|$; all these functions, and the f_l, vanish outside A_{R+1}, on which the chart of T_ℓ keeps the distances, the suprema and the Lipschitz constants of $\mathbb{R}^3$. In each of these cumulants some two of the supports lie at a distance $\ge \frac{1}{2}\mathsf{d}$ from each other: those of two of the sources among its entries, or, for $\langle \mathcal{O}(\widetilde{\mathsf{L}f_i}); \mathcal{O}(f_l)\rangle_\nu$ at $n = 2$, the support of $\widetilde{\mathsf{L}f_i}$, which lies within $2a$ of that of f_i, and that of f_l, as $4a \le \mathsf{d}$. Lemma 18.59 bounds each cumulant by a number formed from g, n, R and d times the product of the norms $\|\cdot\|_\sharp$ of its entries; with $\mathsf{b} \le \mathsf{b}_+$, $\|f_l\|_\sharp \le 40M\|f_l\|$ and $\|\chi\| \ge 1$ this gives $|\mathsf{T}_\nu[\mathbb{J}^{\mathrm{s}}](\{1,\dots,n\})| \le C a_K \|\chi\| \prod_i \|f_i\|$.

Small K and the flux. For the finitely many $K < K_1$ the moment–cumulant formula bounds each cumulant of the bulk term, in every law, by op_{n+1} times the product of the suprema of its entries. Each of these suprema is bounded by the norm of the function it is built on, χ or one of the f_i, times a number formed from K_1, R, b_+ and the constants: the label enters $\mathfrak{X}^{(0)}_\chi$ through $\beta = L^K\mathsf{b} \le L^{K_1}\mathsf{b}_+$ and through $\mathsf{b} \le \mathsf{b}_+$ ([7, Lemma 3.12](a)). With $\|\chi\| \ge 1$ and $K^p L^{-cK} \ge L^{-cK_1}$ there, the first bound follows with a C that is still a function of g, n, R, d, δ_1 and c, since $\mathsf{b}_+ = X_g + \bar B$ is formed from g and the constants. The second display is Proposition 18.53(a), χ covering the f_i once $a_K \le \delta_1$. □

Lemma 18.59 (A cumulant bound with one separated pair)**.** Fix g, an integer $q \ge 2$, and $R, \delta > 0$. On every sufficiently large torus in $\mathfrak{L}(g)$, a tuple of real Lipschitz functions $v_1, \dots, v_q$ supported in A_R with one pair of supports at Euclidean distance at least δ satisfies

$$|\langle \mathcal{O}(v_1); \dots; \mathcal{O}(v_q)\rangle_{K,\ell,\beta}| \le C(g, q, R, \delta) \prod_i \|v_i\|_\sharp$$

uniformly over first-passage data at g. The same bound holds for the torus laws in the dilation bulk estimate. ■

Proof. Place all supports in the central cell of a board of fixed side $h = L^m$, with positive wall margin. Take $2h \in \mathfrak{L}(g)$ and $\ell \ge 2h$, so the reference torus is admissible and the central cell has a distinct image on T_ℓ. One may use the board chosen for the transfer in the bulk estimate when $q \le n + 1$ and the supports are in A_{R+1}. It contains this ball with the required margin. The fixed-board source normalizer of Proposition YM3_I:89.2, with the first-passage bounds used in the proof of Proposition YM3_I:91.12, gives a holomorphic $E(z)$ with $E(0) = 0$. Its normalized exponential mean has one bound on the source polydisc independent of the data and side. The full mixed derivative of E has the bound YM3_I:(1793), after numbering the separated pair first. That bound uses only the separation of the first two supports, as its preceding cell estimate shows. The cumulant of the normalized exponential mean is bounded by Proposition YM3_I:91.11. Adding the bound for the mixed derivative of E gives the stated estimate. All board, wall and radius constants are fixed by g, q, R, δ before the cutoff and torus are chosen. □

Corollary 18.60 (The local dilation identity with the flux alone in the limits)**.** Let $0 < g \le \gamma$, let $(K_j, \beta_j, \nu_j)_{j\in\mathbb{N}}$ be a Gibbs sequence at g, in the sense of the subsection on the scalar two-point function, $\mathsf{b}_j = a_{K_j}\beta_j$, let σ' be a limit in its frame with approximants $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$, and put $S'_q = S^{\sigma'}_q$. Let $n \ge 2$, $R, \mathsf{d}, \delta_1 > 0$, and let $f_1, \dots, f_n \in C^3(\mathbb{R}^3)$ and $\chi \in C^{1,1}(\mathbb{R}^3)$ be real functions that vanish outside A_R, with the supports of the f_i at pairwise sup distances $\ge \mathsf{d}$ and $\chi = 1$ on the closed sup δ_1-neighbourhood of $\bigcup_i \mathrm{supp}\, f_i$; $(y \cdot \nabla f)(y) = \sum_\rho y_\rho \partial_\rho f(y)$.

(a) Along the full sequence $\mathfrak{U}^{\mathrm{dil}}_{K_j}[\rho_j](\underline{f})[\chi]\to 0$, and

$$\mathsf{b}_j\, S^T_{n+1}[\rho_j](\chi,\underline{f})+\mathsf{Fl}_{K_j}[\rho_j](\underline{f})[\chi]\ \longrightarrow\ nS'_n(\underline{f})-\sum_{i=1}^n S'_n(f_1,\dots,y\cdot\nabla f_i,\dots,f_n).$$

(b) Along every subsequence on which b_j and $S^T_{n+1}[\rho_j](\chi,\underline{f})$ converge, to b and to $S^+_{n+1}(\chi;\underline{f})$ say, the flux $\mathsf{Fl}_{K_j}[\rho_j](\underline{f})[\chi]$ converges, to $\mathsf{Fl}'(\underline{f})[\chi]$ say, and

$$nS'_n(\underline{f})-\sum_{i=1}^n S'_n(f_1,\dots,y\cdot\nabla f_i,\dots,f_n)=\mathsf{b}\,S^+_{n+1}(\chi;\underline{f})+\mathsf{Fl}'(\underline{f})[\chi]:$$

beside the term of the label, the flux alone carries the rest.

(c) The numbers $S^T_{n+1}[\rho_j](\chi,\underline{f})$ are bounded uniformly in j, so that the subsequences of (b) exist, (i) if $\rho_j\in\mathcal{G}^{\mathrm{tor}}_{K_j,\beta_j}$ for every j, and (ii) for every choice of the approximants $\rho_j\in\mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$ if $0<g\le\gamma^{\mathrm{ref}}_W$.

(d) (a)–(c) hold for every volume-first limit S at g, with $\sigma'=\sigma_S$, $S'_q=S_q$ for $q\ge 2$ and $\rho_j=\nu_j$ a defining sequence of states of S, whose states lie in $\mathcal{G}^{\mathrm{tor}}$, so that (c)(i) applies. For a convergent Gibbs sequence at g, (a) and (b) hold for every component σ_ξ of every canonical decomposition of its limit, an ergodic component with $\ker H_{\sigma_\xi}=\mathbb{C}\,\Omega_{\sigma_\xi}$, with the approximants $\rho_j=(\nu_j)_{1_{E_j}}\in\mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$ of Theorem YM3_I:AP; when $0<g\le\gamma^{\mathrm{ref}}_W$, (c)(ii) applies to these approximants, so that the subsequences of (b) exist, while for $\gamma^{\mathrm{ref}}_W<g\le\gamma$ the components carry what (a) states, and the flux alone enters along every subsequence on which b_j and $S^T_{n+1}[\rho_j](\chi,\underline{f})$ converge.

■□

Sketch. (a) We may take $R\ge 1$ and $\mathsf{d}\le 1$. For the j with $a_{K_j}\le\delta_1$, χ covers the f_i, and Proposition 18.53(a) at $\nu=\rho_j$ gives $\mathsf{b}_jS^T_{n+1}[\rho_j](\chi,\underline{f})+\mathsf{Fl}_{K_j}[\rho_j](\underline{f})[\chi]=\sum_i S^T_n[\rho_j](f_1,\dots,f_i-\nabla^s_{\mathrm{dil}}f_i,\dots,f_n)-\mathfrak{U}^{\mathrm{dil}}_{K_j}[\rho_j](\underline{f})[\chi]$. The bulk term tends to 0 by Theorem BE, as $K_j\to\infty$. Write $\nabla^s_{\mathrm{dil}}f_i=y\cdot\nabla f_i+e_{i,j}$: the function $e_{i,j}$ vanishes beyond sup distance a_{K_j} of $\operatorname{supp}f_i$, and Taylor's formula to the third order gives $\|e_{i,j}\|_\sharp\le C_R a_{K_j}\|f_i\|_{C^3}$. For large j the tuples with the entry $e_{i,j}$ have supports at pairwise Euclidean distances $\ge\frac12\mathsf{d}$ in balls of radius $2R+2$, and Proposition YM3_I:91.13 bounds their cumulants by $C^{\mathrm{per}}_n(\frac12\mathsf{d};2R+2)\|e_{i,j}\|_\sharp\prod_{l\ne i}\|f_l\|_\sharp\to 0$. The tuples $\underline{f}$ and $(f_1,\dots,y\cdot\nabla f_i,\dots,f_n)$ are separated tuples of C^1_c functions, and on them $S^T_n[\rho_j]\to S'_n$ by Proposition YM3_I:101.3, applied to the Gibbs frame classes of Proposition YM3_I:106.3.

(b) follows from (a): along such a subsequence $\mathsf{Fl}_{K_j}[\rho_j](\underline{f})[\chi]$ is the difference of two convergent sequences.

(c)(i) Each $\rho_j\in\mathcal{G}^{\mathrm{tor}}_{K_j,\beta_j}$ is a weak limit of the laws $\tilde\mu_{K_j,\ell_k,\beta_j}$ along sides $\ell_k=2L^{m_k}\to\infty$, which lie in $\mathfrak{L}(g)$ and exceed $16(n+1)(R+1)$ for large k. The joint cumulant of the continuous functions $\mathcal{O}(\chi),\mathcal{O}(f_1),\dots,\mathcal{O}(f_n)$ of finitely many bonds passes to the weak limit, and under $\tilde\mu_{K_j,\ell_k,\beta_j}$ it is the cumulant on T_{ℓ_k} of the periodised functions, at most $C(g,n+1,R,\mathsf{d})\|\chi\|_\sharp\prod_i\|f_i\|_\sharp$ by Lemma 18.59: the supports lie in sup-balls of radius R, those of f_1 and f_2 are at Euclidean distance $\ge\mathsf{d}$, and the support of χ may lie anywhere; the number reads no K, no β and no side.

(c)(ii) Let $0<g\le\gamma^{\mathrm{ref}}_W$. The flux insertion is a rough entry of Lemma 5.7 carried within $2a$ of $\mathrm{Var}(\chi)$: the petal form of $\mathfrak{d}_{b,p,\rho}$ that Lemma 5.7 uses for $h_{\omega,\chi}$, with $(x_b)_\rho$ in the place of $(\omega x_b)_\rho$, gives $-\beta\sum_p h^{\mathrm{dil}}_\chi(p)=\mathsf{b}\,\mathrm{Pf}(k^{\mathrm{dil}})$ with $|k^{\mathrm{dil}}|_1\le 12\,\mathrm{Lip}_\infty(\chi)(3R+1)$, and $\mathfrak{B}^{\mathrm{dil}}_\chi-\mathsf{b}\,\mathrm{Pf}(k^{\mathrm{dil}})=\mathcal{O}(v)$ with $v(p)=\mathsf{b}\nabla^s_{\mathrm{dil}}\chi(x(p))-\frac32 a\,v^{\mathrm{dil}}_\chi(p)$ and $|v|_\infty\le(\mathsf{b}+2a)(3R+1)\mathrm{Lip}_\infty\chi$, each of these vanishing at a plaquette unless χ varies on the points $x(p)\pm ae_\rho$, $x(p)\pm\frac a2 e_\rho$, x_b that it reads. As $\chi=1$ on the closed sup δ_1-neighbourhood of the supports, $\mathrm{Var}(\chi)$ lies at sup distance $\ge\delta_1$ from every $\operatorname{supp}f_i$. The rule of Theorem N(a)(ii), for a rough entry carried within $2a$ of a closed set at distance $\ge\frac12\min\{\delta_1,1\}$ from each support, bounds $|\mathsf{Fl}_{K_j}[\rho_j](\underline{f})[\chi]|$ by a number free of j, of the side and

of the state once K_j is above a threshold. With (a), the bound of $\mathfrak{U}^{\mathrm{dil}}$ in Theorem BE and the bound of Proposition YM3_I:91.13 for the separated tuples $(f_1, \dots, f_i - \nabla^s_{\mathrm{dil}} f_i, \dots, f_n)$, this bounds $\mathsf{b}_j S^T_{n+1}[\rho_j](\chi, \underline{f})$, and $\mathsf{b}_j \geq \gamma^{-2}$; the finitely many other j give finitely many numbers.

(d) In a defining sequence of a volume-first limit, each ν_j is a limit of periodic torus laws at (K_j, β_j) and hence is periodic Gibbs. The convergent cumulants determine all limits of the self-centered products by the moment–cumulant formula. Thus the sequence converges to σ_S with $S_q^{\sigma_S} = S_q$ for $q \geq 2$. This is a limit in its own frame with $\rho_j = \nu_j$. For every convergent Gibbs sequence, Theorem YM3_I:AP obtains each component in the frame of the full sequence by conditioning on invariant events of positive probability, and proves $\ker H_{\sigma_\xi} = \mathbb{C}\Omega_{\sigma_\xi}$. □

18.6. **A logarithmic rate in the leading law of two points.** For $0 < g \leq \gamma_W$ the main text gives the leading law $c_2 b^{-2} \mathcal{K}_6$ of the two-point function with a tolerance $\eta_{g,\vartheta}(d)$ that is one function of the scale d for every state at g at a first-passage datum with $s(d) < K$, for the torus of every side at g, for the continuum limits at g on a torus, along growing tori and volume first, for the limits through periodic Gibbs states and for every component of a canonical decomposition, and that tends to 0 with d (Theorems YM3_I:AV and YM3_I:AW, Proposition YM3_I:127.8, Corollary YM3_I:127.11). Here this tolerance is bounded by an explicit function of d. The couplings $0 < g \leq \gamma_W$ whose carried coupling $\check{g}$ does not exceed γ_W^{sd} form an interval $(0, \gamma_{\mathrm{rt}}]$; it contains $(0, \gamma_{\mathrm{rt}}^\flat]$, where $\gamma_{\mathrm{rt}}^\flat > 0$ is a number formed at the values of the constants in which no least tolerance of a two-point function occurs, and it is all of $(0, \gamma_W]$ as soon as $\gamma_W^{\mathrm{sd}} \geq \gamma^2$ (Proposition 18.61). For these g, every $\vartheta \in (0,1)$ and every d in a set $\mathsf{Z}(g)$ of scales that does not depend on ϑ and contains all small scales, $\eta_{g,\vartheta}(d) \leq C_{\mathrm{un}} \vartheta^{-3} (\log \frac{L}{g^2 d})^{-2p_0} + \vartheta^{-4} \mathsf{C}^\circ_{\mathrm{law}}(g)\, d$, where $p_0 \geq 13$, the number C_{un} depends on the constants alone, and $\mathsf{C}^\circ_{\mathrm{law}}(g)$ is an explicit expression in the radius, the constants and g (Proposition 18.63); below the scale $L^2 \mathsf{d}_0^{\mathrm{ref}}(\check{g}, \vartheta)$ the same holds with a constant $C^{\mathrm{ref}}(\check{g}, \vartheta)$ in the place of $C_{\mathrm{un}} \vartheta^{-3}$. Consequently each of the laws listed above holds with these relative errors at the scales $d \leq \mathsf{d}_0(g, \vartheta)$ of the respective ranges (Proposition 18.64).

We use the constants and notation of Section 8.1, with the scalar two-point law of Theorems YM3_I:AV and YM3_I:AW. The tolerance $\eta_{g,\vartheta}(d)$ and the threshold $\mathsf{d}_0(g, \vartheta)$ are those in YM3_I:(2349)–(2350). The cutoff spacing is $a_K = L^{-K}$, the physical label is $b = a_K \beta$, the first-passage endpoint is $X_g = L(g^{-2} + B_\sharp)$, and $\mathfrak{d}(g)$ and $\mathfrak{L}(g)$ are the sets of first-passage data and admissible sides. We use $r \geq 2$ and $p_0 = \mathfrak{p}_0 \geq 6r + 1$, hence $p_0 \geq 13$, as in the construction constants of Theorem YM3_I:D. The classes $\mathfrak{T}_{\mathbb{E}}(d; \vartheta)$ are the scalar test pairs defined above, and $\mathfrak{T}^1_{\mathbb{E}}(d; \vartheta)$ restricts their entries to C^1. Write $c_2 = 9/(16\pi^2)$.

A state at a datum at g means a periodic Gibbs state on the cutoff lattice or the periodic extension of the Wilson law on a torus of side in $\mathfrak{L}(g)$, as in Section YM3_I:127. Let $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ be the periodic Gibbs laws, $\mathcal{G}^{\mathrm{inv}}_{K,\beta}$ its translation-invariant members and $\mathcal{G}^{\mathrm{tor}}_{K,\beta}$ the weak limit points of the periodic extensions of the cubic Wilson tori at fixed (K, β). A separated tuple is a family of real C^1 functions with compact pairwise disjoint supports, on the relevant torus or on $\mathbb{R}^3$. We use the frame and the centered products X^ν_K defined in the subsection on the scalar two-point function. Proposition YM3_I:106.3 supplies the common bound system for these Gibbs classes.

A fixed-torus limit at g is a limit on all separated tuples at first-passage data at g, on one torus of side in $\mathfrak{L}(g)$ as $K_j \to \infty$. A growing-torus limit at g is formed at (K_j, ℓ_j, β_j) with $\ell_j \in \mathfrak{L}(g)$ tending to infinity, by evaluating at the periodisations of each fixed separated tuple over $\mathbb{R}^3$. A volume-first limit at g is the limit of cumulants of such tuples under $\nu_j \in \mathcal{G}^{\mathrm{tor}}_{K_j,\beta_j}$ at first-passage data with $K_j \to \infty$. A sequence giving one of these limits is a defining sequence. A label of S is a limit of the physical labels along a defining sequence, or a subsequence with converging labels. We write $\mathsf{b}(S)$ when there is just one such value. Theorem YM3_I:AW in fact proves convergence of the labels along every defining sequence in the range of interest.

For a reference coupling $g' \le 1$, an integer $s \ge 0$ and $d > 0$ let $\bar{x}_s[g'] = L^{s+1}(g'^{-2} + \bar{B})$, $Y_s[g'] = \log \bar{x}_s[g']$, $C_W(s)[g'] = \mathsf{c}_W\, Y_s[g']^{2p_0}$ and $s(d)[g'] = \min\{s \in \mathbb{Z} :\ s \ge 0,\ L^s d \ge C_W(s)[g']\}$, where $\mathsf{c}_W = C_{W,0}A_0^2$ and $C_{W,0} = \max\{1, 4L^2M/A_0^2\}$ is the room constant YM3_I:(2320), so that $\mathsf{c}_W \ge 4L^2M$: these are the envelope numbers, the witness rooms and the witness depth. Without a bracket they are taken at $g' = g$; in this subsection $s(d)$ is the witness depth at g, the depth in the hypotheses of Theorem YM3_I:AV. As $s(d)[g']$ is the least element of the set in its definition, $L^{s(d)[g']}d \ge C_W(s(d)[g'])[g']$. We write $R(x)$, for real $x > 1$, for the least power L^u with $u \in \mathbb{Z}$, $u \ge 0$ and $L^u \ge (\log x)^r$.

Let $0 < g' \le \gamma$, $\vartheta \in (0,1)$, $0 < d \le \frac{1}{100}$ and $\ell' = 2M\,R(X_{g'})$. A number $\epsilon \in [0,\infty)$ *serves* at (g', ϑ, d) if $|S^T_{2;K,\ell',\beta}(\Psi) - c_2(a_K\beta)^{-2}\mathcal{K}_6(\Psi)| \le \epsilon\, c_2(a_K\beta)^{-2}\mathcal{K}_6(\Psi)$ for every $(K,\beta) \in \mathfrak{d}(g')$ with $s(d)[g'] \le K$ and every $\Psi \in \mathfrak{T}_{T_{\ell'}}(d;\vartheta)$. The least tolerance $\mathsf{e}_{g',\vartheta}(d) \in [0,\infty]$ is the infimum of these numbers, and when it is finite it serves since the inequalities defining it are closed in the tolerance. The set $\mathfrak{G}$ consists of the $\gamma' \in (0,\gamma]$ such that $\mathsf{e}_{g',\vartheta}(d) \to 0$ as $d \to 0$ for all $g' \in (0,\gamma']$ and all $\vartheta \in (0,1)$, and $\hat{\gamma}_W = \frac{1}{2}\sup\mathfrak{G} \in (0, \frac{1}{2}\gamma]$ is the first ceiling YM3_I:(2345). With $\mathsf{a}_1 := \max\{\hat{\gamma}_W^{-2}, \gamma^{-4}, e^{C_{\mathrm{s}}}\}$ we have $\gamma_W = (L^2(\bar{B} + \mathsf{a}_1))^{-1/2}$, and for $0 < g \le \gamma_W$ the carried coupling $\check{g} = (L^{-2}g^{-2} - \bar{B})^{-1/2}$ is a reference coupling with $\check{g}^{-2} + \bar{B} = L^{-2}g^{-2}$, $\check{g} \le \hat{\gamma}_W$, $\check{g}^{-2} \ge \gamma^{-4}$ and $g^{-2} \ge L^2\check{g}^{-2}$ by YM3_I:(2346)–(2347).

For $0 < g \le \gamma_W$ and $\vartheta \in (0,1)$ use the two-point comparison constant of [1, *Transfer of the two-point law*],

$$C_2^{\mathrm{tr}} = 2\log 2\left(\frac{50}{3}\right)^3 \frac{[160M(\mathsf{Q}_1+1)]^2}{\varrho^2\vartheta^2}, \qquad \mathsf{Q}_1 = \exp[(E_+ + C_{\mathrm{low}} + C_{\mathrm{gap}})L^3 + \Phi_1(2,1;L)],$$

with the constants of that construction at g. Then $\mathsf{C}_{\mathrm{law}}(g,\vartheta) = 10^6 C_2^{\mathrm{tr}}\,\bar{x}_0^2/(c_2\vartheta^2)$ with $\bar{x}_0 = L(g^{-2} + \bar{B})$; for $0 < d \le \frac{1}{100}$, $\eta_{g,\vartheta}(d) = \sup_{0<d'\le L^{-2}d} \mathsf{e}_{\check{g},\vartheta}(d') + \mathsf{C}_{\mathrm{law}}(g,\vartheta)\,d$; and $\mathsf{d}_0(g,\vartheta)$ is one half of the supremum of the $d \in (0, \frac{1}{100}]$ with $\eta_{g,\vartheta}(d) \le \frac{1}{3}$.

For $0 < g' \le \gamma_W^{\mathrm{ref}}$ use the small-torus error functions $\varrho_{g',\vartheta}(s)$ and $\bar{\varepsilon}_{\mathrm{ref}}(d;g',\vartheta)$ and the threshold $\mathsf{d}_0^{\mathrm{ref}}(g',\vartheta) = L^{-s_0(g',\vartheta)-1}$ of YM3_I:(2334)–(2335), with $s_0(g',\vartheta) \ge 3$. Set $\varepsilon^{\mathrm{ref}}(d;g',\vartheta) = \bar{\varepsilon}_{\mathrm{ref}}(d;g',\vartheta)$ and $C^{\mathrm{ref}}(g',\vartheta) = \sup_{s\ge s_0(g',\vartheta)} Y_s[g']^{2p_0}\varrho_{g',\vartheta}(s)$. The error formulas there give a finite supremum. For $0 < d \le \mathsf{d}_0^{\mathrm{ref}}$, the error is non-decreasing in d, takes values in $[0,1/2]$ and is at most $C^{\mathrm{ref}}(g',\vartheta)Y_{s(d)[g']}[g']^{-2p_0}$ since Y_s increases with s. Use γ_W^{ref} and $\gamma_W^{\mathrm{sd}} = \min\{\gamma_W^{\mathrm{ref}}, e^{-Y_{\mathrm{sd}}/2}\}$ from Section YM3_I:126.2 and YM3_I:(2327), with $\gamma_W^{\mathrm{sd}} \le \gamma_W^{\mathrm{ref}} \le \gamma$. Let $Y_{\mathrm{u}} \ge 2\log(2L^3)$ and C_{un} be the constants of Lemma 18.62.

We put $\mathsf{a}_2 := (\gamma_W^{\mathrm{sd}})^{-2}$,

$$\gamma_{\mathrm{rt}} := \big(L^2(\bar{B} + \max\{\mathsf{a}_1, \mathsf{a}_2\})\big)^{-1/2}, \qquad \gamma_{\mathrm{rt}}^{\flat} := \big(L^2(\bar{B} + \max\{4\mathsf{a}_2, \gamma^{-4}, e^{C_{\mathrm{s}}}\})\big)^{-1/2}, \tag{18.x}$$

and, for $0 < g \le \gamma_W$, $d > 0$ and $\vartheta \in (0,1)$, with Q_1 taken at g,

$$\begin{aligned} \mathsf{y}_g(d) &:= \log\frac{L}{g^2 d}, \qquad \mathsf{C}^{\circ}_{\mathrm{law}}(g) := \frac{2\cdot 10^6 \log 2\,(\frac{50}{3})^3\,(160M(\mathsf{Q}_1+1))^2\,L^2(g^{-2}+\bar{B})^2}{c_2\,\varrho^2}, \\ \mathsf{F}_g(d,\vartheta) &:= C_{\mathrm{un}}\,\vartheta^{-3}\,\mathsf{y}_g(d)^{-2p_0} + \vartheta^{-4}\,\mathsf{C}^{\circ}_{\mathrm{law}}(g)\,d \quad \text{where } \mathsf{y}_g(d) > 0, \\ \mathsf{Z}(g) &:= \{d > 0 :\ \mathsf{y}_g(d) \ge Y_{\mathrm{u}},\ 8L^3 d\,(2\,\mathsf{y}_g(d))^{3p_0+1} \le 1\}. \end{aligned} \tag{18.xi}$$

Proposition 18.61 (The ceiling of the carried coupling)**.** (a) $0 < \gamma_{\mathrm{rt}}^{\flat} \le \gamma_{\mathrm{rt}} \le \gamma_W \le \gamma$, and $\gamma_{\mathrm{rt}} = \min\{\gamma_W, (L^2(\bar{B} + (\gamma_W^{\mathrm{sd}})^{-2}))^{-1/2}\}$.

(b) Let $0 < g \le \gamma_W$. Then $\check{g} \le \gamma_W^{\mathrm{sd}}$ if and only if $g \le \gamma_{\mathrm{rt}}$, and for these g we have $\check{g} \le \gamma_W^{\mathrm{sd}} \le \gamma_W^{\mathrm{ref}} \le \gamma$.

(c) $\gamma_{\mathrm{rt}} = \gamma_W$ if and only if $\gamma_W^{\mathrm{sd}} \ge \min\{\hat{\gamma}_W, \gamma^2, e^{-C_{\mathrm{s}}/2}\}$; in particular $\gamma_{\mathrm{rt}} = \gamma_W$ whenever $\gamma_W^{\mathrm{sd}} \ge \gamma^2$.

(d) $\gamma_{\mathrm{rt}}^{\flat}$ is a function of L, $\bar{B}$, γ, C_{s} and γ_W^{sd}; and γ_W^{sd} is the minimum of the explicit construction threshold γ_W^{ref} and $e^{-Y_{\mathrm{sd}}/2}$ in YM3_I:(2327). Neither the least tolerances $\mathsf{e}_{g',\vartheta}$ nor the set $\mathfrak{G}$ occur in the definition of $\gamma_{\mathrm{rt}}^{\flat}$. Every $0 < g \le \gamma_{\mathrm{rt}}^{\flat}$ has $\breve{g} \le \gamma_W^{\mathrm{sd}}$.

■

Sketch of proof. The map $\mathsf{a} \mapsto (L^2(\bar{B}+\mathsf{a}))^{-1/2}$ is positive and strictly decreasing on $(0,\infty)$, since $\bar{B} \ge 0$; so its value at the larger of two numbers is the smaller of its two values, and $\gamma_{\mathrm{rt}} = \min\{\gamma_W, (L^2(\bar{B}+\mathsf{a}_2))^{-1/2}\}$ by YM3_I:(2346). Corollary YM3_I:126.5 gives a reference-torus tolerance tending to zero for every $g' \le \gamma_W^{\mathrm{sd}}$ and every ϑ. Thus $\gamma_W^{\mathrm{sd}} \in \mathfrak{G}$. Hence $\sup\mathfrak{G} \ge \gamma_W^{\mathrm{sd}}$, and the definition of $\hat{\gamma}_W$ gives $\frac{1}{2}\gamma_W^{\mathrm{sd}} \le \hat{\gamma}_W \le \frac{1}{2}\gamma$, that is, $\hat{\gamma}_W^{-2} \le 4\mathsf{a}_2$. Therefore $\max\{\mathsf{a}_1,\mathsf{a}_2\} \le \max\{4\mathsf{a}_2, \gamma^{-4}, e^{C_{\mathrm{s}}}\} < \infty$, which yields $0 < \gamma_{\mathrm{rt}}^{\flat} \le \gamma_{\mathrm{rt}}$; moreover $\gamma_{\mathrm{rt}} \le \gamma_W$, and $\gamma_W \le \gamma$ follows from its defining formula. This is (a).

For (b), let $0 < g \le \gamma_W$; by YM3_I:(2346), $\breve{g}^{-2} = L^{-2}g^{-2} - \bar{B} > 0$. So $\breve{g} \le \gamma_W^{\mathrm{sd}}$ means $L^{-2}g^{-2} - \bar{B} \ge \mathsf{a}_2$, that is, $g \le (L^2(\bar{B}+\mathsf{a}_2))^{-1/2}$; together with $g \le \gamma_W$ this is $g \le \gamma_{\mathrm{rt}}$, by (a). The other two inequalities are part of the construction ceilings.

For (c), the map of the first paragraph is injective; so $\gamma_{\mathrm{rt}} = \gamma_W$ means $\max\{\mathsf{a}_1,\mathsf{a}_2\} = \mathsf{a}_1$, that is, $\mathsf{a}_2 \le \mathsf{a}_1$. As $\mathsf{a} \mapsto \mathsf{a}^{-1/2}$ decreases on $(0,\infty)$, this is $\gamma_W^{\mathrm{sd}} \ge \mathsf{a}_1^{-1/2} = \min\{\hat{\gamma}_W, \gamma^2, e^{-C_{\mathrm{s}}/2}\}$, a minimum that does not exceed γ^2.

For (d), the formula for $\gamma_{\mathrm{rt}}^{\flat}$ shows its listed dependence. The reference ceiling $\gamma_W^{\mathrm{ref}} = x_W^{-1/2}$ comes from the pointwise construction tests YM3_I:(2326) and the accompanying inequalities for $x \ge x_W$. The second ceiling in YM3_I:(2327) uses Y_{sd} large enough that

$$C_{\mathrm{sd}} Y\,[MR(e^Y)]^3 \le \tfrac{1}{2}c' A_0^2 Y^{2p_0} \quad (Y \ge Y_{\mathrm{sd}}).$$

Here C_{sd} is the constant in the small-torus criterion of Section YM3_I:126.2. This choice exists since $R(e^Y) < LY^r$ for large Y and $2p_0 > 3r+2$. Both ceilings are therefore formed entirely from construction constants. The least tolerances and $\mathfrak{G}$ are subsequently defined using the reference-torus estimates. The last assertion follows from (a) and (b). □

Lemma 18.62 (A relative error uniform at the reference torus)**.** There are constants Y_{u} and $C_{\mathrm{un}} > 0$, depending only on the construction constants, with the following property. Let $0 < u \le \gamma_W^{\mathrm{sd}}$, $\bar{x}_s = L^{s+1}(u^{-2}+\bar{B})$, $Y_s = \log \bar{x}_s$ and $s = s(d)[u]$. Let $0 < d < 1$ and $w = \log(\bar{x}_0/d)$. If

$$w \ge Y_{\mathrm{u}}, \qquad 8L^5 d(2w)^{3p_0+1} \le 1,$$

then on the torus of side $2MR(X_u)$, for all first-passage data with $K \ge s$ and all pairs of type $(d;\vartheta)$, the relative error in the short-distance two-point estimate is at most

$$C_{\mathrm{un}}\,\vartheta^{-3} Y_s^{-2p_0} \le C_{\mathrm{un}}\,\vartheta^{-3} w^{-2p_0}.$$

One can take $Y_{\mathrm{u}} \ge 2\log(2L^3)$ and $Y_{\mathrm{u}} > 8p_0$. ■

Proof. Use the witness and the error functions from the short-distance estimate of [1, *Errors depending only on the physical separation*], with $p = p_0$. Write $Y = Y_s$, $\mathsf{L}_s = L^2 C_W(s) Y^{3p}$, and $\mathsf{c}_W = C_{W,0}A_0^2$. By the minimality of the witness and the increase of $C_W(s)$,

$$C_W(s) \le L^s d < L C_W(s), \qquad Y = w + \log(L^s d) \ge w.$$

Increase Y_{u}, using only the construction constants, so that $\log(L\mathsf{c}_W) + 2p\log Y \le Y/2$ when $Y \ge Y_{\mathrm{u}}$. Then $Y < 2w$. Consequently

$$L^s \ge \mathsf{c}_W\, Y^{2p}/d \ge 8L^5 \mathsf{c}_W\, Y^{5p+1}, \qquad \mathsf{L}_s \le L^{s-3}.$$

The same estimate gives $LC_W(s)L^{-s} \le (8L^4 Y^{3p+1})^{-1}$.

Here are the bounds on the small factors in the proof of the short-distance estimate. The normalization gives $\bar{B}u^2 \le 13/24$, so $L^{s+1}u^{-2} \le e^Y \le (37/24)L^{s+1}u^{-2}$ and $s\log L \le Y$. In particular

$$x_s^- = \frac{4L^{s-2}u^{-2}}{5\mathsf{L}_s} \;\ge\; \frac{96\,e^Y}{185L^3\mathsf{L}_s}, \qquad x_s^- \le e^Y.$$

By increasing Y_{u}, we have $x_s^- \ge e^{2p}$ and $\log x_s^- \ge Y/2$. Both entries in the minimum defining $d_s^- + 1$ are at least $2Y+1$ for sufficiently large Y. Indeed the first, $c_A\alpha_0\sqrt{x_s^-}/(2MB_3A_0Y^p)$, grows exponentially divided by a power of Y, and the second satisfies

$$L^{s-1}/(2\mathsf{L}_s) - 2/M \ge 4L^2Y - 2/M.$$

Thus $\bar{x}_s e^{-d_s^-} \le e^{-Y}$. The two entries $(x_s^-)^{-1/2}$ and $\delta(x_s^-) + e^{\mathrm{co}}(x_s^-)$ of $\sigma_u(s)$ decay faster than any inverse power of Y, since the functions $\delta(t)$ and $e^{\mathrm{co}}(t)$ are bounded by constants times $t^{-1/2}(\log t)^p + \exp[-c(\log t)^{2p}]$ for $t \ge e^{2p}$. The other two entries are bounded by $\exp[Y + 3 - 4Y^{2p}/\sqrt{3}]$ and

$$M^{-3}c'A_0^2Y^{2p}\exp[5Y - \tfrac{1}{2}c'A_0^2(Y/2)^{2p}].$$

Here $L^{3s}\bar{x}_s^2 \le e^{5Y}$. Therefore $\sigma_u(s)$ decays faster than any inverse power of Y uniformly in u. Enlarge Y_{u} so that $\sigma_u(s) \le 1$. Since $Y - \log(2L^3) \ge Y/2$, the six terms of $\epsilon_u(s)$ are bounded by constant multiples of

$$Y^{-2p}, \quad Y^{1-5p}, \quad Y^{-6p}, \quad Y^{-3p}, \quad Y^{-14p}, \quad Y^{27p+4}\sigma_u(s),$$

respectively. This gives $\epsilon_u(s) \le CY^{-2p}$ with a constant independent of u.

The reference side is small over the run when $u \le \gamma_W^{\mathrm{sd}}$. The proof of the small-torus read-out bound uses, at the selected witness, $\mathsf{L}_s \le L^{s-3}$, $x_s^- \ge e^{2p}$, $Y - \log(2L^3) > 0$ and $\sigma_u(s) \le 1$. We have checked all four inequalities. Its bound and the other two estimates in the proof of the small-torus two-point law give the relative error $\varrho_{u,\vartheta}(s)$ at this witness. Its lattice-kernel terms are bounded by constants times

$$\vartheta^{-2}\left[\frac{1}{\vartheta\,\mathsf{c}_W Y^{2p}} + (8L^4Y^{3p+1})^{-3} + \sup_{t \ge L^{-2}\mathsf{c}_W Y^{2p}} t^3 e^{-\delta_{\mathrm{tp}}Lt/\sqrt{3}}\right].$$

The supremum is bounded by CY^{-2p}, as $t^3e^{-\delta_{\mathrm{tp}}Lt/\sqrt{3}}$ decreases once $t \ge 3\sqrt{3}/(\delta_{\mathrm{tp}}L)$ and decays exponentially there. The running-coupling term is at most $3\bar{B}u^2L^{2-s} \le (37/8)\bar{B}L^3e^{-Y}$, and the read-out term is at most a constant times $\vartheta^{-2}\epsilon_u(s)$. Summing yields $\varrho_{u,\vartheta}(s) \le C_{\mathrm{un}}\vartheta^{-3}Y^{-2p}$. The last inequality follows from $Y \ge w$. All increases in Y_{u} and all majorants used here involve only the construction constants. □

Proposition 18.63 (The rate of the tolerance)**.** Let $0 < g \le \gamma_{\mathrm{rt}}$ and $\vartheta \in (0,1)$; thus $\check{g} \le \gamma_W^{\mathrm{sd}}$ by Proposition 18.61 (b).

(a) $0 \le C^{\mathrm{ref}}(\check{g},\vartheta) < \infty$ and $L^2\mathsf{d}_0^{\mathrm{ref}}(\check{g},\vartheta) \le L^{-2} < \frac{1}{100}$, and for $0 < d \le L^2\mathsf{d}_0^{\mathrm{ref}}(\check{g},\vartheta)$

$$\eta_{g,\vartheta}(d) \le \varepsilon^{\mathrm{ref}}(L^{-2}d;\check{g},\vartheta) + \mathsf{C}_{\mathrm{law}}(g,\vartheta)\,d \le C^{\mathrm{ref}}(\check{g},\vartheta)\,\mathsf{y}_g(d)^{-2p_0} + \mathsf{C}_{\mathrm{law}}(g,\vartheta)\,d \le C^{\mathrm{ref}}(\check{g},\vartheta)\Big(\log\frac{L^2}{d}\Big)^{-2p_0} + \mathsf{C}_{\mathrm{law}}(g,\vartheta)\,d.$$

(b) $\mathsf{C}_{\mathrm{law}}(g,\vartheta) = \vartheta^{-4}\,\mathsf{C}^\circ_{\mathrm{law}}(g)$, where $\mathsf{C}^\circ_{\mathrm{law}}(g) > 0$ depends on the radius, the constants and g, and not on ϑ; moreover $C_{\mathrm{un}} \ge 0$ and $Y_{\mathrm{u}} > 8p_0$. The set $\mathsf{Z}(g)$ does not depend on ϑ; it is not empty, it lies in $(0,(8L^3)^{-1}]$, and with every number it contains every smaller positive number. For every $d \in \mathsf{Z}(g)$ and every $\vartheta \in (0,1)$ we have $\mathsf{y}_g(d) \ge Y_{\mathrm{u}}$ and

$$\eta_{g,\vartheta}(d) \le \mathsf{F}_g(d,\vartheta) = C_{\mathrm{un}}\,\vartheta^{-3}\Big(\log\frac{L}{g^2d}\Big)^{-2p_0} + \vartheta^{-4}\,\mathsf{C}^\circ_{\mathrm{law}}(g)\,d; \tag{18.xii}$$

the right side is non-decreasing in $d \in \mathsf{Z}(g)$ and tends to 0 as $d \to 0$.

(c) The number $d_\sharp(g,\vartheta) := \min\{L^2\mathsf{d}_0^{\mathrm{ref}}(\check g,\vartheta),\ L^2\exp[-(6\,C^{\mathrm{ref}}(\check g,\vartheta))^{1/(2p_0)}],\ (6\,\mathsf{C}_{\mathrm{law}}(g,\vartheta))^{-1}\}$ is positive, and $\mathsf{d}_0(g,\vartheta) \ge \frac12 d_\sharp(g,\vartheta)$. If $d \in \mathsf{Z}(g)$ and $\mathsf{F}_g(d,\vartheta) \le \frac13$, then $\mathsf{d}_0(g,\vartheta) \ge \frac12 d$ and $(0,\frac12 d] \subset \mathsf{Z}(g) \cap (0,\mathsf{d}_0(g,\vartheta)]$; such numbers d exist.

None of $C^{\mathrm{ref}}(\check g,\vartheta)$, $\mathsf{C}_{\mathrm{law}}(g,\vartheta)$, $\mathsf{C}^\circ_{\mathrm{law}}(g)$, $d_\sharp(g,\vartheta)$, C_{un}, Y_{u} and $\mathsf{Z}(g)$ depends on a cutoff, on β, on a side, a state, a pair or the position of a pair; C_{un} and Y_{u} depend on the constants alone. ■

Sketch of proof. (1) *The carried coupling.* By Proposition 18.61 (a), (b), $g \le \gamma_W$ and $\check g \le \gamma_W^{\mathrm{sd}} \le \gamma_W^{\mathrm{ref}} \le \gamma$. So the tolerance, its threshold and its transfer constant are defined. The small-torus estimates of Theorem YM3_I:AU and Corollary YM3_I:126.5 apply at $\check g$. By the carried-coupling formula, $\bar x_s[\check g] = L^{s+1}L^{-2}g^{-2} = L^{s-1}g^{-2}$ for $s \ge 0$, and since $\check g^{-2} \ge \gamma^{-4}$ and $\gamma \le \frac12$, $g^{-2} \ge L^2\check g^{-2} \ge L^2\gamma^{-4} \ge 16L^2$. Hence $Y_s[\check g] \ge \log(L^{-1}g^{-2}) \ge \log(16L) > 1$ for all $s \ge 0$, and for $0 < d < 1$ we get $\mathsf{y}_g(d) = \log(Lg^{-2}/d) \ge \log(16L) + \log\frac{L^2}{d} > \log\frac{L^2}{d} > 0$.

(2) *What serves at the carried coupling.* Let $\ell' = 2M\,R(X_{\check g})$ and $0 < d' \le 1/100$. The cumulant in YM3_I:(2337) is $S^T_{2;K',\ell',\beta}(f,h)$. Thus every uniform relative tolerance for that law on the reference torus at $\check g$ and d' bounds $\mathsf{e}_{\check g,\vartheta}(d')$ from above by its definition.

(3) *Clause (a).* As $s_0(\check g,\vartheta) \ge 3$, we have $\mathsf{d}_0^{\mathrm{ref}}(\check g,\vartheta) \le L^{-4}$ and $L^2\mathsf{d}_0^{\mathrm{ref}}(\check g,\vartheta) \le L^{-2} \le \frac{1}{169}$. At the scale $\mathsf{d}_0^{\mathrm{ref}}(\check g,\vartheta)$, Theorem YM3_I:AU and the bound on $\varepsilon^{\mathrm{ref}}$ above at $\check g$ give $0 \le \varepsilon^{\mathrm{ref}} \le C^{\mathrm{ref}}(\check g,\vartheta)\,Y^{-2p_0}$ with a number $Y = Y_s[\check g] > 1$ (by (1)); so $C^{\mathrm{ref}}(\check g,\vartheta) \ge 0$. Now let $0 < d \le L^2\mathsf{d}_0^{\mathrm{ref}}(\check g,\vartheta)$, so that $d \le \frac{1}{100}$, and let $0 < d' \le L^{-2}d$. Corollary YM3_I:126.5 at $\check g$ gives YM3_I:(2337) on the side ℓ', at

by (2) and the monotonicity of $\varepsilon^{\mathrm{ref}}$, $\mathsf{e}_{\check g,\vartheta}(d') \le \varepsilon^{\mathrm{ref}}(d';\check g,\vartheta) \le \varepsilon^{\mathrm{ref}}(L^{-2}d;\check g,\vartheta)$. The supremum over d' and YM3_I:(2349) give the first inequality. Put $\check s := s(L^{-2}d)[\check g]$; by the bound on $\varepsilon^{\mathrm{ref}}$ above at $\check g$, $\varepsilon^{\mathrm{ref}}(L^{-2}d;\check g,\vartheta) \le C^{\mathrm{ref}}(\check g,\vartheta)\,Y_{\check s}[\check g]^{-2p_0}$. By (1), $C_W(\check s)[\check g] = \mathsf{c}_W\,Y_{\check s}[\check g]^{2p_0} > 1$, so $L^{\check s}L^{-2}d > 1$ and $e^{Y_{\check s}[\check g]} = L^{\check s-1}g^{-2} > Lg^{-2}/d$; that is, $Y_{\check s}[\check g] > \mathsf{y}_g(d) > \log\frac{L^2}{d} > 0$. As $t \mapsto t^{-2p_0}$ decreases on $(0,\infty)$ and $C^{\mathrm{ref}}(\check g,\vartheta) \ge 0$, the second and the third inequality follow.

(4) *The constants of (b).* The displayed formula for C_2^{tr} and $\bar x_0 = L(g^{-2} + \bar B)$ give $\mathsf{C}_{\mathrm{law}}(g,\vartheta) = \vartheta^{-4}\mathsf{C}^\circ_{\mathrm{law}}(g)$. This number is positive, and Q_1 depends on g and the construction constants. By Lemma 18.62, $Y_{\mathrm{u}} > 8p_0 > 3p_0 + 1$.

(5) *The set* $\mathsf{Z}(g)$. Put $n_0 := 3p_0 + 1$ and $\phi(u) := u\,(2\,\mathsf{y}_g(u))^{n_0}$ for $0 < u < Lg^{-2}$, where $\mathsf{y}_g(u) > 0$; the second condition of $\mathsf{Z}(g)$ is $8L^3\phi(u) \le 1$, and, as the derivative of y_g at u is $-1/u$, $\phi'(u) = 2\,(2\,\mathsf{y}_g(u))^{n_0-1}(\mathsf{y}_g(u) - n_0)$. Let $d \in \mathsf{Z}(g)$. Then $2\,\mathsf{y}_g(d) \ge 2Y_{\mathrm{u}} > 1$, so the second condition gives $8L^3d \le 1$; thus $d \le (8L^3)^{-1} < 1 < Lg^{-2}$. For $0 < u \le d$, $\mathsf{y}_g(u) \ge \mathsf{y}_g(d) \ge Y_{\mathrm{u}} > n_0$ by (4); so the first condition holds at u, ϕ is non-decreasing on $(0,d]$, and $8L^3\phi(u) \le 8L^3\phi(d) \le 1$. Hence $(0,d] \subset \mathsf{Z}(g)$. As $u \to 0$, $\mathsf{y}_g(u) \to \infty$ and $\phi(u) = Lg^{-2}e^{-\mathsf{y}_g(u)}(2\,\mathsf{y}_g(u))^{n_0} \to 0$; so all small $u > 0$ lie in $\mathsf{Z}(g)$. No ϑ occurs in the two conditions.

(6), (7) *The uniform law at the carried coupling.* Let $d'' \in \mathsf{Z}(g)$ and $d' = L^{-2}d''$. At the reference coupling $\check g$ the logarithm $\log(\bar x_0[\check g]/d')$ equals $\mathsf{y}_g(d'')$. The two conditions of Lemma 18.62 become exactly the two inequalities defining $\mathsf{Z}(g)$ at d''. Apply that lemma at $\check g$ on $T_{\ell'}$. For every admitted first-passage datum (K',β) with $s(d')[\check g] \le K'$, the relative error is at most $C_{\mathrm{un}}\vartheta^{-3}Y^{-2p_0}$, where $Y = Y_{s(d')[\check g]}[\check g] \ge \mathsf{y}_g(d'')$. The constant C_{un} is positive by its construction.

(8) *Clause (b).* By (6), (7) and $Y \ge \mathsf{y}_g(d'') > 0$, the number $C_{\mathrm{un}}\vartheta^{-3}\mathsf{y}_g(d'')^{-2p_0} \in [0,\infty)$ bounds the relative error in the reference-torus law for all these data and pairs; by (2) it serves at $(\check g,\vartheta,L^{-2}d'')$, and $\mathsf{e}_{\check g,\vartheta}(L^{-2}d'') \le C_{\mathrm{un}}\vartheta^{-3}\mathsf{y}_g(d'')^{-2p_0}$ for every $d'' \in \mathsf{Z}(g)$. Let $d \in \mathsf{Z}(g)$; then $d \le \frac{1}{100}$ by (5). Each $d' \in (0,L^{-2}d]$ is $L^{-2}d''$ with $d'' \in (0,d] \subset \mathsf{Z}(g)$, and $\mathsf{y}_g(d'') \ge \mathsf{y}_g(d) > 0$; as $C_{\mathrm{un}} \ge 0$, $\mathsf{e}_{\check g,\vartheta}(d') \le C_{\mathrm{un}}\vartheta^{-3}\mathsf{y}_g(d)^{-2p_0}$. The supremum over d', YM3_I:(2349) and (4) give eq. 18.xii. Its right side is non-decreasing in d, because $C_{\mathrm{un}} \ge 0$, $\mathsf{C}^\circ_{\mathrm{law}}(g) > 0$ and y_g decreases, and it tends to 0 with d, because $\mathsf{y}_g(d) \to \infty$.

(9) *Clause (c).* The three members of the minimum are positive, as $\mathsf{C}_{\mathrm{law}}(g,\vartheta) > 0$ by (4). At $d := d_\sharp(g,\vartheta) \le L^2\mathsf{d}_0^{\mathrm{ref}}(\check g,\vartheta) \le L^{-2}$ clause (a) applies: $\log\frac{L^2}{d} \ge (6\,C^{\mathrm{ref}}(\check g,\vartheta))^{1/(2p_0)}$ gives $C^{\mathrm{ref}}(\check g,\vartheta)(\log\frac{L^2}{d})^{-2p_0} \le \frac16$, this term being 0 when $C^{\mathrm{ref}}(\check g,\vartheta) = 0$, and $\mathsf{C}_{\mathrm{law}}(g,\vartheta)\,d \le \frac16$. So $\eta_{g,\vartheta}(d) \le \frac13$, and $d \in (0, \frac{1}{100}]$ lies in the set of YM3_I:(2350), whose supremum is therefore at least d. For $d \in \mathsf{Z}(g)$ with $\mathsf{F}_g(d,\vartheta) \le \frac13$ the same argument, with (b) in the place of (a), gives $\mathsf{d}_0(g,\vartheta) \ge \frac12 d$, and $(0,\frac12 d] \subset \mathsf{Z}(g)$ by (5). Such d exist, since all small scales lie in $\mathsf{Z}(g)$ and $\mathsf{F}_g(d,\vartheta) \to 0$ as $d \to 0$. The dependence of the constants follows from Lemma 18.62, the definition of $\mathsf{C}_{\mathrm{law}}$ and the reference-torus error formulas of [1, *Errors depending only on the physical separation*]. □

Proposition 18.64 (The leading law with the logarithmic rate)**.** Let $0 < g \le \gamma_{\mathrm{rt}}$ and $\vartheta \in (0,1)$, and let $0 < d \le \mathsf{d}_0(g,\vartheta)$ satisfy $d \in \mathsf{Z}(g)$ or $d \le L^2\mathsf{d}_0^{\mathrm{ref}}(\check g,\vartheta)$. In the first case let $\varepsilon_{\mathrm{rt}} := \mathsf{F}_g(d,\vartheta)$, in the second $\varepsilon_{\mathrm{rt}} := C^{\mathrm{ref}}(\check g,\vartheta)\,\mathsf{y}_g(d)^{-2p_0} + \mathsf{C}_{\mathrm{law}}(g,\vartheta)\,d$; when both hold, either number may be taken. Then $\eta_{g,\vartheta}(d) \le \varepsilon_{\mathrm{rt}}$, and the following hold.

(1) *States at a finite cutoff.* For every $(K,\beta) \in \mathfrak{d}(g)$ with $s(d) < K$ and $b = a_K\beta$, every state $\mathfrak{s}$ at g at (K,β), among them every $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, and every $\Psi \in \mathfrak{T}_{\mathbb{R}^3}(d;\vartheta)$: $S_2^T[\mathfrak{s}](\Psi) = c_2 b^{-2}\mathcal{K}_6(\Psi)(1+\eta)$ with $|\eta| \le \varepsilon_{\mathrm{rt}}$.

(2) *Tori at a finite cutoff.* For the same (K,β), every $\ell \in \mathfrak{L}(g)$ and every $\Psi \in \mathfrak{T}_{T_\ell}(d;\vartheta)$: $S^T_{2;K,\ell,\beta}(\Psi) = c_2 b^{-2}\mathcal{K}_6(\Psi)(1+\eta)$ with $|\eta| \le \varepsilon_{\mathrm{rt}}$.

(3) *Continuum limits.* Let S be a continuum limit at g on a torus T_ℓ with $\ell \in \mathfrak{L}(g)$, and $\mathbb{E} := T_\ell$, or a continuum limit at g along growing tori or a volume-first limit at g, and $\mathbb{E} := \mathbb{R}^3$. Then S has exactly one label $\mathsf{b}(S)$ at g, and $S_2(\Psi) = c_2\mathsf{b}(S)^{-2}\mathcal{K}_6(\Psi)(1+\eta)$ with $|\eta| \le \varepsilon_{\mathrm{rt}}$ for every $\Psi \in \mathfrak{T}^1_{\mathbb{E}}(d;\vartheta)$.

(4) *Limits through periodic Gibbs states; frames and components.* Let $(K_j,\beta_j) \in \mathfrak{d}(g)$ for $j \in \mathbb{N}$, with $K_j \to \infty$. (i) If $\rho_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$ and the limit $S_2(\Phi) := \lim_j S_2^T[\rho_j](\Phi)$ exists for every separated pair Φ, then $a_{K_j}\beta_j$ converges to a number b, and $S_2(\Psi) = c_2 b^{-2}\mathcal{K}_6(\Psi)(1+\eta)$ with $|\eta| \le \varepsilon_{\mathrm{rt}}$ for every $\Psi \in \mathfrak{T}^1(d;\vartheta)$. (ii) If $\nu_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$ and the frame $\mathfrak{j} = (K_j,\nu_j)_j$ converges, then $a_{K_j}\beta_j$ converges to a number b, and for every limit σ' in $\mathfrak{j}$, every canonical decomposition $(\mathsf{X},\lambda,(\sigma_\xi))$ of $\sigma_{\mathfrak{j}}$, every $\xi \in \mathsf{X}$ and every $\Psi \in \mathfrak{T}^1(d;\vartheta)$: $S_2^{\sigma'}(\Psi) = c_2 b^{-2}\mathcal{K}_6(\Psi)(1+\eta')$ and $S_2^{\sigma_\xi}(\Psi) = c_2 b^{-2}\mathcal{K}_6(\Psi)(1+\eta_\xi)$ with $|\eta'| \le \varepsilon_{\mathrm{rt}}$ and $|\eta_\xi| \le \varepsilon_{\mathrm{rt}}$.

(5) *Volume-first limits and their components.* For every volume-first limit S at g, every canonical decomposition $(\mathsf{X},\lambda,(\sigma_\xi))$ of σ_S, for $\mathsf{S} = S_2$ and $\mathsf{S} = S_2^\xi$, $\xi \in \mathsf{X}$, and for every $\Psi \in \mathfrak{T}^1(d;\vartheta)$: $|\mathsf{S}(\Psi) - c_2\mathsf{b}(S)^{-2}\mathcal{K}_6(\Psi)| \le \varepsilon_{\mathrm{rt}}\,c_2\mathsf{b}(S)^{-2}\mathcal{K}_6(\Psi)$.

At fixed g and ϑ, $\varepsilon_{\mathrm{rt}}$ is a function of d alone: one bound serves all the data, states, sides, pairs and positions of pairs, limits, frames, functionals and components of (1)–(5). For each of the two choices of $\varepsilon_{\mathrm{rt}}$ the admitted scales d include all sufficiently small positive numbers (Proposition 18.63 (c)). ■

Sketch of proof. (1) *The bound.* By Proposition 18.61 (a), $g \le \gamma_W$. If $d \in \mathsf{Z}(g)$, Proposition 18.63 (b) gives $\eta_{g,\vartheta}(d) \le \mathsf{F}_g(d,\vartheta)$; if $d \le L^2\mathsf{d}_0^{\mathrm{ref}}(\check g,\vartheta)$, its clause (a) gives $\eta_{g,\vartheta}(d) \le C^{\mathrm{ref}}(\check g,\vartheta)\,\mathsf{y}_g(d)^{-2p_0} + \mathsf{C}_{\mathrm{law}}(g,\vartheta)\,d$. So $\eta_{g,\vartheta}(d) \le \varepsilon_{\mathrm{rt}}$ in each case.

(2) *A larger tolerance.* Since $\mathcal{K}_6(\Psi) > 0$ at every test pair, the relative form and the absolute difference form of the estimate are equivalent. Increasing the tolerance from $\eta_{g,\vartheta}(d)$ to $\varepsilon_{\mathrm{rt}}$ preserves both forms.

(3) *The statements.* Theorem YM3_I:AV gives (1) and (2) at finite cutoff. Theorem YM3_I:AW gives (3), including convergence of the labels along every defining sequence. Proposition YM3_I:127.8 gives (4)(i). For (4)(ii), Corollary YM3_I:127.11 gives the same label and estimate for the limit in the frame and all components. The component approximation is along the full chosen sequence by Theorem YM3_I:AP. A volume-first defining sequence has converging self-centered moments by the moment–cumulant formula, with the functional σ_S. Applying (3) and (4)(ii) to this sequence gives (5). In every case use (2) to substitute the larger tolerance.

(4) *One bound.* The number $\varepsilon_{\mathrm{rt}}$ is formed from g, ϑ, d and the numbers C_{un}, $\mathsf{C}^{\circ}_{\mathrm{law}}(g)$, $C^{\mathrm{ref}}(\check{g},\vartheta)$ and $\mathsf{C}_{\mathrm{law}}(g,\vartheta)$, which depend on no datum, state, side, pair or position (Proposition 18.63).

(5) *The objects exist.* Choose a label $b' \in I(g)$ and take first-passage data $(K, L^K b')$ from Corollary YM3_I:74.2, with $K > s(d)$. The admissible sides are all powers of the stated form beyond a fixed size, hence are infinite in number. Proposition YM3_I:91.2 gives nonempty $\mathcal{G}^{\mathrm{tor}}_{K,\beta} \subset \mathcal{G}^{\mathrm{inv}}_{K,\beta} \subset \mathcal{G}^{\mathrm{per}}_{K,\beta}$. Lemma YM3_I:127.5 gives smooth Euclidean test pairs and periodisation preserves the test-pair conditions by Lemma YM3_I:127.2. Fixed-torus limits exist by Theorem YM3_I:A, and growing-torus and volume-first limits exist by the compactness of Proposition YM3_I:92.1 applied to sequences of the respective laws. To get a convergent frame choose periodic Gibbs states along first-passage data with $K_j \to \infty$ and extract a subsequence by Theorem YM3_I:AP. It also gives the canonical decomposition. By Proposition 18.63 (c) the admitted scales include, for the first choice of $\varepsilon_{\mathrm{rt}}$, the interval $(0, \frac{1}{2}d_1]$ for every $d_1 \in \mathsf{Z}(g)$ with $\mathsf{F}_g(d_1,\vartheta) \le \frac{1}{3}$, and, for the second, the interval $(0, \frac{1}{2}d_\sharp(g,\vartheta)]$, as $\frac{1}{2}d_\sharp(g,\vartheta) \le \min\{\mathsf{d}_0(g,\vartheta), L^2\mathsf{d}_0^{\mathrm{ref}}(\check{g},\vartheta)\}$. □

18.7. **Three complements: the lattice gradient flow and the continuum Yang–Mills flow; the limit form of the block observables, with nothing cut; a torus with one unit of centre flux.** This subsection adds three groups of results to Section 15.1, to which the words *the section* refer in what follows, and it uses the signs of that Section wherever it does not set them anew. The first compares the gradient flow Φ_s of Wilson's action, started at the lattice field $U_K[Q]$ of a 1-form Q of class C^3 on T_ℓ, with the Yang–Mills flow line q of Q: up to a lattice gauge transformation, bond by bond and for $0 \le s \le s_1$, the two configurations lie within $c\,e^{cs_1}a_K^3(1+\|Q\|_{C^3})^{3p}\exp(120\int_0^{s_1}\sup|F_{q_r}|\,dr)$ of each other, with absolute numbers c and p, for every side ℓ and every cutoff K (Proposition 18.66); behind this stand the existence and the uniqueness of the flow line and bounds of its curvature and of three covariant derivatives of the curvature that read neither the side nor the cutoff (Proposition 18.65). The second treats the block observables read through a smoothed block map $\tilde{\mathcal{M}}$, with no cutoff in the functions and none in the measures: at every depth d the lattice Dirichlet forms converge along the full sequence of cutoffs to a form $\mathcal{E}_\infty^{\tilde{\mathcal{M}}}$ given by a matrix field $\mathsf{Mat}_d^{\tilde{\mathcal{M}}}$ of the threads, which reads neither the depth at which an observable is read nor more than its class, and which lies between $\frac{1}{6}\Gamma_d$ and $\frac{7}{6}\Gamma_d$ at every thread Y such that $\varpi(Y_j) < \theta_j$ for all large j, a property of $\mu_{\ell,\mathsf{b}}$-almost every thread, and such that $\varpi(Y_j) \le \varepsilon_{\mathrm{tr}}$ and $\varpi(Y_j) < \omega_{\tilde{\mathcal{M}}}$ for all $j > d$ and $\sum_{j>d}\varpi(Y_j) \le (36C_{\mathrm{tr}})^{-1}$, where $\varepsilon_{\mathrm{tr}}$, C_{tr} are numbers of L and $\omega_{\tilde{\mathcal{M}}}$ is a number of the map; once d is at least a depth $d_{\tilde{\mathcal{M}}}$ of the map, these threads include all threads with $\varpi(Y_j) < \theta_j$ for every $j > d$ (Propositions 18.67, 18.68); for the smoothed map $\mathcal{M}^\chi$ of Proposition 18.67(d), the form of every single depth is closable (Proposition 18.69); and when the forms of the single depths are closable and a contraction of the energy holds at infinitely many depths, the form on all depths is closable, its closure is a symmetric Dirichlet form for which $\mu_{\ell,\mathsf{b}}$ is invariant and reversible, and every observable of positive energy moves under its semigroup (Proposition 18.70). The third concerns a cube of side l with twisted boundary conditions that carry one unit of centre flux: modulo gauge the action has exactly two minimisers, exchanged by a flip, with the floor $4l^{-2}$ of the Hessian across the gauge directions, and when ϵ obeys the explicit bounds (h1), (h2) in terms of the size of the lattice, the fields with all plaquettes within ϵ of $\mathbf{1}$ form, modulo gauge, two pieces, one around each minimiser, which the flip interchanges; each is a copy of one subset of the Landau slice, and a radial reparametrisation of the slice makes this subset convex and open (Proposition 18.71); on the cube with $N = lL^n$ sites along each axis, a measure there whose density is the exponential of minus the multiple $x = L^n\mathsf{b}$ of an analytic action with that floor, plus an analytic term, obeys a log-Sobolev inequality of the order l^2/b on the gauge-invariant even functions once x is large and $N \le C_N(\log x)^{r_N}$ for fixed numbers $C_N > 0$ and $r_N \ge 0$ with $5r_N < 2\mathfrak{p}_0$, $\mathfrak{p}_0$ the power of the logarithm in the thresholds θ_d, and the gauge invariance cannot be dropped (Proposition 18.72); an entropy tower adds the fibres of a chain with log-concave fibres (Proposition 18.73); and if, with x and N as just said, the small-field chain of the twisted cube is

given as a measure below the Wilson measure, with log-concave fibres, an analytic top and one-step bounds of its tower (the data (D1), (D2) below), then, for gauge-invariant even functions (real and smooth ones in the inequalities of the two measures, bounded Borel ones in those of the dynamics), the chain measure obeys a log-Sobolev inequality of the order l^2/b uniformly in the cutoff, the Wilson measure a weak Poincaré inequality with the defect $\mathsf{R}_{\rm tw}\,\mathrm{osc}^2$, the Langevin dynamics relaxes exponentially down to the level $\mathsf{R}_{\rm tw}\,\mathrm{osc}^2$, and, if $\mathsf{R}_{\rm tw} < 0.19$, along every sequence of cutoffs on which, under the stationary dynamics, the joint laws at two times of all bounded Borel functions of the top field V_n converge, some $\{0,1\}$-valued function of V_n changes its value with positive probability over every positive time in the limit (Proposition 18.74).

I. The lattice gradient flow and the continuum flow. The statements of this part hold for every side $\ell = 2L^m$ and every cutoff K; the setting (E) does not enter. In this part a flow line, with or without the words Yang–Mills, is always a solution in the classical sense, started at a 1-form, as set out below: a map into the 1-forms on T_ℓ, and never the line of gauge orbits of the setting of the section. As in the setting of the section, Φ_s is the flow of $\frac{d}{ds}U(b) = -ia_K J(U)(b)U(b)$ on Ω_K, with the current $J(U) = D_U^{\mathsf{T}} F_U$ of YM3_I:(69) in physical units.

Continuum fields and their lattice fields. A 1-form of class C^k on T_ℓ is $Q = (Q_1, Q_2, Q_3)$ with $Q_\mu \in C^k(T_\ell; \mathfrak{g})$, and $\|Q\|_{C^k} = \max_\mu \max_{|\alpha|\le k} \sup |\partial^\alpha Q_\mu|$, α a multi-index; we write $N_Q := \|Q\|_{C^3}$. For a piecewise C^1 path $\gamma : [t_0, t_1] \to T_\ell$ the holonomy $\mathrm{hol}_Q(\gamma) := H(t_1)$ is the solution of $H'(t) = H(t)\, iQ_\lambda(\gamma(t))\dot\gamma^\lambda(t)$, $H(t_0) = \mathbf{1}$, earlier points standing on the left; it does not read the parametrisation, $\mathrm{hol}_Q(\gamma_1\gamma_2) = \mathrm{hol}_Q(\gamma_1)\mathrm{hol}_Q(\gamma_2)$, and the lattice field $U_K[Q] \in \Omega_K$ takes at a bond b the holonomy of the straight segment from b_- to b_+, so that $U_K[Q](\Gamma) = \mathrm{hol}_Q(\Gamma)$ for every path Γ of $\Lambda_{K,\ell}$. With $F_{\mu\nu} = \partial_\mu Q_\nu - \partial_\nu Q_\mu + i[Q_\mu, Q_\nu]$, $D_\lambda\Psi = \partial_\lambda\Psi + i[Q_\lambda, \Psi]$, $(d_Q\vartheta)_\mu = D_\mu\vartheta$, $(d_Q\eta)_{\mu\nu} = D_\mu\eta_\nu - D_\nu\eta_\mu$ and $(d_Q^* F)_\mu = \sum_\nu D_\nu F_{\mu\nu}$ one has $[D_\mu, D_\nu]\Psi = i[F_{\mu\nu}, \Psi]$, the Bianchi identity $D_\lambda F_{\mu\nu} + D_\mu F_{\nu\lambda} + D_\nu F_{\lambda\mu} = 0$, $\partial_\lambda\langle\Psi, \Psi'\rangle = \langle D_\lambda\Psi, \Psi'\rangle + \langle\Psi, D_\lambda\Psi'\rangle$, and $\int_{T_\ell}\sum_\mu\langle\eta_\mu, (d_Q^* F)_\mu\rangle = \int_{T_\ell}\sum_{\mu<\nu}\langle(d_Q\eta)_{\mu\nu}, F_{\mu\nu}\rangle$; so the flow $\partial_s q = -d_q^* F_q$ is the gradient flow of $\frac12\int_{T_\ell}\sum_{\mu<\nu}|F_{\mu\nu}|^2$. For $g \in C^1(T_\ell; G)$ put $Q_\mu^g = gQ_\mu g^{-1} + i(\partial_\mu g)g^{-1}$; then $\mathrm{hol}_{Q^g}(\gamma) = g(\gamma(t_0))\,\mathrm{hol}_Q(\gamma)\,g(\gamma(t_1))^{-1}$, so that $U_K[Q^g] = U_K[Q]^{g|}$ exactly, $g|$ the restriction of g to the sites of $\Lambda_{K,\ell}$, and for $g \in C^2$ one has $F^{Q^g} = \mathrm{Ad}(g)F^Q$ and $D^{Q^g}(\mathrm{Ad}(g)\Psi) = \mathrm{Ad}(g)D^Q\Psi$. The numbers $\Phi_k(Q) := \max\sup_x |D_{\lambda_1}\cdots D_{\lambda_k}F_{\mu\nu}(x)|$, the maximum over all indices, are gauge invariant, and by the rule of Leibniz and $|[X,Y]| \le 2|X||Y|$, $\Phi_k(Q) \le 2^{k^2+k+1}(1 + \|Q\|_{C^{k+1}})^{k+2}$; in particular $\Phi_0 \le 2(1+N_Q)^2$, $\Phi_1 \le 8(1+N_Q)^3$, $\Phi_2 \le 128(1+N_Q)^4$, and $\Phi_3 \le 2\|Q\|_{C^4} + 2^{13}(1+N_Q)^5$. For a 1-form η and $b = \langle x, x + a_K e_\mu\rangle$ the bond average is $\bar\eta(b) := a_K^{-1}\int_0^{a_K}\mathrm{Ad}(H_b(t))\,\eta_\mu(x + te_\mu)\,dt$, $H_b(t)$ the holonomy of Q along the segment from x to $x + te_\mu$.

Flow lines and gauged flows. A Yang–Mills flow line from Q on $[0, s_1]$ is a map $q : [0, s_1] \times T_\ell \to \mathfrak{g}^3$ such that q, $\partial_s q$ and $\partial_x^\alpha q$, $|\alpha| \le 2$, are continuous, $\partial_s q = -d_q^* F_q$ and $q_0 = Q$; it is a flow line on $[0, \infty)$ if this holds on every $[0, s_1]$. A regular gauged flow on $[s', s'']$ is a pair of maps $q : [s', s''] \times T_\ell \to \mathfrak{g}^3$, $\vartheta : [s', s''] \times T_\ell \to \mathfrak{g}$ such that q, $\partial_s q$, $\partial_x q$, $\partial_x^2 q$, ϑ and $\partial_x\vartheta$ are continuous, $\partial_s q = -d_q^* F_q - d_q\vartheta$, $s \mapsto q_s$ is continuous from $(s', s'']$ into C^4, and $\mathfrak{t}(s) := 2[\frac{1}{12}\Phi_3 + \frac{37}{3}\Phi_0\Phi_1 + \frac13\Phi_0^3 + 12\Phi_0^2\Phi_1](q_s)$ is integrable on $(s', s'']$. A piecewise regular gauged flow from Q on $[0, s_1]$ consists of points $0 = \sigma_0 < \cdots < \sigma_k = s_1$ and regular gauged flows $(q^{(j)}, \vartheta^{(j)})$ on $[\sigma_{j-1}, \sigma_j]$ with $q_0^{(1)} = Q$ and $q_{\sigma_j}^{(j+1)} = (q_{\sigma_j}^{(j)})^{g_j}$, $g_j \in C^1(T_\ell; G)$; its numbers are $\mathfrak{T} := \sum_j\int_{\sigma_{j-1}}^{\sigma_j}\mathfrak{t}\,ds$ and $\mathfrak{E} := \exp(10s_1 + 40\int_0^{s_1}\Phi_0(q_s)\,ds)$, q_s the field of a piece that holds s (the Φ_k do not see the joints, being gauge invariant). For $Q \in C^3$ with its flow line q (Proposition 18.65(a)) and a cutoff K put $\mathrm{err}_K(Q; s) := \min_u \max_b \|\Phi_s(U_K[Q])^u(b) - U_K[q_s](b)\|$, the minimum over the gauge transformations u of $\Lambda_{K,\ell}$, $\|\cdot\|$ the operator norm.

Lattice notation. On $\Lambda_{K,\ell}$, with $a = a_K$: for a bond $b = \langle x, x + ae_\mu\rangle$ and $\alpha \in \{\pm1, \pm2, \pm3\}$ with $|\alpha| \ne \mu$, $e_{-\nu} := -e_\nu$, $W_x(\mu, \alpha)$ is the value of a configuration along the closed path $x \to x + ae_\mu \to x + ae_\mu + ae_\alpha \to x + ae_\alpha \to x$. For a 2×2 matrix V, $\mathbf{w}(V) := \frac{1}{2i}(V - V^*)$ and $\mathbf{c}(V) := \frac12\mathrm{Re}\,\mathrm{tr}\,V$; for $V \in G$, $V = \mathbf{c}(V)\mathbf{1} + i\mathbf{w}(V)$, $\|V - \mathbf{1}\|^2 = 2(1 - \mathbf{c}(V))$ and $|\mathbf{w}(V)|^2 = (1 - \mathbf{c}(V))(1 + \mathbf{c}(V))$.

$\Phi_0^{\mathrm{lat}}(V) := a^{-2}\max\|W_x(\mu,\alpha)(V)-\mathbf{1}\|$, the maximum over x,μ,α. For 1-forms, D_V is the covariant exterior derivative and D_V^{T} its transpose in physical units at spacing a, as in YM3_I:(67)–(68). On site functions D_V is the covariant gradient and D_V^* is its adjoint on 1-forms, with the formulas below. With $V(x,\nu)$ the value at $\langle x, x+ae_\nu\rangle$, put $(\nabla_\nu^V f)(x) := a^{-1}[\mathrm{Ad}(V(x,\nu))f(x+ae_\nu)-f(x)]$ and $(\nabla_\nu^{V*}f)(x) := a^{-1}[\mathrm{Ad}(V(x-ae_\nu,\nu)^{-1})f(x-ae_\nu)-f(x)]$ on site functions, so that $(D_V\lambda)(\langle x, x+ae_\mu\rangle) = (\nabla_\mu^V\lambda)(x)$ and $D_V^*E = \sum_\nu \nabla_\nu^{V*}E_\nu$; $\Delta^V := -\sum_\nu \nabla_\nu^{V*}\nabla_\nu^V$ acts on each component of a 1-form, and $|E|_\infty := \max_b |E(b)|$.

Proposition 18.65 (The Yang–Mills flow from a field of class C^3; curvature bounds free of the side)**.** Let $Q\in C^3(T_\ell;\mathfrak{g}^3)$ and $N_Q = \|Q\|_{C^3}$.

(a) There is exactly one Yang–Mills flow line q from Q on $[0,\infty)$. With $c_* := (1152\pi)^{-2}$, $s_0 := c_*(1+N_Q)^{-2}$, Δ the Laplacian of T_ℓ acting on each component and $\mathcal{N}(q)_\mu := \sum_\nu\{2i[q_\nu,\partial_\nu q_\mu]-i[q_\nu,\partial_\mu q_\nu]-[q_\nu,[q_\nu,q_\mu]]\}$, there is exactly one $\hat q\in C([0,s_0];C^3)$ with $\hat q_s = e^{s\Delta}Q+\int_0^s e^{(s-r)\Delta}\mathcal{N}(\hat q_r)\,dr$; it has $\|\hat q_s\|_{C^3}\le 2N_Q$ and $\|\hat q_s\|_{C^4}\le 2N_Q s^{-1/2}$, and with $\hat\vartheta := -\sum_\nu \partial_\nu\hat q_\nu$ the pair $(\hat q,\hat\vartheta)$ is a regular gauged flow on $[0,s_0]$; if h solves $\partial_s h = -ih\hat\vartheta$, $h_0=\mathbf{1}$, then $q_s = \hat q_s^{h_s}$ for $s\le s_0$, so that $U_K[q_s] = U_K[\hat q_s]^{h_s|}$. For every $s_1>0$ there is a piecewise regular gauged flow from Q on $[0,s_1]$ whose first piece is $(\hat q,\hat\vartheta)$ on $[0,\min\{s_0,s_1\}]$; if $s_1\le s_0$ this is its only piece, and if $s_1>s_0$ it has exactly one piece more, defined on $[s_0,s_1]$, of class C^∞ and with vanishing ϑ; its numbers Φ_k are those of q.

(b) Let $s_1>0$, let $e_k := \sum_{\lambda_1,\dots,\lambda_k}\sum_{\mu<\nu}|D_{\lambda_1}\cdots D_{\lambda_k}F_{\mu\nu}|^2$, formed with q_s, $y_k(s) := \max_x e_k(s,x)$, $\mathsf{E}_{\mathrm{loc}}(s) := \sup_x\int_{x+[0,1]^3} e_0(s,z)\,dz$ with e_0 read as a periodic function on $\mathbb{R}^3$, $\bar{\mathsf{E}} := 27\mathsf{E}_{\mathrm{loc}}(0)e^{324s_1}$, $\tau_* := \min\{1,155^{-4}\bar{\mathsf{E}}^{-2}\}$ if $\bar{\mathsf{E}}>0$ and $\tau_*:=1$ if $\bar{\mathsf{E}}=0$, and let $\mathsf{u}_1,\mathsf{u}_2,\mathsf{u}_3$ be the absolute numbers of the equations of the curvature set out in the proof. Then for $0\le s\le s_1$, with no number that reads ℓ or K: (i) $\mathsf{E}_{\mathrm{loc}}(s)\le 27\mathsf{E}_{\mathrm{loc}}(0)e^{324s}\le\bar{\mathsf{E}}$; (ii) $y_0(s)\le \mathsf{Y}_0 := 2\max\{y_0(0),[2(4\pi\tau_*)^{-1/2}+1]^3\bar{\mathsf{E}}\}$, and we put $\mathsf{h}_0 := \mathsf{Y}_0^{1/2}$; (iii) $y_1(s)\le\mathsf{Y}_1 := y_1(0)+2\mathsf{u}_1\mathsf{h}_0y_0(0)+10\mathsf{u}_1\mathsf{h}_0^4 s_1$ and $y_2(s)\le\mathsf{Y}_2 := y_2(0)+\mathsf{q}_2y_1(0)+(\mathsf{u}_2\mathsf{Y}_1^2+4\mathsf{u}_1\mathsf{q}_2\mathsf{h}_0\mathsf{Y}_1)s_1$, $\mathsf{q}_2 := \frac12\mathsf{u}_2(4\mathsf{h}_0+1)$; (iv) for $0<s\le s_1$: $\min\{s,1\}\,y_3(s)\le\mathsf{Y}_3 := \mathsf{q}_3\mathsf{Y}_2+2\mathsf{u}_3\mathsf{Y}_1\mathsf{Y}_2+\mathsf{q}_3[\mathsf{u}_2(4\mathsf{h}_0+1)\mathsf{Y}_2+\mathsf{u}_2\mathsf{Y}_1^2]$, $\mathsf{q}_3 := \frac12[1+\mathsf{u}_3(4\mathsf{h}_0+2)]$.

(c) There are absolute numbers c and p such that for every side ℓ, every $Q\in C^3(T_\ell;\mathfrak{g}^3)$ and every $s>0$: $\Phi_0(q_s)\le ce^{cs}(1+N_Q)^8$, $\Phi_1(q_s)\le ce^{cs}(1+N_Q)^p$, $\Phi_2(q_s)\le ce^{cs}(1+N_Q)^p$ and $\Phi_3(q_s)\le ce^{cs}(1+N_Q)^p(1+s^{-1/2})$; and $\Phi_0(q_s)\le 8(1+N_Q)^2$ for $s\le s_0$.

■

Sketch. (a) *The local fixed point.* The heat semigroup $e^{s\Delta}$ commutes with derivatives and contracts every $C^k(T_\ell)$, and the heat kernel p_s of $\mathbb{R}^3$ has $\|\partial_\lambda p_s\|_{L^1} = (\pi s)^{-1/2}$, so $\|e^{s\Delta}f\|_{C^{k+1}}\le s^{-1/2}\|f\|_{C^k}$ for $0<s\le 1$. $\mathcal{N}=\mathcal{N}_2+\mathcal{N}_3$ with $\mathcal{N}_2$ bilinear in $(q,\partial q)$ and $\mathcal{N}_3$ trilinear; by the rule of Leibniz and $|[X,Y]|\le 2|X||Y|$, $\|\mathcal{N}_2(q)-\mathcal{N}_2(q')\|_{C^k}\le 18\cdot 2^k(\|q-q'\|_{C^k}\|q\|_{C^{k+1}}+\|q'\|_{C^k}\|q-q'\|_{C^{k+1}})$ and $\|\mathcal{N}_3(q)-\mathcal{N}_3(q')\|_{C^k}\le 12\cdot 3^k(\|q\|_{C^k}^2+\|q\|_{C^k}\|q'\|_{C^k}+\|q'\|_{C^k}^2)\|q-q'\|_{C^k}$. On the ball of radius $2N_Q$ of the Banach space of the $q\in C([0,s_0];C^3)\cap C((0,s_0];C^4)$ with the norm $\max\{\sup_s\|q_s\|_{C^3},\sup_s s^{1/2}\|q_s\|_{C^4}\}$, the map $q\mapsto e^{s\Delta}Q+\int_0^s e^{(s-r)\Delta}\mathcal{N}(q_r)\,dr$ moves $e^{\cdot\Delta}Q$ (of norm at most N_Q) by at most $576\pi N_Q^2 s_0^{1/2}+5184N_Q^3 s_0\le N_Q$ and contracts with the factor $576\pi N_Q s_0^{1/2}+7776N_Q^2 s_0\le\frac34$, by the choice of c_*; here $\int_0^s(s-r)^{-1/2}dr = 2s^{1/2}$ and $\int_0^s(s-r)^{-1/2}r^{-1/2}dr=\pi$ enter. This gives $\hat q$ with its two bounds. Two mild solutions in $C([0,s];C^1)$ from one datum agree: the function $s\mapsto\|q_s-q'_s\|_{C^1}$ is at most $C\int_0^s\max\{1,(s-r)^{-1/2}\}\|q_r-q'_r\|_{C^1}\,dr$, and one iteration and Gronwall's lemma make it vanish. The same fixed point with (C^k,C^{k+1}) in the place of (C^3,C^4) gives, for every $k\ge1$, solutions on intervals of the length $c_{*,k}(1+\|\cdot\|_{C^k})^{-4}$ from data of class C^k, with absolute numbers $c_{*,k}$; restarted at small positive times, by the semigroup law, it shows that a mild solution is C^∞ on $(0,s]\times T_\ell$ and solves $\partial_s\hat q=\Delta\hat q+\mathcal{N}(\hat q)$ there, and for data of class C^3 the equation holds on $[0,s_0]$, all its terms being

continuous. The algebra $\sum_\nu[D_\nu F_{\nu\mu}+D_\mu(\partial_\nu q_\nu)]=\Delta q_\mu+\mathcal{N}(q)_\mu$, in which the terms $\pm i[\partial_\nu q_\nu,q_\mu]$ cancel, shows that $(\hat q,\hat\vartheta)$ is a regular gauged flow, with $\Phi_3(\hat q_s)\le 4N_Q s^{-1/2}+2^{13}(1+2N_Q)^5$, an integrable function.

Back to the flow line; uniqueness. $\hat\vartheta\in C([0,s_0];C^2)$ and $\|\hat\vartheta_s\|_{C^3}\le 6N_Q s^{-1/2}$, so the linear equation $\partial_s h=-ih\hat\vartheta$, $h_0=\mathbf{1}$, has a solution with $\partial_x^\alpha h$, $|\alpha|\le 3$, and $\partial_s\partial_x h$ continuous (differentiation in the parameter x under an integrable majorant). With $\partial_s h=i\eta h$, $\eta=-\mathrm{Ad}(h)\hat\vartheta$, one has $\partial_s(\hat q^h)_\mu=\mathrm{Ad}(h)\partial_s\hat q_\mu-D^{\hat q^h}_\mu\eta$, and with the covariance of F and of D this is $-(d^*_{\hat q^h}F_{\hat q^h})_\mu$: $q:=\hat q^h$ is a flow line on $[0,s_0]$, and $U_K[q_s]=U_K[\hat q_s]^{h_s|}$. If q,q' are two flow lines from Q and $\eta:=q-q'$, then $F_q=F_{q'}+d_{q'}\eta+\mathsf{c}$ and $d_q\eta=d_{q'}\eta+2\mathsf{c}$ with $\mathsf{c}_{\mu\nu}=i[\eta_\mu,\eta_\nu]$, and in $L^2(T_\ell)$: $\frac12\frac{d}{ds}\|\eta\|^2=-(d_q\eta,F_q)+(d_{q'}\eta,F_{q'})=-\|d_{q'}\eta\|^2-3(d_{q'}\eta,\mathsf{c})-2\|\mathsf{c}\|^2-2(\mathsf{c},F_{q'})\le\frac14\|\mathsf{c}\|^2+2\|\mathsf{c}\|_{L^1}\|F_{q'}\|_\infty$ (as $-x^2+3xy-2y^2\le\frac14y^2$); with $|\mathsf{c}|\le 2|\eta|^2$ this gives $\frac{d}{ds}\|\eta\|^2\le C(\|\eta\|^2_\infty+\|F_{q'}\|_\infty)\|\eta\|^2$ and $\eta_0=0$, so $\eta=0$.

All times. From a datum $p\in C^\infty$ the fixed point at the level $k=1$, the regularity and the gauge transformation give a C^∞ flow line on $[0,c_{*,1}(1+\|p\|_{C^1})^{-4}]$. Let a C^∞ flow line exist on $[t_0,T)$, $T<\infty$. For $t_0<s<T$ the bounds of (b), whose proof reads only the equations of the curvature, hold on $[t_0,s]$ with $s-t_0$ in the place of s_1 and the values at t_0 in the place of those at 0; the numbers $\mathsf{Y}_0,\mathsf{Y}_1,\mathsf{Y}_2$ increase with s_1, so, for every $s<T$, y_0,y_1,y_2 are bounded on $[t_0,s]$ by the numbers that $s_1:=T-t_0$ gives, finite numbers that do not depend on s; as $|\partial_s q_\mu|\le 2y_1^{1/2}$ and $|\partial_\rho\partial_s q_\mu|\le|D_\rho\partial_s q_\mu|+2|q_\rho||\partial_s q_\mu|\le 2y_2^{1/2}+4\|q\|_\infty y_1^{1/2}$, the norm $\|q_s\|_{C^1}$ stays bounded on $[t_0,T)$, so the length of the local interval of existence from q_t stays bounded below, and the local flow line from q_t, t close to T, continues the flow line beyond T; by the uniqueness the local pieces fit together, and the flow line exists on $[0,\infty)$. For $Q\in C^3$ and $s_1>s_0$ take $(\hat q,\hat\vartheta)$ on $[0,s_0]$ and, behind it, the C^∞ flow line from the C^∞ field $\hat q_{s_0}$ on $[s_0,s_1]$ (with $g_1=\mathbf{1}$): a piecewise regular gauged flow with two pieces; for $s_1\le s_0$ the restriction of $(\hat q,\hat\vartheta)$ to $[0,s_1]$, again a regular gauged flow, is the only piece; and $\hat q^h$ on $[0,s_0]$, followed by the flow line from $\hat q_{s_0}$ transformed by h_{s_0}, held fixed in time, is the flow line from Q.

(b) *The equations of the curvature.* On a gauged flow write $\partial_s q=\mathsf{j}+d_q\vartheta_c$, $\mathsf{j}_\nu=\sum_\mu D_\mu F_{\mu\nu}$, $\vartheta_c=-\vartheta$. From $\partial_s F_{\mu\nu}=D_\mu\partial_s q_\nu-D_\nu\partial_s q_\mu$, the commutation rule and the Bianchi identity: $\partial_s F_{\mu\nu}=\sum_\lambda D_\lambda D_\lambda F_{\mu\nu}+2i\sum_\lambda[F_{\mu\lambda},F_{\lambda\nu}]+i[F_{\mu\nu},\vartheta_c]$. By induction every component T of D^kF obeys $\partial_s T=\Delta_D T+R_T+i[T,\vartheta_c]$, $\Delta_D=\sum_\lambda D_\lambda D_\lambda$, where R_T is a sum, with absolute coefficients, of commutators of a component of D^iF with one of D^jF, $i+j=k$ (one more derivative: $\partial_s(D_\kappa T)=\Delta_D(D_\kappa T)+2i\sum_\lambda[F_{\kappa\lambda},D_\lambda T]+D_\kappa R_T+i[D_\kappa T,\vartheta_c]$, the two terms with $\partial_s q_\kappa$ cancelling). As $\langle T,i[T,\vartheta_c]\rangle=0$ and $\Delta|T|^2=2\langle T,\Delta_D T\rangle+2\sum_\lambda|D_\lambda T|^2$: $\partial_s e_k=\Delta e_k-2e_{k+1}+\varrho_k$ with $|\varrho_k|\le 2\mathsf{u}_k\sqrt{e_k}\sum_{i+j=k}\sqrt{e_ie_j}$, absolute numbers u_k, and $|\varrho_0|\le 5e_0^{3/2}$: for $k=0$ only the third index contributes to each pair $\mu<\nu$, each of the twelve terms is at most $2|F_{12}||F_{13}||F_{23}|\le 2(e_0/3)^{3/2}$, and $24\cdot 3^{-3/2}<5$. These identities hold on each piece of the flow of (a); e_0,e_1,e_2 are continuous on $[0,s_1]\times T_\ell$ and e_3 on $(0,s_1]\times T_\ell$. *The maximum principle used:* if u,h are bounded, continuous and periodic on $[t_a,t_b]\times\mathbb{R}^3$, $\partial_s u,\partial_x u,\partial_x^2 u$ are continuous on each of finitely many intervals $(t,t']$ that make up $(t_a,t_b]$, and $\partial_s u-\Delta u\le h$ there, then $u_s\le e^{(s-t_a)\Delta}u_{t_a}+\int_{t_a}^s e^{(s-t)\Delta}h_t\,dt$ (differentiate $t\mapsto(e^{(s-t)\Delta}u_t)(x)$; the heat kernel is positive); in particular $\max u_s\le\max u_{t_a}+h_0(s-t_a)$ if $h\le h_0$, a constant.

(i) Let ϕ_1 be 1 on $[0,1]$, 0 off $[-1,2]$ and linear in between, and $\phi_x(z):=\prod_i\phi_1(z_i-x_i)$: $|\nabla\phi_x|^2\le 3$ almost everywhere and the support lies in 27 unit cubes. From $\partial_s e_0=2\sum_{\mu,\nu}\langle F_{\mu\nu},D_\mu\mathsf{j}_\nu\rangle$ (the gauge term drops, being orthogonal to F) and an integration by parts on $\mathbb{R}^3$: $\frac{d}{ds}\int\phi_x^2e_0=-2\int\phi_x^2\sum_\nu|\mathsf{j}_\nu|^2-4\int\phi_x\sum_\nu\langle G_\nu,\mathsf{j}_\nu\rangle\le 4\int|\nabla\phi_x|^2e_0\le 324\,\mathsf{E}_{\mathrm{loc}}(s)$, $G_\nu:=\sum_\mu\partial_\mu\phi_x F_{\mu\nu}$, $\sum_\nu|G_\nu|^2\le 2|\nabla\phi_x|^2e_0$; so $\mathsf{E}_{\mathrm{loc}}(s)\le 27\mathsf{E}_{\mathrm{loc}}(0)+324\int_0^s\mathsf{E}_{\mathrm{loc}}$, $\mathsf{E}_{\mathrm{loc}}$ is continuous, and Gronwall's lemma gives (i).

(ii) Cut $\mathbb{R}^3$ into unit cubes, eight of which have a corner at the point at which $e^{\tau\Delta}u$ is read; with the one-dimensional heat kernel, $\sup|e^{\tau\Delta}u| \le [2(4\pi\tau)^{-1/2}+1]^3 \sup_x \int_{x+[0,1]^3}|u|$ and, by Cauchy–Schwarz on each cube, $\sup|e^{\tau\Delta}u| \le [2(8\pi\tau)^{-1/4}+1]^3 \sup_x(\int_{x+[0,1]^3} u^2)^{1/2}$. The maximum principle with $u = e_0$, $h = 5e_0^{3/2}$, started at $\max\{0, s-\tau_*\}$, and $\int_{x+[0,1]^3} e_0(r)^3 \le y_0(r)^2\bar{\mathsf{E}}$ by (i), give $y_0(s) \le \max\{y_0(0), [2(4\pi\tau_*)^{-1/2}+1]^3\bar{\mathsf{E}}\} + 77.1\,\bar{\mathsf{E}}^{1/2}\tau_*^{1/4}\sup_{[0,s_1]} y_0$, using $(x+y)^3 \le 4(x^3+y^3)$, $\tau_* \le 1$ and $20[32(8\pi)^{-3/4}+1] < 77.1$; and $77.1\,\bar{\mathsf{E}}^{1/2}\tau_*^{1/4} \le \frac12$ by the choice of τ_*. The supremum is finite, and (ii) follows.

(iii) With $|\varrho_1| \le 4\mathsf{u}_1\sqrt{e_0}\,e_1$, $u = e_1 + 2\mathsf{u}_1\mathsf{h}_0 e_0$ has $\partial_s u - \Delta u \le (4\mathsf{u}_1\sqrt{e_0} - 4\mathsf{u}_1\mathsf{h}_0)e_1 + 10\mathsf{u}_1\mathsf{h}_0 e_0^{3/2} \le 10\mathsf{u}_1\mathsf{h}_0^4$; with $|\varrho_2| \le \mathsf{u}_2(4\mathsf{h}_0+1)e_2 + \mathsf{u}_2 e_1^2$, $u = e_2 + \mathsf{q}_2 e_1$ has $\partial_s u - \Delta u \le \mathsf{u}_2\mathsf{Y}_1^2 + 4\mathsf{u}_1\mathsf{q}_2\mathsf{h}_0\mathsf{Y}_1$; the maximum principle on $[0,s]$.

(iv) Let $0 < t < s \le s_1$, $s-t \le 1$. On $[t,s]$ the function $u(r) = (r-t)e_3 + \mathsf{q}_3 e_2$ has, by $|\varrho_3| \le \mathsf{u}_3(4\mathsf{h}_0+2)e_3 + 2\mathsf{u}_3 e_1 e_2$, $\partial_r u - \Delta u \le [1+\mathsf{u}_3(4\mathsf{h}_0+2) - 2\mathsf{q}_3]e_3 + \mathsf{h}_3$ with $\mathsf{h}_3 := 2\mathsf{u}_3\mathsf{Y}_1\mathsf{Y}_2 + \mathsf{q}_3[\mathsf{u}_2(4\mathsf{h}_0+1)\mathsf{Y}_2 + \mathsf{u}_2\mathsf{Y}_1^2]$, and the bracket vanishes; so $(s-t)y_3(s) \le \max u(s) \le \mathsf{q}_3 y_2(t) + \mathsf{h}_3(s-t) \le \mathsf{Y}_3$. Let $t \downarrow 0$ if $s \le 1$, and take $t = s-1$ if $s > 1$.

(c) $\mathsf{E}_{\mathrm{loc}}(0) \le y_0(0) \le 3\Phi_0(Q)^2$, $y_1(0) \le 9\Phi_1(Q)^2$, $y_2(0) \le 27\Phi_2(Q)^2$, and the bounds of the $\Phi_k(Q)$ by N_Q give $\bar{\mathsf{E}} \le 324(1+N_Q)^4 e^{324 s_1}$, $\tau_*^{-1/2} \le 1 + 155^2\bar{\mathsf{E}}$, $\mathsf{Y}_0 \le c e^{1296 s_1}(1+N_Q)^{16}$, $\mathsf{h}_0 \le c e^{648 s_1}(1+N_Q)^8$; $\mathsf{Y}_1, \mathsf{Y}_2, \mathsf{Y}_3$ are polynomials with absolute coefficients in $\mathsf{h}_0, y_0(0), y_1(0), y_2(0), s_1$. Apply (b) with $s_1 := s$; $\Phi_k(q_s)^2 \le y_k(s)$, $s \le e^s$, $\min\{s,1\}^{-1/2} \le 1 + s^{-1/2}$. No step reads ℓ. For $s \le s_0$: $\Phi_0(q_s) = \Phi_0(\hat{q}_s) \le 2(1+\|\hat{q}_s\|_{C^1})^2 \le 2(1+2N_Q)^2 \le 8(1+N_Q)^2$. □

Proposition 18.66 (The lattice gradient flow against the Yang–Mills flow)**.** Let K be a cutoff, $a := a_K$, and let all lattice objects be those of $\Lambda_{K,\ell}$.

(a) (Exact identities.) For $U \in \Omega_K$ and $b = \langle x, x+ae_\mu\rangle$: $J(U)(b) = a^{-3}\sum_{|\alpha|\ne\mu} \mathbf{w}(W_x(\mu,\alpha))$. $\Phi_s(U^u) = \Phi_s(U)^u$ for every gauge transformation u. If $s \mapsto \lambda_s$ is a continuous family of site functions on $[s', s'']$ and $\hat{U}$ solves $\partial_s\hat{U}(b) = -ia[J(\hat{U}) + D_{\hat{U}}\lambda_s](b)\hat{U}(b)$, then $\hat{U}_s = (\Phi_{s-s'}\hat{U}_{s'})^{u_s}$ with $\partial_s u_s(x) = i\lambda_s(x)u_s(x)$, $u_{s'} = \mathbf{1}$. For every 1-form E: $(D_V^{\mathsf{T}}D_V E + D_V D_V^* E)_\mu = -(\Delta^V E)_\mu + \sum_{\nu\ne\mu}[\nabla_\mu^V, \nabla_\nu^{V*}]E_\nu$, and $|\sum_{\nu\ne\mu}[\nabla_\mu^V, \nabla_\nu^{V*}]E_\nu| \le 4\Phi_0^{\mathrm{lat}}(V)|E|_\infty$.

(b) (The current near a configuration.) Let $V, \hat{U} \in \Omega_K$, $R(b) := \hat{U}(b)V(b)^{-1}$, $\eta := \max_b\|R(b) - \mathbf{1}\| \le \frac14$, $y := \eta/a$ and $\tilde{E}(b) := a^{-1}\mathbf{w}(R(b))$. Then $|\tilde{E}|_\infty \le y$ and $|J(\hat{U}) - J(V) - D_V^{\mathsf{T}}D_V\tilde{E}|_\infty \le 36\,\Phi_0^{\mathrm{lat}}(V)\,y + 40\,a^{-1}y^2$.

(c) (Consistency.) For $q \in C^4$ and $V = U_K[q]$: $\Phi_0^{\mathrm{lat}}(V) \le \Phi_0(q)$, and, the bond average being formed with q, $|J(V)(b) - \overline{d_q^* F_q}(b)| \le 2a^2[\frac{1}{12}\Phi_3 + \frac{37}{3}\Phi_0\Phi_1 + \frac13 a\Phi_0^3 + 12a^2\Phi_0^2\Phi_1](q)$, which is at most $a^2\mathfrak{t}$ if $a \le 1$.

(d) (Comparison along a regular gauged flow.) Let (q,ϑ) be a regular gauged flow on $[s', s'']$, $U' \in \Omega_K$, $y' := a^{-1}\max_b\|U'(b) - U_K[q_{s'}](b)\|$ and $\mathfrak{Y} := (y' + a^2\int_{s'}^{s''}\mathfrak{t}\,ds)\exp(10(s''-s') + 40\int_{s'}^{s''}\Phi_0(q_s)\,ds)$. If $a \le 1$ and $\mathfrak{Y} < a/4$, there are gauge transformations u_s of $\Lambda_{K,\ell}$, C^1 in s, $u_{s'} = \mathbf{1}$, with $\max_b\|(\Phi_{s-s'}U')^{u_s}(b) - U_K[q_s](b)\| \le a\,\mathfrak{Y}$ for $s' \le s \le s''$.

(e) (Every cutoff.) For a piecewise regular gauged flow from Q on $[0, s_1]$ with the numbers $\mathfrak{T}, \mathfrak{E}$ and every $s \in [\sigma_{j-1}, \sigma_j]$ there is a gauge transformation v_s with $\max_b\|\Phi_s(U_K[Q])^{v_s}(b) - U_K[q_s^{(j)}](b)\| \le a^3\max\{\mathfrak{T}\mathfrak{E}, 128\,\mathfrak{T}^3\mathfrak{E}^3\}$, and with the bound $a^3\mathfrak{T}\mathfrak{E}$ when $4a\mathfrak{T}\mathfrak{E} < 1$.

(f) There are absolute numbers c and p such that for every side ℓ, every cutoff K, every $s_1 > 0$, every $Q \in C^3(T_\ell;\mathfrak{g}^3)$ with its Yang–Mills flow line q and every $0 \le s \le s_1$: $\mathrm{err}_K(Q;s) \le c\,e^{cs_1}a_K^3(1+N_Q)^{3p}\exp(120\int_0^{s_1}\Phi_0(q_r)\,dr)$, where $\Phi_0(q_r) = \sup|F_{q_r}|$. The exponential factor is at most e^{960c_*} if $s_1 \le c_*(1+N_Q)^{-2}$, and at most $\exp(ce^{cs_1}(1+N_Q)^8)$ always.

■

Sketch. Facts on G used throughout: for $X \in \mathfrak{g}$, $\|e^{iX} - \mathbf{1}\| = 2|\sin\frac{|X|}{2}| \le |X|$ and $|\mathbf{w}(e^{iX}) - X| \le \frac{1}{6}|X|^3$; for $\Sigma \in \mathfrak{g}$ and $W \in G$, $\mathbf{c}(i\Sigma W) = -\langle \Sigma, \mathbf{w}(W)\rangle$ and $\langle \mathrm{Ad}(W)Z, \mathbf{w}(W)\rangle = \langle Z, \mathbf{w}(W)\rangle$; $\|\mathrm{Ad}(V) - \mathrm{Ad}(V')\| \le 2\|V - V'\|$; and if $V' = i\Xi_1 V$, $V_0' = i\Xi_0 V_0$ on $[0,r]$ with $V(0) = V_0(0)$, then $\|V(r) - V_0(r)\| \le \int_0^r |\Xi_1 - \Xi_0|$.

(a) By the curvature formula YM3_I:(69), $F_V(p) = a^{-2}\mathbf{w}(\partial V(p))$, and for $\mu \ne \nu$ the component $F_{\mu\nu}(x)$ is $a^{-2}\mathbf{w}(W_x(\mu,\nu))$, as $W_x(\nu,\mu) = W_x(\mu,\nu)^{-1}$ and $\mathbf{w}(V^{-1}) = -\mathbf{w}(V)$; the term $-\mathrm{Ad}(V(x - ae_\nu,\nu)^{-1})F_{\mu\nu}(x - ae_\nu)$ of YM3_I:(68) is $a^{-2}\mathbf{w}(W_x(\mu,-\nu))$, the transported loop reducing to $W_x(\mu,-\nu)^{-1}$; this is the plaquette form of $J = D_V^{\mathsf{T}} F_V$. The covariance of Φ_s follows from $J(U^u) = \mathrm{Ad}(u)J(U)$ since each based holonomy transforms by conjugation at its base and the uniqueness of solutions, the flow existing for all s as its field is tangent to the compact manifold Ω_K. For the gauged flow put $\tilde U_s := (\Phi_{s-s'}\hat U_{s'})^{u_s}$; with $\partial_s(u^{-1}) = -u^{-1}i\lambda$ and the covariance of J, $\partial_s\tilde U(b) = [i\lambda(b_-) - iaJ(\tilde U)(b) - i\mathrm{Ad}(\tilde U(b))\lambda(b_+)]\tilde U(b) = -ia[J(\tilde U) + D_{\tilde U}\lambda](b)\tilde U(b)$ by the covariant-gradient formula: the equation of $\hat U$ with the same initial value. For the identity of Weitzenböck type: by YM3_I:(67), YM3_I:(68), $(D_V^{\mathsf{T}} D_V E)_\mu = \sum_{\nu\ne\mu}\nabla_\nu^{V*}\nabla_\nu^V E_\mu - \sum_{\nu\ne\mu}\nabla_\nu^{V*}\nabla_\mu^V E_\nu$ and $(D_V D_V^* E)_\mu = \sum_\nu \nabla_\mu^V\nabla_\nu^{V*}E_\nu$; $\nabla_\nu^{V*}\nabla_\nu^V = \nabla_\nu^V\nabla_\nu^{V*}$, and the sum of these over ν is $-\Delta^V$; for $\nu \ne \mu$ the expressions $\nabla_\mu^V\nabla_\nu^{V*}f$ and $\nabla_\nu^{V*}\nabla_\mu^V f$ agree but for the terms at $z = x + ae_\mu - ae_\nu$, and $V(x,\mu)V(z,\nu)^{-1} = W_x(\mu,-\nu)V(x - ae_\nu,\nu)^{-1}V(x - ae_\nu,\mu)$ gives $([\nabla_\mu^V, \nabla_\nu^{V*}]f)(x) = a^{-2}[\mathrm{Ad}(W_x(\mu,-\nu)) - 1]\mathrm{Ad}(V(x - ae_\nu,\nu)^{-1}V(x - ae_\nu,\mu))f(z)$, of norm at most $2\Phi_0^{\mathrm{lat}}(V)|f|_\infty$.

(b) $|\tilde E| \le a^{-1}\|R - \mathbf{1}\|$. Fix b and α, let $\beta_1,\dots,\beta_4$ be the positively oriented bonds of the loop of $W_x(\mu,\alpha)$, run in the orientations $\epsilon_j = \pm 1$, and P_j the product of the values of V on the bonds that the loop runs from x until it reaches $(\beta_j)_-$, the initial point of the positively oriented bond β_j; the loop reaches this point before it runs β_j if $\epsilon_j = 1$, and after it if $\epsilon_j = -1$. With $\mathsf{e} := \mathbf{w}(R) = a\tilde E$: $\hat W = \tilde R_1\tilde R_2\tilde R_3\tilde R_4 W$, $\tilde R_j := \mathrm{Ad}(P_j)R(\beta_j)^{\epsilon_j} = \mathbf{c}_j + i\tilde{\mathsf{e}}_j$, $\tilde{\mathsf{e}}_j = \epsilon_j\mathrm{Ad}(P_j)\mathsf{e}(\beta_j)$; $\|\tilde R_j - \mathbf{1}\| \le \eta$ and $0 \le 1 - \mathbf{c}_j \le \eta^2/2$, so $\prod_j \tilde R_j = \mathbf{1} + i\tilde\Sigma + Z$, $\tilde\Sigma := \sum_j \tilde{\mathsf{e}}_j$, $\|Z\| \le 10\eta^2$ for $\eta \le \frac14$, and $\mathbf{w}(\hat W) - \mathbf{w}(W) = \tilde\Sigma + r_1$, $|r_1| \le 4\eta a^2\Phi_0^{\mathrm{lat}}(V) + 10\eta^2$. For $\alpha = \nu > 0$, $\tilde\Sigma$ differs from $a(D_V\mathsf{e})_{\mu\nu}(x)$ (YM3_I:(67)) by two factors $\mathrm{Ad}(W)$, that is by at most $4a^2\Phi_0^{\mathrm{lat}}\eta$; for $\alpha = -\nu$ it differs from $-a\,\mathrm{Ad}(V(x - ae_\nu,\nu)^{-1})(D_V\mathsf{e})_{\mu\nu}(x - ae_\nu)$ by three such factors, by at most $6a^2\Phi_0^{\mathrm{lat}}\eta$. Summing over the four α with (a) and YM3_I:(68): $a^3(J(\hat U) - J(V))(b) = a^2(D_V^{\mathsf{T}} D_V\mathsf{e})(b) + r_2$, $|r_2| \le 36a^2\Phi_0^{\mathrm{lat}}\eta + 40\eta^2$; divide by a^3 and put $\eta = ay$.

(c) For the rectangle $x \to x + a_1e_\mu \to x + a_1e_\mu + re_\nu \to x + re_\nu \to x$ the holonomy $W(r)$ has $W'(r)W(r)^{-1} = i\Xi(r)$, $\Xi(r) = \int_0^{a_1}\mathrm{Ad}(T(r,t))F_{\mu\nu}(x + te_\mu + re_\nu)\,dt$, $T(r,t)$ the holonomy along the boundary up to the point $x + te_\mu + re_\nu$; this is the variation formula $W'W^{-1} = i\int \mathrm{Ad}(H)F_{\alpha\beta}\partial_r\sigma^\alpha\partial_t\sigma^\beta dt$ of the holonomy of a family $\sigma(r,\cdot)$ of closed paths with fixed ends. So $|\Xi| \le a_1\Phi_0$ and $\|W(a_2) - \mathbf{1}\| \le |a_1a_2|\Phi_0$: $\Phi_0^{\mathrm{lat}}(V) \le \Phi_0(q)$. Fix $\nu \ne \mu$ and let $W(r)$ be as above with $a_1 = a$, $|r| \le a$, so that $W(\pm a) = W_x(\mu,\pm\nu)$. Iterating $W(r) = \mathbf{1} + i\int_0^r \Xi W$ twice and using $[\Xi(r),\Xi(r')] = [\Xi(r) - \Xi(r'),\Xi(r')]$ with $|\Xi(r) - \Xi(r')| \le a|r - r'|\Phi_1 + 12a^4\Phi_0\Phi_1$: $\mathbf{w}(W(a)) = \int_0^a \Xi(r)\,dr + \varepsilon_+$, $|\varepsilon_+| \le \frac16 a^5\Phi_0\Phi_1 + 6a^7\Phi_0^2\Phi_1 + \frac16 a^6\Phi_0^3$, and likewise $\mathbf{w}(W(-a)) = -\int_0^a \Xi(-r)\,dr + \varepsilon_-$. With $H(t)$ the holonomy from x to $z := x + te_\mu$, $S_\nu(r)$ that from z to $z + re_\nu$, and Rect that of the small rectangle $z \to z + (a-t)e_\mu \to z + (a-t)e_\mu + re_\nu \to z + re_\nu \to z$: $T(r,t) = H(t)\,\mathrm{Rect}\,S_\nu(r)$; the matrix $\exp(i(a-t)rF_{\mu\nu}(z))$ commutes with $F_{\mu\nu}(z)$ and lies within $\frac23|(a-t)r|(2(a-t) + |r|)\Phi_1 \le 2a^3\Phi_1$ of Rect, so $\mathrm{Ad}(T(r,t))F_{\mu\nu}(z + re_\nu) = \mathrm{Ad}(H(t))[\varphi_t(r) + \delta]$ with $\varphi_t(r) := \mathrm{Ad}(S_\nu(r))F_{\mu\nu}(z + re_\nu)$ and $|\delta| \le 6a^3\Phi_0\Phi_1$. By the covariant Taylor formula, $\varphi_t^{(j)}(r) = \mathrm{Ad}(S_\nu(r))(D_\nu^j F_{\mu\nu})(z + re_\nu)$, so $|\varphi_t(r) - \varphi_t(-r) - 2rD_\nu F_{\mu\nu}(z)| \le \frac13 r^3\Phi_3$, the even orders cancelling. Integrating in t and r: $\mathbf{w}(W_x(\mu,\nu)) + \mathbf{w}(W_x(\mu,-\nu)) = a^2\int_0^a \mathrm{Ad}(H(t))(D_\nu F_{\mu\nu})(x + te_\mu)\,dt + \varepsilon_\nu$, $|\varepsilon_\nu| \le a^5[\frac{1}{12}\Phi_3 + \frac{37}{3}\Phi_0\Phi_1 + \frac13 a\Phi_0^3 + 12a^2\Phi_0^2\Phi_1]$. Sum over the two $\nu \ne \mu$, divide by a^3, and use (a) and $(d_q^*F)_\mu = \sum_\nu D_\nu F_{\mu\nu}$.

(d) *The equation of* $V_s := U_K[q_s]$. The variation of a holonomy under a variation of the field is $\partial_s \mathrm{hol}\cdot \mathrm{hol}^{-1} = i\int \mathrm{Ad}(H)\,\partial_s q_\lambda \dot\gamma^\lambda dt$, and the transport rule $\frac{d}{dt}\mathrm{Ad}(H(t))\Psi(x+te_\mu) = \mathrm{Ad}(H(t))(D_\mu\Psi)(x+te_\mu)$ gives $\int_0^a \mathrm{Ad}(H(t))(D_\mu\vartheta)(x+te_\mu)\,dt = \mathrm{Ad}(V(b))\vartheta(x+ae_\mu) - \vartheta(x)$; with (c): $\partial_s V(b)V(b)^{-1} = -ia[J(V) - \tau_s + D_V\vartheta_s](b)$, $|\tau_s|_\infty \le a^2\mathfrak{t}(s)$ for $s > s'$. *The gauged lattice flow, with the continuum flow as the reference.* Let $\hat U$ solve $\partial_s\hat U(b) = -ia[J(\hat U) + D_{\hat U}\lambda](b)\hat U(b)$, $\hat U_{s'} = U'$, with $\lambda := \vartheta_s| + D^*_{V_s}\tilde E$ and $\tilde E(b) := a^{-1}\mathbf{w}(\hat U(b)V_s(b)^{-1})$; the field is continuous in s and tangent to the compact manifold, so $\hat U$ exists on $[s', s'']$, and $\hat U_s = (\Phi_{s-s'}U')^{u_s}$ by (a). *A scalar identity.* With $R := \hat U V^{-1}$, $\mathsf{e} := \mathbf{w}(R) = a\tilde E$ and $n_b := 1 - \mathbf{c}(R(b)) = \frac12\|R(b) - \mathbf{1}\|^2$: $\partial_s R\, R^{-1} = ia\mathsf{y}$, $\mathsf{y} = -J(\hat U) - D_{\hat U}\lambda + \mathrm{Ad}(R)[J(V) - \tau + D_V\vartheta]$, and $n_b' = a\langle \mathsf{y}, \mathsf{e}\rangle(b)$. As $\langle \mathrm{Ad}(R)Z, \mathsf{e}\rangle = \langle Z, \mathsf{e}\rangle$, also $\langle D_{\hat U}\lambda, \mathsf{e}\rangle(b) = \langle D_V\lambda, \mathsf{e}\rangle(b)$; so ϑ drops out, and with (a): $n_b' = a\langle \Delta^V\tilde E - \sum_{\nu\neq\mu}[\nabla^V_\mu, \nabla^{V*}_\nu]\tilde E_\nu - (J(\hat U) - J(V) - D_V^{\mathsf{T}}D_V\tilde E) - \tau, \mathsf{e}\rangle(b)$. *The maximum principle.* Let $y(s) := a^{-1}\max_b \|R_s(b) - \mathbf{1}\|$ and $n := \max_b n_b = \frac12 a^2y^2$; n is Lipschitz, and where it is differentiable $n' = n_b'$ at every b where the maximum is attained; there $|\mathsf{e}(b')| \le |\mathsf{e}(b)|$ for all b', as $|\mathsf{e}|^2 = n_b(2 - n_b)$ increases with $n_b \le 1$, so that $\langle(\Delta^V\tilde E)_\mu(x), \mathsf{e}(b)\rangle \le 0$. By (a), (b), $\Phi_0^{\mathrm{lat}}(V_s) \le \Phi_0(q_s)$ and $40a^{-1}y^2 \le 10y$, as long as $y \le a/4$: $n' \le a\sqrt{2n}\,[|\tau_s|_\infty + (40\Phi_0(q_s) + 10)y]$ almost everywhere; so $(\sqrt{n+\delta})' \le \frac{a}{\sqrt2}[\cdots]$, and letting $\delta \downarrow 0$: $y(s) \le y' + \int_{s'}^s [a^2\mathfrak{t} + (40\Phi_0 + 10)y]$. Gronwall's lemma gives $y \le \mathfrak{Y} < a/4$ wherever $y \le a/4$ held before, and y is continuous: the bound holds on all of $[s', s'']$, and $\|\hat U_s(b) - V_s(b)\| = \|R_s(b) - \mathbf{1}\| \le a\mathfrak{Y}$.

(e) Apply (d) on each piece with $U' := \Phi_{\sigma_{j-1}}(U_K[Q])^v$, v the gauge transformation reached at σ_{j-1}, and $\Phi_{s-\sigma_{j-1}}(U') = \Phi_s(U_K[Q])^v$ by (a); at σ_j pass from v to $(g_j|)v$, as $U_K[q^{(j+1)}_{\sigma_j}] = U_K[q^{(j)}_{\sigma_j}]^{g_j|}$ and a common gauge transformation keeps the distances. Starting from $y' = 0$, the bounds compose to $y \le a^2\mathfrak{T}\mathfrak{E}$ whenever $a^2\mathfrak{T}\mathfrak{E} < a/4$, that is, whenever $4a\mathfrak{T}\mathfrak{E} < 1$; this is the bound $a^3\mathfrak{T}\mathfrak{E}$. If $4a\mathfrak{T}\mathfrak{E} \ge 1$, then $\|\cdot\| \le 2 \le 2(4a\mathfrak{T}\mathfrak{E})^3 = 128a^3\mathfrak{T}^3\mathfrak{E}^3$.

(f) By Proposition 18.65(a) the flow line q from Q is, up to the gauge transformations h_s for $s \le s_0$ and h_{s_0} for $s > s_0$, the field of a piecewise regular gauged flow from Q, with one piece if $s_1 \le s_0$ and with two if $s_1 > s_0$, whose numbers $\mathfrak{T}, \mathfrak{E}$ are formed with the $\Phi_k(q_s)$; a gauge transformation of the continuum field changes $U_K[q_s]$ by a lattice gauge transformation, which the minimum in err_K absorbs. By Proposition 18.65(c) and $\int_0^{s_1}(1 + s^{-1/2})\,ds = s_1 + 2s_1^{1/2}$: $\mathfrak{T} \le ce^{cs_1}(1 + N_Q)^p$; and $\max\{\mathfrak{T}\mathfrak{E}, 128\mathfrak{T}^3\mathfrak{E}^3\} \le 128(1 + \mathfrak{T})^3\mathfrak{E}^3$, $\mathfrak{E}^3 = e^{30s_1}\exp(120\int_0^{s_1}\Phi_0(q_r)\,dr)$; with (e) this is the bound, with new numbers c, p. For $s_1 \le c_*(1 + N_Q)^{-2} = s_0$: $120\int_0^{s_1}\Phi_0 \le 120s_1 \cdot 8(1 + N_Q)^2 \le 960c_*$; always $120\int_0^{s_1}\Phi_0 \le 120s_1ce^{cs_1}(1 + N_Q)^8$. □

II. The limit form of the block observables. Throughout this part the setting (E) of §2.3.1 holds, and $\Lambda_{d,\ell}$, a_d, Ω_d, μ^K, the averaging map $\mathcal{M}$, ϖ, θ_d, I_d, R_n, o_n, $\mathsf{t}_\natural$, n_2, ω_L, the threads, $\mu = \mu_{\ell,\mathsf{b}}$, μ_d, μ_d^K, $\pi_{K,d}$, Γ_d, $\mathcal{E}_K$, L^2_{inv}, the strong convergence and the limits, together with the tangent vectors X at V, with their curves $s \mapsto e^{isX}V$ and their norm $\|X\|^2 = \sum_b |X(b)|^2$, the gradient ∂g, the gauge directions $d_V\lambda$, $(d_V\lambda)(b) = \lambda(b_-) - \mathrm{Ad}(V(b))\lambda(b_+)$ for $\mathfrak{g}$-valued functions λ of the sites, and the horizontal vectors, which are orthogonal to the gauge directions, are those of the setting of Section 15.1; $\omega_M = (200L^2)^{-1}$ is the averaging radius of YM3_I:(30). For each coarse bond c write $\mathcal{S}_c$ for the configurations with $|\partial U(p) - \mathbf{1}| < \omega_M$ at every plaquette of its double block. The block map on $\mathcal{S}_c$ is the analytic formula YM3_I:(37), with $U[c]$ the straight transport along c and W_x the relative contour transports in that formula.

Horizontal vectors, the forms t*, the transport constants.* For $V \in \Omega_d$, Π_V is the orthogonal projection, for the norm $\|B\|^2 = \sum_b |B(b)|^2$ of the 1-forms of $\Lambda_{d,\ell}$, onto the horizontal vectors at V; $C^1_{\mathrm{inv}}(\Omega_d)$ is the space of the invariant C^1 functions on Ω_d, and the gradient $\partial g(V)$ of such a function is horizontal. For a map F from $\Omega_{j'}$ to Ω_j, $j \le j'$, that is differentiable at W, the tangent vector $DF(W)X$ at $F(W)$ is given by $\frac{d}{ds}F(e^{isX}W)(b)|_{s=0} = i\,(DF(W)X)(b)\,F(W)(b)$ at every bond b of $\Lambda_{j,\ell}$, and $DF(W)^*$ is the transpose of $DF(W)$ for the scalar products $\sum_b\langle X(b), Y(b)\rangle$ of the two lattices. A covariant map carries gauge directions to gauge directions: if $F(W^u) = F(W)^{u|}$

for all gauge transformations u and F is differentiable at W, then $DF(W)\,d_W\varphi = d_{F(W)}(\varphi|)$ (differentiate at $u = e^{it\varphi}$), so that $DF(W)^*$ maps the horizontal vectors at $F(W)$ to horizontal vectors at W, and $g \circ F$ is invariant with $\partial(g\circ F) = DF^*(\partial g \circ F)$ for invariant g. The forms $\mathsf{t}[\alpha,\beta;V]$ are those of Proposition 15.2(b); for every $\varrho \in [0,1]$ the form $\mathsf{t}[(\frac23,\frac16)+\varrho(\frac13,-\frac16);V]$ lies between $\frac13\|\cdot\|^2$ and $\|\cdot\|^2$, and $\mathsf{t}[2,-1;V](B) = \sum_c |B(c) - \mathrm{Ad}(V(c))B(c^+)|^2 \le 4\|B\|^2$. A_L is the linear map $(\alpha,\beta)\mapsto(\frac{(2L^2+1)\alpha+4(L^2-1)\beta}{3L^2}, \frac{(L^2-1)\alpha+2(L^2+2)\beta}{6L^2})$, so that $A_L(\frac23,\frac16) = (\frac23,\frac16)$ and $A_L(\frac13,-\frac16) = L^{-2}(\frac13,-\frac16)$. The transport constants are two numbers $\varepsilon_{\rm tr} \in (0,(48000L^4)^{-1}]$ and $C_{\rm tr} \ge 1$, functions of L alone, such that (Tr) holds: for every $d \ge 0$, every $U \in \Omega_{d+1}$ with $\varpi(U) \le \epsilon \le \varepsilon_{\rm tr}$, $V := \mathcal{M}U$, every horizontal B at V and all real α,β, the map $\mathcal{M}$ is real-analytic near U and $|L\,\mathsf{t}[\alpha,\beta;U](D\mathcal{M}(U)^*B) - \mathsf{t}[A_L(\alpha,\beta);V](B)| \le C_{\rm tr}(|\alpha|+|\beta|)\,\epsilon\,\|B\|^2$; such numbers exist by the transport of the forms t under the transpose of the differential of $\mathcal{M}$ in the proof of Proposition 15.2(b), taken at one step, whose linear part is computed in the proof of Proposition 18.67.

Depths and events. n_θ is the least integer $n \ge 1$ with $L^n\mathsf{b} \ge \mathsf{t}_\natural$, and $d_\diamond$ the least integer $d \ge \max\{n_\theta, n_2\}$ with $\theta_j \le \varepsilon_{\rm tr}$ for $j > d$ and $36C_{\rm tr}\sum_{j>d}\theta_j \le 1$, which exists as θ_j decreases to 0 and $\sum_j \theta_j < \infty$. For a thread Y, $\mathfrak{d}(Y)$ is the least $n \ge n_\theta$ with $\varpi(Y_j) < \theta_j$ for all $j \ge n$, and ∞ if there is none; by Lemma 15.1(c), $\mu(\mathfrak{d} > n) \le \mathsf{R}_n$, so that $\mathrm{Thr}^\circ := \{Y : \mathfrak{d}(Y) < \infty\}$ has full measure. At a cutoff K and for $n_\theta \le n \le K$, $\mathsf{A}_n^K := \{U \in \Omega_K : \varpi(\pi_{K,j}U) < \theta_j \text{ for } n \le j \le K\}$, an invariant Borel set ($\mathcal{M}$ is Borel, Proposition YM3_I:4.5) with $\mu^K(\Omega_K \setminus \mathsf{A}_n^K) \le \mathsf{R}_n$ for $n < K$ (Lemma 15.1(c)); $\mathsf{A}_{K+1}^K := \Omega_K$; the sets A_n^K increase with n. For $n \ge n_2$ the set A_n^K is open, and $\pi_{K,n}$ is continuous on it, by induction on j from K down to n: $\mathsf{A}_K^K = \{\varpi < \theta_K\}$ is open; for $n \le j < K$, on A_{j+1}^K the map $\pi_{K,j+1}$ is continuous and $\varpi(\pi_{K,j+1}U) < \theta_{j+1} \le \omega_L < \omega_M$ (by the choice of n_2, $\theta_i \le \omega_L$ for $i \ge n_2$), and $\mathcal{M}$ is real-analytic on the open set $\{\varpi < \omega_M\}$, which lies in every set $\mathcal{S}_c$ (Proposition YM3_I:4.5); so $\pi_{K,j} = \mathcal{M}\circ\pi_{K,j+1}$ is continuous on A_{j+1}^K, and A_j^K is open. $\mathsf{tv}_j^K := \sup_E |\mu_j^K(E) - \mu_j(E)|$, which tends to 0 as $K\to\infty$ (Corollary 2.8). A gauge transformation v of $\bigcup_d \Lambda_{d,\ell}$ acts on the threads by $(v\cdot Y)_d := Y_d^{v|}$, $v|$ the restriction to $\Lambda_{d,\ell}$; μ is invariant under these maps, as μ^K is invariant under the bare gauge transformations and $\pi_{K,d}(U^u) = (\pi_{K,d}U)^{u|}$ YM3_I:(40).

Smoothed block maps. A family of maps $\tilde{\mathcal{M}} : \Omega_{j+1} \to \Omega_j$, $j \ge 0$, is admissible if there are numbers $\omega_{\tilde{\mathcal{M}}} \in (0,\omega_M]$ and $c_{\tilde{\mathcal{M}}} \ge 1$, which read neither j nor m, such that: (N1) $\tilde{\mathcal{M}}$ is C^1; (N2) $\tilde{\mathcal{M}}(U^u) = \tilde{\mathcal{M}}(U)^{u|}$ for every gauge transformation u of $\Lambda_{j+1,\ell}$; (N3) $\tilde{\mathcal{M}}(U) = \mathcal{M}(U)$ whenever $\varpi(U) < \omega_{\tilde{\mathcal{M}}}$; (N4) $\|D\tilde{\mathcal{M}}(U)\| \le c_{\tilde{\mathcal{M}}}$ for all U and j, in the operator norm for $\|\cdot\|$. Put $\mathsf{k}_{\tilde{\mathcal{M}}} := Lc_{\tilde{\mathcal{M}}}^2$, $d_{\tilde{\mathcal{M}}}$ the least $d \ge d_\diamond$ with $\theta_j < \omega_{\tilde{\mathcal{M}}}$ for $j > d$, and $\tilde{\mathcal{M}}^n$ the n-fold composite. For $Y \in \mathrm{Thr}^\circ$ and $d \ge 0$ let $\mathsf{j}_0(Y) := \max\{d, d_{\tilde{\mathcal{M}}}, \mathfrak{d}(Y)-1\}$ and $Y_d^{\tilde{\mathcal{M}}} := \tilde{\mathcal{M}}^{J-d}Y_J$ for $J \ge \mathsf{j}_0(Y)$, which does not read J (Proposition 18.67(c)); $Y_d^{\tilde{\mathcal{M}}} := \mathbf{1}$ off Thr°. For $g \in C^1_{\rm inv}(\Omega_d)$ and $J \ge d$ put $g^{(J)} := g\circ\tilde{\mathcal{M}}^{J-d}$, and at a cutoff $K \ge d$, $f_g^K := g\circ\tilde{\mathcal{M}}^{K-d}$ on Ω_K; $d^\vee := \max\{d, d_{\tilde{\mathcal{M}}}\}$ and $\mathsf{z}_J(g) := a_d^{-1/2}\mathsf{k}_{\tilde{\mathcal{M}}}^{(J-d)/2}\|\partial g\|_\infty$. $\mathcal{C}_d^{\tilde{\mathcal{M}}} := \{g(Y_d^{\tilde{\mathcal{M}}}) : g \in C^1_{\rm inv}(\Omega_d)\}$ and $\mathrm{Cyl}^{\tilde{\mathcal{M}}} := \bigcup_d \mathcal{C}_d^{\tilde{\mathcal{M}}}$.

Proposition 18.67 (The matrix of the threads; smoothed block maps)**.** (a) (Many steps.) Let $0 \le d < j$, $W \in \Omega_j$, $V_i := \mathcal{M}^{j-i}W$ for $d \le i \le j$, with $\varpi(V_i) \le \varepsilon_{\rm tr}$ for $d < i \le j$ and $\sigma := \sum_{d<i\le j}\varpi(V_i) \le (6C_{\rm tr})^{-1}$. Then $\mathcal{M}^{j-d}$ is real-analytic near W, and for horizontal λ at V_d, with $q_i(\lambda) := a_i^{-1}|D\mathcal{M}^{i-d}(V_i)^*\lambda|^2$: $|a_dq_j(\lambda) - \mathsf{t}[(\frac23,\frac16)+L^{-2(j-d)}(\frac13,-\frac16);V_d](\lambda)| \le 6C_{\rm tr}\sigma\|\lambda\|^2$, so that $(\frac13 - 6C_{\rm tr}\sigma)\|\lambda\|^2 \le a_dq_j(\lambda) \le (1+6C_{\rm tr}\sigma)\|\lambda\|^2$; and for $d \le J \le j$: $a_d|q_j(\lambda) - q_J(\lambda)| \le \rho_{d,J}\|\lambda\|^2$ with $\rho_{d,J} := \frac23 L^{-2(J-d)} + 12C_{\rm tr}(\sum_{d<i\le J}L^{-2(J-i)}\varpi(V_i) + \sum_{J<i\le j}\varpi(V_i))$; the same holds for the polarised forms, with $\|\lambda\|\|\lambda'\|$ in the place of $\|\lambda\|^2$.

(b) (The matrix.) For $Y \in \mathrm{Thr}^\circ$ and $d \ge \max\{d_\diamond, \mathfrak{d}(Y)-1\}$ the limit $\mathsf{Mat}_d(Y) := \lim_j a_j^{-1}\Pi_{Y_d}D\mathcal{M}^{j-d}(Y_j)D\mathcal{M}^{j-d}(Y_j)^*\Pi_{Y_d}$ exists; $|a_d\langle\lambda, \mathsf{Mat}_d(Y)\lambda\rangle - \mathsf{t}[\frac23,\frac16;Y_d](\lambda)| \le 6C_{\rm tr}\sum_{j>d}\varpi(Y_j)\,\|\lambda\|^2$ for horizontal λ, so that $\frac16\Gamma_d(g)(Y_d) \le \langle\partial g(Y_d), \mathsf{Mat}_d(Y)\partial g(Y_d)\rangle \le$

$\frac{7}{6}\Gamma_d(g)(Y_d)$ for $g \in C^1_{\mathrm{inv}}(\Omega_d)$; $\mathsf{Mat}_d = \Pi_{Y_d} D\mathcal{M}(Y_{d+1})\mathsf{Mat}_{d+1} D\mathcal{M}(Y_{d+1})^* \Pi_{Y_d}$; $Y \mapsto \mathsf{Mat}_d(Y)$ is Borel on $\{\mathfrak{d} \le d+1\}$, and $\mathsf{Mat}_d(v\cdot Y) = \mathrm{Ad}_v \mathsf{Mat}_d(Y)\mathrm{Ad}_v^{-1}$, $(\mathrm{Ad}_v X)(b) := \mathrm{Ad}(v(b_-))X(b)$.

(c) (Admissible maps.) Let $\tilde{\mathcal{M}}$ be admissible, $Y \in \mathrm{Thr}^\circ$ and $d \ge 0$. Then $Y_d^{\tilde{\mathcal{M}}}$ does not read $J \ge \mathsf{j}_0(Y)$, $Y_d^{\tilde{\mathcal{M}}} = \tilde{\mathcal{M}}(Y_{d+1}^{\tilde{\mathcal{M}}})$, and $Y_j^{\tilde{\mathcal{M}}} = Y_j$ for $j \ge \max\{d_{\tilde{\mathcal{M}}}, \mathfrak{d}(Y)-1\}$. The limit $\mathsf{Mat}_d^{\tilde{\mathcal{M}}}(Y) := \lim_j a_j^{-1} \Pi_{Y_d^{\tilde{\mathcal{M}}}} D\tilde{\mathcal{M}}^{j-d}(Y_j) D\tilde{\mathcal{M}}^{j-d}(Y_j)^* \Pi_{Y_d^{\tilde{\mathcal{M}}}}$ exists and equals $\Pi_{Y_d^{\tilde{\mathcal{M}}}} D\tilde{\mathcal{M}}^{J-d}(Y_J)\mathsf{Mat}_J(Y) D\tilde{\mathcal{M}}^{J-d}(Y_J)^* \Pi_{Y_d^{\tilde{\mathcal{M}}}}$ for every $J \ge \mathsf{j}_0(Y)$; with the value 0 off Thr° it is a Borel map into the non-negative symmetric operators, $\mathsf{Mat}_d^{\tilde{\mathcal{M}}}(v\cdot Y) = \mathrm{Ad}_v \mathsf{Mat}_d^{\tilde{\mathcal{M}}}(Y)\mathrm{Ad}_v^{-1}$, $\mathsf{Mat}_d^{\tilde{\mathcal{M}}} = \Pi_{Y_d^{\tilde{\mathcal{M}}}} D\tilde{\mathcal{M}}(Y_{d+1}^{\tilde{\mathcal{M}}}) \mathsf{Mat}_{d+1}^{\tilde{\mathcal{M}}} D\tilde{\mathcal{M}}(Y_{d+1}^{\tilde{\mathcal{M}}})^* \Pi_{Y_d^{\tilde{\mathcal{M}}}}$, $\|a_d \mathsf{Mat}_d^{\tilde{\mathcal{M}}}(Y)\| \le \frac{7}{6}\mathsf{k}_{\tilde{\mathcal{M}}}^{\mathsf{j}_0(Y)-d}$, and $\int \|a_d \mathsf{Mat}_d^{\tilde{\mathcal{M}}}\|^p d\mu \le (\frac{7}{6})^p [\mathsf{k}_{\tilde{\mathcal{M}}}^{p(d^\vee - d)} + \sum_{J > d^\vee} \mathsf{k}_{\tilde{\mathcal{M}}}^{p(J-d)} \mathsf{R}_J] < \infty$ for $1 \le p < \infty$. If $d \ge d_{\tilde{\mathcal{M}}}$ and $\mathfrak{d}(Y) \le d+1$, then $Y_d^{\tilde{\mathcal{M}}} = Y_d$ and $\mathsf{Mat}_d^{\tilde{\mathcal{M}}}(Y) = \mathsf{Mat}_d(Y)$.

(d) (Existence.) Let $\chi_0 \in C^\infty(\mathbb{R}; [0,1])$ be 1 on $(-\infty, \frac{1}{4}]$ and 0 on $[\frac{1}{2}, \infty)$; for a positively oriented bond c of $\Lambda_{j,\ell}$ and $U \in \Omega_{j+1}$ let $\vartheta_c(U) := \prod_p \chi_0(|\partial U(p) - \mathbf{1}|^2/\omega_M^2)$, the product over the plaquettes of the double block of c, and $\mathcal{M}^\chi(U)(c) := \exp(\vartheta_c(U) L^{-3} \sum_{x \in B(c_-)} \log W_x)\, U[c]$ for $U \in \mathcal{S}_c$, $\mathcal{M}^\chi(U)(c) := U[c]$ where $\vartheta_c(U) = 0$, with W_x and $U[c]$ from the analytic block formula above. Then $\mathcal{M}^\chi$ is C^∞ and admissible, with $\omega_{\mathcal{M}^\chi} = \frac{1}{2}\omega_M$, $d_{\mathcal{M}^\chi} = d_\diamond$ and $c_{\mathcal{M}^\chi} = \max\{1, \sqrt{6}\, r_\chi\}$, where $r_\chi < \infty$ is a number of L and χ_0 alone.

■

Sketch. (a) $\mathcal{M}$ is real-analytic near every V_i, as $\varpi(V_i) \le \varepsilon_{\mathrm{tr}} < \omega_M$ (Proposition YM3_I:4.5). Put $\lambda_d := \lambda$, $\lambda_i := D\mathcal{M}(V_i)^* \lambda_{i-1}$, horizontal at V_i, so that $\lambda_j = D\mathcal{M}^{j-d}(W)^* \lambda$, and $\tau_i(\alpha,\beta) := L^{i-d}\, \mathsf{t}[\alpha,\beta; V_i](\lambda_i)$, so that $a_d q_i(\lambda) = \tau_i(1,0)$. (Tr) at the step from V_{i-1} to V_i, multiplied by L^{i-1-d}, reads $\tau_i(\alpha,\beta) = \tau_{i-1}(A_L(\alpha,\beta)) + e_i$ with $|e_i| \le C_{\mathrm{tr}}(|\alpha|+|\beta|)\varpi(V_i)\tau_{i-1}(1,0)$. The iterates $A_L^k(1,0) = (\frac{2}{3}, \frac{1}{6}) + L^{-2k}(\frac{1}{3}, -\frac{1}{6})$ have $|\alpha|+|\beta| \le \frac{7}{6}$; by induction on i, $\tau_i(1,0) \le (1 + \frac{7}{3} C_{\mathrm{tr}}\sigma)\|\lambda\|^2 \le 2\|\lambda\|^2$, and $|\tau_j(1,0) - \mathsf{t}[A_L^{j-d}(1,0); V_d](\lambda)| \le \frac{7}{3} C_{\mathrm{tr}}\sigma \|\lambda\|^2$. For the differences: $\tau_j(1,0) - \tau_J(1,0) = -\frac{1}{6}(1 - L^{-2(j-J)})\tau_J(2,-1) + \sum_{J<i\le j} e_i$, as $A_L^{j-J}(1,0) - (1,0) = -\frac{1}{6}(1 - L^{-2(j-J)})(2,-1)$, and $(2,-1)$ is an eigenvector of A_L with the eigenvalue L^{-2}, so $\tau_J(2,-1) = L^{-2(J-d)}\mathsf{t}[2,-1; V_d](\lambda) + \sum_{d<i\le J} L^{-2(J-i)} e_i'$ with $|e_i'| \le 6 C_{\mathrm{tr}}\varpi(V_i)\|\lambda\|^2$; with $\mathsf{t}[2,-1] \le 4\|\cdot\|^2$ this gives $\rho_{d,J}$. The polarised forms follow by polarisation. *The linear part of (Tr).* At the configuration $\mathbf{1}$ the differential of $\mathcal{M}$ is the linear average $\mathbf{Q}^{\mathrm{lin}}$ of YM3_I:(42) (Lemma YM3_I:4.6); as the contour paths of $B(c_+)$ are the translates of those of $B(c_-)$, $(\mathbf{Q}^{\mathrm{lin}} A)(c) = (SA)(c) + \Lambda_A(c_-) - \Lambda_A(c_+)$ with the straight average $(SA)(c) := L^{-3}\sum_{x \in B(c_-)} A([x,x'])$ and $\Lambda_A(y) := L^{-3}\sum_{x \in B(y)} \bar{A}(y,x)$; the transpose of the second part is the transpose of a coarse gradient, which kills the horizontal vectors, so $\mathbf{Q}^{\mathrm{lin}*} B = S^* B$ for horizontal B. Along the axis of a coarse bond c of the direction μ, S^*B takes at the fine bonds of the direction μ that start in $B(c_-)$, at the m-th position along the axis ($1 \le m \le L$), the value $L^{-3}[mB(c) + (L-m)B(c^-)]$, c^- the coarse bond before c on its axis; at a fine bond of another direction, S^*B takes the value given by the same rule from the coarse bonds of that direction, so that $B(c)$ enters only the values at fine bonds of the direction μ. With $\sum_m [m^2 + (L-m)^2] = \frac{1}{3}L(2L^2+1)$, $\sum_m 2m(L-m) = \frac{1}{3}L(L^2-1)$ for the norm, and the analogous sums $\frac{2}{3}(L^2-1)L$, $\frac{1}{3}L(L^2+2)$ for the pairing of neighbouring fine bonds along the axis: $L\,\mathsf{t}[\alpha,\beta;\mathbf{1}](S^*B) = \mathsf{t}[A_L(\alpha,\beta);\mathbf{1}](B)$. At a field U with $\varpi(U) \le \epsilon$ one goes over, for each coarse bond, to the gauge of its triple block in which the bond variables lie within $15L^2\epsilon$ of $\mathbf{1}$ (Lemma YM3_I:4.1); by the gauge covariance YM3_I:(40) and the real-analyticity of $\mathcal{M}$ on $\mathcal{S}_c$ (Proposition YM3_I:4.5), the differential differs there from the linear average by at most a number of L times ϵ, the supremum of a second differential on a compact ball of configurations of one double block, and the transports along the axes enter the forms t through $\mathrm{Ad}(V(c))$; this is the one-step transport of the proof of Proposition 15.2(b).

(b) For $d \geq \max\{d_\diamond, \mathfrak{d}(Y)-1\}$ and $j > d$, (a) applies to $W = Y_j$ with $\sigma \leq \sum_{i>d}\theta_i \leq (36C_{\rm tr})^{-1}$. The polarised forms $a_j^{-1}\langle D\mathcal{M}^{j-d}(Y_j)^*\lambda, D\mathcal{M}^{j-d}(Y_j)^*\lambda'\rangle$ are Cauchy in j, uniformly in unit λ,λ', as $\rho_{d,J} \to 0$ when $J \to \infty$ (split the middle sum at $i = \frac12(d+J)$ and use $\theta_i \to 0$); the limit, extended by Π_{Y_d}, is $\mathsf{Mat}_d(Y)$, and the bound follows from (a) with $6C_{\rm tr}\sigma \leq \frac16$. Consistency follows from $D\mathcal{M}^{j-d}(Y_j) = D\mathcal{M}(Y_{d+1})D\mathcal{M}^{j-d-1}(Y_j)$ and the horizontality of the values of $D\mathcal{M}(Y_{d+1})^*\Pi_{Y_d}$. Borel: on $\{\mathfrak{d} = D\}$ the matrix is a pointwise limit of continuous functions of finitely many coordinates, and $W \mapsto \Pi_W = \lim_{t\to\infty}\exp(-t\,d_W d_W^*)$ is a pointwise limit of continuous maps. Covariance: $\mathcal{M}^n(W^u) = \mathcal{M}^n(W)^{u|}$ gives $D\mathcal{M}^n(W^u) = \mathrm{Ad}_{u|}D\mathcal{M}^n(W)\mathrm{Ad}_u^{-1}$, and $\Pi_{W^u} = \mathrm{Ad}_u\Pi_W\mathrm{Ad}_u^{-1}$.

(c) For $J \geq \mathsf{j}_0(Y)$, $\varpi(Y_{J+1}) < \theta_{J+1} < \omega_{\tilde{\mathcal{M}}}$, so $\tilde{\mathcal{M}}(Y_{J+1}) = \mathcal{M}(Y_{J+1}) = Y_J$ by (N3), and $\tilde{\mathcal{M}}^{J+1-d}Y_{J+1} = \tilde{\mathcal{M}}^{J-d}Y_J$; the other identities follow at one J that serves all the depths named. For $j \geq J \geq \mathsf{j}_0(Y)$ the open set $\{W \in \Omega_j : \varpi(\mathcal{M}^{j-i}W) < \theta_i,\ J < i \leq j\}$ holds Y_j, and on it $\tilde{\mathcal{M}}^{j-J} = \mathcal{M}^{j-J}$, by downward induction with (N3); so $D\tilde{\mathcal{M}}^{j-d}(Y_j) = D\tilde{\mathcal{M}}^{J-d}(Y_J)D\mathcal{M}^{j-J}(Y_j)$; for horizontal λ at $Y_d^{\tilde{\mathcal{M}}}$ the vector $\eta := D\tilde{\mathcal{M}}^{J-d}(Y_J)^*\lambda$ is horizontal at Y_J, by (N2) and the remark on covariant maps, and $a_j^{-1}\langle D\mathcal{M}^{j-J}(Y_j)^*\eta, D\mathcal{M}^{j-J}(Y_j)^*\eta'\rangle \to \langle\eta, \mathsf{Mat}_J(Y)\eta'\rangle$ by (b). By (N4), $|\eta| \leq c_{\tilde{\mathcal{M}}}^{J-d}|\lambda|$, and by (b) $a_d\langle\eta, \mathsf{Mat}_J\eta\rangle \leq \frac76 a_d a_J^{-1}|\eta|^2 \leq \frac76 \mathsf{k}_{\tilde{\mathcal{M}}}^{J-d}|\lambda|^2$ at $J = \mathsf{j}_0(Y)$; $\{\mathsf{j}_0 = J\} \subset \{\mathfrak{d} > J\}$ for $J > d^\vee$ gives the moments. Borel, covariance and consistency follow as in (b), with (N2) for the covariance of $\tilde{\mathcal{M}}^n$. If $d \geq d_{\tilde{\mathcal{M}}}$ and $\mathfrak{d}(Y) \leq d+1$, then $\varpi(Y_j) < \theta_j < \omega_{\tilde{\mathcal{M}}}$ for $j > d$, so $\tilde{\mathcal{M}}^{J-d}Y_J = \mathcal{M}^{J-d}Y_J = Y_d$ and $D\tilde{\mathcal{M}}^{J-d}(Y_J) = D\mathcal{M}^{J-d}(Y_J)$, whence $\mathsf{Mat}_d^{\tilde{\mathcal{M}}} = \mathsf{Mat}_d$ by the consistency of (b).

(d) The set F_c of the U with $|\partial U(p) - \mathbf{1}|^2 \leq \frac12\omega_M^2$ at the plaquettes of the double block of c is closed and lies in $\mathcal{S}_c$, and $\vartheta_c = 0$ off F_c; so the two clauses define $\mathcal{M}^\chi(U)(c)$ on the two open sets $\mathcal{S}_c$ and $\Omega_{j+1}\setminus F_c$, which cover Ω_{j+1}, and they agree where both apply ($\exp(0)U[c] = U[c]$). On $\mathcal{S}_c$ the W_x are real-analytic with $|W_x - \mathbf{1}| < 1$ (Proposition YM3_I:4.5), where the logarithm is analytic, and ϑ_c is χ_0 composed with polynomials of the entries: $\mathcal{M}^\chi$ is C^∞ and reads U on the double block of c alone. (N2): plaquette variables are conjugated by gauge transformations, $W_x(U^u) = u(c_-)W_x(U)u(c_-)^{-1}$ and $U^u[c] = u(c_-)U[c]u(c_+)^{-1}$ (the intermediate factors of a path product cancel under a gauge transformation), and log and exp are covariant under conjugation. (N3): if $\varpi(U) < \frac12\omega_M$, every argument of χ_0 is below $\frac14$, $\vartheta_c = 1$, and $\mathcal{M}^\chi(U)(c)$ is the analytic branch of $\mathcal{M}$ (Proposition YM3_I:4.5); as $\theta_j \leq \varepsilon_{\rm tr} < \frac12\omega_M$ for $j > d_\diamond$, $d_{\mathcal{M}^\chi} = d_\diamond$. (N4): in the coordinates of a double block, $\mathcal{M}^\chi(U)(c)$ is one C^∞ function F_ν of the values on the double block, the same at every depth, for every side and at every bond of one direction ν, since the shift between two double blocks of one direction keeps the coordinates, the plaquettes, the contour families and the straight paths; $r_\chi := \max_\nu \sup\|DF_\nu\|$ is finite on the compact space of these values; a fine bond lies in at most six double blocks, so $\|D\mathcal{M}^\chi(U)\xi\|^2 \leq 6r_\chi^2\|\xi\|^2$. □

Proposition 18.68 (The limit of the lattice forms on block observables, with nothing cut)**.** Assume (E); let $\tilde{\mathcal{M}}$ be admissible, $d \geq 0$ and $g, h \in C^1_{\rm inv}(\Omega_d)$.

(a) For every $K \geq d$, f_g^K is C^1 and invariant on Ω_K, so it lies in $D(\mathcal{E}_K)$; for $\tilde{\mathcal{M}} = \mathcal{M}^\chi$ and $g \in C^\infty$ it is C^∞. For every $1 \leq p < \infty$: $\sup_{K>d^\vee}\int\Gamma_K(f_g^K)^p d\mu^K \leq (\frac76)^p[\mathsf{z}_{d^\vee}(g)^{2p} + \sum_{J>d^\vee}\mathsf{z}_J(g)^{2p}\mathsf{R}_{J-1}] < \infty$.

(b) Along the full sequence of cutoffs, $\lim_K \mathcal{E}_K(f_g^K, f_h^K) = \mathcal{E}_\infty^{\tilde{\mathcal{M}}}(g,h) := \int\langle\partial g(Y_d^{\tilde{\mathcal{M}}}), \mathsf{Mat}_d^{\tilde{\mathcal{M}}}\,\partial h(Y_d^{\tilde{\mathcal{M}}})\rangle\,d\mu$. For $d^\vee \leq J < J'$ and $J'+1 < K$ the difference is at most $a_d^{-1}\|\partial g\|_\infty\|\partial h\|_\infty\{\mathsf{k}_{\tilde{\mathcal{M}}}^{J-d}[2\bar\rho_{J,J'} + \frac73\mathsf{R}_{J'+1} + \frac73\mathsf{tv}_{J'}^K] + \frac76\sum_{i>J}\mathsf{k}_{\tilde{\mathcal{M}}}^{i-d}(\mathsf{R}_{i-1}+\mathsf{R}_i)\}$, with $\bar\rho_{J,J'} := \frac23 L^{-2(J'-J)} + 12C_{\rm tr}(\sum_{J<i\leq J'}L^{-2(J'-i)}\theta_i + \sum_{i>J'}\theta_i)$; it tends to 0 as first K, then J', then J tends to ∞.

(c) The integrand $\Gamma_\infty^{\tilde{\mathcal{M}}}(g,h) := \langle\partial g(Y_d^{\tilde{\mathcal{M}}}), \mathsf{Mat}_d^{\tilde{\mathcal{M}}}\,\partial h(Y_d^{\tilde{\mathcal{M}}})\rangle$ is the same function for (d,g,h) and for $(d+1, g\circ\tilde{\mathcal{M}}, h\circ\tilde{\mathcal{M}})$; if $g(Y_d^{\tilde{\mathcal{M}}}) = \tilde g(Y_{\tilde d}^{\tilde{\mathcal{M}}})$ μ-almost everywhere, the integrands of (g,h)

and of $(\tilde g, h)$ agree μ-almost everywhere. So $\mathcal{E}^{\tilde{\mathcal{M}}}_\infty$ and $\Gamma^{\tilde{\mathcal{M}}}_\infty$ are defined on the classes of $\mathrm{Cyl}^{\tilde{\mathcal{M}}}$; $\Gamma^{\tilde{\mathcal{M}}}_\infty(\varphi\circ u, w) = \varphi'(u)\Gamma^{\tilde{\mathcal{M}}}_\infty(u,w)$ for $\varphi\in C^1(\mathbb{R})$; $\Gamma^{\tilde{\mathcal{M}}}_\infty(u,u)\ge 0$ lies in every $L^p(\mu)$, $p<\infty$.

(d) If $Y\in \mathrm{Thr}^\circ$ has $\varpi(Y_j)\le \varepsilon_{\mathrm{tr}}$ and $\varpi(Y_j)<\omega_{\tilde{\mathcal{M}}}$ for all $j>d$, and $\sum_{j>d}\varpi(Y_j)\le (36C_{\mathrm{tr}})^{-1}$, then $Y^{\tilde{\mathcal{M}}}_d = Y_d$ and $\frac16\Gamma_d(g)(Y_d)\le \Gamma^{\tilde{\mathcal{M}}}_\infty(g,g)(Y)\le \frac76\Gamma_d(g)(Y_d)$. If $d\ge d_{\tilde{\mathcal{M}}}$, every thread of the event $\{\mathfrak{d}\le d+1\}$, whose μ-mass is at least $1-\mathsf{R}_{d+1}$, is such a thread; so, for $d\ge d_{\tilde{\mathcal{M}}}$, $\mathcal{E}^{\tilde{\mathcal{M}}}_\infty(g,g)\ge \frac16\int_{\{\mathfrak{d}\le d+1\}}\Gamma_d(g)(Y_d)\,d\mu$, $\mu(Y^{\tilde{\mathcal{M}}}_d\ne Y_d)\le \mathsf{R}_{d+1}$, and $\mu^K(\tilde{\mathcal{M}}^{K-d}U\ne \pi_{K,d}U)\le \mathsf{R}_{d+1}$ for $K>d+1$.

(e) $f^K_g\to g(Y^{\tilde{\mathcal{M}}}_d)$ strongly along the full sequence of cutoffs; so $\mathcal{E}_\star(g(Y^{\tilde{\mathcal{M}}}_d))\le \mathcal{E}^{\tilde{\mathcal{M}}}_\infty(g,g)$ for every limit. $\mathrm{Cyl}^{\tilde{\mathcal{M}}}$ is an algebra of bounded Borel invariant functions on the threads, nested in d, with $1\in\mathcal{C}^{\tilde{\mathcal{M}}}_0$ and $\varphi\circ u\in\mathrm{Cyl}^{\tilde{\mathcal{M}}}$ for $u\in\mathrm{Cyl}^{\tilde{\mathcal{M}}}$, $\varphi\in C^1(\mathbb{R})$; its classes are dense in L^2_{inv}. ∎

Sketch. (a) $\tilde{\mathcal{M}}^{K-d}$ is C^1 and covariant, so $f^K_g\in C^1_{\mathrm{inv}}(\Omega_K)$ and $|\partial f^K_g|\le c^{K-d}_{\tilde{\mathcal{M}}}\|\partial g\|_\infty$ by (N4). For $U\in\Omega_K$ let $\mathsf{j}_*(U)$ be the least $J\ge d^\vee$ with $U\in\mathsf{A}^K_{J+1}$. For $J>d^\vee$, $\{\mathsf{j}_*=J\}\subset\Omega_K\setminus\mathsf{A}^K_J\subset\Omega_K\setminus\mathsf{A}^K_{J-1}$, so $\mu^K(\mathsf{j}_*=J)\le\mathsf{R}_{J-1}$. On the open set A^K_{J+1}, $\tilde{\mathcal{M}}^{K-J}=\mathcal{M}^{K-J}$ (downward induction with (N3), $\theta_i<\omega_{\tilde{\mathcal{M}}}$ for $i>J\ge d_{\tilde{\mathcal{M}}}$), so $f^K_g = g^{(J)}\circ\mathcal{M}^{K-J}$ near U; $\partial g^{(J)}(V_J)$ is horizontal at $V_J:=\pi_{K,J}U$, of norm at most $c^{J-d}_{\tilde{\mathcal{M}}}\|\partial g\|_\infty$, and by Proposition 18.67(a), with $\sigma\le\sum_{i>J}\theta_i\le(36C_{\mathrm{tr}})^{-1}$: $\frac16 a_J^{-1}|\partial g^{(J)}(V_J)|^2\le\Gamma_K(f^K_g)(U)\le\frac76 a_J^{-1}|\partial g^{(J)}(V_J)|^2\le\frac76\mathsf{z}_J(g)^2$. Summing over the values of j_* gives the moment bound; the series converges, as R_J decays faster than every exponential in J.

(b) Fix $d^\vee\le J<J'$ with $J'+1<K$. Then $\mathcal{E}_K(f^K_g,f^K_h)=\int_{\mathsf{A}^K_{J+1}}\Gamma_K(g^{(J)}\circ\mathcal{M}^{K-J}, h^{(J)}\circ\mathcal{M}^{K-J})\,d\mu^K + \int_{\{\mathsf{j}_*>J\}}\Gamma_K(f^K_g,f^K_h)\,d\mu^K$, and by (a) the second term is at most $\frac76\sum_{i>J}\mathsf{z}_i(g)\mathsf{z}_i(h)\mathsf{R}_{i-1}$. In the first, with $\lambda:=\partial g^{(J)}(V_J)$, $\lambda':=\partial h^{(J)}(V_J)$, the integrand is $a_K^{-1}\langle D\mathcal{M}^{K-J}(U)^*\lambda, D\mathcal{M}^{K-J}(U)^*\lambda'\rangle$; by Proposition 18.67(a) it lies within $a_J^{-1}|\lambda||\lambda'|\bar\rho_{J,J'}$ of $\phi(V_{J'}):=a_{J'}^{-1}\langle D\mathcal{M}^{J'-J}(V_{J'})^*\lambda, D\mathcal{M}^{J'-J}(V_{J'})^*\lambda'\rangle$, a function of $V_{J'}=\pi_{K,J'}U$ with $|\phi|\le\frac76 a_J^{-1}|\lambda||\lambda'|$. Replacing A^K_{J+1} by the event of $V_{J'}$ that the fields of the depths $J+1,\dots,J'$ are small costs at most $\mathsf{R}_{J'+1}$ in mass; passing from $\mu^K_{J'}$ to $\mu_{J'}$ costs at most $2\mathsf{tv}^K_{J'}$ in total variation; returning to the event $\{\mathfrak{d}\le J+1\}$ costs $\mathsf{R}_{J'+1}$ again; and on $\{\mathfrak{d}\le J+1\}$, $\phi(Y_{J'})$ lies within $a_J^{-1}|\lambda||\lambda'|\bar\rho_{J,J'}$ of $\langle\lambda,\mathsf{Mat}_J(Y)\lambda'\rangle=\Gamma^{\tilde{\mathcal{M}}}_\infty(g,h)(Y)$, by Proposition 18.67(b), (c). Finally $|\int_{\{\mathfrak{d}>J+1\}}\Gamma^{\tilde{\mathcal{M}}}_\infty(g,h)\,d\mu|\le\frac76\sum_{i>J}\mathsf{z}_i(g)\mathsf{z}_i(h)\mathsf{R}_i$, as $\{\mathsf{j}_0=i\}\subset\{\mathfrak{d}=i+1\}$. With $a_J^{-1}|\lambda||\lambda'|\le a_d^{-1}\mathsf{k}^{J-d}_{\tilde{\mathcal{M}}}\|\partial g\|_\infty\|\partial h\|_\infty$ this is the error bound. It tends to 0 as $K\to\infty$ (Corollary 2.8), then $J'\to\infty$ ($\bar\rho_{J,J'}\to0$, $\mathsf{R}_{J'+1}\to0$), then $J\to\infty$ (the decay of R_i beats the growth of $\mathsf{k}^i_{\tilde{\mathcal{M}}}$).

(c) $g\circ\tilde{\mathcal{M}}\in C^1_{\mathrm{inv}}(\Omega_{d+1})$ and $(g\circ\tilde{\mathcal{M}})^{(J)}=g^{(J)}$ for $J\ge d+1$, so both integrands are $\langle\partial g^{(J)}(Y_J),\mathsf{Mat}_J\partial h^{(J)}(Y_J)\rangle$ at $J\ge\mathsf{j}_0(Y)$. For the classes, let $g(Y^{\tilde{\mathcal{M}}}_d)=0$ on a Borel set A of threads; for $J\ge d^\vee$ the set $Z_J:=\{W: g^{(J)}(W)=0,\ \partial g^{(J)}(W)\ne0\}$ is a C^1 hypersurface, hence Haar-null, and the image of $\mathbf{1}_{\{\mathfrak{d}\le J\}}\mu$ under Y_J is absolutely continuous (Proposition 18.69(a)); on $A\cap\{\mathfrak{d}\le J\}$, where $\mathsf{j}_0\le J$, $g^{(J)}(Y_J)=g(Y^{\tilde{\mathcal{M}}}_d)=0$, so $\partial g^{(J)}(Y_J)=0$ and $\Gamma^{\tilde{\mathcal{M}}}_\infty(g,g)=\langle\partial g^{(J)}(Y_J),\mathsf{Mat}_J\partial g^{(J)}(Y_J)\rangle=0$ μ-almost everywhere there; the union over J of these sets is $A\cap\mathrm{Thr}^\circ$; by Cauchy–Schwarz for the non-negative form $\Gamma^{\tilde{\mathcal{M}}}_\infty$, the integrand of (g,h) reads the class of $g(Y^{\tilde{\mathcal{M}}}_d)$ alone. The chain rule is that of ∂ at the point Y_J; the L^p bounds follow from Proposition 18.67(c).

(d) For $j>d$ the field Y_j lies in the open set $\{\varpi<\omega_{\tilde{\mathcal{M}}}\}$, on which $\tilde{\mathcal{M}}=\mathcal{M}$ by (N3); so $\tilde{\mathcal{M}}Y_j=Y_{j-1}$ and $D\tilde{\mathcal{M}}(Y_j)=D\mathcal{M}(Y_j)$, whence $Y^{\tilde{\mathcal{M}}}_d=Y_d$ and, by the chain rule, $D\tilde{\mathcal{M}}^{j-d}(Y_j)=D\mathcal{M}^{j-d}(Y_j)$. For horizontal λ at Y_d, Proposition 18.67(c) gives $\langle\lambda,\mathsf{Mat}^{\tilde{\mathcal{M}}}_d(Y)\lambda\rangle=\lim_j a_j^{-1}|D\mathcal{M}^{j-d}(Y_j)^*\lambda|^2$, and Proposition 18.67(a) at $W=Y_j$, where $\sigma\le(36C_{\mathrm{tr}})^{-1}$, puts a_d times each term of this sequence

between $\frac{1}{6}\|\lambda\|^2$ and $\frac{7}{6}\|\lambda\|^2$; take $\lambda = \partial g(Y_d)$. If $d \geq d_{\tilde{\mathcal{M}}}$ and $\mathfrak{d}(Y) \leq d+1$, then $\varpi(Y_j) < \theta_j$ for $j > d$, while $\theta_j \leq \varepsilon_{\rm tr}$, $\theta_j < \omega_{\tilde{\mathcal{M}}}$ for $j > d$ and $\sum_{j>d}\theta_j \leq (36C_{\rm tr})^{-1}$, by the choice of $d_\diamond$ and of $d_{\tilde{\mathcal{M}}} \geq d_\diamond$; and $\mu(\mathfrak{d} > d+1) \leq \mathsf{R}_{d+1}$. On A^K_{d+1}, $\tilde{\mathcal{M}}^{K-d}U = \pi_{K,d}U$, by the induction of (a).

(e) For $n \geq d^\vee$, $\Psi_n := g^{(n)}(Y_n)$ is a bounded invariant cylinder function; $\Psi_n = g(Y_d^{\tilde{\mathcal{M}}})$ on $\{\mathfrak{d} \leq n+1\}$, so $\|\Psi_n - g(Y_d^{\tilde{\mathcal{M}}})\|^2_{L^2(\mu)} \leq 4\|g\|^2_\infty \mathsf{R}_{n+1}$; and $\Psi_{n,K} = g^{(n)} \circ \pi_{K,n} = f_g^K$ on A^K_{n+1}, so $\|\Psi_{n,K} - f_g^K\|^2_{L^2(\mu^K)} \leq 4\|g\|^2_\infty \mathsf{R}_{n+1}$ for $K > n+1$: this is the strong convergence of the setting, and Lemma 15.1(b) gives $\mathcal{E}_\star(g(Y_d^{\tilde{\mathcal{M}}})) \leq \liminf_j \mathcal{E}_{K_j}(f_g^{K_j}) = \mathcal{E}^{\tilde{\mathcal{M}}}_\infty(g,g)$ for every limit (K_j). Two members of $\mathrm{Cyl}^{\tilde{\mathcal{M}}}$ are read at one common depth, by (c), where sums, products and $\varphi \circ \cdot$ stay in $C^1_{\rm inv}$; $1 = g(Y_0^{\tilde{\mathcal{M}}})$ at $g = 1$. Density: let $u \in L^2_{\rm inv}$ and $\eta > 0$. By the definition of $L^2_{\rm inv}$ there are a depth J_1 and a bounded invariant Borel function Ψ on Ω_{J_1} with $\|\Psi(Y_{J_1}) - u\|_{L^2(\mu)} \leq \eta$; put $B := \sup|\Psi|$ and choose $J \geq \max\{J_1, d_{\tilde{\mathcal{M}}}\}$ so large that $4(B+1)^2\mathsf{R}_{J+1} \leq \eta^2$. Then $F := \Psi \circ \mathcal{M}^{J-J_1}$ is a bounded invariant Borel function on Ω_J with $F(Y_J) = \Psi(Y_{J_1})$ on the threads. There is a polynomial g_0 of the matrix entries with $\|g_0 - F\|_{L^2(\mu_J)} \leq \eta$ (Stone–Weierstrass); take a smooth ψ with $\psi(t) = t$ for $|t| \leq B$, $|\psi'| \leq 1$ and $|\psi| \leq B+1$, so that $|\psi(g_0) - F| = |\psi(g_0) - \psi(F)| \leq |g_0 - F|$; the average g of $\psi(g_0)$ over the gauge group of $\Lambda_{J,\ell}$ is smooth and invariant, has $|g| \leq B+1$, a bound that reads neither g_0 nor J, and has $\|g - F\|_{L^2(\mu_J)} \leq \eta$ (Minkowski's inequality and the invariance of μ_J and of F), that is, $\|g(Y_J) - \Psi(Y_{J_1})\|_{L^2(\mu)} \leq \eta$, as μ_J is the law of Y_J. Last, $g(Y_J^{\tilde{\mathcal{M}}}) = g(Y_J)$ on $\{\mathfrak{d} \leq J+1\}$, by Proposition 18.67(c), and the complement has mass at most R_{J+1}; so $\|g(Y_J^{\tilde{\mathcal{M}}}) - g(Y_J)\|^2_{L^2(\mu)} \leq 4(B+1)^2\mathsf{R}_{J+1} \leq \eta^2$, and $\|g(Y_J^{\tilde{\mathcal{M}}}) - u\|_{L^2(\mu)} \leq 3\eta$. □

Proposition 18.69 (The laws of one depth; the form of one depth is closable)**.** Assume (E).

(a) For $J \geq d_\diamond$ and $K > J$: $\mu^K(\pi_{K,J}U \notin \mathsf{I}_J) \leq \mathsf{R}_J$ and $\mu(Y_J \notin \mathsf{I}_J) \leq \mathsf{R}_J$. For every Borel set $E \subset \mathsf{I}_J$: $\mu(Y_J \in E,\ \mathfrak{d} \leq J) \geq (1 - \mathsf{R}_J)e^{-\mathsf{o}_J}\,\mathrm{Haar}(E)$. The image of $\mathbf{1}_{\{\mathfrak{d}\leq J\}}\mu$ under $Y \mapsto Y_J$ is absolutely continuous with respect to the Haar measure of Ω_J.

(b) Let $\tilde{\mathcal{M}}$ be the map $\mathcal{M}^\chi$ of Proposition 18.67(d). For every $d \geq 0$ the form $\mathcal{E}^{\tilde{\mathcal{M}}}_\infty$ on $\mathcal{C}_d^{\tilde{\mathcal{M}}}$ is closable in $L^2_{\rm inv}$; equivalently, $g \mapsto \mathcal{E}^{\tilde{\mathcal{M}}}_\infty(g,g)$ on $C^1_{\rm inv}(\Omega_d)$ is closable in $L^2(\mu_d^{\tilde{\mathcal{M}}})$, $\mu_d^{\tilde{\mathcal{M}}}$ the law of $Y_d^{\tilde{\mathcal{M}}}$ under μ.

■

Sketch. (a) Proposition 15.2(c) at the depth J, at the cutoff K and with no cutoff, applied to the invariant function $f = \mathbf{1}_{\Omega_J \setminus \mathsf{I}_J}$, whose integral over I_J vanishes, gives the first two bounds. For invariant E the lower bound is Proposition 15.2(c) at the depth J and $f = \mathbf{1}_E$, as $|\mathsf{I}_J| \leq 1$ and $\{\varpi(Y_e) < \theta_e \text{ for all } e \geq J\} = \{\mathfrak{d} \leq J\}$. Absolute continuity: let $E \subset \Omega_J$ be Haar-null and $D > J$; the set $E_D := \{W \in \Omega_D : \mathcal{M}^{D-J}W \in E,\ \varpi(\mathcal{M}^{D-e}W) < \theta_e \text{ for } J < e \leq D\}$ is Haar-null, because $\mathcal{M}^{D-J}$ is a real-analytic submersion on the open set of the second condition (there $\theta_e \leq \omega_L$, and the derivative of $\mathcal{M}$ in the values at the pivot bonds is invertible: proof of Lemma 15.3(iv)); in the same way, for $K > D+1$, the set of the $U \in \mathsf{A}^K_{D+1}$ with $\pi_{K,D}U \in E_D$ is Haar-null, and μ^K has a density; so $\mu^K_D(E_D) \leq \mathsf{R}_{D+1}$, $\mu_D(E_D) \leq \mathsf{R}_{D+1}$ by total variation, and $\mu(Y_J \in E,\ \mathfrak{d} \leq J) \leq \mu(Y_D \in E_D) \leq \mathsf{R}_{D+1} \to 0$. General $E \subset \mathsf{I}_J$: the measure $m_J(E) := \mu(Y_J \in E,\ \mathfrak{d} \leq J)$ is invariant under the gauge transformations of $\Lambda_{J,\ell}$ (the invariance of μ under the maps $Y \mapsto v \cdot Y$; $\mathfrak{d}$ and I_J are invariant) and has a density r; its average $\bar{r}$ over the gauge group is again a density, invariant, and the invariant set $\{\bar{r} < (1 - \mathsf{R}_J)e^{-\mathsf{o}_J}\} \cap \mathsf{I}_J$ carries a non-negative integral of a negative function, by the bound for invariant sets: it is Haar-null.

(b) Here J runs over the depths $J \geq d^\vee$ at which $\mathsf{R}_J < 1$; every large J is one of them, as $\mathsf{R}_J \to 0$. Put $B_J := \{\mathfrak{d} \leq J\} \cap \{Y_J \in \mathsf{I}_J\}$. On B_J, $J \geq \mathfrak{j}_0(Y)$, so $u := g(Y_d^{\tilde{\mathcal{M}}}) = g^{(J)}(Y_J)$ and, by Proposition 18.67(b), (c), $\frac{1}{6}a_J^{-1}|\partial g^{(J)}(Y_J)|^2 \leq \Gamma^{\tilde{\mathcal{M}}}_\infty(g,g) \leq \frac{7}{6}a_J^{-1}|\partial g^{(J)}(Y_J)|^2$. By (a), $\mu(B_J) \geq 1 - 2\mathsf{R}_J \to 1$, and the image m_J of $\mathbf{1}_{B_J}\mu$ under Y_J is absolutely continuous and at least

$c_J\,dW$ on I_J, with the positive number $c_J := (1-\mathsf{R}_J)e^{-\mathsf{o}_J}$. Let $u_n = g_n(Y_d^{\tilde{\mathcal{M}}}) \in \mathcal{C}_d^{\tilde{\mathcal{M}}}$ with $\|u_n\|_{L^2} \to 0$ and $\mathcal{E}_\infty^{\tilde{\mathcal{M}}}(u_n - u_m) \to 0$. Fix J and put $G_n := g_n^{(J)}$, a C^1 function on Ω_J (the map $g \mapsto g^{(J)}$ is linear, and on I_J it reads the class of $g(Y_d^{\tilde{\mathcal{M}}})$ alone, as $m_J \geq c_J\,dW$ there and $g^{(J)}$ is continuous): $\int_{\mathsf{I}_J} G_n^2 dm_J = \int_{B_J} u_n^2 d\mu \to 0$ and $\int_{\mathsf{I}_J} |\partial G_n - \partial G_m|^2 dm_J \leq 6a_J \int_{B_J} \Gamma_\infty^{\tilde{\mathcal{M}}}(u_n - u_m)\,d\mu \to 0$; so $\partial G_n \to \xi$ in $L^2(\mathsf{I}_J, m_J)$, and, as $m_J \geq c_J\,dW$ on I_J, $G_n \to 0$ and $\partial G_n \to \xi$ in $L^2(\mathsf{I}_J, dW)$. For a smooth vector field ϕ with compact support in I_J, $\int \langle \xi, \phi\rangle dW = \lim \int \langle \partial G_n, \phi\rangle dW = -\lim \int G_n \operatorname{div}\phi\, dW = 0$, the derivatives along $e^{itX}V$ being skew for the Haar measure; so $\xi = 0$ dW-almost everywhere on I_J, hence m_J-almost everywhere, and $\int_{B_J} \Gamma_\infty^{\tilde{\mathcal{M}}}(u_n)\,d\mu \leq \frac{7}{6} a_J^{-1} \int |\partial G_n|^2 dm_J \to 0$. Now let $\epsilon > 0$ and n_0 with $\mathcal{E}_\infty^{\tilde{\mathcal{M}}}(u_n - u_{n_0}) \leq \epsilon$ for $n \geq n_0$; as $\Gamma_\infty^{\tilde{\mathcal{M}}}(u_{n_0}) \in L^1(\mu)$ and $\mu(B_J) \to 1$, there is J with $\int_{B_J^c} \Gamma_\infty^{\tilde{\mathcal{M}}}(u_{n_0}) \leq \epsilon$; and $\Gamma_\infty^{\tilde{\mathcal{M}}}(u_n) \leq 2\Gamma_\infty^{\tilde{\mathcal{M}}}(u_{n_0}) + 2\Gamma_\infty^{\tilde{\mathcal{M}}}(u_n - u_{n_0})$ pointwise; so $\limsup_n \mathcal{E}_\infty^{\tilde{\mathcal{M}}}(u_n) \leq 4\epsilon$. Last, $g \mapsto g(Y_d^{\tilde{\mathcal{M}}})$ maps $L^2(\mu_d^{\tilde{\mathcal{M}}})$ isometrically into $L^2(\mu)$; it carries $C^1_{\mathrm{inv}}(\Omega_d)$ onto $\mathcal{C}_d^{\tilde{\mathcal{M}}}$, which lies in the closed subspace L^2_{inv} (Proposition 18.68(e)), and the form on the one onto the form on the other. A form whose domain lies in a closed subspace is closable in that subspace exactly when it is closable in the whole space; hence the two wordings of (b) agree. □

Proposition 18.70. *Closability of the limit form from a contraction of the energy; the Dirichlet form, its semigroup, motion.*

(a) Let $(\mathfrak{X}, \mathfrak{B}, \nu)$ be a probability space, $\mathsf{H} := L^2(\nu)$, $\mathcal{C}_0 \subset \mathcal{C}_1 \subset \cdots$ linear spaces of bounded measurable functions with $1 \in \mathcal{C}_0$ and $\mathcal{C} := \bigcup_d \mathcal{C}_d$ dense in H, and $\mathcal{E}$ a symmetric non-negative bilinear form on $\mathcal{C}$ with $\mathcal{E}(1) = 0$ and a square field: a symmetric bilinear $\Gamma : \mathcal{C} \times \mathcal{C} \to L^1(\nu)$ with $\Gamma(u,u) \geq 0$, $\mathcal{E}(u,w) = \int \Gamma(u,w)\,d\nu$, and $\varphi \circ u \in \mathcal{C}$, $\Gamma(\varphi \circ u, w) = \varphi'(u)\Gamma(u,w)$ for $\varphi \in C^1(\mathbb{R})$ with bounded φ'. Let H_d be the closure of $\mathcal{C}_d$ and $\mathcal{P}_d$ the orthogonal projection onto it. Suppose (Cl) for every d the form $(\mathcal{E}, \mathcal{C}_d)$ is closable in H, with the closure $(\bar{\mathcal{E}}_d, \mathrm{Dom}_d)$; and (CE) there are numbers $C > 0$ and $\lambda_0 \geq 0$ and an infinite set $\mathbb{I}$ of depths with $\mathcal{P}_d u \in \mathrm{Dom}_d$ and $\bar{\mathcal{E}}_d(\mathcal{P}_d u) \leq C(\mathcal{E}(u) + \lambda_0 \|u\|^2)$ for all $u \in \mathcal{C}$, $d \in \mathbb{I}$. Then: (1) $(\mathcal{E}, \mathcal{C})$ is closable in H; (2) its closure $(\bar{\mathcal{E}}, \mathrm{Dom})$ is a symmetric Dirichlet form with $1 \in \mathrm{Dom}$, $\bar{\mathcal{E}}(1) = 0$, and $\bar{\mathcal{E}}(u,w) = \int \bar{\Gamma}(u,w)\,d\nu$ with the continuous extension $\bar{\Gamma}$ of Γ, which keeps the chain rule; (3) its semigroup $P_t = e^{-tA}$ is a strongly continuous semigroup of self-adjoint contractions, $0 \leq f \leq 1$ implies $0 \leq P_t f \leq 1$, $P_t 1 = 1$, $\int P_t f\,d\nu = \int f\,d\nu$ and $\int g\,P_t f\,d\nu = \int f\,P_t g\,d\nu$: ν is invariant and reversible; $t^{-1}(u, (1-P_t)u)$ is non-increasing in t and tends to $\bar{\mathcal{E}}(u) \in [0,\infty]$ as $t \downarrow 0$, so that $(u,(1-P_t)u) > 0$ for every $t > 0$ whenever $\bar{\mathcal{E}}(u) > 0$, the value $+\infty$ included; (4) $\mathcal{P}_d \mathrm{Dom} \subset \mathrm{Dom}_d$ and $\bar{\mathcal{E}}_d(\mathcal{P}_d u) \leq C(\bar{\mathcal{E}}(u) + \lambda_0\|u\|^2)$ for $d \in \mathbb{I}$, and $\mathcal{P}_d u \to u$ in the norm $(\bar{\mathcal{E}} + \|\cdot\|^2)^{1/2}$ along $\mathbb{I}$, for $u \in \mathrm{Dom}$; (5) $e^{-tA_d}\mathcal{P}_d f \to P_t f$ in H, A_d the operator of $\bar{\mathcal{E}}_d$ in H_d; (6) if $\lambda_0 = 0$: $(u,(1-P_t)u) \geq \mathfrak{J}^{\bar{\mathcal{E}}_d}_{t/C}(\mathcal{P}_d u) \geq \frac{1}{2}(\mathcal{P}_d u, (1 - e^{-(t/C)A_d})\mathcal{P}_d u)$ for $u \in \mathsf{H}$, $t > 0$, $d \in \mathbb{I}$, where $\mathfrak{J}^{\mathcal{Q}}_s(v) := \inf_w \{s\mathcal{Q}(w) + \|v - w\|^2\}$.

(b) (The block observables.) Assume (E), let $\tilde{\mathcal{M}}$ be admissible, ν the restriction of μ to the invariant σ-algebra (so that $\mathsf{H} = L^2_{\mathrm{inv}}$), $\mathcal{C}_d := \mathcal{C}_d^{\tilde{\mathcal{M}}}$, $\mathcal{E} := \mathcal{E}_\infty^{\tilde{\mathcal{M}}}$ and $\Gamma := \Gamma_\infty^{\tilde{\mathcal{M}}}$. Then every datum of (a) other than (Cl) and (CE) holds, and (Cl) holds when $\tilde{\mathcal{M}} = \mathcal{M}^\chi$. So (1)–(6) hold for $(\mathcal{E}_\infty^{\tilde{\mathcal{M}}}, \mathrm{Cyl}^{\tilde{\mathcal{M}}})$ whenever (Cl) and (CE) hold for these data; for $\tilde{\mathcal{M}} = \mathcal{M}^\chi$ it suffices that (CE) holds.

■

Sketch. (a) (1) For $u \in \mathsf{H}$ put $\mathfrak{N}(u) := \sup_{d \in \mathbb{I}} \bar{\mathcal{E}}_d(\mathcal{P}_d u) \in [0,\infty]$; each $u \mapsto \bar{\mathcal{E}}_d(\mathcal{P}_d u)$ is lower semicontinuous on H (a closed form is lower semicontinuous, $\mathcal{P}_d$ is continuous), and so is $\mathfrak{N}$. On $\mathcal{C}$: $\mathfrak{N} \leq C(\mathcal{E} + \lambda_0\|\cdot\|^2)$ by (CE), and $\mathcal{E}(u) = \bar{\mathcal{E}}_d(\mathcal{P}_d u) \leq \mathfrak{N}(u)$ for $u \in \mathcal{C}_e$ and $d \in \mathbb{I}$, $d \geq e$. If $u_n \in \mathcal{C}$, $u_n \to 0$ and $\mathcal{E}(u_n - u_m) \to 0$, then for a fixed m, $u_m - u_n \to u_m$ as $n \to \infty$, and $\mathcal{E}(u_m) \leq \mathfrak{N}(u_m) \leq \liminf_n \mathfrak{N}(u_m - u_n) \leq C \sup_{n \geq m}(\mathcal{E} + \lambda_0\|\cdot\|^2)(u_m - u_n) \to 0$. (4) By the lower semicontinuity (CE) passes to the closure; so the $\mathcal{P}_d$, $d \in \mathbb{I}$, are uniformly bounded operators of

the Hilbert space $(\mathrm{Dom}, \bar{\mathcal{E}} + \|\cdot\|^2)$, equal to the identity on $\mathcal{C}_e$ for $d \geq e$, and $\mathcal{P}_d u \to u$ there along $\mathbb{I}$. (2) $|\Gamma(u,w)| \leq \Gamma(u,u)^{1/2}\Gamma(w,w)^{1/2}$ almost everywhere, so Γ extends continuously to $\bar{\Gamma} : \mathrm{Dom} \times \mathrm{Dom} \to L^1(\nu)$; if $u_n \in \mathcal{C}$ tends to u in the norm of the closure and almost everywhere, then $\Gamma(\varphi \circ u_n - \varphi \circ u_m) = \varphi'(u_n)^2\Gamma(u_n) - 2\varphi'(u_n)\varphi'(u_m)\Gamma(u_n,u_m) + \varphi'(u_m)^2\Gamma(u_m) \to 0$ in L^1, so $\varphi \circ u \in \mathrm{Dom}$ and $\bar{\Gamma}(\varphi \circ u, w) = \varphi'(u)\bar{\Gamma}(u,w)$; with the near-unit contractions φ_ϵ ($0 \leq \varphi_\epsilon' \leq 1$, $\varphi_\epsilon(t) = t$ on $[0,1]$, $|\varphi_\epsilon(t) - (0 \vee t) \wedge 1| \leq \epsilon/2$) and the lower semicontinuity, $\bar{\mathcal{E}}((0 \vee u) \wedge 1) \leq \bar{\mathcal{E}}(u)$. (3) By the spectral theorem for A, with the spectral measure m_u of u: P_t is a strongly continuous semigroup of self-adjoint contractions; for $0 \leq f \leq 1$ and $\alpha > 0$, $\alpha(\alpha + A)^{-1} f$ is the minimiser of $v \mapsto \bar{\mathcal{E}}(v) + \alpha\|v - f\|^2$, which the truncation $(0 \vee v) \wedge 1$ does not increase, so $0 \leq \alpha(\alpha + A)^{-1} f \leq 1$, and $((n/t)(n/t + A)^{-1})^n f \to P_t f$; $\bar{\mathcal{E}}(1) = 0$ puts m_1 at 0, so $P_t 1 = 1$, and with the self-adjointness $\int P_t f = (P_t f, 1) = (f, 1)$; $(u, (1 - P_t)u) = \int (1 - e^{-t\lambda})\, m_u(d\lambda)$, and $(1 - e^{-t\lambda})/t$ decreases in t to λ as $t \downarrow 0$; if $\bar{\mathcal{E}}(u) = \int \lambda\, dm_u > 0$, then $m_u((0,\infty)) > 0$. (5) $(\alpha + A_d)^{-1}\mathcal{P}_d f$ is the orthogonal projection, in $(\mathrm{Dom}, \bar{\mathcal{E}} + \alpha\|\cdot\|^2)$, of $(\alpha + A)^{-1} f$ onto Dom_d, and these closed subspaces increase with a dense union; so the resolvents converge strongly, and with them every continuous function of the resolvents, $e^{-tA_d}\mathcal{P}_d$ among them. (6) $(u, (1 - P_t)u) \geq \mathfrak{J}_t^{\bar{\mathcal{E}}}(u) = \int \frac{t\lambda}{1+t\lambda} dm_u$, as $\frac{x}{1+x} \leq 1 - e^{-x}$; for $w \in \mathrm{Dom}$, $t\bar{\mathcal{E}}(w) \geq \frac{t}{C}\bar{\mathcal{E}}_d(\mathcal{P}_d w)$ and $\|u - w\| \geq \|\mathcal{P}_d u - \mathcal{P}_d w\|$; and $1 - e^{-x} \leq \frac{2x}{1+x}$ gives the last inequality.

(b) $\mathcal{C}_d^{\tilde{\mathcal{M}}} \subset \mathcal{C}_{d+1}^{\tilde{\mathcal{M}}}$, $1 \in \mathcal{C}_0^{\tilde{\mathcal{M}}}$, density in L^2_{inv}, the definition on classes, $\mathcal{E}_\infty^{\tilde{\mathcal{M}}}(1) = 0$ and the square field with the chain rule and values in L^1: Proposition 18.68(c), (e). The values of $\Gamma_\infty^{\tilde{\mathcal{M}}}$ are Borel functions on the threads that the maps $Y \mapsto v \cdot Y$ keep, by the covariance in Proposition 18.67(c); such a function agrees μ-almost everywhere with a function measurable for the invariant σ-algebra, as its conditional means given Y_d, averaged over the gauge group of $\Lambda_{d,\ell}$, are invariant cylinder functions that converge to it as $d \to \infty$ (the martingale convergence theorem for bounded truncations). (Cl) for $\tilde{\mathcal{M}} = \mathcal{M}^\chi$: Proposition 18.69(b). □

III. A torus with one unit of centre flux. This part works on a twisted torus; its lattices, configurations and gauge groups, and the maps and measures on them, are all introduced below. From outside it takes G, $\mathfrak{g}$, $\langle\cdot,\cdot\rangle$, the blocking factor L and the spacings $a_d = L^{-d}$ of the setting of the section ($|\cdot|$ is the operator norm of 2×2 matrices, which on $\mathfrak{g}$ is the norm of the setting, and of linear maps of $\mathfrak{g}$, and the Euclidean norm on coordinate spaces), the constants A_0, $\mathfrak{p}_0$ and the threshold function $\varepsilon(t) = A_0 t^{-1/2}(\log t)^{\mathfrak{p}_0}$ for $t > 1$, the Pauli matrices

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \qquad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

and the map $\mathbf{w}$ of Part I. The setting (E) is not assumed in this part: here $\mathsf{b} > 0$ is a free number, and the conditions on it are stated where they are used.

A twisted lattice. Let $N_1, N_2, N_3 \geq 3$ be integers, $\mathsf{v} := N_1N_2N_3$, $N := \max_\mu N_\mu$, $\mathsf{B}_{\mathrm{tw}} := \prod_\mu \{0, \dots, N_\mu - 1\}$; we work in lattice units on $\mathbb{Z}^3$, with bonds (x,μ) from x to $x + e_\mu$, plaquettes $p_{\mu\nu}(x)$, $\mu < \nu$, and $\partial U(p_{\mu\nu}(x)) = U(x,\mu)U(x+e_\mu,\nu)U(x+e_\nu,\mu)^{-1}U(x,\nu)^{-1}$. Put $\mathsf{i}_a := i\sigma_a$ and $\mathsf{z}_1 := \mathsf{i}_1$, $\mathsf{z}_2 := \mathsf{i}_2$, $\mathsf{z}_3 := \mathbf{1}$, so that $\mathsf{z}_1\mathsf{z}_2 = -\mathsf{z}_2\mathsf{z}_1$ while the rotations $\mathrm{Ad}(\mathsf{z}_\mu)$ commute. $\boldsymbol{\Omega} = \boldsymbol{\Omega}(N_1,N_2,N_3)$ is the set of the maps U from the bonds of $\mathbb{Z}^3$ to G with $U(b + N_\mu e_\mu) = \mathsf{z}_\mu U(b)\mathsf{z}_\mu^{-1}$, and $\mathcal{G}^{\mathrm{tw}}$ the group of the maps $g : \mathbb{Z}^3 \to G$ with $g(x + N_\mu e_\mu) = \mathsf{z}_\mu g(x)\mathsf{z}_\mu^{-1}$, acting by $U^g(b) = g(b_-)U(b)g(b_+)^{-1}$; the values at the bonds and at the sites based in B_{tw} are free coordinates, and dU, dg are the products of the Haar probability measures over them. $A(U) := \sum_p (1 - \frac{1}{2}\mathrm{tr}\,\partial U(p))$ and $\varpi(U) := \max_p |\partial U(p) - \mathbf{1}|$, over the plaquettes based in B_{tw}; as the $\mathrm{Ad}(\mathsf{z}_\mu)$ are commuting isometries, sums over B_{tw} of invariant expressions do not read the fundamental domain. For $\varsigma = \pm$, $R_\varsigma \in \boldsymbol{\Omega}$ is $\varsigma\mathbf{1}$ at the bonds $(x,3)$ with $x_3 \equiv N_3 - 1 \bmod N_3$ and $\mathbf{1}$ at the other bonds; the flip $U \mapsto R_- U$ keeps dU, every $\partial U(p)$, A and ϖ, and a function is even if the flip keeps it. The line $\mathcal{P}(U)(x) := \prod_{j=0}^{N_3-1} U(x + je_3, 3)$ has $\mathcal{P}(U^g)(x) = g(x)\mathcal{P}(U)(x)g(x)^{-1}$ and $\mathcal{P}(R_- U) = -\mathcal{P}(U)$.

Forms, the slice, the sets. $\mathscr{F}^0$ and $\mathscr{F}^1$ are the spaces of the $\mathfrak{g}$-valued functions f on the sites, resp. the bonds, of $\mathbb{Z}^3$ with $f(\cdot+N_\mu e_\mu)=\mathrm{Ad}(\mathsf{z}_\mu)f(\cdot)$; $\|f\|^2:=\sum_{\mathsf{B}_{\rm tw}}|f|^2$, $|f|_\infty:=\max|f|$; $(\nabla\lambda)(b):=\lambda(b_+)-\lambda(b_-)$ and ∇^* is its adjoint; $dX(p):=X(b_1)+X(b_2)-X(b_3)-X(b_4)$ for the bonds $b_1,\dots,b_4$ of p in the order of $\partial U(p)$; $\mathscr{H}:=\ker\nabla^*\subset\mathscr{F}^1$, the Landau slice, with the Euclidean structure of $\|\cdot\|$ and its Lebesgue measure dX; $(D_U\lambda)(b):=\mathrm{Ad}(U(b))\lambda(b_+)-\lambda(b_-)$. A tangent vector at U is an $X\in\mathscr{F}^1$, through $s\mapsto e^{isX}U$, and the gradient $\partial h(U)\in\mathscr{F}^1$ of a C^1 function is given by $\frac{d}{ds}h(e^{isX}U)|_{s=0}=\langle X,\partial h(U)\rangle$; for $X\in\mathfrak{g}$, $\mathsf{T}_X:=\int_0^1\mathrm{Ad}(e^{i\tau X})\,d\tau$, so that $\frac{d}{ds}e^{i(X+sY)}|_{s=0}=i(\mathsf{T}_XY)e^{iX}$, applied bond by bond. Put $\lambda_*:=\min\{4\sin^2\frac{\pi}{2N_1},4\sin^2\frac{\pi}{2N_2}\}\in[4N^{-2},1]$, $\Xi_N:=\frac{N}{2}\sqrt{3\mathsf{v}}$ and $r_1:=(16\Xi_N)^{-1}$. For $\epsilon>0$: $\mathrm{In}(\epsilon):=\{U\in\mathbf{\Omega}:\varpi(U)<\epsilon\}$, $\mathrm{In}^\varsigma(\epsilon):=\{U\in\mathrm{In}(\epsilon):\varsigma\,\mathrm{tr}\,\mathcal{P}(U)(0)>0\}$, $\mathcal{D}(\epsilon):=\{X\in\mathscr{H}:|X|_\infty\le r_1,\ \varpi(e^{iX})<\epsilon\}$, $f_p(X):=1-\frac12\mathrm{tr}\,\partial e^{iX}(p)=\frac12|\partial e^{iX}(p)-\mathbf{1}|^2$ and $f:=\sum_p f_p=A(e^{i\cdot})$; $\varkappa_\epsilon:=6/\epsilon$ and $\Sigma_\epsilon(Z):=(1+\varkappa_\epsilon\|Z\|^2)Z$ on $\mathscr{H}$, a radial real-analytic diffeomorphism of $\mathscr{H}$ with the inverse Θ_ϵ; $\Upsilon_\varsigma(g,X):=(R_\varsigma e^{iX})^g$; $\mathbb{A}(X):\mathscr{F}^0\oplus\mathscr{H}\to\mathscr{F}^1$, $\mathbb{A}(X)(\lambda,Y):=-D_{e^{iX}}\lambda+\mathsf{T}_XY$, and $\mathcal{J}(X):=|\det\mathbb{A}(X)|$ in orthonormal bases. The conditions on ϵ are (h1) $36\pi\mathsf{v}N^3\epsilon\le1$ and (h2) $1800N^2\mathsf{v}\epsilon\le1$.

The cube, the units, the measure. Let $l\ge L$ be a power of L; at the depth d put $N_1=N_2=N_3=lL^d$, $\mathbf{\Omega}_d:=\mathbf{\Omega}(lL^d,lL^d,lL^d)$, $\mathcal{G}_d^{\rm tw}$ its gauge group and $x_d:=L^d\mathsf{b}$. Physical fields are X/a_d, with the inner product $a_d^3\sum_b$, and $\Gamma_d(h):=a_d^{-1}\|\partial h\|^2$; so a lower bound $\varrho\|Y\|^2$ of a Hessian in lattice units is the bound ϱ/a_d in the physical inner product, and $\mathrm{Ent}\le c\int\|\partial h\|^2$ reads $\mathrm{Ent}\le c\,a_d\int\Gamma_d(h)$. At the cutoff K: $\mu_K^{\rm tw}:=Z^{-1}e^{-\beta A}dU$ on $\mathbf{\Omega}_K$, $\beta=L^K\mathsf{b}$; $\mathcal{L}_K^{\rm tw}:=a_K^{-1}[\sum_b\partial_b^2-\beta\langle\partial A,\partial\cdot\rangle]$, $\mathcal{E}_K^{\rm tw}(F):=\int\Gamma_K(F)\,d\mu_K^{\rm tw}$ and $P_u^{\rm tw}:=e^{u\mathcal{L}_K^{\rm tw}}$, $u\ge0$: the Langevin dynamics, a reversible elliptic diffusion with smooth coefficients on a compact manifold; $P_u^{\rm tw}$ commutes with $\mathcal{G}_K^{\rm tw}$ and with the flip, maps bounded Borel functions to smooth ones for $u>0$, and $\mathrm{osc}(P_u^{\rm tw}F)\le\mathrm{osc}(F)$. For a finite positive measure m and a bounded Borel $F\ge0$: $\Xi(F,c):=F\log\frac{F}{c}-F+c\ge0$ for $c>0$ (with $0\log0=0$), $\mathrm{Ent}_m(F):=\inf_{c>0}\int\Xi(F,c)\,dm=\int F\log F\,dm-m(F)\log\frac{m(F)}{m(1)}$, the infimum being taken at $c=m(F)/m(1)$ when $m(F)>0$, and $\mathrm{Var}_m(G):=\min_c\int(G-c)^2dm$.

Two data. Fix a top depth $n\ge1$ with $L^n\mathsf{b}>1$ and put $N:=lL^n$, $x:=L^n\mathsf{b}$ and $\epsilon:=2\varepsilon(x)$, with the function $\varepsilon(\mathsf{t})=A_0\mathsf{t}^{-1/2}(\log\mathsf{t})^{\mathsf{p}_0}$, $\mathsf{t}>1$, the one that enters the thresholds θ_d of the setting of the section. All the numbers named in the data are free of K. (D1) For every $K>n$ there are: (D1.1) Borel maps $\mathcal{M}^{\rm tw}:\mathbf{\Omega}_d\to\mathbf{\Omega}_{d-1}$, $n<d\le K$, that carry gauge equivalent fields to gauge equivalent fields and R_-U to a field gauge equivalent to $R_-\mathcal{M}^{\rm tw}(U)$, so that a gauge-invariant even function of $V_d:=(\mathcal{M}^{\rm tw})^{K-d}U$ is a gauge-invariant even function of U, and open sets $\mathrm{Cut}_d^{\rm tw}\subset\mathbf{\Omega}_d$, $n\le d\le K$, carried onto themselves by $\mathcal{G}_d^{\rm tw}$ and by the flip, with $\mathrm{In}(\epsilon)\subset\mathrm{Cut}_n^{\rm tw}$; (D1.2) a positive Borel measure $\tilde\mu_K$ on $\mathbf{\Omega}_K$ and a number $\mathsf{R}_{\rm tw}\in[0,1)$ with $\int F\,d\tilde\mu_K\le\int F\,d\mu_K^{\rm tw}\le\int F\,d\tilde\mu_K+\mathsf{R}_{\rm tw}\sup F$ for every bounded Borel gauge-invariant $F\ge0$; the image $\tilde\mu_{K,[d]}$ of $\tilde\mu_K$ under $U\mapsto V_d$ sits on $\mathrm{Cut}_d^{\rm tw}$, and $\tilde{\mathcal{E}}_K(G):=\int\Gamma_K(G)\,d\tilde\mu_K$; (D1.3) for $n<d\le K$ and $W\in\mathrm{Cut}_{d-1}^{\rm tw}$: an open bounded convex set $\mathrm{Rg}_d\subset\mathbb{R}^{\dim_d}$, a C^1 map $\tilde V_W:\mathrm{Rg}_d\to\mathrm{Cut}_d^{\rm tw}$ with $\|D\tilde V_W(B)\zeta\|^2\le C_{\rm ch}^{\rm tw}x_d^{-1}|\zeta|^2$, and a probability measure $\tilde p_W=e^{-\tilde\Psi_W}dB$ on Rg_d with $\tilde\Psi_W\in C^2$, $D^2\tilde\Psi_W\ge\gamma_\flat>0$, such that $\int h(V_d)\phi(V_{d-1})\,d\tilde\mu_K=\int\phi(W)[\int h(\tilde V_W(B))\tilde p_W(dB)]\,\tilde\mu_{K,[d-1]}(dW)$ for bounded Borel h,ϕ, the inner integral being Borel in W; (D1.4) if h on $\mathrm{Cut}_d^{\rm tw}$ is gauge invariant and even, so is $W\mapsto\int h(\tilde V_W(B))\tilde p_W(dB)$; (D1.5) $\tilde\mu_{K,[n]}=\mathbf{1}_{\mathrm{In}(\epsilon)}\mathsf{g}^{\rm tw}dV$ with $\mathsf{g}^{\rm tw}=\mathsf{c}_K^{\rm tw}\exp[-x\mathcal{A}^{\rm tw}+\mathcal{S}^{\rm tw}]$, a number $\mathsf{c}_K^{\rm tw}>0$ and real gauge-invariant even functions $\mathcal{A}^{\rm tw},\mathcal{S}^{\rm tw}$ on $\mathrm{In}(\epsilon)$ such that $\mathsf{a}(X):=\mathcal{A}^{\rm tw}(e^{iX})$ and $\mathsf{s}(X):=\mathcal{S}^{\rm tw}(e^{iX})$ satisfy (a1)–(a3) and (s) of Proposition 18.72(b) with $M_\mathsf{a}=C_\mathsf{a}N^3\rho_\mathsf{a}^2$, $M_\mathsf{s}=E_\mathsf{s}N^3$ and $\rho_\mathsf{s}=\vartheta_\mathsf{s}\varepsilon(x)$. (D2) For $n\le d\le K$ and $V\in\mathrm{Cut}_d^{\rm tw}$ there are seminorms $\mathsf{n}_d(V;\cdot)$ on the tangent vectors at V, with $\mathsf{n}_K(U;\xi)^2=a_K\min_\lambda\|\xi-D_U\lambda\|^2$ and (N) $\mathsf{n}_d(V;\xi)^2\le c_\flat^{-1}a_d\|\xi\|^2$; put $\hat\Gamma_d(g)(V):=\sup\{\langle\xi,\partial g(V)\rangle^2:\mathsf{n}_d(V;\xi)\le1\}$, a Borel function of V for $g\in C^1$. For every real gauge-invariant $f_0\in C^\infty(\mathbf{\Omega}_K)$ with its tower $f_{k+1}(W):=\int f_k(\tilde V_W(B))\tilde p_W(dB)$, $W\in\mathrm{Cut}_{K-k-1}^{\rm tw}$, every $n<d\le K$, $k=K-d$, every $W\in\mathrm{Cut}_{d-1}^{\rm tw}$ and every tangent vector ξ at W: (S0) $f_{k+1}\in$

$C^1(\mathrm{Cut}^{\mathrm{tw}}_{d-1})$, and there are a Borel field $B \mapsto \dot V_B$ of tangent vectors at $\tilde V_W(B)$ and a $\psi_\xi \in C^1(\mathrm{Rg}_d)$, neither reading f_0, with $\langle \xi, \partial f_{k+1}(W)\rangle = \int \langle \dot V_B, \partial f_k(\tilde V_W(B))\rangle\, \tilde p_W(dB) + \mathrm{Cov}_{\tilde p_W}(f_k \circ \tilde V_W, \psi_\xi)$; (S1a) $\mathsf{n}_d(\tilde V_W(B); \dot V_B) \le (1+\eta'_d)\,\mathsf{n}_{d-1}(W;\xi)$ for all B; (S1b) $|\nabla_B \psi_\xi| \le \iota_d\, \mathsf{n}_{d-1}(W;\xi)$ on Rg_d; (Σ) with $\eta_d := \eta'_d + \gamma_\flat^{-1}\iota_d (C^{\mathrm{tw}}_{\mathrm{ch}}/c_\flat)^{1/2} a_d \mathsf{b}^{-1/2}$: $\prod_{d>n}(1+\eta_d)^2 \le \Pi_{\mathrm{tw}} < \infty$.

Proposition 18.71 (The fields with small plaquettes on a twisted lattice)**.** Let $N_1, N_2, N_3 \ge 3$.

(o) (The sign picture.) The map J that keeps the value at every bond (x,μ), $x \in \mathsf{B}_{\mathrm{tw}}$, $x_\mu < N_\mu - 1$, and multiplies the value at the seam bonds (x,μ), $x_\mu = N_\mu - 1$, on the right by z_μ, is a bijection of $\mathbf{\Omega}$ onto the configurations of the periodic lattice $\prod_\mu \mathbb{Z}/N_\mu\mathbb{Z}$ that carries dU to the Haar measure and U^g to $(\mathsf{J}U)^{g|_{\mathsf{B}_{\mathrm{tw}}}}$, and $\partial(\mathsf{J}U)(p) = \eta(p)\,\partial U(p)$ with $\eta(p) = -1$ at the plaquettes $p_{12}(x)$, $x_1 = N_1 - 1$, $x_2 = N_2 - 1$, and $\eta(p) = 1$ elsewhere: A is the Wilson action with one column of plaquettes of the planes $(1,2)$ taken with the sign -1, one unit of centre flux through these planes.

(a) $A(U) = 0$ if and only if $U = R_\varsigma^g$ for some $g \in \mathcal{G}^{\mathrm{tw}}$ and $\varsigma = \pm$; the two orbits are disjoint ($\frac12 \mathrm{tr}\,\mathcal{P} = \varsigma$ on the orbit of R_ς) and exchanged by the flip, and the stabiliser of R_ς is $\{\pm\mathbf{1}\}$.

(b) $\frac{d^2}{ds^2} A(e^{isX} R_\varsigma)|_{s=0} = \|dX\|^2$; the tangent space of the orbit at R_ς is $\nabla\mathscr{F}^0$, with the orthogonal complement $\mathscr{H}$; $\|dX\|^2 + \|\nabla^* X\|^2 \ge \lambda_* \|X\|^2$ on $\mathscr{F}^1$ and $\|\nabla\lambda\|^2 \ge \lambda_*\|\lambda\|^2$ on $\mathscr{F}^0$, with equality for some $X \in \mathscr{H}$ and some λ; so $\dim \mathscr{H} = 6\mathsf{v}$ and $\|dX\|^2 \ge \lambda_* \|X\|^2 \ge 4N^{-2}\|X\|^2$ on $\mathscr{H}$. On the cube of side l at the depth d, the Hessian at R_ς of $a_d^{-1}A$, on the orthogonal complement of the gauge directions and in the inner product $a_d^3 \sum_b$ of the physical fields, is at least $a_d^{-2} 4 \sin^2 \frac{\pi a_d}{2l} \ge 4l^{-2}$, and this floor tends to $\pi^2 l^{-2}$ as $d \to \infty$.

(c) If $\varpi(U) \le \epsilon$ and $4N^2\epsilon \le 1$, there are $g \in \mathcal{G}^{\mathrm{tw}}$ and ς with $\max_b |U^g(b) - R_\varsigma(b)| \le 3N^2\epsilon$ and $\varsigma\, \frac12 \mathrm{tr}\,\mathcal{P}(U)(x) \ge \frac{23}{32}$ for all x.

(d) Under (h1): $\mathrm{In}(\epsilon)$ is the disjoint union of $\mathrm{In}^+(\epsilon)$ and $\mathrm{In}^-(\epsilon)$, both open, carried onto themselves by $\mathcal{G}^{\mathrm{tw}}$ and exchanged by the flip; $\mathcal{D}(\epsilon)$ is open in $\mathscr{H}$, and $\max_p |dX(p)| < 2\epsilon$ and $|X|_\infty \le \|X\| < 2\Xi_N \epsilon < r_1$ on it; $\Upsilon_\varsigma : \mathcal{G}^{\mathrm{tw}} \times \mathcal{D}(\epsilon) \to \mathrm{In}^\varsigma(\epsilon)$ is real-analytic, onto, a local diffeomorphism, and $\Upsilon_\varsigma(g,X) = \Upsilon_\varsigma(g',X')$ if and only if $X' = X$ and $g' = \pm g$; for every bounded Borel F on $\mathrm{In}^\varsigma(\epsilon)$: $\int_{\mathrm{In}^\varsigma(\epsilon)} F\, dU = \frac12 (2\pi^2)^{-2\mathsf{v}} \int_{\mathcal{G}^{\mathrm{tw}}} dg \int_{\mathcal{D}(\epsilon)} dX\, \mathcal{J}(X) F(\Upsilon_\varsigma(g,X))$.

(e) Let (h1) and (h2) hold. Then $\Theta_\epsilon(\mathcal{D}(\epsilon))$ is a convex open subset of $\mathscr{H}$ containing 0 and contained in $\mathcal{B}_\epsilon := \{\|Z\|^2 < \epsilon/600\}$, and throughout $\mathcal{B}_\epsilon$ one has $\varkappa_\epsilon \|Z\|^2 < \frac{1}{100}$ and $\|Y\| \le \|\Sigma'_\epsilon(Z)Y\| \le 1.03\|Y\|$. So $\mathcal{D}(\epsilon)$ is star-shaped, $\mathrm{In}^\pm(\epsilon)$ are connected, and modulo gauge $\mathrm{In}(\epsilon)$ consists of two pieces, $\mathrm{In}^+(\epsilon)$ and $\mathrm{In}^-(\epsilon)$, exchanged by the flip, each of which is parametrised by $\mathcal{D}(\epsilon)$ through (d), and the coordinate $Z = \Theta_\epsilon(X)$ of the slice maps $\mathcal{D}(\epsilon)$ to a convex open subset of the $6\mathsf{v}$-dimensional space $\mathscr{H}$.

(f) For $X, Y \in \mathscr{F}^1$ with $r := |X|_\infty$ and $\varpi := \varpi(e^{iX}) \le 1$: $(1 - \frac12\varpi^2)(\|dY\| - 36r\|Y\|)_+^2 - 16\varpi\|Y\|^2 \le D^2 f(X)(Y,Y) \le (\|dY\| + 36r\|Y\|)^2 + 16\varpi\|Y\|^2$ and $|Df(X)Y| \le (\|dY\| + 36r\|Y\|)\sqrt{3\mathsf{v}}\,\varpi$. Under (h1), (h2), for $X \in \mathcal{D}(\epsilon)$ and $Y \in \mathscr{H}$: $D^2 f(X)(Y,Y) \ge 0.99\|dY\|^2 \ge 0.99\lambda_*\|Y\|^2$ and $|Df(X)Y| \le 4.01\sqrt{3\mathsf{v}}\,\epsilon\|Y\|$.

(g) On $\{X \in \mathscr{F}^1 \otimes \mathbb{C} : |X|_\infty < (5N)^{-1}\}$ the function $\mathfrak{l}(X) := \log\det(\mathbb{A}(0)^{-1}\mathbb{A}(X))$ is holomorphic with $|\mathfrak{l}| \le 9\mathsf{v}\log 2$; for real X, $\mathcal{J}(X) = \mathcal{J}(0) e^{\mathfrak{l}(X)} > 0$, $\mathcal{J}(0) = \det(\nabla^*\nabla)^{1/2}$; and for real X with $|X|_\infty \le (10N)^{-1}$ and real Y: $|D\log\mathcal{J}(X)Y| \le 63\mathsf{v}N|Y|_\infty$ and $|D^2 \log\mathcal{J}(X)(Y,Y)| \le 1250\mathsf{v}N^2|Y|_\infty^2$.

■

Sketch. Facts on G: for $u \in G$, $u = \mathbf{c} + i\mathbf{v}$ with $\mathbf{c} = \frac12\mathrm{tr}\,u$, $\mathbf{v} = \mathbf{w}(u)$, $\mathbf{c}^2 + |\mathbf{v}|^2 = 1$ and $1 - \frac12\mathrm{tr}\,u = \frac12|u - \mathbf{1}|^2$; $|e^{iX} - \mathbf{1}| \le |X|$, $|e^{iX} - \mathbf{1} - iX| \le \frac12|X|^2$; for $u \ne -\mathbf{1}$, $\mathsf{d}(u) := |\log u|$, the geodesic distance from u to $\mathbf{1}$ on the unit sphere G, is at most $\frac{\pi}{2}|u - \mathbf{1}|$; $|\mathrm{Ad}(e^{iX}) - 1| \le 2|X|$; $|\mathsf{T}_X Y| \le |Y|$, $|\mathsf{T}_X Y - Y| \le |X||Y|$, and on the plane orthogonal to X, $\langle \mathsf{T}_X^{-1} Y, Y\rangle \ge \theta\cot\theta\,|Y|^2$,

$\theta = |X| < \frac{\pi}{2}$; for unitaries $|u_1 \cdots u_k - \mathbf{1} - \sum_j (u_j - \mathbf{1})| \le \sum_{i<j} |u_i - \mathbf{1}||u_j - \mathbf{1}|$; on the ball $|\lambda| \le \Lambda_0 < \frac{\pi}{2}$ of $\mathfrak{g}$, $|e^{i\lambda} - e^{i\lambda'}| \le |\lambda - \lambda'| \le (\cos \Lambda_0)^{-1} |e^{i\lambda} - e^{i\lambda'}|$.

(o) At a seam bond, with $x' = x + e_\mu - N_\mu e_\mu$: $g(x)U(x,\mu)g(x+e_\mu)^{-1}\mathsf{z}_\mu = g(x)U(x,\mu)\mathsf{z}_\mu g(x')^{-1}$, by the twisted periodicity of g. In a plaquette the seam factors cancel or commute, except at the corner of the planes $(1,2)$, where they meet as $\mathsf{z}_2\mathsf{z}_1^{-1} = -\mathsf{z}_1^{-1}\mathsf{z}_2$.

(a) $\partial R_\varsigma(p) = \mathbf{1}$, as a plaquette holds none or two of the bonds with the value $\varsigma\mathbf{1}$, in opposite orientations; and $\partial U^g(p) = g(x)\partial U(p) g(x)^{-1}$. Conversely, if all $\partial U(p) = \mathbf{1}$, the product $h(x)$ of U along a path from x to 0 does not depend on the path, and $U(b) = h(b_-)h(b_+)^{-1}$; the twisted periodicity gives $h(x + N_\mu e_\mu) = \mathsf{z}_\mu h(x) C_\mu$ with constants $C_\mu \in G$, and adding two periods in the two orders, $C_1C_2 = -C_2C_1$ and C_3 commutes with C_1, C_2. The algebraic fact below at $\delta = 0$, applied to $(-C_1, -C_2, C_3)$, gives c and ς with $c(-C_j)c^{-1} = \mathsf{i}_j$, $C_3 = \varsigma\mathbf{1}$; then $h' := hc^{-1}$ has $h'(x + N_j e_j) = \mathsf{z}_j h'(x) \mathsf{z}_j^{-1}$ $(j = 1,2)$ and $h'(x + N_3 e_3) = \varsigma h'(x)$, and with $s(x) := \varsigma^{\lfloor x_3/N_3 \rfloor}$, $g := sh' \in \mathcal{G}^{\mathrm{tw}}$ and $U = R_\varsigma^g$. $\mathcal{P}(R_\varsigma) = \varsigma\mathbf{1}$, and $\operatorname{tr}\mathcal{P}$ is gauge invariant; $R_\varsigma^g = R_\varsigma$ forces g constant and commuting with $\mathsf{i}_1, \mathsf{i}_2$: $g = \pm\mathbf{1}$.

The algebraic fact. If $C_1, C_2, C_3 \in G$, $0 \le \delta \le \frac{1}{4}$, $|C_1C_2 + C_2C_1| \le \delta$ and $|C_3C_j - C_jC_3| \le \delta$ $(j = 1,2)$, there are $c \in G$ and $\varsigma = \pm 1$ with $|cC_1c^{-1} - \mathsf{i}_1| \le 0.71\delta$, $|cC_2c^{-1} - \mathsf{i}_2| \le 0.72\delta$ and $|C_3 - \varsigma\mathbf{1}| \le 0.77\delta$. Write $C_j = \cos\vartheta_j + i \sin\vartheta_j\, n_j \cdot \sigma$, $\sin\vartheta_j \ge 0$, $\nu := n_1 \cdot n_2$: $\frac{1}{4}|C_1C_2 + C_2C_1|^2 = \cos^2\vartheta_1 + \sin^2\vartheta_1(\cos^2\vartheta_2 + \sin^2\vartheta_2\nu^2)$ and the same with $1 \leftrightarrow 2$; so $|\cos\vartheta_j| \le \frac{\delta}{2}$ and $|\nu| \le 0.508\delta$; turning n_1 to e_1 and n_2 into the plane of e_1, e_2 gives the first two bounds; $|C_3C_j - C_jC_3| = 2\sin\vartheta_3 \sin\vartheta_j |n_3 \times n_j|$ and $\sum_j |n_3 \times n_j|^2 \ge 1 - |\nu| \ge 0.873$ give $\sin^2\vartheta_3 \le 0.582\delta^2$, and $|C_3 - \varsigma\mathbf{1}|^2 = 2 - 2|\cos\vartheta_3|$ with ς the sign of $\cos\vartheta_3$.

(b) $\partial(e^{isX}R_\varsigma)(p) = e^{isX_1}e^{isX_2}e^{-isX_3}e^{-isX_4}$, the central factors multiplying to $\mathbf{1}$, and $1 - \frac{1}{2}\operatorname{tr} u = \frac{1}{2}|u - \mathbf{1}|^2 = \frac{1}{2}s^2|dX(p)|^2 + O(s^3)$; $R_\varsigma^{e^{is\lambda}}$ has the velocity $-\nabla\lambda$. As $\operatorname{Ad}(\mathsf{i}_a)\sigma_c = \pm\sigma_c$, with $+$ if and only if $c = a$, the colours $X = \sum_a X^a\sigma_a$ decouple, $X^a(\cdot + N_\mu e_\mu) = (-1)^{\theta^a_\mu} X^a$ with $\theta^1 = (0,1,0)$, $\theta^2 = (1,0,0)$, $\theta^3 = (1,1,0)$, and Fourier series in the momenta $p_\mu \in \frac{2\pi}{N_\mu}(\mathbb{Z} + \frac{1}{2}\theta^a_\mu)$ with $k_\mu = e^{ip_\mu} - 1$ and the identity of Lagrange $\sum_{\mu<\nu} |k_\mu \hat{X}_\nu - k_\nu \hat{X}_\mu|^2 + |\sum_\mu \bar{k}_\mu \hat{X}_\mu|^2 = |k|^2|\hat{X}|^2$ give the inequalities: every colour has a direction $\mu \in \{1,2\}$ with $\theta^a_\mu = 1$, and there $|k_\mu|^2 \ge 4\sin^2\frac{\pi}{2N_\mu}$. Equality: if $N_2 \ge N_1$, $X = \cos(\pi x_2/N_2)\sigma_1$ at the bonds $(x,1)$ and 0 elsewhere. The physical floor: $a_d^{-1}\|dX\|^2 \ge a_d^{-2}\lambda_* \cdot a_d\|X\|^2$ with $N = l/a_d$, and $4\sin^2 y \ge 4(2y/\pi)^2$.

(c) *The comb.* For $x \in \mathsf{B}_{\mathrm{tw}}$ let $h(x)$ be the product of U along the path from 0 by x_1 steps e_1, then x_2 steps e_2, then x_3 steps e_3, and $U'(b) := h(b_-)U(b)h(b_+)^{-1}$ at the bonds with both ends in B_{tw}. As the value along the boundary of a ladder of k plaquettes is within $k\epsilon$ of $\mathbf{1}$: $U'(x,3) = \mathbf{1}$, $|U'(x,2) - \mathbf{1}| \le x_3\epsilon$, $|U'(x,1) - \mathbf{1}| \le (x_2 + x_3)\epsilon$. *The seams.* For $x \in \mathsf{B}_{\mathrm{tw}}$ with $x_\mu = N_\mu - 1$ and $x' = x + e_\mu - N_\mu e_\mu$ put $C_\mu(x) := h(x)U(x,\mu)\mathsf{z}_\mu h(x')^{-1}$; a plaquette through the seam bonds (x,μ), $(x + e_\nu, \mu)$ gives $|C_\mu(x) - C_\mu(x + e_\nu)| \le \epsilon + |U'(x',\nu) - \mathbf{1}| + |U'(x,\nu) - \mathbf{1}|$; moving along the seams in a suitable order, $C_\mu(x)$ lies within $2N(N-1)\epsilon$ of $C_1 := C_1(N_1 - 1, 0, 0)$, $C_2 := C_2(0, N_2 - 1, 0)$, $C_3 := C_3(0, 0, N_3 - 1)$ respectively. *The corners.* At $x = (N_1 - 1, N_2 - 1, 0)$ the plaquette of the planes $(1,2)$, read in the sign picture (o), gives $|C_1(x)C_2C_1^{-1}C_2(x)^{-1} + \mathbf{1}| \le \epsilon$; along the seams at $x_3 = 0$ the comb gives $|C_1(x) - C_1| \le (N_2 - 1)\epsilon$ and $|C_2(x) - C_2| \le (N_1 - 1)N_2\epsilon$, so $|C_1C_2 + C_2C_1| = |C_1C_2C_1^{-1}C_2^{-1} + \mathbf{1}| \le N_1N_2\epsilon$; in the same way the corners $(N_1 - 1, 0, N_3 - 1)$ and $(0, N_2 - 1, N_3 - 1)$ give $|C_1C_3 - C_3C_1| \le N_1N_3\epsilon$ and $|C_2C_3 - C_3C_2| \le N_2N_3\epsilon$. The algebraic fact at $\delta = N^2\epsilon \le \frac{1}{4}$ gives c, ς; with $g \in \mathcal{G}^{\mathrm{tw}}$ extending $(ch)|_{\mathsf{B}_{\mathrm{tw}}}$: at the inner bonds $U^g = cU'c^{-1}$ lies within $2(N-1)\epsilon$ of $\mathbf{1}$; at a seam bond $U^g(x,\mu) = cC_\mu(x)c^{-1}\mathsf{z}_\mu^{-1}$ lies within $2N(N-1)\epsilon + 0.77N^2\epsilon \le 3N^2\epsilon$ of $R_\varsigma(x,\mu)$. $\mathcal{P}(U^g)(x_1, x_2, 0) = cC_3(x_1, x_2, N_3 - 1)c^{-1}$ lies within $3N^2\epsilon \le \frac{3}{4}$ of $\varsigma\mathbf{1}$, and $\varsigma\frac{1}{2}\operatorname{tr} u = 1 - \frac{1}{2}|u - \varsigma\mathbf{1}|^2 \ge 1 - \frac{9}{32}$; the trace of $\mathcal{P}(U)(x)$ reads no x beyond (x_1, x_2) in the box.

(d) *The slice.* For $X \in \mathscr{H}$ with $|X|_\infty \le r_1$ and $\varpi(e^{iX}) < \epsilon$, put $D_X := \max_p |dX(p)|$; by (b), $|X|_\infty \le \|X\| \le \lambda_*^{-1/2}\|dX\| \le \Xi_N D_X$, and by (f) below, $|\partial e^{iX}(p) - \mathbf{1} - i\,dX(p)| \le 8|X|_\infty^2$,

so $D_X < \epsilon + 8r_1\Xi_N D_X = \epsilon + \frac12 D_X$: $D_X < 2\epsilon$, $\|X\| < 2\Xi_N\epsilon$, and $2\Xi_N\epsilon < r_1$ by (h1): the constraint $|X|_\infty \le r_1$ is not active, and $\mathcal{D}(\epsilon)$ is open. *Onto.* Let $\varpi(U) < \epsilon$; (c) gives g_0, ς with $U_1 := R_\varsigma U^{g_0}$ within $3N^2\epsilon$ of $\mathbf{1}$ at every bond. Let g_1 minimise $\Phi(g) := \sum_b \mathsf{d}(U_1^g(b))^2$ on the compact group $\mathcal{G}^{\mathrm{tw}}$; $\Phi(g_1) \le \Phi(\mathbf{1}) \le 3\mathsf{v}(\frac{\pi}{2}\,3N^2\epsilon)^2$, so $|X|_\infty \le r_1$ for $X := \log U_1^{g_1} \in \mathscr{F}^1$, by (h1). As $\frac{d}{ds}\frac12\mathsf{d}(e^{is\lambda}e^{iX})^2|_{s=0} = \langle\lambda, X\rangle$ and $\frac{d}{ds}\frac12\mathsf{d}(e^{iX}e^{-is\lambda})^2|_{s=0} = -\langle\lambda, X\rangle$, the minimality gives $\langle X, \nabla\lambda\rangle = 0$ for all λ: $X \in \mathscr{H}$, so $X \in \mathcal{D}(\epsilon)$, and as R_ς is central with $R_\varsigma^2 = \mathbf{1}$, $U = \Upsilon_\varsigma((g_1g_0)^{-1}, X)$. *The two pieces.* For $U = \Upsilon_\varsigma(g, X)$, $\operatorname{tr}\mathcal{P}(U)(0) = \varsigma \operatorname{tr}\mathcal{P}(e^{iX})(0)$ and $|\mathcal{P}(e^{iX}) - \mathbf{1}| \le N_3 r_1 \le \frac{1}{72}$: $\mathrm{In}(\epsilon)$ is the disjoint union of the two open invariant sets $\mathrm{In}^\pm(\epsilon)$, exchanged by the flip as $\mathcal{P}(R_- U) = -\mathcal{P}(U)$. *One to one.* Let $R_\varsigma e^{iX'} = (R_\varsigma e^{iX})^g$ with $X, X' \in \mathcal{D}(\epsilon)$. By (h1), $|X|_\infty, |X'|_\infty < 2\Xi_N\epsilon \le \frac{2}{3\pi N} r_1 < 0.071 r_1$, and $e^{iX'(b)} = g(b_-)e^{iX(b)}g(b_+)^{-1}$ gives $|g(b_-) - g(b_+)| < 0.142 r_1$ at every bond; following the periods of the torus in the directions 1 and 2 gives $|[\mathsf{i}_j, g(0)]| < 0.142 N r_1$ for $j = 1, 2$, which puts $g(0)$ within $0.15 N r_1$ of $\pm\mathbf{1}$; as $N r_1 \le \frac{1}{72}$, after the choice of the sign $g = e^{i\lambda}$ with $\lambda \in \mathscr{F}^0$, $|\lambda|_\infty \le 0.02$ and $|\nabla\lambda|_\infty \le 0.15 r_1$. Along $U_\tau := (e^{iX})^{e^{i\tau\lambda}}$, $0 \le \tau \le 1$, with $X_\tau := \log U_\tau$, of $|X_\tau|_\infty \le 0.23 r_1$, the function $\varphi(\tau) := \frac12\|X_\tau\|^2$ has $\varphi'(\tau) = -\langle X_\tau, \nabla\lambda\rangle$, which vanishes at $\tau = 0$ and at $\tau = 1$, as $X_0 = X$ and $X_1 = X'$ lie in $\mathscr{H}$; and $\varphi'' \ge (1 - \frac12|X_\tau|_\infty^2)\|\nabla\lambda\|^2 - 2.1\sqrt{3}|X_\tau|_\infty\|\lambda\|\|\nabla\lambda\| \ge 0.99\|\nabla\lambda\|^2$, by $\langle \mathsf{T}_Z^{-1}Y, Y\rangle \ge \min\{1, \theta\cot\theta\}|Y|^2 \ge (1 - \frac12\theta^2)|Y|^2$ and $\|\mathsf{T}_Z^{-1}\| \le \theta/\sin\theta$ for $\theta = |Z|$, $|\mathrm{Ad}(e^{iZ}) - 1| \le 2|Z|$ and $\|\lambda\| \le \frac{N}{2}\|\nabla\lambda\|$; so $\nabla\lambda = 0$, and λ, a constant fixed by $\mathrm{Ad}(\mathsf{i}_1)$ and by $\mathrm{Ad}(\mathsf{i}_2)$, is 0: $g = \pm\mathbf{1}$ and $X' = X$. *The integral.* The velocity of $s \mapsto \Upsilon_\varsigma(e^{is\lambda'}g, X)$ is $-D_V\lambda'$, $V = \Upsilon_\varsigma(g, X)$, that of $s \mapsto \Upsilon_\varsigma(g, X + sY)$ is $\mathrm{Ad}_g(\mathsf{T}_X Y)$, $(\mathrm{Ad}_g\xi)(b) := \mathrm{Ad}(g(b_-))\xi(b)$, and $D_V(\mathrm{Ad}(g)\lambda) = \mathrm{Ad}_g(D_{e^{iX}}\lambda)$, R_ς being central; so $D\Upsilon_\varsigma(g, X)(\lambda', Y) = \mathrm{Ad}_g\mathbb{A}(X)(\mathrm{Ad}(g)^{-1}\lambda', Y)$, of the determinant $\pm\det\mathbb{A}(X) \ne 0$ by (g) (on $\mathcal{D}(\epsilon)$, $|X|_\infty < 2\Xi_N\epsilon \le (10N)^{-1}$ by (h1)). The metrics are bi-invariant, each factor G is the unit sphere S^3 of the volume $2\pi^2$, and Υ_ς is two-to-one.

(e) *Step 1.* $\Theta_\epsilon(\mathcal{D}(\epsilon)) = \{Z \in \mathcal{B}_\epsilon : \tilde f_p(Z) < \frac12\epsilon^2 \text{ for all } p\}$, $\tilde f_p := f_p \circ \Sigma_\epsilon$: on one side $\|Z\| \le \|X\| < 2\Xi_N\epsilon$ and $4\Xi_N^2\epsilon^2 \le \epsilon/600$ by (h2); on the other $|X|_\infty \le (\epsilon/400)^{1/2} \le r_1$, as $256\Xi_N^2\epsilon \le 400$. On $\mathcal{B}_\epsilon$: $\theta := \varkappa_\epsilon\|Z\|^2 < \frac{1}{100}$, $q := 1 + \theta$, $\Sigma_\epsilon'(Z)Y = qY + 2\varkappa_\epsilon\langle Z, Y\rangle Z$ with the eigenvalues q and $1 + 3\theta$, $\Sigma_\epsilon''(Z)(Y, Y) = 2\varkappa_\epsilon\|Y\|^2 Z + 4\varkappa_\epsilon\langle Z, Y\rangle Y$; for $X = \Sigma_\epsilon(Z) = qZ$, $\omega := |X|_\infty^2 \le \epsilon/400$ and $|u_p - \mathbf{1}| \le 2\|X\| \le \frac12$. *Step 2.* At every $Z \in \mathcal{B}_\epsilon$ with $|u_p - \mathbf{1}| \ge \frac{\epsilon}{2}$: $D^2\tilde f_p(Z)(Y, Y) \ge 0$ for all Y. Indeed, with the notation of (f) at X, $Y' := \Sigma_\epsilon'(Z)Y$, $\mathbf{v}_p = \mathbf{w}(u_p)$, $c_p \ge \frac78$, $\alpha := \varkappa_\epsilon\langle Z, Y\rangle$ and $P := \langle\zeta_p(Z), \mathbf{v}_p\rangle$: $D^2\tilde f_p(Y, Y) = c_p|\zeta_p(Y')|^2 + \langle\dot\zeta_p(Y', Y'), \mathbf{v}_p\rangle + 2\varkappa_\epsilon\|Y\|^2 P + 4\alpha\langle\zeta_p(Y), \mathbf{v}_p\rangle$, $\zeta_p(Y') = q\zeta_p(Y) + 2\alpha\zeta_p(Z)$, $\alpha^2 \le \varkappa_\epsilon\theta\|Y\|^2$, $|\dot\zeta_p(Y', Y')| \le 4(1 + 3\theta)^2\|Y\|^2$, $|\zeta_p(X) - \mathbf{v}_p| \le 20\omega$, so $P \ge q^{-1}|\mathbf{v}_p|(|\mathbf{v}_p| - 20\omega) > 0$ as $|\mathbf{v}_p| \ge |u_p - \mathbf{1}|(1 - \frac{1}{16})^{1/2} \ge 0.484\epsilon$; completing the square in $|\zeta_p(Y')|$: $D^2\tilde f_p(Y, Y) \ge \|Y\|^2|\mathbf{v}_p|\{1.855\varkappa_\epsilon|\mathbf{v}_p| - 40\varkappa_\epsilon\omega - 4.244\}$, and $1.855 \cdot 6 \cdot 0.484 - 40 \cdot \frac{6}{400} - 4.244 > 0.54$. *Step 3.* On a segment of $\mathcal{B}_\epsilon$, a C^2 function that is convex wherever it exceeds the level $c_0 := \frac18\epsilon^2$ has the maximum with c_0 convex: a component of the set where it exceeds c_0 with both ends inside the segment would carry a convex function equal to c_0 at both ends and larger between. *Step 4.* $\Theta_\epsilon(\mathcal{D}(\epsilon)) = \bigcap_p\{Z \in \mathcal{B}_\epsilon : \max\{\tilde f_p, \frac18\epsilon^2\} < \frac12\epsilon^2\}$ is an intersection of open convex sets that holds 0; Σ_ϵ is radial, so $\mathcal{D}(\epsilon)$ is star-shaped, and $\mathrm{In}^\varsigma(\epsilon) = \Upsilon_\varsigma(\mathcal{G}^{\mathrm{tw}} \times \mathcal{D}(\epsilon))$ is connected, $\mathcal{G}^{\mathrm{tw}}$ being connected.

(f) Let $X_s = X + sY$, $U_j = e^{iX_j(s)}$ at the bonds $1, \dots, 4$ of p in the order of $\partial U(p)$; then $\dot U_j = i\xi_j U_j$, $\xi_j = \mathsf{T}_{X_j + sY_j}Y_j$, and $\dot u_p = i\zeta_p u_p$ with $\zeta_p(Y) := \xi_1 + \mathrm{Ad}(U_1)\xi_2 - \mathrm{Ad}(U_1U_2U_3^{-1})\xi_3 - \mathrm{Ad}(u_p)\xi_4$. So $Df_p(X)Y = \langle\zeta_p(Y), \mathbf{v}_p\rangle$ and $D^2f_p(X)(Y, Y) = c_p|\zeta_p(Y)|^2 + \langle\dot\zeta_p, \mathbf{v}_p\rangle$, $c_p = \frac12\mathrm{tr}\,u_p$, with $|\dot\zeta_p| \le (\sum_{b\in p}|Y_b|)^2$, $|\zeta_p(Y) - dY(p)| \le 9r\sum_{b\in p}|Y_b|$, $|\zeta_p(X) - dX(p)| \le 12r^2$, and $|u_p - \mathbf{1} - i\,dX(p)| \le \frac12(\sum_{b\in p}|X_b|)^2 \le 8r^2$. Summing over the plaquettes, each bond lying in four: $\|\zeta(Y) - dY\| \le 36r\|Y\|$, $\sum_p|\dot\zeta_p| \le 16\|Y\|^2$, $c_p \in [1 - \frac12\varpi^2, 1]$, $|\mathbf{v}_p| \le \varpi$ and $\sum_p|\mathbf{v}_p|^2 \le 3\mathsf{v}\varpi^2$. On $\mathcal{D}(\epsilon)$: $r < 2\Xi_N\epsilon$, $\varpi < \epsilon$, $\|Y\| \le \frac{N}{2}\|dY\|$ on $\mathscr{H}$, and by (h2) $36N\Xi_N\epsilon \le 0.0034$, $4N^2\epsilon \le 10^{-4}$, $72\Xi_N\epsilon \le 0.01$.

(g) On $\mathfrak{g} \otimes \mathbb{C}$ with the Hermitian norm, $\|\mathrm{ad}X\| \le 2|X|$; for $|X| \le \frac14$, $\|e^{i\,\mathrm{ad}X} - 1\| \le 2.6|X|$ and $\|\mathsf{T}_X - 1\| \le 1.19|X|$; so $\|\mathbb{A}(X) - \mathbb{A}(0)\| \le 4.66|X|_\infty$, while $\mathbb{A}(0)(\lambda, Y) = -\nabla\lambda + Y$ is an

orthogonal sum with $\|\mathbb{A}(0)^{-1}\| \le \lambda_*^{-1/2} \le \frac{N}{2}$ and $|\det \mathbb{A}(0)| = \det(\nabla^*\nabla)^{1/2}$. For $|X|_\infty < (5N)^{-1}$, $\mathfrak{e} := \mathbb{A}(0)^{-1}\mathbb{A}(X) - 1$ has $\|\mathfrak{e}\| \le 2.33N|X|_\infty < \frac12$, and $\mathfrak{l} = \operatorname{tr}\log(1+\mathfrak{e})$ is holomorphic with $|\mathfrak{l}| \le 9\mathsf{v}\log 2$, $9\mathsf{v}$ being the dimension; for real X the determinant is real, non-zero and 1 at 0, on a convex set, hence positive. Cauchy's estimate on the disc $|z| < (10N|Y|_\infty)^{-1}$ for $z \mapsto \mathfrak{l}(X+zY)$ gives the two bounds. □

Proposition 18.72 (A log-Sobolev inequality on the small fields of the twisted lattice)**.** Let (h1), (h2) hold.

(a) Let $\nu = \mathsf{g}\,dU$ be a finite measure on $\mathrm{In}(\epsilon)$ with $\mathsf{g} > 0$ Borel, $\mathsf{g}(U^g) = \mathsf{g}(U) = \mathsf{g}(R_- U)$, and $\mathsf{g}(e^{iX}) = \exp[-w(X) - w_0(X)]$ on $\mathcal{D}(\epsilon)$, where (i) $w \in C^2(\mathcal{D}(\epsilon))$, $D^2w(X)(Y,Y) \ge \varrho_0\|Y\|^2$ and $|Dw(X)Y| \le \mathsf{L}_0\|Y\|$ for $X \in \mathcal{D}(\epsilon)$, $Y \in \mathscr{H}$; (ii) w_0 is Borel with $\operatorname{osc} w_0 \le \mathsf{e}_{\mathrm{osc}}$; (iii) $\varrho := \varrho_0 - 1250\mathsf{v}N^2 - 72\Xi_N(\mathsf{L}_0 + 63\mathsf{v}N) - 84\mathsf{v}/\epsilon > 0$. Then for gauge-invariant bounded Borel F: $\int_{\mathrm{In}^\varsigma(\epsilon)} F\,d\nu = \mathsf{k}\int_{\mathcal{D}(\epsilon)} F(R_\varsigma e^{iX})e^{-W(X)-w_0(X)}dX$ with a number $\mathsf{k} > 0$, $W := w - \log\mathcal{J}$, $D^2W \ge \varrho_0 - 1250\mathsf{v}N^2$ and $\|DW\| \le \mathsf{L} := \mathsf{L}_0 + 63\mathsf{v}N$; in the coordinate $Z = \Theta_\epsilon(X)$ the density on the convex set $\Theta_\epsilon(\mathcal{D}(\epsilon))$ is $e^{-\tilde W - w_0\circ\Sigma_\epsilon}$ with $D^2\tilde W \ge \varrho$; and for every bounded, gauge-invariant, even $h \in C^1(\mathrm{In}(\epsilon))$: $\mathrm{Ent}_\nu(h^2) \le \frac{2.13\,e^{\mathsf{e}\mathrm{osc}}}{\varrho}\int\|\partial h\|^2 d\nu$.

(b) Let $x > 0$, $w = x\mathsf{a} - \mathsf{s}$ and $w_0 = 0$, with real functions on $\mathcal{D}(\epsilon)$ such that (a1) a extends holomorphically to $\{X \in \mathscr{H}\otimes\mathbb{C} : |X|_\infty < \rho_\mathsf{a}\}$, with $|\mathsf{a}| \le M_\mathsf{a}$ there, and $4\Xi_N\epsilon \le \rho_\mathsf{a}$; (a2) $D\mathsf{a}(0) = 0$; (a3) $D^2\mathsf{a}(0)(Y,Y) \ge c_\mathsf{a}\|dY\|^2$ for real Y; (s) $\mathsf{s} \in C^2(\mathcal{D}(\epsilon))$, and for real $X \in \mathcal{D}(\epsilon)$ and $Y \in \mathscr{H}$ the function $z \mapsto \mathsf{s}(X+zY)$ extends holomorphically to $\{|z||Y|_\infty < \rho_\mathsf{s}\}$, with modulus at most M_s. Then (a)(i) holds with $\varrho_0 = x[c_\mathsf{a}\lambda_* - 216M_\mathsf{a}\Xi_N\epsilon\rho_\mathsf{a}^{-3}] - 2M_\mathsf{s}\rho_\mathsf{s}^{-2}$ and $\mathsf{L}_0 = 32xM_\mathsf{a}\Xi_N\epsilon\rho_\mathsf{a}^{-2} + M_\mathsf{s}\rho_\mathsf{s}^{-1}$.

(c) (The top of the cube.) In the setting of (a) and (b), let $N_1 = N_2 = N_3 = N = lL^n$, $x = L^n\mathsf{b} > 1$, $\epsilon = 2\varepsilon(x)$, and suppose $N \le C_N(\log x)^{r_N}$ with numbers $C_N > 0$ and $r_N \ge 0$, $2\mathfrak{p}_0 > 5r_N$, $M_\mathsf{a} = C_\mathsf{a}N^3\rho_\mathsf{a}^2$, $M_\mathsf{s} = E_\mathsf{s}N^3$ and $\rho_\mathsf{s} = \vartheta_\mathsf{s}\varepsilon(x)$, with fixed $\rho_\mathsf{a}, C_\mathsf{a}, c_\mathsf{a}, E_\mathsf{s}, \vartheta_\mathsf{s}$. There is $x_\sharp$, formed from $C_N, r_N, A_0, \mathfrak{p}_0, \rho_\mathsf{a}, C_\mathsf{a}, c_\mathsf{a}, E_\mathsf{s}, \vartheta_\mathsf{s}$ alone, such that for $x \ge x_\sharp$: (h1), (h2), $4\Xi_N\epsilon \le \rho_\mathsf{a}$ and $\varrho \ge \frac12 c_\mathsf{a}x\lambda_* \ge 2c_\mathsf{a}x/N^2$ hold; in physical units the Hessian of W is at least $2c_\mathsf{a}\mathsf{b}\,l^{-2}$, and $\mathrm{Ent}_\nu(h^2) \le \frac{1.07}{c_\mathsf{a}}\frac{l^2}{\mathsf{b}}\int\Gamma_n(h)\,d\nu$ for every bounded, gauge-invariant, even $h \in C^1(\mathrm{In}(\epsilon))$.

(d) (The gauge invariance cannot be dropped.) In the setting of (a), for a site x_0 let $h(\Upsilon_\varsigma(g,X)) := \langle\sigma_3, \mathrm{Ad}(g(x_0))\sigma_3\rangle$; it is well defined, real-analytic on $\mathrm{In}(\epsilon)$, even and not gauge invariant, and $\mathrm{Var}_\nu(h) \ge (8N^2)^{-1}\int\|\partial h\|^2 d\nu$. So on the even functions the Poincaré constant of ν is at least $a_n/(8N^2)$ in physical units, which exceeds $C\,l^2/\mathsf{b} = CN^2a_n/x$ as soon as $x > 8CN^4$.

■

Sketch. Three facts on measures are used. (LC) A probability measure $e^{-V}dz$ on an open convex set with $D^2V \ge \varrho > 0$ obeys $\mathrm{Ent}(\phi^2) \le \frac{2}{\varrho}\int|\nabla\phi|^2$ for bounded $\phi \in C^1$ (the fact used in the proof of Lemma 15.3(iv)). (BP) If $\mathrm{Ent}_p(\phi^2) \le c\int|\nabla\phi|^2dp$ and $dp' = Z'^{-1}e^{-\psi}dp$ with $\operatorname{osc}\psi \le e_1$, then $\mathrm{Ent}_{p'}(\phi^2) \le e^{e_1}c\int|\nabla\phi|^2dp'$: with $c' = p(\phi^2)$, $\mathrm{Ent}_{p'}(\phi^2) \le \int\Xi(\phi^2,c')\,dp' \le Z'^{-1}e^{-\inf\psi}\mathrm{Ent}_p(\phi^2)$, and $dp \le Z'e^{\sup\psi}dp'$. (Cov) If a probability p on an open bounded convex set obeys $\mathrm{Ent}_p(\phi^2) \le \frac{2}{\gamma}\int|\nabla\phi|^2dp$, $|\nabla\psi| \le \ell_\psi$, and $F \in C^1$ is bounded with $\inf F > 0$, then $|\mathrm{Cov}_p(F,\psi)| \le \frac{\ell_\psi}{\gamma}(\int F\,dp\int|\nabla F|^2F^{-1}dp)^{1/2}$: the inequality at $\phi = e^{s\psi/2}$ gives $\frac{d}{ds}(s^{-1}\log\int e^{s\psi}dp) \le \frac{\ell_\psi^2}{2\gamma}$, so $\log\int e^{s(\psi-\bar\psi)}dp \le \frac{s^2\ell_\psi^2}{2\gamma}$; the entropy inequality $s\int\varphi(\psi-\bar\psi)\,dp \le \mathrm{Ent}_p(\varphi) + \log\int e^{s(\psi-\bar\psi)}dp$ at $\varphi = F/\int F$, optimised in s, and $\mathrm{Ent}_p(\varphi) \le \frac{1}{2\gamma}\int|\nabla\varphi|^2\varphi^{-1}dp$.

(a) Proposition 18.71(d) at $F\mathsf{g}$, both gauge invariant, and $\mathsf{g}(R_\varsigma e^{iX}) = \mathsf{g}(e^{iX})$ (evenness) give the integral; on $\mathcal{D}(\epsilon)$, $|X|_\infty < (10N)^{-1}$, so Proposition 18.71(g) with $|Y|_\infty \le \|Y\|$ bounds the derivatives of $\log\mathcal{J}$. In the coordinate Z: $dX = \det\Sigma_\epsilon'(Z)\,dZ$, $\det\Sigma_\epsilon'(Z) = (1+\varkappa_\epsilon\|Z\|^2)^{6\mathsf{v}-1}(1+3\varkappa_\epsilon\|Z\|^2)$,

so $\tilde W(Z)=W(\Sigma_\epsilon Z)-(6\mathsf v-1)\log(1+\varkappa_\epsilon\|Z\|^2)-\log(1+3\varkappa_\epsilon\|Z\|^2)$; $D^2(W\circ\Sigma_\epsilon)(Y,Y)\ge(\varrho_0-1250\mathsf v N^2)\|\Sigma'_\epsilon(Z)Y\|^2-\mathsf L\|\Sigma''_\epsilon(Z)(Y,Y)\|$ with $\|\Sigma'_\epsilon(Z)Y\|\ge\|Y\|$ and $\|\Sigma''_\epsilon(Z)(Y,Y)\|\le 6\varkappa_\epsilon\|Z\|\|Y\|^2\le 72\Xi_N\|Y\|^2$; and $D^2\log(1+c\|Z\|^2)\le 2c$, so the two logarithms take away at most $\frac{12(6\mathsf v+2)}{\epsilon}\le\frac{84\mathsf v}{\epsilon}$. For h as stated, $\hat h(Z):=h(e^{i\Sigma_\epsilon(Z)})$: as h^2, $\|\partial h\|^2$ and $\mathsf g$ are gauge invariant and even and the flip exchanges $\mathrm{In}^\pm(\epsilon)$, $\mathrm{Ent}_\nu(h^2)=\nu(1)\mathrm{Ent}_{\hat p}(\hat h^2)$ with the normalised measure $\hat p$ on $\Theta_\epsilon(\mathcal D(\epsilon))$; (LC) for $e^{-\tilde W}$ and (BP) for $w_0\circ\Sigma_\epsilon$ give $\mathrm{Ent}_{\hat p}(\hat h^2)\le e^{\mathsf e_{\mathrm{osc}}}\frac{2}{\varrho}\int|\nabla\hat h|^2d\hat p$; and $D\hat h(Z)Y=\langle\partial h(e^{iX}),\mathsf T_X(\Sigma'_\epsilon(Z)Y)\rangle$, so $|\nabla\hat h|^2\le 1.0609\|\partial h\|^2$.

(b) For real $X\in\mathcal D(\epsilon)$, $|X|_\infty<2\Xi_N\epsilon\le\frac12\rho_{\mathsf a}$; for $0\le\tau\le1$ the function $(z,z')\mapsto\mathsf a(\tau X+zX+z'Y)$ is holomorphic and bounded by $M_{\mathsf a}$ on $|z||X|_\infty<\frac16\rho_{\mathsf a}$, $|z'||Y|_\infty<\frac13\rho_{\mathsf a}$, so by Cauchy's estimate $|D^3\mathsf a(\tau X)(X,Y,Y)|\le 108M_{\mathsf a}\rho_{\mathsf a}^{-3}|X|_\infty|Y|_\infty^2$, and integrating in τ: $|D^2\mathsf a(X)(Y,Y)-D^2\mathsf a(0)(Y,Y)|\le 216M_{\mathsf a}\Xi_N\epsilon\rho_{\mathsf a}^{-3}\|Y\|^2$; on the polydisc of the radii $\frac14\rho_{\mathsf a}$, $|D^2\mathsf a(\tau X)(X,Y)|\le 16M_{\mathsf a}\rho_{\mathsf a}^{-2}|X|_\infty|Y|_\infty$, and with (a2) $|D\mathsf a(X)Y|\le 32M_{\mathsf a}\Xi_N\epsilon\rho_{\mathsf a}^{-2}\|Y\|$. By (s), $|D\mathsf s(X)Y|\le M_{\mathsf s}\rho_{\mathsf s}^{-1}|Y|_\infty$ and $|D^2\mathsf s(X)(Y,Y)|\le 2M_{\mathsf s}\rho_{\mathsf s}^{-2}|Y|_\infty^2$. With (a3) and $\|dY\|^2\ge\lambda_*\|Y\|^2$ on $\mathscr H$ this is (a)(i).

(c) With $\mathsf v=N^3$, $\Xi_N=\frac{\sqrt3}{2}N^{5/2}$, $\lambda_*\ge 4N^{-2}$ and $x\varepsilon(x)^2=A_0^2(\log x)^{2\mathfrak p_0}$, it suffices that: (1) $36\pi N^6\epsilon\le1$; (2) $1800N^5\epsilon\le1$; (3) $4\Xi_N\epsilon\le\rho_{\mathsf a}$; (4) $216C_{\mathsf a}N^3\Xi_N\epsilon\rho_{\mathsf a}^{-1}\le\frac12 c_{\mathsf a}N^{-2}$; (5) $2E_{\mathsf s}N^3\vartheta_{\mathsf s}^{-2}\varepsilon(x)^{-2}\le\frac12 c_{\mathsf a}xN^{-2}$; (6) $1250N^5+72\Xi_N(32xC_{\mathsf a}N^3\Xi_N\epsilon+E_{\mathsf s}N^3\vartheta_{\mathsf s}^{-1}\varepsilon(x)^{-1}+63N^4)+84N^3\epsilon^{-1}\le c_{\mathsf a}xN^{-2}$; for then $\varrho\ge xc_{\mathsf a}\lambda_*(1-\frac18-\frac18-\frac14)$. Divided by x where x stands on the right, the left members of (1)–(4) and (6) are at most a number times $N^{10}x^{-1/2}(\log x)^{\mathfrak p_0}$, which tends to 0 as $N\le C_N(\log x)^{r_N}$; (5) reads $4E_{\mathsf s}N^5\le c_{\mathsf a}\vartheta_{\mathsf s}^2A_0^2(\log x)^{2\mathfrak p_0}$, which holds for large x as $5r_N<2\mathfrak p_0$. Units: $\varrho/a_n\ge 2c_{\mathsf a}x/(N^2a_n)=2c_{\mathsf a}\mathsf b/l^2$, and $\frac{2.13}{\varrho}a_n\le\frac{1.07}{c_{\mathsf a}}\frac{l^2}{\mathsf b}$.

(d) Since ν is gauge invariant, Proposition 18.71(d) shows that, with respect to $\nu/\nu(1)$, the variable g is independent of X and, modulo $\pm$, Haar distributed; the function $\phi(g_0):=\langle\sigma_3,\mathrm{Ad}(g_0)\sigma_3\rangle$ on $G=S^3$ is a matrix coefficient of the spin-one representation, and it has mean 0, $\int\phi^2=\frac13$ and $-\Delta\phi=8\phi$ (the Laplacian of S^3 has the eigenvalues $j(j+2)$), whence $\int|\nabla\phi|^2=\frac83$. Every tangent vector ξ at $V=\Upsilon_\varsigma(g,X)$ has the form $\xi=\mathrm{Ad}_g\mathbb A(X)(\mathrm{Ad}(g)^{-1}\lambda',Y)$, where $\|(\lambda',Y)\|\le\|(1+\mathfrak e)^{-1}\|\|\mathbb A(0)^{-1}\|\|\xi\|\le N\|\xi\|$, and $\langle\xi,\partial h(V)\rangle$ equals the derivative of ϕ at the point $g(x_0)$ in the direction $\lambda'(x_0)$; it follows that $\int\|\partial h\|^2d\nu\le N^2\frac83\nu(1)=8N^2\mathrm{Var}_\nu(h)$. As the flip takes $\Upsilon_\varsigma(g,X)$ to $\Upsilon_{-\varsigma}(g,X)$, the function h is even; besides, $\mathrm{Ad}(-g)=\mathrm{Ad}(g)$. □

Proposition 18.73 (An entropy tower)**.** Let $t\ge1$. For $0\le k\le t$ let $\mathcal U_k$ be an open subset of a product of copies of G indexed by the bonds of a lattice, with tangent vectors and gradients as above, m_k a finite positive Borel measure on $\mathcal U_k$, $\mathsf n_k(V;\cdot)$ seminorms on the tangent vectors at V, and $\hat\Gamma_k(g)(V):=\sup\{\langle\xi,\partial g(V)\rangle^2:\mathsf n_k(V;\xi)\le1\}$, Borel in V. For each $k<t$ and each $W\in\mathcal U_{k+1}$, let an open, bounded, convex set $\mathrm{Rg}_k\subset\mathbb R^{\dim_k}$, a map $\tilde V_W:\mathrm{Rg}_k\to\mathcal U_k$ of class C^1 and a probability measure $\tilde p_W$ on Rg_k be given, subject to: (T1) $\int h\,dm_k=\int[\int h(\tilde V_W(B))\tilde p_W(dB)]\,m_{k+1}(dW)$ for every Borel $h\ge0$; (T2) $\mathrm{Ent}_{\tilde p_W}(\phi^2)\le\frac{2}{\kappa_k}\int|\nabla\phi|^2d\tilde p_W$ for every bounded $\phi\in C^1(\mathrm{Rg}_k)$; (T3) $\mathsf n_k(\tilde V_W(B);D\tilde V_W(B)\zeta)\le\mathsf l_k|\zeta|$. Fix a bounded $f_0\in C^1(\mathcal U_0)$ with $\inf f_0>0$, and let its tower $f_{k+1}(W):=\int f_k(\tilde V_W(B))\,\tilde p_W(dB)$ meet the following conditions for all $k<t$, all $W\in\mathcal U_{k+1}$ and every tangent vector ξ at W: (S0) $f_{k+1}\in C^1(\mathcal U_{k+1})$, and for some Borel field $B\mapsto\dot V_B$ of tangent vectors at $\tilde V_W(B)$ and some $\psi_\xi\in C^1(\mathrm{Rg}_k)$ one has $\langle\xi,\partial f_{k+1}(W)\rangle=\int\langle\dot V_B,\partial f_k(\tilde V_W(B))\rangle\,\tilde p_W(dB)+\mathrm{Cov}_{\tilde p_W}(f_k\circ\tilde V_W,\psi_\xi)$; (S1a) $\mathsf n_k(\tilde V_W(B);\dot V_B)\le(1+\eta'_k)\,\mathsf n_{k+1}(W;\xi)$; (S1b) $|\nabla_B\psi_\xi|\le\iota_k\,\mathsf n_{k+1}(W;\xi)$. Put $\eta_k:=\eta'_k+\iota_k\mathsf l_k/\kappa_k$ and $\mathcal I_k:=\int\hat\Gamma_k(f_k)f_k^{-1}dm_k$. Then $\mathcal I_{k+1}\le(1+\eta_k)^2\mathcal I_k$, and $\mathrm{Ent}_{m_0}(f_0)=\sum_{k<t}\int\mathrm{Ent}_{\tilde p_W}(f_k\circ\tilde V_W)\,m_{k+1}(dW)+\mathrm{Ent}_{m_t}(f_t)\le\sum_{k<t}\frac{\mathsf l_k^2}{2\kappa_k}\mathcal I_k+\mathrm{Ent}_{m_t}(f_t)$. ■

Sketch. The identity. By (T1) at $h=f_k\log f_k$: $\int f_k\log f_k\,dm_k=\int[\mathrm{Ent}_{\tilde p_W}(f_k\circ\tilde V_W)+f_{k+1}(W)\log f_{k+1}(W)]\,m_{k+1}(dW)$; sum over $k<t$, and use $m_k(f_k)=m_0(f_0)$ and $m_k(1)=m_0(1)$, by (T1) at $h=f_k$ and $h=1$. *One fibre.* (T2) at $\phi=(f_k\circ\tilde V_W)^{1/2}$: $\mathrm{Ent}_{\tilde p_W}(f_k\circ\tilde V_W)\le$

$\frac{1}{2\kappa_k}\int|\nabla_B(f_k\circ\tilde V_W)|^2(f_k\circ\tilde V_W)^{-1}d\tilde p_W$, and $|\nabla_B(f_k\circ\tilde V_W)|\le \mathsf{l}_k\hat\Gamma_k(f_k)^{1/2}\circ\tilde V_W$ by (T3) and the definition of $\hat\Gamma_k$ ($|\langle\eta,\partial g(V)\rangle|\le \mathsf{n}_k(V;\eta)\hat\Gamma_k(g)(V)^{1/2}$); integrate with m_{k+1} and use (T1). *The Fisher information contracts.* Let $\mathcal{I}_k<\infty$; for m_{k+1}-almost every W, $\mathsf{I}(W):=\int\hat\Gamma_k(f_k)f_k^{-1}(\tilde V_W(B))\,\tilde p_W(dB)<\infty$. Fix such a W, a tangent vector ξ and $\mathsf{n}:=\mathsf{n}_{k+1}(W;\xi)$. In (S0) the first term is at most $(1+\eta_k')\mathsf{n}\int\hat\Gamma_k(f_k)^{1/2}d\tilde p_W\le(1+\eta_k')\mathsf{n}\,\mathsf{I}(W)^{1/2}f_{k+1}(W)^{1/2}$, by (S1a) and Cauchy–Schwarz; the second, by (Cov) of the proof of Proposition 18.72 with $\gamma=\kappa_k$, $\ell_\psi=\iota_k\mathsf{n}$ by (S1b), $F=f_k\circ\tilde V_W$ and the bound of $|\nabla_BF|$ above, is at most $\frac{\iota_k\mathsf{n}}{\kappa_k}\mathsf{l}_k(f_{k+1}(W)\mathsf{I}(W))^{1/2}$. So $\langle\xi,\partial f_{k+1}(W)\rangle^2\le(1+\eta_k)^2\mathsf{n}^2f_{k+1}(W)\mathsf{I}(W)$, that is $\hat\Gamma_{k+1}(f_{k+1})/f_{k+1}\le(1+\eta_k)^2\mathsf{I}$ at W; integrate with m_{k+1} and use (T1). □

Proposition 18.74 (The twisted cube: the chain measure, the Wilson measure, the dynamics)**.** Let $N=lL^n$, $x=L^n\mathsf{b}$, $\epsilon=2\varepsilon(x)$; assume (D1), (D2), and let the hypotheses of Proposition 18.72(c) hold with $x\ge x_\sharp$. Put $C_{\mathrm{LS}}:=\frac{\Pi_{\mathrm{tw}}}{c_\flat}\big[\frac{2C_{\mathrm{ch}}^{\mathrm{tw}}}{\gamma_\flat(L^2-1)N^2}+\frac{1.07}{c_{\mathsf{a}}}\big]$ and $C_{\mathrm{W}}:=\frac12C_{\mathrm{LS}}\,l^2/\mathsf{b}$, numbers free of K.

(a) For all $K>n$ and all real gauge-invariant even $G\in C^\infty(\mathbf{\Omega}_K)$, with $\mathsf{f}_{\mathrm{top}}$ the top of the tower of G^2: $\mathrm{Ent}_{\tilde\mu_K}(G^2)\le\frac{2\Pi_{\mathrm{tw}}C_{\mathrm{ch}}^{\mathrm{tw}}}{c_\flat\gamma_\flat(L^2-1)}\frac{a_n^2}{\mathsf{b}}\tilde{\mathcal{E}}_K(G)+\mathrm{Ent}_{\tilde\mu_{K,[n]}}(\mathsf{f}_{\mathrm{top}})\le C_{\mathrm{LS}}\frac{l^2}{\mathsf{b}}\tilde{\mathcal{E}}_K(G)\le C_{\mathrm{LS}}\frac{l^2}{\mathsf{b}}\mathcal{E}_K^{\mathrm{tw}}(G)$.

(b) For the same G: $\mathrm{Var}_{\mu_K^{\mathrm{tw}}}(G)\le C_{\mathrm{W}}\,\mathcal{E}_K^{\mathrm{tw}}(G)+\mathsf{R}_{\mathrm{tw}}\,\mathrm{osc}(G)^2$, where $\mathsf{S}_G=\sup G^2$. If $c=\tilde\mu_K(G^2)/\tilde\mu_K(1)>0$, then $\mathrm{Ent}_{\mu_K^{\mathrm{tw}}}(G^2)\le C_{\mathrm{LS}}\frac{l^2}{\mathsf{b}}\mathcal{E}_K^{\mathrm{tw}}(G)+\mathsf{R}_{\mathrm{tw}}\mathsf{S}_G(1+\log\frac{\mathsf{S}_G}{c})$. If $c=0$, write $m_G=\mu_K^{\mathrm{tw}}(G^2)\le\mathsf{R}_{\mathrm{tw}}\mathsf{S}_G$. The entropy is at most $m_G\log(\mathsf{S}_G/m_G)$ when $m_G>0$ and is zero when $m_G=0$.

(c) For all $K>n$, $u\ge0$ and all bounded real Borel gauge-invariant even H on $\mathbf{\Omega}_K$: $(H,(1-P_u^{\mathrm{tw}})H)_{L^2(\mu_K^{\mathrm{tw}})}\ge(1-e^{-u/C_{\mathrm{W}}})[\mathrm{Var}_{\mu_K^{\mathrm{tw}}}(H)-\mathsf{R}_{\mathrm{tw}}\,\mathrm{osc}(H)^2]$ and $\|P_u^{\mathrm{tw}}H-\int H\,d\mu_K^{\mathrm{tw}}\|^2_{L^2(\mu_K^{\mathrm{tw}})}\le e^{-2u/C_{\mathrm{W}}}\mathrm{Var}_{\mu_K^{\mathrm{tw}}}(H)+\mathsf{R}_{\mathrm{tw}}\,\mathrm{osc}(H)^2$.

(d) A finite set $\mathcal{F}_{\mathrm{tw}}$ of even, gauge-invariant Borel functions $\phi:\mathbf{\Omega}_n\to\{0,1\}$ can be chosen independently of K so that each $K>n$ admits a $\phi\in\mathcal{F}_{\mathrm{tw}}$ with $\mathrm{Var}_{\mu_K^{\mathrm{tw}}}(\phi(V_n))\ge0.24(1-\mathsf{R}_{\mathrm{tw}})$. Consequently, when $\mathsf{R}_{\mathrm{tw}}<0.19$, along every sequence $K_j\to\infty$ one can pass to a subsequence and pick one $\phi\in\mathcal{F}_{\mathrm{tw}}$ such that the stationary Langevin process (U_u) at the cutoff K_j satisfies $\liminf_j\frac12\mathbb{E}|\phi(V_n(U_u))-\phi(V_n(U_0))|^2\ge(1-e^{-u/C_{\mathrm{W}}})(0.24-1.24\mathsf{R}_{\mathrm{tw}})>0$ for every $u>0$. In particular, if along a sequence $K_j\to\infty$ the laws of the pairs $(F(V_n(U_0)),F(V_n(U_u)))$ converge for all bounded Borel F on $\mathbf{\Omega}_n$ and all $u\ge0$, then for the ϕ found for that sequence the limit law of $(\phi(V_n(U_0)),\phi(V_n(U_u)))$ gives positive mass to $\{(a,b):a\ne b\}$, for every $u>0$.

■

Sketch. (a) Proposition 18.73 with $t=K-n$, $\mathcal{U}_k=\mathrm{Cut}_{K-k}^{\mathrm{tw}}$, $m_k=\tilde\mu_{K,[K-k]}$ and the seminorms of (D2): (T1) is (D1.3) at $\phi=1$ with monotone limits; (T2) is (LC) of the proof of Proposition 18.72 with $\kappa_k=\gamma_\flat$; (T3) follows from (N) and (D1.3): $\mathsf{n}_d(\tilde V_W(B);D\tilde V_W(B)\zeta)^2\le c_\flat^{-1}a_dC_{\mathrm{ch}}^{\mathrm{tw}}x_d^{-1}|\zeta|^2=\frac{C_{\mathrm{ch}}^{\mathrm{tw}}}{c_\flat}\frac{a_d^2}{\mathsf{b}}|\zeta|^2=:\mathsf{l}_d^2|\zeta|^2$, so that the η_d of (Σ) are those of Proposition 18.73. Let $\delta>0$ and $f_0=G^2+\delta$; its tower is that of G^2 plus δ, and $\hat\Gamma_K=\Gamma_K$ on gauge-invariant functions; $\mathcal{I}_0=\int4G^2\Gamma_K(G)(G^2+\delta)^{-1}d\tilde\mu_K\le4\tilde{\mathcal{E}}_K(G)$, so $\mathcal{I}_k\le4\Pi_{\mathrm{tw}}\tilde{\mathcal{E}}_K(G)$ for all k. The fibres contribute at most $\sum_{d>n}\frac{\mathsf{l}_d^2}{2\gamma_\flat}4\Pi_{\mathrm{tw}}\tilde{\mathcal{E}}_K(G)$ with $\sum_{d>n}a_d^2=\frac{a_n^2}{L^2-1}$. The top $f_t=\mathsf{f}_{\mathrm{top}}+\delta$: $f_t^{1/2}$ is bounded, C^1 on $\mathrm{Cut}_n^{\mathrm{tw}}\supset\mathrm{In}(\epsilon)$ by (S0), as $f_t\ge\delta$, gauge invariant and even by (D1.4), and $\tilde\mu_{K,[n]}$ is a measure ν as in Proposition 18.72(c) by (D1.5), the number $\mathsf{c}_K^{\mathrm{tw}}$ dropping out of both members; so $\mathrm{Ent}_{\tilde\mu_{K,[n]}}(f_t)\le\frac{1.07}{c_{\mathsf{a}}}\frac{l^2}{\mathsf{b}}\int\Gamma_n(f_t^{1/2})\,d\tilde\mu_{K,[n]}$, and $\Gamma_n(f_t^{1/2})=\Gamma_n(f_t)/(4f_t)\le\hat\Gamma_n(f_t)/(4c_\flat f_t)$ by (N), of the integral at most $\mathcal{I}_t/(4c_\flat)\le\Pi_{\mathrm{tw}}\tilde{\mathcal{E}}_K(G)/c_\flat$. With $a_n=l/N$ this gives the first two inequalities for $G^2+\delta$ and its top f_t; let $\delta\downarrow0$, the entropies of bounded functions being continuous in δ. The last one is (D1.2) at the gauge-invariant $\Gamma_K(G)$.

(b) (a) at $1+sG$: $\mathrm{Ent}_{\tilde\mu_K}((1+sG)^2) = 2s^2\int (G-c)^2 d\tilde\mu_K + O(s^3)$ with $c = \tilde\mu_K(G)/\tilde\mu_K(1)$, and $\tilde{\mathcal{E}}_K(1+sG) = s^2\tilde{\mathcal{E}}_K(G)$; so $\int (G-c)^2 d\tilde\mu_K \le C_{\mathrm{W}}\tilde{\mathcal{E}}_K(G)$, and (D1.2) at $F=(G-c)^2$, with $\inf G \le c \le \sup G$, gives the first inequality. For the entropy bound when $c = \tilde\mu_K(G^2)/\tilde\mu_K(1) > 0$, $\mathrm{Ent}_{\mu_K^{\mathrm{tw}}}(G^2) \le \int \Xi(G^2,c)\, d\mu_K^{\mathrm{tw}} \le \mathrm{Ent}_{\tilde\mu_K}(G^2) + \mathsf{R}_{\mathrm{tw}} \sup \Xi(G^2,c)$ by (D1.2), and $\Xi(\cdot,c)$ is convex with $0 \le G^2 \le \mathsf{S}_G$, $c \le \mathsf{S}_G$, so $\sup \Xi(G^2,c) \le \mathsf{S}_G(1+\log \frac{\mathsf{S}_G}{c})$. If $c=0$, (D1.2) at $F=G^2$ gives $m_G \le \mathsf{R}_{\mathrm{tw}}\mathsf{S}_G$. When $m_G > 0$, $\int G^2 \log G^2\, d\mu_K^{\mathrm{tw}} \le m_G \log \mathsf{S}_G$, and subtracting $m_G \log m_G$ gives the stated bound. When $m_G = 0$ the entropy is zero.

(c) For $s>0$, $H_s := P_s^{\mathrm{tw}} H$ is smooth, gauge invariant and even, with $\mathrm{osc}(H_s) \le o := \mathrm{osc}(H)$. $y(s) := \mathrm{Var}(H_s) - \mathsf{R}_{\mathrm{tw}} o^2$ has $y' = -2\mathcal{E}_K^{\mathrm{tw}}(H_s) \le -\frac{2}{C_{\mathrm{W}}} y$ by (b); so $y(s) \le e^{-2(s-s_0)/C_{\mathrm{W}}} y(s_0)$ whatever the sign, and $s_0 \downarrow 0$ gives $\mathrm{Var}(P_u^{\mathrm{tw}} H) \le e^{-2u/C_{\mathrm{W}}}\mathrm{Var}(H) + (1-e^{-2u/C_{\mathrm{W}}})\mathsf{R}_{\mathrm{tw}} o^2$, the second inequality, since $\int P_u^{\mathrm{tw}} H\, d\mu_K^{\mathrm{tw}} = \int H\, d\mu_K^{\mathrm{tw}}$, the probability measure μ_K^{tw} being invariant for the dynamics; and $(H, (1-P_u^{\mathrm{tw}})H) = \mathrm{Var}(H) - \mathrm{Var}(P_{u/2}^{\mathrm{tw}} H)$ gives the first.

(d) Fix a unit vector $e \in \mathscr{H}$ of the top lattice. By Proposition 18.71(d), $V = \Upsilon_\varsigma(g,X) \mapsto X =: X(V)$ is a continuous, gauge-invariant, even map $\mathrm{In}(\epsilon) \to \mathcal{D}(\epsilon)$; put $\phi_\upsilon := \mathbf{1}\{V \in \mathrm{In}(\epsilon),\ \langle e, X(V)\rangle \le \upsilon\}$ for real υ. With $\hat\mu := \tilde\mu_{K,[n]}/\tilde\mu_K(1)$ and Proposition 18.72(a) (here $w_0 = 0$): $\varphi_K(\upsilon) := \hat\mu(\phi_\upsilon) = \int_{\mathcal{D}(\epsilon)\cap\{\langle e,X\rangle \le \upsilon\}} e^{-W} dX / \int_{\mathcal{D}(\epsilon)} e^{-W} dX$. $\mathcal{D}(\epsilon)$ is star-shaped, $\|X\| < 2\Xi_N\epsilon$ and $\|DW\| \le \mathsf{L}$ there, so $\mathrm{osc}\, W \le 4\Xi_N\epsilon\mathsf{L} =: \mathsf{O}$, a number free of K, the normalised density is at most $e^{\mathsf{O}}|\mathcal{D}(\epsilon)|^{-1}$, and $0 \le \varphi_K(\upsilon') - \varphi_K(\upsilon) \le \mathsf{L}'(\upsilon'-\upsilon)$ with $\mathsf{L}' := e^{\mathsf{O}}|\mathcal{D}(\epsilon)|^{-1} \sup_\upsilon \mathrm{vol}_{6\mathsf{v}-1}(\mathcal{D}(\epsilon) \cap \{\langle e, \cdot\rangle = \upsilon\}) < \infty$, free of K; $\varphi_K(-2\Xi_N\epsilon) = 0$ and $\varphi_K(2\Xi_N\epsilon) = 1$. On the grid $\upsilon_j = -2\Xi_N\epsilon + 0.1j/\mathsf{L}'$ there is a j with $\varphi_K(\upsilon_j) \le \frac12 < \varphi_K(\upsilon_{j+1})$, so $\varphi_K(\upsilon_j) \in [0.4, 0.5]$ and $\mathrm{Var}_{\hat\mu}(\phi_{\upsilon_j}) \ge 0.24$; $\mathcal{F}_{\mathrm{tw}}$ is the set of the ϕ_{υ_j} with $|\upsilon_j| \le 2\Xi_N\epsilon$. By (D1.1), $\phi(V_n)$ is gauge invariant and even on $\mathbf{\Omega}_K$; by (D1.2), $\mathrm{Var}_{\mu_K^{\mathrm{tw}}}(\phi(V_n)) = \min_c \int (\phi(V_n)-c)^2 d\mu_K^{\mathrm{tw}} \ge \min_c \int (\phi - c)^2 d\tilde\mu_{K,[n]} = \tilde\mu_K(1)\mathrm{Var}_{\hat\mu}(\phi)$, and $\tilde\mu_K(1) \ge 1 - \mathsf{R}_{\mathrm{tw}}$. Along a sequence one $\phi \in \mathcal{F}_{\mathrm{tw}}$ serves infinitely often; (c) with osc $= 1$, and $\frac12 \mathbb{E}|\phi(V_n(U_u)) - \phi(V_n(U_0))|^2 = (H, (1-P_u^{\mathrm{tw}})H)$ for $H = \phi(V_n)$ and the stationary process. As ϕ takes the values 0 and 1, this mean is half the mass that the law of the pair gives to $\{a \ne b\}$, and a law on the four points of $\{0,1\}^2$ converges point by point; so, where the laws of the pairs converge along the whole sequence, the limit of this mass is its limit along the subsequence. □

18.8. **The measure on the threads of one torus: the one invariant measure with the limits of the lattice means of the block algebra, the continuous translations on the gauge-invariant functions, and the local semigroup at a pair of mirrors.** This subsection adds three groups of statements to Proposition 10.2(a). Proposition 18.75 holds on every side $\ell = 2L^m$ and at every label $\mathsf{b} > 0$: the laws of the block fields converge in total variation; their images under $V \mapsto (\mathcal{M}^D V, \dots, \mathcal{M}V, V)$ are the finite pieces of exactly one Borel probability measure $\mu_{\ell,\mathsf{b}}$ on $\mathcal{X}$, which is carried by the threads; the joint laws of the block fields of the depths $0, \dots, D$ converge to its images in total variation; it is invariant under every θ_v; the lattice means of every element of the block algebra converge to its integral against $\mu_{\ell,\mathsf{b}}$; and among the Borel probability measures on $\mathcal{X}$ that are invariant under all the θ_v, these integrals single out $\mu_{\ell,\mathsf{b}}$. Proposition 18.76 is set in the one-torus setting. In its part (A), shifting the threads through vectors of $\mathbb{Q}_L^3$, $\mathbb{Q}_L = \bigcup_s a_s\mathbb{Z}$, gives Borel bijections that preserve μ; restricted to $\mathcal{K}^{\mathrm{inv}}$, the closed linear hull in $L^2(\mu)$ of the gauge-invariant functions of block fields, these shifts continue in a unique way to a strongly continuous unitary representation of $\mathbb{R}^3/\ell\mathbb{Z}^3$, and $\mathcal{K}^{\mathrm{inv}}$ splits orthogonally into the joint eigenspaces of the three momenta. In its part (B) we fix a coordinate mirror of T_ℓ, i.e. the two planes $x_\mu = c$ and $x_\mu = c + \frac{\ell}{2}$; on the functions of the block variables strictly between them the reflection form is non-negative; shifts normal to the planes act continuously for this form, with explicit moduli when the functions stay away from both planes; a shifted class vanishes only when the class itself vanishes; the classes of functions that stay away from the planes are dense; and a single self-adjoint operator $\mathfrak{h}_c$ has a semigroup that reproduces the shifts on these classes, so that the shifts make up a local semigroup with one generator. The continuity in (A) rests on Lemma 18.93. Together with a depth D_1 formed

from the constants and b, set below, it supplies numbers s_1 and C_A, formed from the constants, ℓ and b, with this property: for $s \geq s_1$, when the field of the depth s is shifted by one spacing a_s and transported back along the shifted bonds, the block field of a depth d with $D_1 \leq d < \lfloor s/5 \rfloor$ moves at a given bond by more than ρ, for any $\rho \in [L^{-s/6}, 2]$, on the threads whose plaquettes are small from the depth d to the depth s, with probability at most $\mathsf{C}_A \rho^{-1} L^{-s/21}$. There, the displacement of a block bond at the depth $j = \lfloor s/5 \rfloor + \lfloor \frac{1}{2} \lfloor s/5 \rfloor \rfloor$ is controlled by the plaquette moduli; the displacement at the depth $\lfloor s/5 \rfloor$ is, up to small errors, an average over columns of such displacements; and the average over one column is smaller by a power of the spacing, which comes from the reflection positivity of the Wilson measure at mirrors of both types, used for quantities with one adjoint charge carried along straight bare segments. Iterating the block averaging map is Lipschitz near small fields, and this lets one compose the shifts of all the finer spacings.

Further signs. We keep the setting and the labels of Section 10.1, and its signs wherever they are not set anew; the one-torus setting is the one that Section sets, with its constants. Several of its letters are set anew here for other objects, each at the place where it is used: among them are k, κ, N, γ and r, the letter m apart from the side $\ell = 2L^m$, and c', which also names bonds. Where one letter carries two meanings, its arguments tell them apart: with a depth alone as index, π_d is the coordinate of $\mathcal{X}$, whereas $\pi_i(b)$, with a bond as argument, is the imaginary part of the defect set below; with two sites as arguments, $\mathcal{G}(y,x)$ is a contour family, whereas $\mathcal{G}$ and $\mathcal{G}_i$, without arguments, are events, set in Lemmas 18.91 and 18.92 and in the proof of the latter. $\mathbb{Q}_L = \bigcup_{s \geq 0} a_s \mathbb{Z}$; as L is odd, $\frac{1}{2} \notin \mathbb{Q}_L$ and $\frac{1}{2}\mathbb{Q}_L \setminus \mathbb{Q}_L = \bigcup_s a_s(\mathbb{Z} + \frac{1}{2})$. For $y \in \Lambda_j$ and $n \geq 0$, the block of order n is

$$B^n(y) = \left\{ y + a_{j+n} \sum_{\mu=1}^{3} r_\mu e_\mu : r_\mu \in \mathbb{Z}, \quad |r_\mu| \leq (L^n - 1)/2 \right\}, \qquad B(y) = B^1(y).$$

The blocks partition the fine lattice and satisfy $B^{n+n'}(y) = \bigsqcup_{x \in B^n(y)} B^{n'}(x)$. Both facts follow by successive integer division with the centered remainder. A fine bond either stays in one such block or crosses to the adjacent block in its own direction. In the latter case it lies over the coarse bond joining the two block centers. Let c be a bond of Λ_j. We write P_c for the set of those bonds of Λ_{j+1} whose two end points lie in $B(c_-) \cup B(c_+)$, $\mathcal{G}(y,x)$ for the paths from $y \in \{c_-, c_+\}$ to $x \in B(y)$ that traverse each nonzero coordinate displacement in one straight segment, with all orders of those segments allowed, $[x, x']$ for the straight path leading from $x \in B(c_-)$ to $x' = x + c_+ - c_-$, $V[c]$ for the transport of a field V of Λ_{j+1} along the straight path leading from c_- to c_+, and $V(y,x)$, where it is defined, for the unique logarithmic group mean of $\{V(\Gamma) : \Gamma \in \mathcal{G}(y,x)\}$ in YM3_I:(31). The averaging radius is $\omega_M = 1/(200L^2)$ by YM3_I:(30). $\mathfrak{g}$ denotes the hermitian traceless 2×2 matrices, a real vector space carrying $\langle X, Y \rangle = \frac{1}{2} \operatorname{tr} XY$, so that $\langle X, X \rangle = |X|^2$; ${}^w X = wXw^{-1}$ for $w \in G$. For a complex 2×2 matrix Y put $\operatorname{Im} Y = \frac{1}{2i}(Y - Y^*)$, and for $w \in G$ put $\operatorname{Re} w = \frac{1}{2} \operatorname{tr} w \in [-1, 1]$; then $w = (\operatorname{Re} w)\mathbf{1} + i \operatorname{Im} w$, $\operatorname{Im} w \in \mathfrak{g}$ and $|w - \mathbf{1}|^2 = 2 - 2 \operatorname{Re} w$. By a 1-form we mean a function A of the bonds of a lattice, real or $\mathfrak{g}$-valued, with $A(\bar{b}) = -A(b)$; $A(\Gamma)$ adds its values along a path Γ, $\sup |A| = \max_b |A(b)|$, $(\mathrm{d}\lambda)(b) = \lambda(b_+) - \lambda(b_-)$ for a function λ on the sites, and $\mathrm{d}A(p) = A(\partial p)$ for a plaquette p; e^{iA} is the field $b \mapsto e^{iA(b)}$. For two fields W, W' of one lattice, $\operatorname{dist}_{\mathrm{orb}}(W', W) = \min_v \max_b |W'(b) - W^v(b)|$, the minimum over the gauge transformations v; it is symmetric, and the triangle inequality holds for it since multiplying by elements of G does not change the norm.

Block observables and symmetries. The block algebra consists of bounded continuous functions of finitely many bond variables from depths $0, \dots, s$ which are invariant under the joint action of any gauge transformation of Λ_s. At each smaller depth the gauge transformation is restricted to that depth. For such a function F, the notation $F \circ \mathcal{M}^{K-s}$ means evaluation of F on all the block fields it uses at the cutoff K.

Let Iso_i be the group of affine isometries of the torus that preserve Λ_i and its nearest-neighbor bonds. Their linear parts are signed coordinate permutations, and their translation vectors lie in $a_i\mathbb{Z}^3$ modulo the period. Thus $\mathsf{Iso}_i \subset \mathsf{Iso}_{i'}$ for $i \le i'$. We use the action $(rV)(b) = V(r^{-1}b)$ on oriented bonds. Isometries of the coarse lattice carry its centered blocks, contour families and straight paths onto the corresponding objects of the image bond. In the three real rules preceding Proposition YM3_I:4.5 a positively oriented image preserves the formula by relabeling these objects. If the image bond is reversed, set $P = V[c]$ and write the transport from c_- to c_+ through the two blocks as T, so that the relative loop is $W = TP^{-1}$. This applies to both averaged-contour and individual-contour transports. Reversal replaces T, P by T^{-1}, P^{-1} and W by $T^{-1}P = P^{-1}W^{-1}P$. It preserves the tests for each rule, since the operator norm is unitarily invariant and the exceptional point $-\mathbf{1}$ is central. Both logarithms send the new loop to $-P^{-1}(\log W)P$. Therefore the exponential of the mean followed by P^{-1} is the inverse of the old output. The rule with just P also transforms by inversion. This proves $\mathcal{M}(rV) = r\mathcal{M}(V)$ for a coarse-lattice isometry, and iteration gives the same identity for any compatible depths. The Wilson law at a finite cutoff is invariant under its lattice isometries. Indeed, the action is preserved by relabeling plaquettes, conjugating their holonomies or replacing them by their inverses, and the product Haar measure is preserved by relabeling or reversing bonds.

Numbers. $\varepsilon_{[i]} = \varepsilon(x_{[i]}) = A_0(L^i\mathsf{b})^{-1/2}(\log L^i\mathsf{b})^{\mathfrak{p}_0}$. Whenever $L^i\mathsf{b} > 1$, both $\varepsilon_{[i]}$ and $\varepsilon_{[i+1]}$ are defined, $0 < \log L^i\mathsf{b} < \log L^{i+1}\mathsf{b}$, and $\varepsilon_{[i]} \le L^{1/2}\varepsilon_{[i+1]}$ because $(\log L^i\mathsf{b})^{\mathfrak{p}_0} \le (\log L^{i+1}\mathsf{b})^{\mathfrak{p}_0}$; and if $\log(L^i\mathsf{b}) \ge 8\mathfrak{p}_0$, then $\varepsilon_{[i+1]}/\varepsilon_{[i]} = L^{-1/2}(1 + \frac{\log L}{\log L^i\mathsf{b}})^{\mathfrak{p}_0} \le L^{-1/2}e^{(\log L)/8} = L^{-3/8}$, so that $\sum_{i'>i}\varepsilon_{[i']} \le 0.62\,\varepsilon_{[i]}$ for $L \ge 13$. In the one-torus setting, $R_d \le \mathsf{A}_R L^{3d} e^{-a_R d^2}$ with $\mathsf{A}_R = 2\ell^3 M^{-3}\exp[(\mathsf{C}^{\Sigma}_{\mathrm{maj}} + 2 + c_{\mathrm{low}} + \frac{9}{2}\log\mathsf{b})\ell^3]$ and $a_R = c'A_0^2(\log L)^2$, because $(\log x_{[d]})^{2\mathfrak{p}_0} \ge (d\log L)^2$; d_Σ is the least integer $d \ge d_\natural$ with $c'A_0^2\log x_{[d]} \ge 2$, so that $R_{d+1} \le L^{-1}R_d$ and $\sum_{d'\ge d} R_{d'} \le \frac{L}{L-1}R_d$ for $d \ge d_\Sigma$ (Proposition 10.2(b) and its proof). For integers $D \le s$, $\mathsf{Gd}_{D,s}$ is the set of the $V \in \mathcal{V}_s$ with $\mathcal{M}^{s-i}V \in I_i$ for $D \le i \le s$, a Borel set, and Gd_D is the set of the threads $V_\bullet$ with $V_i \in I_i$ for all $i \ge D$.

Translations and reflections of fields and of threads. For $h \in a_s\mathbb{Z}^3$ and a field V of a depth $j \ge s$ put $(\mathrm{t}_h V)(b) = V(b-h)$; the translation by h lies in Iso_s. An element of Iso_j is called diagonal when its linear part is a diagonal matrix. The diagonal elements of Iso_j form a group; each of them is the composite of a translation through a vector of $a_j\mathbb{Z}^3$ and of a change of sign of some of the coordinates, and among them are the translations through vectors of $a_j\mathbb{Z}^3$ and the coordinate mirrors $x \mapsto x - 2(x_\mu - c)e_\mu$ with $c \in \frac{a_j}{2}\mathbb{Z}$. For $h \in \mathbb{Q}^3_L$, s the smallest non-negative integer with $h \in a_s\mathbb{Z}^3$, and $V_\bullet \in \mathcal{X}$ put $(\mathrm{T}_h V_\bullet)_j = \mathrm{t}_h V_j$ for $j \ge s$ and $(\mathrm{T}_h V_\bullet)_j = \mathcal{M}^{s-j}(\mathrm{t}_h V_s)$ for $j < s$; for a function F on $\mathcal{X}$, or on Thr, put $\mathcal{U}_h F = F \circ \mathrm{T}_{-h}$, which on Thr is defined because T_{-h} maps Thr into itself (Lemma 18.77(b)). In the same way, for a diagonal element r of $\bigcup_{s\ge 0}\mathsf{Iso}_s$, with s now the smallest non-negative integer such that $\mathsf{r} \in \mathsf{Iso}_s$, put $(\mathsf{r}^\bullet V_\bullet)_j = \mathsf{r}V_j$ for $j \ge s$ and $(\mathsf{r}^\bullet V_\bullet)_j = \mathcal{M}^{s-j}(\mathsf{r}V_s)$ for $j < s$. Since $\mathsf{Iso}_s \subset \mathsf{Iso}_{s'}$ for $s \le s'$, these formulas make sense with any integer $s' \ge s$ in the place of s; on threads the outcome is then unchanged (Lemma 18.77(b)), while elsewhere the choice just made fixes $\mathsf{r}^\bullet$. $\mathcal{K}^{\mathrm{inv}}$ is the closed span in $L^2(\mu)$ of the functions $F \circ \pi_d$, $d \ge 0$, F a bounded gauge-invariant Borel function on $\mathcal{V}_d$.

The covariant shift. Let $\nu \in \{1,2,3\}$, $s \ge 1$, $h = a_s e_\nu$ or $h = -a_s e_\nu$, and $V \in \mathcal{V}_s$; put $V_i = \mathcal{M}^{s-i}V$ and $V'_i = \mathcal{M}^{s-i}(\mathrm{t}_h V)$ for $i \le s$. With $g(x) = V(\langle x-h, x\rangle)$, $x \in \Lambda_s$, the covariantly shifted field is $\check V(b) = g(b_-)^{-1}(\mathrm{t}_h V)(b)\,g(b_+)$; we put $\check V_i = \mathcal{M}^{s-i}\check V$, and for the bonds b of Λ_i, $i \le s$, the defect $\mathsf{P}_i(b) = \check V_i(b)V_i(b)^{-1}$ and $\pi_i(b) = \operatorname{Im}\mathsf{P}_i(b) \in \mathfrak{g}$. Where a thread $V_\bullet$ is given, these objects are formed from its entry V_s, and $V'_{d,s} = \mathcal{M}^{s-d}(\mathrm{t}_h V_s) = (\mathrm{T}_h V_\bullet)_d$ for threads.

Bare lines. At a cutoff $K > s$ the bare field is $U \in \mathcal{V}_K$, $V_i = \mathcal{M}^{K-i}U$, and then $V'_i = \mathcal{M}^{K-i}(\mathrm{t}_h U)$ by block equivariance; $\mathbb{E}$ is the Wilson mean $\langle\cdot\rangle_K$ at any $\beta > 0$, and at $\beta = L^K\mathsf{b}$ when the one-torus setting is assumed; $\|F\|_2 = (\mathbb{E}|F|^2)^{1/2}$ and $\mathbb{E}[F;\mathcal{E}] = \mathbb{E}[F\mathbf{1}_\mathcal{E}]$. The height of a point

is its coordinate x_ν, and a column is the set of the sites of Λ_K with two given coordinates x_κ, $\kappa \neq \nu$. When x, y are sites on a common column with $|x_\nu - y_\nu| < \frac{\ell}{2}$, we write $\mathsf{L}(x,y) = U([x,y])$ for the bare transport along the straight segment from x to y: $\mathsf{L}(x,x) = \mathbf{1}$, $\mathsf{L}(y,x) = \mathsf{L}(x,y)^{-1}$, $\mathsf{L}(x,y)\mathsf{L}(y,w) = \mathsf{L}(x,w)$ for three sites of one column in a window of heights shorter than $\frac{\ell}{2}$, and a gauge transformation v of Λ_K carries $\mathsf{L}(x,y)$ to $v(x)\mathsf{L}(x,y)v(y)^{-1}$. A function S of the bare field with values in G or in $\mathfrak{g}$ is covariant at a site x if $S(U^v) = v(x)S(U)v(x)^{-1}$ for all v. For a positively oriented bond $b \parallel e_\nu$ of Λ_i, $i \le K$, a site x of Λ_i and $n \ge 0$ with $na_i < \frac{\ell}{4}$ put $z_i(b) = V_i(b)\mathsf{L}(b_+, b_-)$, $Z_i(x;n) = V_i([x, x+na_ie_\nu])\,\mathsf{L}(x+na_ie_\nu, x)$ and $\sigma_i(n) = \|Z_i(x;n) - \mathbf{1}\|_2$. $z_i(b)$ and $Z_i(x;n)$ are covariant at b_- and at x; $\sigma_i(n)$ is the same for all x, since translating Λ_K leaves the Wilson measure unchanged and $\mathcal{M}^{K-i}$ commutes with the translations by $a_i\mathbb{Z}^3$ by block equivariance; $\sigma_i(0) = 0$, $\sigma_K \equiv 0$, and $\sigma_i(n)^2 = 2 - 2\,\mathbb{E}\,\mathrm{Re}\,Z_i(x;n)$.

Constants of the shift. $\rho_L = \frac{1}{1600L^2}$, $C_g = 50L^2$, $\mathsf{k}_1 = 600L^3$, $c_{\mathrm{d}} = 2(\sqrt{2}+1)$; C_N is the number of Lemma 18.80(a), $\mathsf{k}_2 = 8C_NL^{-1}(3.9\,C_g\mathsf{k}_1 + 2.8\,\mathsf{k}_1^2)$ and $c_* = \min\{\frac{L(L-1)}{32C_N}, \frac{\rho_L}{4}\}$; all these are formed from L alone. D_g is the least integer $j \ge 0$ with $\log(L^j\mathsf{b}) \ge 8\mathfrak{p}_0$, $C_g\varepsilon_{[j]} \le \frac{\rho_L}{2}$, $\mathsf{k}_1\varepsilon_{[j]} \le \frac{\rho_L}{4}$ and $53\,C_NC_g\varepsilon_{[j]} \le L$; it is formed from the constants and b, and $17000L^3\varepsilon_{[j]} \le 1$ for $j \ge D_g$. $D_1 = \max\{D_g, d_\Sigma, d_\Theta\}$, where d_Θ is the least integer $d \ge 1$ with $x_{[d]} = L^d\mathsf{b} \ge \Theta_\star$, and $\Theta_\star > 1$ is chosen from the fixed constants so that $2c_\rho\varepsilon(x) < \omega_M$ for all $x \ge \Theta_\star$, possible since $x^{-1/2}(\log x)^{\mathfrak{p}_0} \to 0$; so $2c_\rho\varepsilon_{[i]} < \omega_M$ for every $i \ge D_1$. For integers $j \le s$ put $\mathsf{E}_s = L^s\varepsilon_{[s]}^2 = A_0^2\mathsf{b}^{-1}(\log L^s\mathsf{b})^{2\mathfrak{p}_0}$ and $\bar\eta_j = \mathsf{k}_1(2+s-j)\varepsilon_{[s]} + \mathsf{k}_2\mathsf{E}_sL^{-j}$; and, for the integer $j < s$ that the context fixes, $\mathsf{H}_s = \mathsf{k}_2\mathsf{E}_s + \mathsf{k}_1(2+s)L^j\varepsilon_{[s]}$. The diagonal of an integer s: $D = \lfloor s/5 \rfloor$, $\mathfrak{m} = \lfloor D/2 \rfloor$, $j = D + \mathfrak{m}$, $N = L^{\mathfrak{m}}$, $K = 1260s$, $\mathfrak{t} = 31000$; $\mathsf{e} = \mathsf{e}(s) = \max\{1, A_0\mathsf{b}^{-1/2}(\log L^{1260s}\mathsf{b})^{\mathfrak{p}_0}\}$, so that $L^{i/2}\varepsilon_{[i]} \le \mathsf{e}$ for $i \le K$, $\mathsf{E}_s \le \mathsf{e}^2$ and $\mathsf{e} \le C_{\mathsf{e}}s^{\mathfrak{p}_0}$ with C_{e} formed from A_0, $\mathfrak{p}_0$, L and b; on the diagonal, H_s takes the j of the diagonal. We say that a statement holds for large s when it is true for every integer s beyond some threshold formed from the constants, ℓ and b.

Mirrors acting on threads. Let $\mu \in \{1,2,3\}$, $d_0 \ge 0$ an integer and $c \in \frac{a_{d_0}}{2}\mathbb{Z}$; θ is the coordinate mirror $x \mapsto x - 2(x_\mu - c)e_\mu$, a diagonal element of Iso_{d_0}; it fixes the two planes $x_\mu = c$ and $x_\mu = c + \frac{\ell}{2}$, and $\mathbb{E}_+ = \{c < x_\mu < c + \frac{\ell}{2}\}$. It is of the site type if $c \in \mathbb{Q}_L$, and then $c \in a_j\mathbb{Z}$ for every $j \ge d_0$; it is of the bond type otherwise, and then $c \in a_j(\mathbb{Z} + \frac{1}{2})$ for every $j \ge d_0$, as L^{j-d_0} is odd. For $j \ge d_0$ and real $\alpha, \alpha' \ge 0$, $\mathsf{Bd}_j(\alpha,\alpha')$ collects the bonds of Λ_j whose two end points obey $c + \alpha + \frac{1}{2}a_j \le x_\mu \le c + \frac{\ell}{2} - \alpha' - \frac{1}{2}a_j$; $\mathcal{A}_j(\alpha,\alpha')$ consists of the functions $V_\bullet \mapsto \mathsf{f}(V_j|_{\mathsf{Bd}_j(\alpha,\alpha')})$ on Thr, f bounded, complex and Borel, and $\mathcal{A}(\alpha,\alpha') = \bigcup_{j \ge d_0}\mathcal{A}_j(\alpha,\alpha')$. As $\mathcal{M}$ is Borel, Thr is a Borel subset of $\mathcal{X}$, and $\mu(\mathsf{Thr}) = 1$ (Proposition 18.75(2)); so these functions are elements of $L^2(\mu)$, and the maps T_h and $\mathsf{r}^\bullet$, r diagonal, which send Thr into itself (Lemma 18.77(b)), act on them by composition. For functions F on Thr, $\Theta F = F \circ \theta^\bullet$; $\langle F, F'\rangle_c = \int \overline{\Theta F}\,F'\,d\mu$ and $\|F\|_c = \langle F, F\rangle_c^{1/2}$ for $F, F' \in \mathcal{A}(0,0)$; $\mathcal{K}_c$ is the completion of $\mathcal{A}(0,0)$ modulo the vectors F with $\|F\|_c = 0$, and $[F]$ the class of F. For $t \in \mathbb{Q}_L$, $\mathcal{U}_t = \mathcal{U}_{te_\mu}$, and $\varphi_F(t) = \int \overline{\Theta F}\,\mathcal{U}_tF\,d\mu$. The objects of a second mirror (μ, c^*) carry the index c^*: Θ_{c^*}, $\langle\cdot,\cdot\rangle_{c^*}$, $\mathcal{A}^{c^*}(\alpha,\alpha')$. ϱ is the reflection at the plane $x_\mu = c + \frac{\ell}{4}$, and $RF = F \circ \varrho^\bullet$.

Proposition 18.75 (One measure on the threads at every label, and the integrals of the block algebra)**.** Let $m \in \mathbb{N}$, $\ell = 2L^m$ and let $\mathsf{b} > 0$ be real; let $\langle\cdot\rangle_K$ be the Wilson measure on $\mathcal{V}_K$ with the density $Z^{-1}e^{-L^K\mathsf{b}\sum_p a_p}$ for dU, and for $K \ge \max\{d,1\}$ let μ_d^K be the law of $\mathcal{M}^{K-d}U$ under it. Put $\iota_D(V) = (\mathcal{M}^DV, \dots, \mathcal{M}V, V)$ for $V \in \mathcal{V}_D$ and $\pi_{\le D} = (\pi_0, \dots, \pi_D)$.

(1) For every $d \ge 0$ the laws μ_d^K converge in total variation, as $K \to \infty$ along all the integers, to a gauge-invariant Borel probability measure μ_d on $\mathcal{V}_d$, and $\mathcal{M}_*\mu_{d+1} = \mu_d$.

(2) Exactly one Borel probability measure $\mu_{\ell,\mathsf{b}}$ on $\mathcal{X}$ satisfies $(\pi_{\le D})_*\mu_{\ell,\mathsf{b}} = (\iota_D)_*\mu_D$ for all $D \ge 0$; moreover $(\pi_D)_*\mu_{\ell,\mathsf{b}} = \mu_D$ and $\mu_{\ell,\mathsf{b}}(\mathsf{Thr}) = 1$. For every $D \ge 0$ the joint law ν_D^K of

$(\mathcal{M}^K U, \mathcal{M}^{K-1}U, \dots, \mathcal{M}^{K-D}U)$ under $\langle\cdot\rangle_K$ converges to the image of $\mu_{\ell,\mathsf{b}}$ under $\pi_{\le D}$ in total variation as $K\to\infty$. In the one-torus setting $\mu_{\ell,\mathsf{b}}$ is the measure μ of Proposition 10.2(a).

(3) For every map $v\colon \bigcup_d \Lambda_d \to G$, θ_v is a homeomorphism of $\mathcal{X}$ that carries Thr onto itself and $\mu_{\ell,\mathsf{b}}$ to itself.

(4) Let F belong to the block algebra, with s the largest depth occurring in it, and regard F as a function on $\mathcal{V}_0\times\cdots\times\mathcal{V}_s$ of the variables $V_{s'}(b)$, $s'\le s$. Then $\lim_{K\to\infty}\langle F\circ\mathcal{M}^{K-s}\rangle_K = \int F\circ\pi_{\le s}\,d\mu_{\ell,\mathsf{b}}$. If μ' is a Borel probability measure on $\mathcal{X}$ that is invariant under every θ_v and satisfies $\int F\circ\pi_{\le s}\,d\mu' = \lim_K\langle F\circ\mathcal{M}^{K-s}\rangle_K$ for every element F of the block algebra, s its largest depth, then $\mu'=\mu_{\ell,\mathsf{b}}$.

■

Sketch of proof. (1), (2). Choose an integer $s\ge 0$ so that $\mathsf{b}' = L^s\mathsf{b}\ge\gamma^{-2}$ and $MQ(\mathsf{b}')\le L^{m+s}$. Such an s exists because Q grows at most as a power of the logarithm. At depth $d\ge s$, the dilation $D_s : x\mapsto L^s x$ identifies the lattice of T_ℓ with the depth-$d-s$ lattice of $T_{L^s\ell}$, preserving bond orientation and the relative positions of the blocks. The block map commutes with this identification. For $K\ge d$ the Wilson couplings agree, $L^{K-s}\mathsf{b}' = L^K\mathsf{b}$, and the Haar measures correspond bond by bond. Thus

$$(D_s)_*\mu_d^K[\ell,\mathsf{b}] = \mu_{d-s}^{K-s}[L^s\ell,\mathsf{b}'].$$

Proposition 10.2(a) gives total variation convergence on the admitted torus on the right. Pulling back gives convergence for $d\ge s$. For $d<s$ the identity $\mu_d^K = (\mathcal{M}^{s-d})_*\mu_s^K$ and contraction of total variation under a push-forward give convergence. Gauge invariance follows from gauge covariance of the block map and gauge invariance of the finite-cutoff measures. The finite-cutoff relation $\mathcal{M}_*\mu_{d+1}^K = \mu_d^K$ passes to the limit by the same contraction. Consequently the laws $(\iota_D)_*\mu_D$ on the finite products are consistent. Kolmogorov extension gives a unique measure $\mu_{\ell,\mathsf{b}}$ with these finite pieces and marginals μ_D. It gives each relation $\mathcal{M}V_{d+1}=V_d$ probability one, hence gives the threads full measure by countable intersection. In the one-torus setting it agrees with the measure of Proposition 10.2(a) under every $\pi_{\le D}$, hence the two measures coincide. For $d\le D\le K$ one has $\mathcal{M}^{K-d} = \mathcal{M}^{D-d}\circ\mathcal{M}^{K-D}$, so $\nu_D^K = (\iota_D)_*\mu_D^K$, and ι_D is Borel because $\mathcal{M}$ is (Proposition YM3_I: 4.5). Pushing two measures forward by one measurable map cannot enlarge their distance in total variation; thus $\sup_B|\nu_D^K(B)-(\iota_D)_*\mu_D(B)|\le\sup_E|\mu_D^K(E)-\mu_D(E)|$, which tends to 0, while $(\iota_D)_*\mu_D = (\pi_{\le D})_*\mu_{\ell,\mathsf{b}}$.

(3). At a bond b of Λ_d the entry of $\theta_v V_\bullet$ equals $v(b_-)V_d(b)v(b_+)^{-1}$, which depends continuously on $V_\bullet$; hence θ_v is continuous, the gauge rule $V^v(b) = v(b_-)V(b)v(b_+)^{-1}$ gives $\theta_{v'}\theta_v=\theta_{v'v}$, and $\theta_{v^{-1}}$ undoes θ_v. Averaging commutes with gauge transformations by YM3_I:(40). Iterating this identity restricts the gauge transformation to the coarsest lattice. In particular, $\mathcal{M}(V_{d+1}^{v|\Lambda_{d+1}}) = \mathcal{M}(V_{d+1})^{v|\Lambda_d}$. Therefore θ_v and $\theta_{v^{-1}}$ send threads to threads. On $\mathcal{X}_D=\mathcal{V}_0\times\cdots\times\mathcal{V}_D$ let a gauge transformation w of Λ_D act entrywise, $\theta_w^{(D)}\colon V_d\mapsto V_d^{w|\Lambda_d}$. Then $\pi_{\le D}\circ\theta_v = \theta^{(D)}_{v|\Lambda_D}\circ\pi_{\le D}$, and $D-d$ applications of the covariance give $\iota_D(V^w) = \theta_w^{(D)}\iota_D(V)$. Consequently $(\pi_{\le D})_*(\theta_v)_*\mu_{\ell,\mathsf{b}}$ is the push-forward of μ_D by $V\mapsto\iota_D(V^{v|\Lambda_D})$; as μ_D is gauge invariant, this is $(\iota_D)_*\mu_D$, and the uniqueness part of (2) yields $(\theta_v)_*\mu_{\ell,\mathsf{b}}=\mu_{\ell,\mathsf{b}}$.

(4), the limit. Unwinding the definitions, $\langle F\circ\mathcal{M}^{K-s}\rangle_K = \int F\circ\iota_s\,d\mu_s^K$, with a bounded Borel integrand. If ν,ν' are probability measures on a common σ-algebra and f is bounded, complex and measurable, then $|\int f\,d\nu-\int f\,d\nu'|\le 4\sup|f|\sup_E|\nu(E)-\nu'(E)|$, as one sees by writing f as a signed and complex combination of four non-negative functions, each bounded by $\sup|f|$. By (1), therefore, the means converge to $\int F\circ\iota_s\,d\mu_s$, and (2) identifies this number with $\int F\circ\pi_{\le s}\,d\mu_{\ell,\mathsf{b}}$.

(4), the uniqueness. Fix D. The gauge transformations of Λ_D form the compact group G^{Λ_D}; write dw for its normalized Haar measure. A continuous f on the compact metrisable space $\mathcal{X}_D$ is averaged over the gauge orbits: $\bar f(X) = \int f(\theta_w^{(D)}X)\,dw$. The integrand is jointly continuous in

(w, X) and bounded, so dominated convergence makes $\bar f$ continuous; and $\bar f \circ \theta^{(D)}_{w'} = \bar f$ for all w', since $\theta^{(D)}_w \theta^{(D)}_{w'} = \theta^{(D)}_{ww'}$ and right translation by w' preserves dw. Thus $\bar f$ is a bounded continuous function of the finitely many variables $V_d(b)$, $d \le D$, unchanged when one gauge transformation of Λ_D acts on all of them together; that is, $\bar f$ belongs to the block algebra, with largest depth D. Write $\nu'_D = (\pi_{\le D})_* \mu'$ and $\nu_D = (\pi_{\le D})_* \mu_{\ell,\mathsf{b}}$. Extending w by $\mathbf{1}$ off Λ_D gives a map v with $\pi_{\le D} \circ \theta_v = \theta^{(D)}_w \circ \pi_{\le D}$, so the hypothesis on μ' and part (3) make ν'_D and ν_D invariant under all the $\theta^{(D)}_w$. Averaging the identity $\int f \, d\nu'_D = \int f \circ \theta^{(D)}_w \, d\nu'_D$ in w and exchanging the integrals (Fubini's theorem) yields $\int f \, d\nu'_D = \int \bar f \, d\nu'_D$; likewise $\int f \, d\nu_D = \int \bar f \, d\nu_D$. Applying the hypothesis to $F = \bar f$ and comparing with the limit above, $\int \bar f \, d\nu'_D = \int \bar f \, d\nu_D$. So ν'_D and ν_D integrate every continuous function alike; as finite Borel measures on compact metrisable spaces are determined by their integrals of continuous functions, $\nu'_D = \nu_D$. As D was arbitrary, the uniqueness part of (2) gives $\mu' = \mu_{\ell,\mathsf{b}}$. □

Proposition 18.76 (Translations of the threads; the local semigroup at a pair of mirrors)**.** Assume the one-torus setting.

(A) *The translations.*

(A1) Let $h, h' \in \mathbb{Q}^3_L$. Then $\mathrm{T}_h \colon \mathcal{X} \to \mathcal{X}$ is Borel, restricts to a bijection of Thr, and satisfies $(\mathrm{T}_h)_* \mu = \mu$. On Thr, moreover, T_h is unchanged when any integer $s' \ge s$ takes the place of s in its definition, $\mathrm{T}_h \mathrm{T}_{h'} = \mathrm{T}_{h+h'}$, and T_h is the identity when $h \in \ell\mathbb{Z}^3$. Hence $h \mapsto \mathcal{U}_h$ represents the group $\mathbb{Q}^3_L/\ell\mathbb{Z}^3$ by unitary operators on $L^2(\mu)$, each mapping $\mathcal{K}^{\mathrm{inv}}$ onto itself. In the same way, for each diagonal element r of $\bigcup_s \mathsf{Iso}_s$, $\mathsf{r}^\bullet$ is Borel, permutes Thr and preserves μ.

(A2) For every $d \ge 0$ and every bounded gauge-invariant Borel function F on $\mathcal{V}_d$, $\|\mathcal{U}_v(F \circ \pi_d) - F \circ \pi_d\|_{L^2(\mu)} \to 0$ as $v \to 0$ in $\mathbb{Q}^3_L$.

(A3) A unique strongly continuous unitary representation $x \mapsto \mathcal{U}(x)$ of $\mathbb{R}^3/\ell\mathbb{Z}^3$ on $\mathcal{K}^{\mathrm{inv}}$ satisfies $\mathcal{U}(v) = \mathcal{U}_v|_{\mathcal{K}^{\mathrm{inv}}}$ for all $v \in \mathbb{Q}^3_L$; and $\mathcal{K}^{\mathrm{inv}}$ decomposes as the orthogonal direct sum of the spaces $\mathcal{K}_k = \{\psi \in \mathcal{K}^{\mathrm{inv}} : \mathcal{U}(x)\psi = e^{ik\cdot x}\psi \text{ for all } x\}$, $k \in \frac{2\pi}{\ell}\mathbb{Z}^3$.

(B) *A pair of mirrors.* Fix a coordinate mirror (μ, c), $c \in \frac{a_{d_0}}{2}\mathbb{Z}$, of either type, together with the objects that the notation attaches to it.

(B1) On $\mathcal{A}(0,0)$ the form $\langle \cdot, \cdot \rangle_c$ is hermitian, $\langle F, F\rangle_c \ge 0$, and $\|F\|_c \le \|F\|_{L^2(\mu)}$.

(B2) For every $F \in \mathcal{A}(0,0)$, $\int \overline{\Theta F}\, \mathcal{U}_t F \, d\mu \to \int \overline{\Theta F}\, F \, d\mu$ as $t \to 0$ in $\mathbb{Q}_L$, from either side. For $\alpha' > 0$ and $F \in \mathcal{A}(0, \alpha')$, $\|\mathcal{U}_t F - F\|_c \to 0$ as $t \downarrow 0$ in $\mathbb{Q}_L$; for $\alpha > 0$ and $F \in \mathcal{A}(\alpha, 0)$, $\|\mathcal{U}_{-t} F - F\|_c \to 0$ as $t \downarrow 0$ in $\mathbb{Q}_L$. For $\alpha, \alpha' > 0$, $F \in \mathcal{A}(\alpha, \alpha')$ and $t \in \mathbb{Q}_L$: $\|\mathcal{U}_t F - F\|_c^2 \le t(\frac{1}{2\alpha} + \frac{1}{\alpha'})\|F\|^2_{L^2(\mu)}$ if $0 \le t \le \frac{\alpha'}{2}$, and $\|\mathcal{U}_{-t} F - F\|_c^2 \le t(\frac{1}{\alpha} + \frac{1}{2\alpha'})\|F\|^2_{L^2(\mu)}$ if $0 \le t < \frac{\alpha}{2}$.

(B3) For $\alpha' > 0$, $F \in \mathcal{A}(0, \alpha')$ and $t \in \mathbb{Q}_L$ with $0 < t < \alpha'$: $\|\mathcal{U}_t F\|_c = 0$ if and only if $\|F\|_c = 0$.

(B4) $\bigcup_{\alpha, \alpha' > 0} \mathcal{A}(\alpha, \alpha')$ is dense in $\mathcal{A}(0,0)$ for the norm of $L^2(\mu)$, with approximants of a function F bounded by $\sup |F|$; so the classes of its elements are dense in $\mathcal{K}_c$.

(B5) On $\mathcal{K}_c$ a unique self-adjoint operator $\mathfrak{h}_c$ has the following property: whenever $\alpha' > 0$, $F \in \mathcal{A}(0, \alpha')$ and $t \in \mathbb{Q}_L \cap [0, \alpha')$, the class $[F]$ belongs to the domain of $e^{-t\mathfrak{h}_c}$ and $e^{-t\mathfrak{h}_c}[F] = [\mathcal{U}_t F]$. Moreover $\mathfrak{h}_c[1] = 0$; the identity holds also at $t = \alpha'$ if $\alpha' \in \mathbb{Q}_L$; and for $\alpha, \alpha' > 0$, $F \in \mathcal{A}(\alpha, \alpha')$ and $t \in \mathbb{Q}_L \cap (0, \alpha]$, $[F]$ lies in the domain of $e^{t\mathfrak{h}_c}$ and $e^{t\mathfrak{h}_c}[F] = [\mathcal{U}_{-t} F]$.

■

Lemma 18.77 (Translations and reflections of the threads; the form at a mirror)**.** Assume the one-torus setting.

(a) For every diagonal element r of Iso_j: $\mathsf{r}_* \mu_j^K = \mu_j^K$ for $K \ge \max\{j, 1\}$, and $\mathsf{r}_* \mu_j = \mu_j$.

(b) Let $s \ge 0$ be an integer and $h, h' \in a_s \mathbb{Z}^3$. For a thread $V_\bullet$ and every integer $s' \ge s$, the sequence that the definition of $\mathrm{T}_h V_\bullet$ gives with s' in the place of the smallest non-negative

integer used there is $\mathrm{T}_h V_\bullet$. The map $\mathrm{T}_h\colon \mathcal{X}\to\mathcal{X}$ is Borel and sends Thr into Thr; on Thr, $\mathrm{T}_h\mathrm{T}_{h'}=\mathrm{T}_{h+h'}$, and T_h is the identity when $h\in\ell\mathbb{Z}^3$; and $(\mathrm{T}_h)_*\mu=\mu$. Any Borel probability measure on $\mathcal{X}$ that gives Thr full measure and is mapped by π_j to μ_j for every $j\ge s$ equals μ. The same holds for $\mathsf{r}^\bullet$, r a diagonal element of Iso_s; and for two diagonal elements $\mathsf{r}_1,\mathsf{r}_2$ of Iso_s, whose product is again one, $(\mathsf{r}_1\mathsf{r}_2)^\bullet=\mathsf{r}_1^\bullet\mathsf{r}_2^\bullet$ on Thr.

(c) Let (μ,c) be a mirror with $c\in\frac{a_{d_0}}{2}\mathbb{Z}$ and let $j\ge d_0$; all functions are understood as functions on Thr, where $\mathcal{U}_t$, Θ, Θ_{c^*} and R act by means of (b). Then $\mathcal{A}_j(\alpha,\alpha')\subset\mathcal{A}_{j+1}(\alpha,\alpha')$, hence $\mathcal{A}(\alpha,\alpha')$ is an algebra that is stable under conjugation; $\mathsf{Bd}_j(0,0)$ consists of those bonds of Λ_j whose two end points lie in $\mathbb{E}_+$; if the mirror is of the site type, then $\mathcal{A}_j(0,0)=\mathcal{A}_j(\frac{a_j}{2},\frac{a_j}{2})$; for $t\in\mathbb{Q}_L$ with $-\alpha\le t\le\alpha'$ one has $\mathcal{U}_t\mathcal{A}(\alpha,\alpha')\subset\mathcal{A}(\alpha+t,\alpha'-t)$; $\Theta\mathcal{U}_t=\mathcal{U}_{-t}\Theta$ and $\Theta^2=1$, while $\Theta_{c^*}\mathcal{U}_t=\Theta_c$ when $c^*=c+\frac{t}{2}$; further, ϱ is one of the diagonal elements of Iso_{d_0}, and $R\mathcal{A}(\alpha,\alpha')=\mathcal{A}(\alpha',\alpha)$, $R\Theta=\Theta R$, $R\mathcal{U}_tR=\mathcal{U}_{-t}$, $R^2=1$.

(d) For mirrors of both types, the form $\langle\cdot,\cdot\rangle_c$ on $\mathcal{A}(0,0)$ is hermitian and non-negative, and $\|F\|_c\le\|F\|_{L^2(\mu)}$.

■

Sketch of proof. (a) Take a Borel set $E\subset\mathcal{V}_j$. Since r is a diagonal isometry of each Λ_i with $i\ge j$, block equivariance lets it pass through all the averaging steps from Λ_K down to Λ_j: $\mu_j^K(\mathsf{r}^{-1}E)=\langle\mathbf{1}_E(\mathsf{r}\mathcal{M}^{K-j}U)\rangle_K=\langle\mathbf{1}_E(\mathcal{M}^{K-j}(\mathsf{r}U))\rangle_K$. Diagonal isometries of Λ_K do not change the Wilson measure, so the last mean is $\mu_j^K(E)$; letting $K\to\infty$ in total variation (Corollary 2.8(c)) gives $\mathsf{r}_*\mu_j=\mu_j$. (b) Let $V_\bullet$ be a thread, $h\in a_s\mathbb{Z}^3$ and $s'>s$. For $s\le j<s'$, block equivariance yields $\mathcal{M}^{s'-j}(\mathrm{t}_hV_{s'})=\mathrm{t}_h\mathcal{M}^{s'-j}V_{s'}=\mathrm{t}_hV_j$, and for $j<s$ one has $\mathcal{M}^{s'-j}(\mathrm{t}_hV_{s'})=\mathcal{M}^{s-j}(\mathcal{M}^{s'-s}(\mathrm{t}_hV_{s'}))=\mathcal{M}^{s-j}(\mathrm{t}_hV_s)$. Thus s and s' produce one and the same sequence, and the same computation shows $\mathcal{M}((\mathrm{T}_hV_\bullet)_{j+1})=(\mathrm{T}_hV_\bullet)_j$, so that $\mathrm{T}_hV_\bullet$ is again a thread. Using one s for both h and h', the entries of $\mathrm{T}_h\mathrm{T}_{h'}V_\bullet$ are $\mathrm{t}_{h+h'}V_j$ for $j\ge s$ and $\mathcal{M}^{s-j}(\mathrm{t}_{h+h'}V_s)$ for $j<s$, i.e. those of $\mathrm{T}_{h+h'}V_\bullet$; and t_h is the identity for $h\in\ell\mathbb{Z}^3$. Hence T_h permutes Thr, with the inverse T_{-h}, and its entries are Borel because $\mathcal{M}$ is (Proposition YM3_I:4.5). The push-forward $(\mathrm{T}_h)_*\mu$ gives Thr full measure, and for $j\ge s$ its image under π_j is $(\mathrm{t}_h)_*\mu_j=\mu_j$ by (a). Now let μ' be any Borel probability measure on $\mathcal{X}$ with $\mu'(\mathsf{Thr})=1$ and $(\pi_j)_*\mu'=\mu_j$ for $j\ge s$. On Thr the identity $\pi_{\le j}=\iota_j\circ\pi_j$ holds, so $(\pi_{\le j})_*\mu'=(\iota_j)_*\mu_j$ for $j\ge s$, and the smaller j follow by projecting; the uniqueness in Proposition 10.2(a) then gives $\mu'=\mu$, and in particular $(\mathrm{T}_h)_*\mu=\mu$. For $\mathsf{r}^\bullet$ the argument is identical, and the rule for products comes from $(\mathsf{r}_1(\mathsf{r}_2V))(b)=V(\mathsf{r}_2^{-1}\mathsf{r}_1^{-1}b)$. (c) *Nesting.* On a thread $V_j(b)=\mathcal{M}(V_{j+1})(b)$, and by Proposition YM3_I:4.5 this value involves only those bonds of Λ_{j+1} whose two end points lie in $B(b_-)\cup B(b_+)$, and the coordinate x_μ of such a point is within $\frac12(a_j-a_{j+1})$ of that of b_- or of b_+. So if both end points of b obey $c+\alpha+\frac12a_j\le x_\mu\le c+\frac{\ell}{2}-\alpha'-\frac12a_j$, these points obey the same bounds with a_{j+1} in place of a_j. *The case $\alpha=\alpha'=0$.* For $x\in\Lambda_j\cap\mathbb{E}_+$, the number $x_\mu-c$ is positive and lies in $a_j(\mathbb{Z}+\frac12)$ for the bond type and in $a_j\mathbb{Z}$ for the site type; so it is at least $\frac12a_j$, resp. at least a_j. The same is true of $c+\frac{\ell}{2}-x_\mu$, because $\frac{\ell}{2}=L^m\in a_j\mathbb{Z}$. *Shifts.* For $t\in a_j\mathbb{Z}$ one has $(\mathrm{T}_{-te_\mu}V_\bullet)_j(b)=V_j(b+te_\mu)$; hence $\mathcal{U}_tF$ depends on V_j only through the bonds of $\mathsf{Bd}_j(\alpha,\alpha')+te_\mu=\mathsf{Bd}_j(\alpha+t,\alpha'-t)$. *Reflections.* As maps of points, θ followed by the translation through $-te_\mu$ is the translation through te_μ followed by θ; and the reflection at $c^*=c+\frac{t}{2}$ followed by the translation through $-te_\mu$ is θ. Part (b) carries these relations over to threads, which gives $\Theta\mathcal{U}_t=\mathcal{U}_{-t}\Theta$ and $\Theta_{c^*}\mathcal{U}_t=\Theta_c$; and $\Theta^2=1$ because θ^2 is the identity. For $j\ge d_0$ the height $c+\frac{\ell}{4}$ lies in $\frac{a_j}{2}\mathbb{Z}$, as $\frac{\ell}{4}=\frac{a_j}{2}L^{m+j}$; so ϱ is a diagonal element of Iso_{d_0}. It preserves $\mathbb{E}_+$ and swaps the two boundary planes, whence $\varrho\,\mathsf{Bd}_j(\alpha,\alpha')=\mathsf{Bd}_j(\alpha',\alpha)$; the products $\varrho\theta$ and $\theta\varrho$ are the translations through $\pm\frac{\ell}{2}e_\mu$, which are the same map of T_ℓ; and conjugation by ϱ turns the translation through $-te_\mu$ into the one through te_μ. (d) The form is hermitian, since $\overline{\langle F,F'\rangle_c}=\int\Theta F\,\overline{F'}\,d\mu=\int F\,\overline{\Theta F'}\,d\mu$ by (b) and $\Theta^2=1$. For its sign write $F=\mathsf{f}(V_j|_{\mathsf{Bd}_j(0,0)})$ with $j\ge d_0$, and let $K\ge j$. Applying

the nesting $K-j$ times, $\tilde F(U)=\mathsf f((\mathcal M^{K-j}U)|_{\mathsf{Bd}_j(0,0)})$ is a bounded Borel function of those bonds of Λ_K whose end points both lie in $\mathbb E_+$, so all these bonds belong to the positive half of the bare lattice; moreover $\mathsf f((\theta\mathcal M^{K-j}U)|_{\mathsf{Bd}_j(0,0)})=\tilde F(\theta U)$ by block equivariance. Since $c\in\frac{a_K}{2}\mathbb Z$, θ is a lattice mirror at cutoff K. Apply Proposition 18.1(a) for a site mirror and Corollary YM3_I:85.3 for a bond mirror. They give $\int\overline{\mathsf f((\theta V)|_{\mathsf{Bd}_j(0,0)})}\,\mathsf f(V|_{\mathsf{Bd}_j(0,0)})\,d\mu_j^K(V)=\langle\overline{\tilde F(\theta U)}\tilde F(U)\rangle_K\ge 0$. Let $K\to\infty$ in total variation, recalling $(\theta^\bullet V_\bullet)_j=\theta V_j$. Finally $\|\tilde F\|_c\le\|F\|_{L^2(\mu)}$ follows from the Schwarz inequality in $L^2(\mu)$, because $\|\Theta F\|_{L^2(\mu)}=\|F\|_{L^2(\mu)}$. □

Lemma 18.78 (Elementary facts on SU(2) and on one averaging step at small fields)**.** (a) For $a,b,w\in G$: $|awb-\mathbf 1|\le|w-\mathbf 1|+|ab-\mathbf 1|$. For $w,w'\in G$ and $X,Y\in\mathfrak g$: $|{}^wX-{}^{w'}X|\le 2|w-w'||X|$ and $\langle{}^wX,{}^wY\rangle=\langle X,Y\rangle$. For complex 2×2 matrices, $|\operatorname{Im}Y-\operatorname{Im}Y'|\le|Y-Y'|$; for $w,w'\in G$, $|\operatorname{Im}w|\le|w-\mathbf 1|$, $\operatorname{Im}w^{-1}=-\operatorname{Im}w$ and $\operatorname{Im}({}^{w'}w)={}^{w'}\operatorname{Im}w$.

(b) For hermitian X,Y: $|e^{iX}e^{iY}-e^{i(X+Y)}|\le\frac12|[X,Y]|\le|X||Y|$ and $|e^{iX}-e^{iY}|\le|X-Y|$. For $X,Y\in\mathfrak g$: $|e^{iX}-\mathbf 1|=2\sin\frac{|X|}{2}\ge\frac{2}{\pi}|X|$ if $|X|\le\pi$; $|X-Y|\le(1-\rho)^{-1}|e^{iX}-e^{iY}|$ if $|X|,|Y|\le\rho<1$; and $|X-Y|\le2|e^{iX}-e^{iY}|$ if $|X|,|Y|\le1.1$.

(c) Let U be a field of a lattice Λ_i, and suppose that a path γ' is obtained from a path γ with the same two ends by k swaps of two consecutive steps, each swap crossing one plaquette, and by deleting steps that are immediately retraced. Then $|U(\gamma)U(\gamma')^{-1}-\mathbf 1|\le k\varpi(U)$, and $|A(\gamma)-A(\gamma')|\le k\max_p|\mathrm dA(p)|$ for a 1-form A. Any two members of a contour family differ by fewer than $\frac34L^2$ swaps; so if $\varpi(U)<\omega_M$, then $|U(\Gamma)U(y,x)^{-1}-\mathbf 1|\le3L^2\varpi(U)$ for every $\Gamma\in\mathcal G(y,x)$.

(d) If $V\in\mathcal V_i$ and $\varpi(V)<\omega_M$, then $|\mathcal M(V)(c)V[c]^{-1}-\mathbf 1|\le8L^2\varpi(V)$ for every bond c of Λ_{i-1}. ■

Sketch of proof. (a) Multiplication by unitaries leaves the norm unchanged; so $|awb-\mathbf 1|=|w-a^{-1}b^{-1}|\le|w-\mathbf 1|+|\mathbf 1-a^{-1}b^{-1}|$, and $|\mathbf 1-a^{-1}b^{-1}|=|ba-\mathbf 1|=|ab-\mathbf 1|$ after conjugating by a. The identity ${}^wX-{}^{w'}X=(w-w')Xw^{-1}+w'X(w^{-1}-w'^{-1})$ gives the bound for conjugates; Im is a contraction with $\operatorname{Im}\mathbf 1=0$, and $w^{-1}=w^*$ for $w\in G$. (b) Differentiating $t\mapsto e^{itX}e^{itY}e^{i(1-t)(X+Y)}$ produces $e^{itX}[iX,e^{itY}]e^{i(1-t)(X+Y)}$, whose norm is at most $t|[X,Y]|$, since $|[X,e^{itY}]|\le t|[X,Y]|$; integrating over $[0,1]$ gives the first bound, and $|[X,Y]|\le2|X||Y|$ because only the traceless parts enter and $[x\cdot\sigma,y\cdot\sigma]=2i(x\times y)\cdot\sigma$ for $x,y\in\mathbb R^3$, σ the triple of the Pauli matrices. Next, $e^{iX}-e^{iY}=\int_0^1e^{iuX}\,i(X-Y)\,e^{i(1-u)Y}du$; hence $|e^{iX}-e^{iY}|\le|X-Y|$, and as the integrand differs from $i(X-Y)$ by at most $(u|X|+(1-u)|Y|)\,|X-Y|$, also $|e^{iX}-e^{iY}-i(X-Y)|\le\rho|X-Y|$ when $|X|,|Y|\le\rho$, which gives the bound with the factor $(1-\rho)^{-1}$. Identify G with the unit sphere of the quaternions, the norm becoming the euclidean norm of $\mathbb R^4$; then $X\mapsto e^{iX}$ is the exponential map at $\mathbf 1$, and $|X|$ is the spherical distance of e^{iX} from $\mathbf 1$, which gives the formula $2\sin\frac{|X|}{2}$. If $|X|,|Y|\le1.1<\frac\pi2$, both points lie in a geodesically convex ball, where the logarithm is Lipschitz with the constant $1.1/\sin1.1$ for the spherical distance, and there the spherical distance is at most $1.1/\sin1.1$ times the chord, being at most 2.2; since $(1.1/\sin1.1)^2<2$, the last bound follows. (c) A swap across the plaquette p changes the transport, on one side, by a factor conjugate to $\partial U(p)^{\pm1}$, and (a) bounds each such change. Two shortest paths from y to x inside a box with $|n_\mu|\le\frac12(L-1)$ are turned into each other by at most $|n_1n_2|+|n_1n_3|+|n_2n_3|<\frac34L^2$ swaps, by sorting the three coordinate directions through adjacent exchanges. Thus the transports $\{U(\Gamma)\}_{\Gamma\in\mathcal G(y,x)}$ form a family of diameter $d=\max_{\Gamma,\Gamma'}|U(\Gamma)-U(\Gamma')|\le\frac34L^2\varpi(U)<\frac{1}{40}$, and Proposition YM3_I: 4.3 gives $|U(\Gamma)U(y,x)^{-1}-\mathbf 1|\le4d$. (d) When $\varpi<\omega_M$, the small-curvature formula YM3_I: (37) applies, and $\mathcal M(V)(c)V[c]^{-1}=\exp(L^{-3}\sum_x\log W_x)$, $W_x=V(c_-,x)V([x,x'])V(c_+,x')^{-1}V[c]^{-1}$. Pick $\Gamma\in\mathcal G(c_-,x)$ and let Γ'' be Γ moved by c_+-c_-; it belongs to $\mathcal G(c_+,x')$ by the contour definition. Then W_x factors into three pieces: $V(c_-,x)V(\Gamma)^{-1}$; the transport $V(\Gamma)V([x,x'])V(\Gamma'')^{-1}V[c]^{-1}$

around the strip of at most $\frac{3}{2}(L-1)L$ plaquettes that Γ covers while sliding along c; and a conjugate of $V(\Gamma'')V(c_+,x')^{-1}$. By (a) and (c), $|W_x-\mathbf{1}|\le(3+\frac{3}{2}+3)L^2\varpi\le 0.0375$, hence $|\log W_x|\le|W_x-\mathbf{1}|/(1-|W_x-\mathbf{1}|)\le 7.8L^2\varpi$. The exponent $L^{-3}\sum_x\log W_x$ lies in $i\mathfrak{g}$ and has norm at most $7.8L^2\varpi$, and (b) concludes. □

Lemma 18.79 (Linearizing the averaging map)**.** Let $\mathbf{Q}$ be the linear map of YM3_I:(42), $(\mathbf{Q}A)(c)=L^{-3}\sum_{x\in B(c_-)}[\bar A(c_-,x)+A([x,x'])-\bar A(c_+,x')]$, $\bar A(y,x)$ the mean of A over the members of $\mathcal{G}(y,x)$; put $(\mathbf{S}A)(c)=L^{-3}\sum_{x\in B(c_-)}A([x,x'])$ and $\mathsf{c}_A(y)=L^{-3}\sum_{x\in B(y)}\bar A(y,x)$ for the sites y of the coarser lattice. For 1-forms A with values in $\mathbb{R}$ or in $\mathfrak{g}$:

(a) $\mathbf{Q}A=\mathbf{S}A-\mathrm{d}\mathsf{c}_A$, and $\mathbf{Q}(\mathrm{d}\lambda)=\mathrm{d}(\lambda|_{\mathrm{coarse}})$.

(b) $\mathbf{Q}^nA=\mathbf{S}^nA+\mathrm{d}\zeta_n(A)$ with $\zeta_n(A)=-\sum_{i<n}\mathsf{c}_{\mathbf{S}^iA}$, restricted to the coarsest lattice, and $(\mathbf{S}^nA)(c)=L^{-3n}\sum_{x\in B^n(c_-)}A([x,x+c_+-c_-])$, which averages over the block the sums of A along straight paths of L^n bonds.

(c) $\sup|\mathbf{S}^nA|\le L^n\sup|A|$, $|\mathsf{c}_A|\le\frac{3}{2}(L-1)\sup|A|$, $|\zeta_n(A)|\le\frac{3}{2}(L^n-1)\sup|A|$, $|\mathrm{d}\zeta_n(A)|\le 3L^n\sup|A|$, and $(\mathbf{Q}^nA)(c)$ is a fixed linear combination of the values $A(b)$ whose coefficients have the total modulus at most $4L^n$; in particular $\sup|\mathbf{Q}^nA|\le 4L^n\sup|A|$, and for random forms ϕ and an event $\mathcal{E}$, $\mathbb{E}[|(\mathbf{Q}^n\phi)(c)|;\mathcal{E}]\le 4L^n\max_b\mathbb{E}[|\phi(b)|;\mathcal{E}]$.

(d) For a path γ of the coarser lattice with $|\gamma|$ bonds, $|(\mathbf{Q}^nA)(\gamma)|\le(|\gamma|L^n+2\mathsf{m}_1\frac{L^n-1}{L-1})\sup|A|$, $\mathsf{m}_1=\frac{3(L^2-1)}{4L}$; so $\sup|\mathbf{Q}^nA|\le c_{\mathbf{Q}}L^n\sup|A|$ with $c_{\mathbf{Q}}=1+\frac{3(L+1)}{2L}\le 2.62$.

(e) If A is a form on Λ_s and $h=\pm a_se_\nu$, then $\sup|\mathbf{S}^k(\mathrm{t}_hA-A)|\le 2\sup|A|$ for every $k\ge 0$, where $(\mathrm{t}_hA)(b)=A(b-h)$.

(f) $(\mathbf{Q}^nA)(c)$ reads A at the bonds with both end points in $B^n(c_-)\cup B^n(c_+)$ alone, and it is the derivative at $\mathbf{1}$ of $\mathcal{M}^n$ as in Lemma YM3_I:4.6.

■

Sketch of proof. (a) Since $x\mapsto x'$ maps $B(c_-)$ bijectively onto $B(c_+)$, the last sum equals $-\mathsf{c}_A(c_+)$. For $A=\mathrm{d}\lambda$ the three contributions are $\lambda(x)-\lambda(c_-)$, $\lambda(x')-\lambda(x)$ and $\lambda(c_+)-\lambda(x')$, adding up to $\lambda(c_+)-\lambda(c_-)$. (b) Induction on n with (a): $\mathbf{Q}(\mathbf{S}^nA+\mathrm{d}\zeta_n)=\mathbf{S}^{n+1}A-\mathrm{d}\mathsf{c}_{\mathbf{S}^nA}+\mathrm{d}(\zeta_n|)$. Concatenating straight paths gives the formula for $\mathbf{S}^n$, because $B^n(c_-)$ splits into the pairwise disjoint blocks $B^{n-1}(z)$, $z\in B(c_-)$. (c) Straight paths have L^n bonds and contours at most $\frac{3}{2}(L-1)$; the bound on ζ_n sums the geometric series $\sum_{i<n}L^i$; the coefficients of $\mathbf{S}^nA$ have total modulus L^n, and those of $\mathrm{d}\zeta_n$ at most $3L^n$. (d) Let γ run in the coarser lattice from Y to Y'. Adding (a) over the bonds of γ, the contour means at the intermediate sites cancel, and $(\mathbf{Q}A)(\gamma)=L^{-3}\sum_o[\bar A(Y,Y+o)+A(\gamma+o)-\bar A(Y',Y'+o)]$, where o ranges over the L^3 offsets inside a block and $\gamma+o$ is the concatenation of the corresponding straight paths of the finer lattice. Every summand averages A along paths of $L|\gamma|+2|o|_1$ bonds, $|o|_1$ being measured in finer spacings, and the average of $|o|_1$ over the offsets is $3\cdot\frac{1}{L}\sum_{|k|\le(L-1)/2}|k|=\mathsf{m}_1$. Inducting on n via $\mathbf{Q}^nA=\mathbf{Q}(\mathbf{Q}^{n-1}A)$ gives $(|\gamma|L+2\mathsf{m}_1)L^{n-1}+2\mathsf{m}_1\frac{L^{n-1}-1}{L-1}=|\gamma|L^n+2\mathsf{m}_1\frac{L^n-1}{L-1}$. (e) If $c\perp e_\nu$, the shifted and the unshifted families of L^{3k} straight paths have all but $2L^{2k}$ of their paths in common, each of L^k bonds; if $c\parallel e_\nu$, shifting a straight path removes one bond and adds one. (f) The locality of the one-step paths and nesting of the centered blocks give the support assertion by induction. The derivative formula follows from Lemma YM3_I:4.6 by the chain rule. □

Lemma 18.80 (One averaging step in coordinates)**.** (a) There is a number C_N, formed from L alone, with the following property. Let c be a bond of a lattice Λ_{i-1}, $i\ge 1$, and let A,A' be $\mathfrak{g}$-valued forms on P_c with $\sup|A|,\sup|A'|\le\rho_L$. Then e^{iA} satisfies the small-field condition of c at the radius ω_M, $\mathcal{M}(e^{iA})(c)=\exp i[(\mathbf{Q}A)(c)+q_c(A)]$ with $q_c(0)=0$, and $|q_c(A)-q_c(A')|\le C_N\max\{\sup|A|,\sup|A'|\}\sup|A-A'|$.

(b) For every $\kappa > 0$ there is $\rho_{\mathrm{Lip}}(\kappa) \in (0, \frac{1}{5}\omega_M]$, formed from κ and L, such that for every bond c as in (a) the map $\psi_c(A) = -i \log \mathcal{M}(e^{iA})(c)$ is real-analytic on $\{\sup|A| < \frac{1}{4}\omega_M\}$ and $|D\psi_c(A)[Y] - (\mathbf{Q}Y)(c)| \le \frac{\kappa}{c_{\mathbf{Q}}} \sup|Y|$ whenever $\sup|A| \le \rho_{\mathrm{Lip}}(\kappa)$.

■

Sketch of proof. Take $\sup|A| < 2\rho_L = \frac{1}{4}\omega_M$. Every plaquette then has $|\partial e^{iA}(p) - \mathbf{1}| \le 4\sup|A| < \omega_M$, so the small-curvature branch YM3_I:(37) applies, and $A \mapsto \mathcal{M}(e^{iA})(c)$ is real-analytic by Proposition YM3_I:4.5. Lemma 18.78(b), (d) gives $|\mathcal{M}(e^{iA})(c) - \mathbf{1}| \le 8L^2\omega_M + \frac{L}{4}\omega_M < 1$; hence ψ_c is real-analytic, with $\psi_c(0) = 0$ and $D\psi_c(0) = (\mathbf{Q}\cdot)(c)$ by Lemma YM3_I:4.6. Next we put integer coordinates on the double block. Let c be positively oriented, along e_ν; the sites of its double block are the points $c_- + a_i n$, n running through the box N_ν of the $n \in \mathbb{Z}^3$ with $-\frac{L-1}{2} \le n_\nu \le \frac{3L-1}{2}$ and $|n_\kappa| \le \frac{L-1}{2}$ for $\kappa \ne \nu$, which has $2L$ points along e_ν and L along each other axis. As $\ell = 2L^m$ with $m \ge 1$, each line of Λ_i, $i \ge 1$, parallel to an axis is a circle of $2L^{m+i} \ge 2L^2$ sites, so more than $2L$; hence $n \mapsto c_- + a_i n$ is one-to-one on N_ν, two points of N_ν are neighbours in $\mathbb{Z}^3$ exactly when their images are neighbours in Λ_i, and so this map matches the unit squares, the straight segments and the contour paths of N_ν with the plaquettes, the straight paths and the members of the contour families inside the double block. The three real block rules form $\mathcal{M}(V)(c)$ out of these objects, the number L and the radius ω_M alone, and it puts $\mathcal{M}(V)(\bar{c}) = \mathcal{M}(V)(c)^{-1}$. Read in the coordinates n, the map $V|_{\mathsf{P}_c} \mapsto \mathcal{M}(V)(c)$ is therefore one and the same for all positively oriented bonds along e_ν, independently of the depth, of the side and of the cutoff; moreover $\psi_{\bar{c}} = -\psi_c$ and $(\mathbf{Q}A)(\bar{c}) = -(\mathbf{Q}A)(c)$. So $q_c = \psi_c - (\mathbf{Q}\cdot)(c)$ is, up to its sign, one of three real-analytic functions, each vanishing at 0 together with its derivative. Define C_N as the largest supremum of $\|D^2 q_c\|$ over the closed ball of radius ρ_L, the operator norm being taken from the sup norm on forms to $|\cdot|$. Then $\|Dq_c(A)\| \le C_N \sup|A|$ on that ball, and the mean value theorem along segments of this convex set proves (a). Part (b) is obtained likewise from the continuity of $D\psi_c$ at 0, there being, up to sign, only three functions to consider. □

Lemma 18.81. *The hierarchical axial gauge; a Lipschitz bound for iterates of the averaging map.*

(a) Let $D' > d' \ge 0$, $V_{D'} \in \mathcal{V}_{D'}$, $V_i = \mathcal{M}^{D'-i}V_{D'}$, and $\varpi_i = \varpi(V_i) < \omega_M$ for $d' < i \le D'$. Given a gauge transformation v of $\Lambda_{d'}$, extend it step by step to $\Lambda_{D'}$ through $v(x) = v(y)V_i(y,x)$ for $d' < i \le D'$, $y \in \Lambda_{i-1}$, $x \in B(y) \setminus \{y\}$, and set $U_i = V_i^{v|\Lambda_i}$. Then $U_{i-1} = \mathcal{M}(U_i)$ and $U_i(y,x) = \mathbf{1}$ for all $y \in \Lambda_{i-1}$, $x \in B(y)$. For a bond b of Λ_i, $d' < i \le D'$: if both end points of b lie in one block $B(y)$, then $|U_i(b) - \mathbf{1}| \le 9.2L^2\varpi_i$; if b lies over the bond b' of Λ_{i-1}, then $|U_i(b) - U_{i-1}(b')| \le 31L^2\varpi_i$.

(b) Let $\kappa > 0$, $\rho = \rho_{\mathrm{Lip}}(\kappa)$, $0 \le d' < D'$, c a bond of $\Lambda_{d'}$, and $\mathcal{R}_i$, $d' \le i \le D'$, the set of the bonds of Λ_i with both end points in $B^{i-d'}(c_-) \cup B^{i-d'}(c_+)$. Let $V_{D'}, \tilde{V}_{D'} \in \mathcal{V}_{D'}$, $V_i = \mathcal{M}^{D'-i}V_{D'}$, $\varpi(V_i) < \omega_M$ for $d' < i \le D'$, $49L^2 \sum_{i=d'+1}^{D'} \varpi(V_i) \le \frac{\rho}{2}$, $|\tilde{V}_{D'}(b) - V_{D'}(b)| \le \eta$ for $b \in \mathcal{R}_{D'}$, and $3(L+\kappa)^{D'-d'}\eta \le \frac{\rho}{2}$. Then $|\mathcal{M}^{D'-d'}(\tilde{V}_{D'})(c) - V_{d'}(c)| \le 3(L+\kappa)^{D'-d'}\eta$.

■

Sketch of proof. (a) Proposition YM3_I:4.5, the gauge covariance of the averaging map and of the averaged contour variables, gives $U_{i-1} = \mathcal{M}(U_i)$ and $U_i(y,x) = v(y)V_i(y,x)v(x)^{-1} = \mathbf{1}$. Consider a bond $b = \langle x, x^+\rangle$, $x^+ = x + a_i e_\kappa$, inside one block $B(y)$. Suppose first that the κ-component of $x - y$ is ≥ 0; then the contour of $\mathcal{G}(y, x^+)$ that moves in the direction κ last has b as its final step, and dropping that step leaves a contour Γ of $\mathcal{G}(y,x)$. Otherwise the roles of x and x^+ are interchanged. Thus $V_i(y,x)V_i(b)V_i(y,x^+)^{-1}$ factors as $V_i(y,\cdot)V_i(\Gamma)^{-1}$ times $V_i(\Gamma^+)V_i(y,\cdot)^{-1}$, both within $3L^2\varpi_i$ of $\mathbf{1}$ by Lemma 18.78(c); conjugating by $v(y)$ gives $U_i(b)$. Next let $b = \langle x, x^+\rangle$ lie over $b' = \langle y, y'\rangle$ with $x \in B(y)$, $x^+ \in B(y')$, and put $x' = x + y' - y$. Then $|U_i(b) - U_{i-1}(b')| = |E\,\mathcal{M}(V_i)(b')^{-1} - \mathbf{1}|$, where $E = V_i(y,x)V_i(b)V_i(y',x^+)^{-1}$. Because $V_i([x,x']) = V_i(b)V_i([x^+,x'])$, we may write $E = W_x V_i[b']Z$ with W_x as in Lemma 18.78(d) and $Z = V_i(y',x')V_i([x^+,x'])^{-1}V_i(y',x^+)^{-1}$. Continuing the contour

of $\mathcal{G}(y',x^+)$ that ends in the direction κ by the segment $[x^+,x']$ backtracks over its final steps and leaves the contour of $\mathcal{G}(y',x')$ that ends in the direction κ; therefore $|Z-\mathbf{1}|\le 6L^2\varpi_i$. Together with $|W_x-\mathbf{1}|\le 7.5L^2\varpi_i$ and $|V_i[b']\mathcal{M}(V_i)(b')^{-1}-\mathbf{1}|\le 7.8L^2\varpi_i$ (Lemma 18.78(d) and its proof) this gives $|E\,\mathcal{M}(V_i)(b')^{-1}-\mathbf{1}|\le(7.5+6+7.8)L^2\varpi_i\le 31L^2\varpi_i$. (b) *Choice of gauge.* Neither the claim nor its hypotheses change if one gauge transformation of $\Lambda_{D'}$ acts on both $V_{D'}$ and $\tilde V_{D'}$ (Proposition YM3_I:4.5). We use the extension, as in (a), of the gauge transformation of $\Lambda_{d'}$ that equals $V_{d'}(c)$ at c_+ and $\mathbf{1}$ at every other site; then $U_{d'}(c)=\mathbf{1}$. Every bond $b\in\mathcal{R}_i$ lies over a bond of Λ_{i-1}, which lies over a bond of Λ_{i-2}, and so on, until either the bond reached at some depth $k>d'$ sits inside a block, or the depth d' is reached, where the bond is c or $\bar c$. Adding the bounds of (a) along this chain, $|U_i(b)-\mathbf{1}|\le 31L^2\sum_{k=d'+1}^{i}\varpi(V_k)$; so $U_i=e^{i\Phi_i}$ on $\mathcal{R}_i$ with $|\Phi_i|\le\frac{\pi}{2}\cdot 31L^2\sum_k\varpi(V_k)\le\frac{\rho}{2}$ (Lemma 18.78(b)). Set $\tilde U_{D'}=\tilde V^v_{D'}$ and $\tilde U_{i-1}=\mathcal{M}(\tilde U_i)$ on $\mathcal{R}_{i-1}$, which involves $\tilde U_i$ on $\mathcal{R}_i$ only. *An adapted norm.* For forms δ on $\mathcal{R}_i$ let $\|\delta\|_{*,i}=\max_{0\le n\le i-d'}L^{-n}\sup_{\mathcal{R}_{i-n}}|\mathbf{Q}^n\delta|$. Lemma 18.79(d) gives $\sup|\delta|\le\|\delta\|_{*,i}\le c_{\mathbf{Q}}\sup|\delta|$, and the definition gives $\|\mathbf{Q}\delta\|_{*,i-1}\le L\|\delta\|_{*,i}$ at once. *Descending induction.* We show that $\tilde U_i=e^{i\tilde\Phi_i}$ on $\mathcal{R}_i$ and that $\delta_i=\tilde\Phi_i-\Phi_i$ satisfies $\|\delta_i\|_{*,i}\le c_{\mathbf{Q}}(1-\rho)^{-1}(L+\kappa)^{D'-i}\eta$. For $i=D'$ we have $|\tilde U_{D'}-U_{D'}|\le\eta\le\frac{\rho}{6}$. The norm $|X|$ of $X\in\mathfrak{g}$ is the spherical distance from $\mathbf{1}$ to e^{iX} on G, and an arc no longer than π is at most $\frac{\pi}{2}$ times its chord; so $|\tilde\Phi_{D'}|\le|\Phi_{D'}|+\frac{\pi}{2}\eta\le\frac{\rho}{2}+\frac{\pi}{12}\rho\le\rho$, and Lemma 18.78(b) gives $\sup|\delta_{D'}|\le(1-\rho)^{-1}\eta$. Passing from i to $i-1$: $\sup|\delta_i|\le\|\delta_i\|_{*,i}\le 2.62\cdot 1.07\,(L+\kappa)^{D'-d'}\eta\le\frac{\rho}{2}$, so the whole segment from Φ_i to $\tilde\Phi_i$ stays in $\{\sup|\cdot|\le\rho\}$, and at each $c'\in\mathcal{R}_{i-1}$, $\delta_{i-1}(c')=\int_0^1 D\psi_{c'}(\Phi_i+\lambda\delta_i)[\delta_i]\,d\lambda=(\mathbf{Q}\delta_i)(c')+\epsilon_i(c')$, where $|\epsilon_i(c')|\le\frac{\kappa}{c_{\mathbf{Q}}}\sup|\delta_i|$ by Lemma 18.80(b). Hence $\|\delta_{i-1}\|_{*,i-1}\le L\|\delta_i\|_{*,i}+c_{\mathbf{Q}}\frac{\kappa}{c_{\mathbf{Q}}}\|\delta_i\|_{*,i}=(L+\kappa)\|\delta_i\|_{*,i}$. At $i=d'$ this yields $|\tilde U_{d'}(c)-U_{d'}(c)|\le|\delta_{d'}(c)|\le 2.79(L+\kappa)^{D'-d'}\eta$; and $\tilde U_{d'}(c)$, $U_{d'}(c)$ come from $\mathcal{M}^{D'-d'}(\tilde V_{D'})(c)$ and $V_{d'}(c)$ by the same multiplications, by $v(c_-)$ on the left and by $v(c_+)^{-1}$ on the right. □

Lemma 18.82 (Gauge fixing on a box, with small bond variables at all depths)**.** Let $j_0\ge 0$ satisfy $\log(L^{j_0}\mathsf{b})\ge 8\mathfrak{p}_0$ and $17000L^3\varepsilon_{[j_0]}\le 1$, let $s>j_0$, and let $V_i\in\mathcal{V}_i$, $j_0\le i\le s$, satisfy $V_{i-1}=\mathcal{M}(V_i)$ and $\varpi(V_i)<2\varepsilon_{[i]}$. For a bond c_0 of Λ_{j_0} let $\mathsf{Box}(c_0)$ be the smallest closed coordinate box containing the four points $c_{0\pm}\pm a_{j_0}(1,1,1)$; for every depth $i\ge j_0$ it contains the double block $B^{i-j_0}(c_{0-})\cup B^{i-j_0}(c_{0+})$, at a distance at least $\frac12 a_{j_0}$ from its boundary. Then one gauge transformation u of Λ_s makes all the bonds in the box small at once: for $j_0\le i\le s$ and every bond b of Λ_i whose end points lie in $\mathsf{Box}(c_0)$, $V_i^{\mathsf{u}|\Lambda_i}(b)=e^{i\Phi_i(b)}$ with $\Phi_i(b)\in\mathfrak{g}$ and $|\Phi_i(b)|\le C_g\varepsilon_{[i]}$. On the Borel set of the V_s satisfying these hypotheses, u and the forms Φ_i may be taken to be Borel functions of V_s. ■

Sketch of proof. Within each step, lengths are expressed in units of the spacing of Λ_i. *Interpolating a form.* Let A be a $\mathfrak{g}$-valued form on the bonds of Λ_{i-1} inside the box and $b=\langle x,x+e_\mu\rangle$ a bond of Λ_i inside the box. Choose a cell of Λ_{i-1} inside the box that contains b (a cube of side L with its corners in Λ_{i-1}), let y^0 be its corner with the smallest coordinates, write $t_\kappa=(x_\kappa-y^0_\kappa)/L\in[0,1]$ for the two directions $\kappa\ne\mu$, and set $(\mathsf{H}A)(b)=L^{-1}\sum_{\epsilon\in\{0,1\}^2}\prod_\kappa t_\kappa^{\epsilon_\kappa}(1-t_\kappa)^{1-\epsilon_\kappa}A(\langle y^\epsilon,y^\epsilon+Le_\mu\rangle)$, $y^\epsilon=y^0+L\sum_\kappa\epsilon_\kappa e_\kappa$. Adjacent cells agree on their common face, so $\mathsf{H}A$ is well defined. It satisfies $|\mathsf{H}A|\le L^{-1}\sup|A|$; its sum over the L bonds beneath a bond $c=\langle y,y'\rangle$ of Λ_{i-1} is $A(c)$; and $\max_p|\mathrm{d}\mathsf{H}A(p)|\le L^{-2}\max_P|\mathrm{d}A(P)|$, since the μ-component of $\mathsf{H}A$ is affine in each t_κ separately. *The first depth.* Let $\mathsf{u}_{j_0}(y)=V_{j_0}(\gamma_y)$, where γ_y runs from the corner of the box with the smallest coordinates to y, first along e_1, then along e_2, then along e_3. For a bond b in the box, $V^{\mathsf{u}}_{j_0}(b)$ equals the transport of V_{j_0} along the closed path $\gamma_{b_-}b\gamma_{b_+}^{-1}$, which encloses at most 5 plaquettes of the box; so $|V^{\mathsf{u}}_{j_0}(b)-\mathbf{1}|<10\varepsilon_{[j_0]}$ and $|\Phi_{j_0}|\le 1.01\cdot 10\varepsilon_{[j_0]}$. *From $i-1$ to i.* Write $\alpha=\sup|\Phi_{i-1}|\le C_g\varepsilon_{[i-1]}$. For $y\in\Lambda_{i-1}$ and $x\in B(y)$ inside the box let $\mathsf{u}_i(x)=e^{-i\lambda(x)}\mathsf{u}_{i-1}(y)V_i(y,x)$, where $\lambda(x)=(\mathsf{H}\Phi_{i-1})(\Gamma^1_{y,x})$ and $\Gamma^1_{y,x}$ is the contour of $\mathcal{G}(y,x)$ that moves along e_1, e_2, e_3 in this order. Then u_i agrees with u_{i-1} on Λ_{i-1}, and $|\lambda|\le\frac32\alpha$. Abbreviate $\varpi=\varpi(V_i)$.

If $b=\langle x,x''\rangle$ has both end points in one block $B(y)$, then $V_i^{\mathsf{u}_i}(b)=e^{-i\lambda(x)\,\mathsf{u}_{i-1}(y)}E\,e^{i\lambda(x'')}$ with $E=V_i(y,x)V_i(b)V_i(y,x'')^{-1}$; Lemma 18.78(c) gives $|E-\mathbf{1}|\le(\frac34+6)L^2\varpi$ and, applied to the form $\mathsf{H}\Phi_{i-1}$, also $|\lambda(x'')-\lambda(x)-(\mathsf{H}\Phi_{i-1})(b)|\le\frac34\max_P|\mathrm{d}\Phi_{i-1}(P)|$. If b leads from $B(y)$ to $B(y'')$ and lies over $c=\langle y,y''\rangle$, put $T_b=V_i(y,x)V_i(b)V_i(y'',x'')^{-1}$; two contour means and at most L^2 plaquettes stand between the path that crosses over, runs along and comes back, and the segment $[y,y'']$, so $|T_bV_i[c]^{-1}-\mathbf{1}|\le7L^2\varpi$. Writing $V_{i-1}(c)=e^YV_i[c]$ with $|e^Y-\mathbf{1}|\le8L^2\varpi$ (Lemma 18.78(d)), we get $T_b=E_bV_{i-1}(c)$ with $|E_b-\mathbf{1}|\le15L^2\varpi$, and $V_i^{\mathsf{u}_i}(b)=e^{-i\lambda(x)\,\mathsf{u}_{i-1}(y)}E_b\,e^{i\Phi_{i-1}(c)}e^{i\lambda(x'')}$. Around the loop $[y,y'']\,\Gamma^1_{y'',x''}\,\bar b\,(\Gamma^1_{y,x})^{-1}$, which encloses at most $2.5L^2$ plaquettes, the sum of $\mathsf{H}\Phi_{i-1}$ equals $\Phi_{i-1}(c)+\lambda(x'')-(\mathsf{H}\Phi_{i-1})(b)-\lambda(x)$ and has modulus at most $2.5\max_P|\mathrm{d}\Phi_{i-1}(P)|$. *Curvature.* Three uses of Lemma 18.78(b) give $|\partial V_{i-1}^{\mathsf{u}}(P)-e^{i\,\mathrm{d}\Phi_{i-1}(P)}|\le6\alpha^2$, hence $|\mathrm{d}\Phi_{i-1}(P)|\le\frac\pi2(\varpi(V_{i-1})+6\alpha^2)$. *Collecting.* Two more uses of Lemma 18.78(b), costing at most $3(\frac32\alpha)^2$, and $|\mathsf{H}\Phi_{i-1}|\le\frac\alpha L$ yield $|V_i^{\mathsf{u}_i}(b)-\mathbf{1}|\le\frac\alpha L+15L^2\varpi(V_i)+4\varpi(V_{i-1})+31\alpha^2$. Insert $\varpi(V_i)<2\varepsilon_{[i]}$, $\varepsilon_{[i-1]}\le L^{1/2}\varepsilon_{[i]}$, $\alpha\le50L^{5/2}\varepsilon_{[i]}$ and $|\Phi|\le1.01|e^{i\Phi}-\mathbf{1}|$ in this range: $|\Phi_i|\le1.01(50L^{3/2}+31L^2+77500L^5\varepsilon_{[i]})\varepsilon_{[i]}\le50L^2\varepsilon_{[i]}$, because $50L^{-1/2}\le13.9$, $1.01(13.9+31)\le45.35$, and $1.01\cdot77500L^3\varepsilon_{[i]}\le4.605$ by $17000L^3\varepsilon_{[j_0]}\le1$ and $\varepsilon_{[i]}\le\varepsilon_{[j_0]}$. Finally let $\mathsf{u}=\mathsf{u}_s$ inside the box and $\mathbf{1}$ outside it; then $\mathsf{u}_s|\Lambda_i=\mathsf{u}_i$. *Measurability.* Only transports, averaged contour variables, which are real-analytic on the open small-curvature set by Lemma YM3_I:4.4, and the logarithm near $\mathbf{1}$ enter the construction. □

Lemma 18.83 (Identities for the covariant shift, and a bound on its defect through the plaquette moduli)**.** Let $s\ge1$, $h=\pm a_se_\nu$ and $V\in\mathcal{V}_s$, with the objects of the covariant shift.

(a) $\mathrm{t}_hV=\check V^{\,g}$ and $V_i'=\check V_i^{\,g|\Lambda_i}$ for $i\le s$; so $\mathrm{dist}_{\mathrm{orb}}(V_i',V_i)\le\max_b|\mathsf{P}_i(b)-\mathbf{1}|$. At every bond b of Λ_s, $|\mathsf{P}_s(b)-\mathbf{1}|\le\varpi(V)$.

(b) For a gauge transformation w of Λ_s, the covariant shift of V^w is $\check V^w$, and the defect formed from V^w at a bond b of Λ_i is $w(b_-)\mathsf{P}_i(b)w(b_-)^{-1}$.

(c) Let $s>j\ge D_g$, $\varpi(\mathcal{M}^{s-i}V)<2\varepsilon_{[i]}$ for $j\le i\le s$, and $\mathsf{k}_2L^{s-j}\varepsilon_{[s]}^2\le c_*$. Then $|\mathsf{P}_j(c)-\mathbf{1}|\le\bar\eta_j$ for every bond c of Λ_j, and so $\mathrm{dist}_{\mathrm{orb}}(V_j',V_j)\le\bar\eta_j$.

■

Sketch of proof. (a) The gauge rule gives $\check V=(\mathrm{t}_hV)^{g^{-1}}$; since the iterates of $\mathcal{M}$ commute with gauge transformations (Proposition YM3_I:4.5), $\check V_i=V_i'^{\,g^{-1}|\Lambda_i}$. Taking $g|\Lambda_i$ as the gauge transformation in the definition of $\mathrm{dist}_{\mathrm{orb}}$, $|V_i'(b)-V_i^g(b)|=|g(b_-)^{-1}V_i'(b)g(b_+)-V_i(b)|=|\mathsf{P}_i(b)-\mathbf{1}|$. At the depth s there are two cases. If $b\perp e_\nu$ and p_b is the plaquette spanned by b and $b-h$, then $\check V(b)V(b)^{-1}=g(b_-)^{-1}\partial V(p_b)^{\pm1}g(b_-)$. If $b\parallel e_\nu$, then $\check V(b)=V(b)$, both factors g being transports along bonds of the line through b. (b) Formed from V^w, the transports become $w(x-h)g(x)w(x)^{-1}$, and $\mathrm{t}_h(V^w)=(\mathrm{t}_hV)^{w(\cdot-h)}$; substituting, the covariant shift of V^w at b is $w(b_-)\check V(b)w(b_+)^{-1}$, and the covariance of $\mathcal{M}^{s-i}$ does the rest. (c) Fix a bond c_0 of Λ_j. As $j\ge D_g$, Lemma 18.82 with $j_0=j$ provides u and the forms Φ_i on the bonds inside $\mathsf{Box}(c_0)$. Let $\mathcal{R}_i$ consist of the bonds of Λ_i whose end points lie in $B^{i-j}(c_{0-})\cup B^{i-j}(c_{0+})$; then $\mathsf{P}_c\subset\mathcal{R}_i$ whenever $c\in\mathcal{R}_{i-1}$. On $\mathcal{R}_s$ let $\Phi_s'=\mathrm{t}_h\Phi_s$, which uses Φ_s only inside the box, and let $\mathsf{u}'=\mathsf{u}(\cdot-h)$; then $e^{i\Phi_s'}=(\mathrm{t}_hV)^{\mathsf{u}'}$ on $\mathcal{R}_s$. With $m_i=s-i$ set $X_i=\mathsf{k}_1(1+m_i)\varepsilon_{[s]}+\mathsf{k}_2L^{m_i}\varepsilon_{[s]}^2$. Since $(1+m)\varepsilon_{[s]}\le(1+m)L^{-3m/8}\varepsilon_{[s-m]}\le\varepsilon_{[s-m]}$, we get $X_i\le\mathsf{k}_1\varepsilon_{[i]}+c_*\le\frac{\rho_L}{2}$. *Claim:* for $j\le i\le s$ the forms $\Phi_i'=-i\log\mathcal{M}^{s-i}(e^{i\Phi_s'})$ on $\mathcal{R}_i$ exist, and $x_i=\sup_{\mathcal{R}_i}|\Phi_i'-\Phi_i|\le X_i$. For $i=s$, $x_s\le2C_g\varepsilon_{[s]}\le X_s$. Assume the claim for all $i>j'$. Then $\sup|\Phi_i'|\le\rho_L$, Lemma 18.80(a) is available at every $c\in\mathcal{R}_{i-1}$, and the covariance gives $\mathcal{M}(e^{i\Phi_i})=e^{i\Phi_{i-1}}$ there; hence $\Phi_{i-1}'-\Phi_{i-1}=\mathbf{Q}(\Phi_i'-\Phi_i)+r_i$ with $|r_i|\le C_N(C_g\varepsilon_{[i]}+X_i)X_i$. Iterating down to j' and writing $m=m_{j'}$: $\Phi_{j'}'-\Phi_{j'}=\mathbf{Q}^m(\mathrm{t}_h\Phi_s-\Phi_s)+\sum_{i=j'+1}^s\mathbf{Q}^{i-1-j'}r_i$. Lemma 18.79(b), (c), (e) bounds the first term by $2C_g\varepsilon_{[s]}(1+3(L-1)m)\le\frac12\mathsf{k}_1(1+m)\varepsilon_{[s]}$. By Lemma 18.79(c) the sum is at most $\mathsf{S}=4C_N\sum_{\mathsf{m}=0}^{m-1}L^{m-\mathsf{m}-1}(2C_g\varepsilon_{[s-\mathsf{m}]}+X)X$, where $X=\mathsf{k}_1(1+\mathsf{m})\varepsilon_{[s]}+\mathsf{k}_2L^{\mathsf{m}}\varepsilon_{[s]}^2$. Using $\varepsilon_{[s-\mathsf{m}]}\le L^{\mathsf{m}/2}\varepsilon_{[s]}$, $X^2\le2\mathsf{k}_1^2(1+\mathsf{m})^2\varepsilon_{[s]}^2+2\mathsf{k}_2^2L^{2\mathsf{m}}\varepsilon_{[s]}^4$, $\sum_{\mathsf{m}\ge0}(1+$

$\mathsf{m})L^{-\mathsf{m}/2} \le 1.92$, $\sum_{\mathsf{m}\ge 0}(1+\mathsf{m})^2 L^{-\mathsf{m}} \le 1.4$, $\sum_{i>j'} \varepsilon_{[i]} \le 1.62\,\varepsilon_{[j']}$ and $\mathsf{k}_2 L^m \varepsilon_{[s]}^2 \le c_*$, one finds $\mathsf{S} \le 4C_N L^{m-1}\varepsilon_{[s]}^2[3.9C_g\mathsf{k}_1 + 2.8\mathsf{k}_1^2 + \mathsf{k}_2(3.3C_g\varepsilon_{[j']} + \frac{2c_*}{L-1})] \le \frac{1}{2}\mathsf{k}_2 L^m\varepsilon_{[s]}^2 + \frac{1}{2}\mathsf{k}_2 L^m \varepsilon_{[s]}^2$; here the first half is the definition of k_2, and the second holds because $4C_N L^{-1}\cdot 3.3 C_g \varepsilon_{[j']} \le \frac{1}{4}$, from $53 C_N C_g \varepsilon_{[j]} \le L$, and $4C_N L^{-1}\frac{2c_*}{L-1} \le \frac{1}{4}$, from $c_* \le \frac{L(L-1)}{32 C_N}$. Therefore $x_{j'} \le X_{j'}$. *Conclusion.* By the covariance, $e^{i\Phi'_j(c_0)} = \mathsf{u}'(c_{0-})V'_j(c_0)\mathsf{u}'(c_{0+})^{-1}$ and $e^{i\Phi_j(c_0)} = \mathsf{u}(c_{0-})V_j(c_0)\mathsf{u}(c_{0+})^{-1}$; so, with $\mathsf{w} = \mathsf{u}'^{-1}\mathsf{u}$, Lemma 18.78(b) gives $|V'_j(c_0) - V_j^{\mathsf{w}}(c_0)| \le x_j$. Moreover $g(y) = \mathsf{u}'(y)^{-1} e^{i\Phi_s(\langle y-h, y\rangle)}\mathsf{u}(y)$, whence $|g(y) - \mathsf{w}(y)| \le C_g\varepsilon_{[s]}$. Altogether $|\mathsf{P}_j(c_0) - \mathbf{1}| = |V'_j(c_0) - V_j^g(c_0)| \le X_j + 2C_g\varepsilon_{[s]} \le \bar\eta_j$, as $2C_g \le \mathsf{k}_1$. □

Lemma 18.84 (One event for all the levels of a cutoff; regular fields and threads)**.** Assume the one-torus setting.

(a) Let $d_\natural \le D < K$, and let G_D^K be the set of the $U \in \mathcal{V}_K$ with $\varpi(\mathcal{M}^{K-D}U) < 2\varepsilon_{[D]}$, $\varpi(\mathcal{M}^{K-i}U) < 2c_\rho\varepsilon_{[i]}$ for $D < i < K$, and $\varpi(U) < c_\rho\varepsilon_{[K]}$. Then $\langle \mathbf{1} - \mathbf{1}_{\mathsf{G}_D^K}\rangle_K \le R_D$.

(b) For $d_\Sigma \le j \le s < K$, $\langle \mathbf{1}\{\mathcal{M}^{K-s}U \notin \mathsf{Gd}_{j,s}\}\rangle_K \le \frac{L}{L-1}R_j$ and $\mu_s(\mathcal{V}_s \setminus \mathsf{Gd}_{j,s}) \le \frac{L}{L-1}R_j$; for $D \ge d_\Sigma$, $\mu(\mathsf{Thr} \setminus \mathsf{Gd}_D) \le \frac{L}{L-1}R_D$.

■

Sketch of proof. (a) The proof of Proposition 10.2(b) uses Theorem F on the line of couplings $x_{[d']} = L^{d'}\mathsf{b}$, with the run in which every u_t vanishes; for $d_\natural \le D < K$ the small-field chain of that run goes up to the level $t = K - D$, at which the lattice is Λ_D. This chain carries the bounded nonnegative Borel weight $\mathfrak{w}_t^{\mathrm{sf}}$ defined immediately before Proposition YM3_I:115.2, containing the factors $\mathbf{1}_{\mathsf{In}_t}(\mathcal{M}^t U)$ and $\mathbf{1}_{\mathsf{Cut}_k}(\mathcal{M}^k U)$, $0 \le k < t$; on this line $\mathsf{In}_t = I_D$, $\mathsf{Cut}_0 = \{\varpi < c_\rho\varepsilon(x_0)\}$ with $x_0 = x_{[K]}$, and $\mathsf{Cut}_k \subset \{\varpi < 2c_\rho\varepsilon(x_k)\}$, $x_k = x_{[K-k]}$, for $1 \le k < t$ by the definitions preceding Lemma YM3_I:113.10 and its cut bound YM3_I:(2159). Consequently $\mathfrak{w}_t^{\mathrm{sf}}$ is zero outside G_D^K, which is Borel and gauge invariant (Proposition YM3_I:4.5). Write $\rho_0 = e^{-\beta\sum_p a_p}$ for the bare density at $\beta = x_0 = L^K\mathsf{b}$, so that $Z = \int \rho_0\, dU$ is the normalisation of $\langle\cdot\rangle_K$. Taking $F = \mathbf{1}_{\mathsf{G}_D^K}$ in YM3_I:(2189) and using the discarded-mass bound in Proposition YM3_I:115.2, $Z\langle \mathbf{1}_{\mathsf{G}_D^K}\rangle_K \ge \int \mathbf{1}_{\mathsf{G}_D^K}\mathfrak{w}_t^{\mathrm{sf}}\rho_0\, dU = \int \mathfrak{w}_t^{\mathrm{sf}}\rho_0\, dU \ge (1 - \mathsf{R}_t)Z$, and on this line the number R_t of YM3_I:(2187) equals R_D. (b) Proposition 10.2(b) gives $\mu_i^K(\mathcal{V}_i \setminus I_i) \le R_i$ and $\mu_i(\mathcal{V}_i \setminus I_i) \le R_i$ for $d_\natural \le i < K$; add these over $j \le i \le s$ and use $\sum_{i\ge j} R_i \le \frac{L}{L-1}R_j$, valid for $j \ge d_\Sigma$. For threads, $\mathsf{Thr} \setminus \mathsf{Gd}_D = \mathsf{Thr} \cap \bigcup_{i\ge D}\pi_i^{-1}(\mathcal{V}_i \setminus I_i)$. □

Lemma 18.85 (Reflection positivity for one adjoint charge)**.** Let $K \ge 1$ and $\beta > 0$. Let $\Sigma = (\nu, c)$, $c \in \frac{a_K}{2}\mathbb{Z}$, be a lattice mirror of T_ℓ at the cutoff K, θ its reflection and $\mathbb{E}_+ = \{c < x_\nu < c + \frac{\ell}{2}\}$, and fix a column. For a bond mirror, $x_\pm$ denote the sites of the column at the heights $c \pm \frac{1}{2}a_K$, $b_x = \langle x_-, x_+\rangle$, and $\mathsf{B}(\Sigma)$ is the set of bonds of Λ_K whose end points both lie in $\mathbb{E}_+$. For a site mirror, $x_+ = x_-$ denotes the site of the column at the height c, $U(b_x) := \mathbf{1}$, and $\mathsf{B}(\Sigma)$ is the set of bonds whose end points both lie in $\{c \le x_\nu \le c + \frac{\ell}{2}\}$. Let S be a bounded Borel $\mathfrak{g}$-valued function of the bare field that depends only on the bonds of $\mathsf{B}(\Sigma)$ and, for a bond mirror, is covariant at x_+. Then $\langle S, S\rangle_\Sigma := \big\langle \langle S(\theta U), {}^{U(b_x)}S(U)\rangle\big\rangle_K \ge 0$. ■

Sketch of proof. Since S takes hermitian values, $\langle S(\theta U), S(U)\rangle = \frac{1}{2}\sum_{i,k}\overline{S_{ki}(\theta U)}\, S_{ki}(U)$. *Site mirror.* Every summand has a non-negative mean by Proposition 18.1(a) applied to the bounded Borel function $F = S_{ki}$ on the closed positive-side bonds; the covariance plays no role here. *Bond mirror.* First, $H(U) = \langle S(\theta U), {}^{U(b_x)}S(U)\rangle$ does not change under gauge transformations: from $\theta(U^v) = (\theta U)^{v\circ\theta}$ one gets $S(\theta(U^v)) = v(x_-)S(\theta U)v(x_-)^{-1}$, while $U^v(b_x) = v(x_-)U(b_x)v(x_+)^{-1}$. Let $\mathcal{C}$ denote the bonds that cross the plane $x_\nu = c$ or the plane $x_\nu = c + \frac{\ell}{2}$, each oriented so that it ends in $\mathbb{E}_+$; as $\frac{\ell}{2} \ge 2a_K$, no site is an end point of two of them. Given U, let v_U equal $U(b)$ at the end point in $\mathbb{E}_+$ of each $b \in \mathcal{C}$, and $\mathbf{1}$ at all remaining sites; then U^{v_U} is $\mathbf{1}$ on $\mathcal{C}$. For fixed

values on $\mathcal{C}$, the substitution $U|_{\mathcal{C}^c} \mapsto U^{v_U}|_{\mathcal{C}^c}$ multiplies every bond variable on both sides by group elements that do not depend on $U|_{\mathcal{C}^c}$, and therefore preserves the Haar measure. Since $H e^{-\beta\sum_p a_p}$ is gauge invariant, it follows that $Z\langle H\rangle_K = \int [H e^{-\beta\sum_p a_p}](\mathbf{1}_{\mathcal{C}}, U_+, U_-)\, dU_+ dU_-$, where $U_\pm$ is the restriction of U to the bonds with both end points in $\mathbb{E}_\pm = \{\pm(x_\nu - c) > 0\}$, heights being read on the circle. For bounded Borel functions Γ, Γ' of U_+, $\Theta\Gamma = \Gamma(\theta\,\cdot)$ depends on U_- only, and $\int \overline{\Theta\Gamma}\,\Gamma'\, dU_+ dU_- = \overline{\int \Gamma\, dU_+}\int \Gamma'\, dU_+$: indeed θ relabels the bonds and inverts the variables on the bonds along e_ν, and both operations preserve the Haar measure. When $U|_{\mathcal{C}} = \mathbf{1}$, every plaquette has either all its corners in $\mathbb{E}_+$, or all in $\mathbb{E}_-$, or it is made of a bond b_p of $\mathbb{E}_+$ parallel to the planes, the bond θb_p and two bonds of $\mathcal{C}$; in the last case $\operatorname{tr}\partial U(p) = \sum_{i,k} C_{p,ik}\overline{\Theta C_{p,ik}}$ with $C_{p,ik} = U(b_p)_{ik}$. Hence, writing A_+ for the action of the plaquettes inside $\mathbb{E}_+$ and $N_\times$ for the number of crossing plaquettes, $e^{-\beta\sum_p a_p} = e^{-\beta A_+}\,\Theta(e^{-\beta A_+})\, e^{-\beta N_\times}\sum_{n\ge 0}\frac{(\beta/2)^n}{n!}\sum_{(p_l,i_l,k_l)_{l\le n}}\prod_l C_{p_l,i_l k_l}\overline{\Theta\prod_l C_{p_l,i_l k_l}}$, with uniform convergence; and at $U(b_x) = \mathbf{1}$ one has $H = \frac12\sum_{i,k}\overline{\Theta S_{ki}}\, S_{ki}$. Inserting both expansions, $Z\langle H\rangle_K = e^{-\beta N_\times}\sum_n \frac{(\beta/2)^n}{n!}\sum_{(p_l,i_l,k_l)}\frac12\sum_{i,k}\bigl|\int e^{-\beta A_+}\prod_l C_{p_l,i_l k_l}\, S_{ki}\, dU_+\bigr|^2 \ge 0$. □

Lemma 18.86 (A bound on second differences for kernels of positive type)**.** Let $n \ge 1$ be an integer, and let $e\colon \{-n,\dots,n\} \to \mathbb{R}$ satisfy $\sum_{\alpha,\beta}\xi_\alpha\xi_\beta\, e(\alpha+\beta) \ge 0$ whenever ξ is a finitely supported real family whose support is contained both in $[-\frac{n}{2}, \frac{n}{2}]$ and in a single one of the classes $\mathbb{Z}$, $\mathbb{Z}+\frac12$. Then $0 \le e(1) + e(-1) - 2e(0) \le n^{-2}[e(n) + e(-n) - 2e(0)]$. ■

Sketch of proof. Introduce a formal variable x and the linear functional $\mathcal{L}$ on the span of the x^k, $|k| \le n$, given by $\mathcal{L}(x^k) = e(k)$. In this language the hypothesis reads $\mathcal{L}(p^2) \ge 0$ for every $p = \sum_\alpha \xi_\alpha x^\alpha$ with ξ as above. Write $\mathsf{q} = x^{1/2} - x^{-1/2}$, so that $\mathsf{q}^2 = x - 2 + x^{-1}$; let $r(\gamma) = \mathcal{L}(\mathsf{q}^2 x^\gamma) = e(\gamma+1) + e(\gamma-1) - 2e(\gamma)$ for $|\gamma| \le n-1$, and $\Delta_k = e(k) + e(-k) - 2e(0) = \mathcal{L}((x^{k/2} - x^{-k/2})^2)$. First, $\Delta_1 = \mathcal{L}(\mathsf{q}^2) \ge 0$. Next, for $0 \le \gamma \le n-1$ the product $\mathsf{q}(x^{\gamma/2} - x^{-\gamma/2})$ has four exponents, all in $[-\frac{n}{2}, \frac{n}{2}]$ and all in the same class; so $0 \le \mathcal{L}(\mathsf{q}^2(x^\gamma - 2 + x^{-\gamma})) = r(\gamma) + r(-\gamma) - 2r(0)$. Finally $x^{n/2} - x^{-n/2} = \mathsf{q}\sum_{a\in I_n} x^a$, where $I_n = \{\frac{n-1}{2}, \frac{n-3}{2}, \dots, -\frac{n-1}{2}\}$ is symmetric about 0; therefore $\Delta_n = \sum_{a,b\in I_n} r(a+b) = \sum_{a,b\in I_n}\frac12[r(a+b) + r(-a-b)] \ge n^2 r(0) = n^2\Delta_1$. □

Lemma 18.87 (Block bonds compared with straight bare segments)**.** (a) Let $K \ge 1$, $\beta > 0$, $0 \le i \le K$ and $n \ge 0$. If $(n+1)a_i < \frac{\ell}{4}$, then $\sigma_i(n+1) \le \sigma_i(n) + \sigma_i(1)$; if $(2n+2)a_i < \frac{\ell}{4}$, then $\sigma_i(2n+1) \le \sqrt{2}\,\sigma_i(n) + \sigma_i(1)$. Consequently $\sigma_i(n) \le c_{\mathrm{d}}(\sqrt{n+1} - 1)\sigma_i(1) \le c_{\mathrm{d}}\sqrt{n}\,\sigma_i(1)$ whenever $(n+1)a_i < \frac{\ell}{4}$.

(b) Assume the one-torus setting, and let $\mathfrak{t} \ge 1$ and $D_1 \le i_* < K$ be integers. Then

$$\sigma_{i_*}(1) \le 0.27\, c_{\mathrm{d}}^{\lceil (K-i_*)/\mathfrak{t}\rceil}\Bigl[23\, c_\rho L^{\mathfrak{t}/2+1}\max_{i_*\le i'\le K} L^{i'/2}\varepsilon_{[i']} + 2L^{K/2}R_{i_*}^{1/2}\Bigr]L^{-i_*/2}.$$

(c) On the diagonal, for large s and every i with $\lfloor s/5\rfloor \le i \le s$: $\sigma_i(1) \le \mathsf{C}_3\,\mathsf{e}\, L^{s/40 - i/2}$ with $\mathsf{C}_3 = 32(c_\rho + 1)L^{15501}$.

■

Sketch of proof. (a) For $i = K$ every σ_K vanishes, so let $i < K$; write $x_k = x + k a_i e_\nu$ and $b_k = \langle x_{k-1}, x_k\rangle$. The rule $\mathsf{L}(p,q)\mathsf{L}(q,w) = \mathsf{L}(p,w)$ gives $Z_i(x; n+1) = V_i([x, x_n])\, z_i(b_{n+1})\,\mathsf{L}(x_n, x)$, from which the first inequality follows by Lemma 18.78(a); it also gives $Z_i(x; 2n+1) = Z^{(1)} \cdot {}^{\mathsf{L}(x,x_n)}z_i(b_{n+1}) \cdot {}^{\mathsf{L}(x,x_{n+1})}Z^{(2)}$, where $Z^{(1)} = Z_i(x; n)$ and $Z^{(2)} = Z_i(x_{n+1}; n)$. By Lemma 18.78(a), $\sigma_i(2n+1) \le \sigma_i(1) + \|Y - \mathbf{1}\|_2$ for $Y = Z^{(1)} \cdot {}^{\mathsf{L}(x,x_{n+1})}Z^{(2)}$, and $\|Y - \mathbf{1}\|_2^2 = 2 - 2\,\mathbb{E}\operatorname{Re} Y$. *The mirror.* We reflect at the midpoint $c = (x_n)_\nu + \frac{a_i}{2}$ of b_{n+1}. Since $a_i/a_K = L^{K-i}$ is odd, $c \in a_K(\mathbb{Z} + \frac12)$; so this is a bond mirror of the cutoff K, and its reflection θ belongs to Iso_i. Let $x_\pm$ be the sites of the column of x next to the mirror, as in Lemma 18.85, and put $\mathcal{Y} = {}^{\mathsf{L}(x_+,x_{n+1})}Z^{(2)}$; it is G-valued and covariant at x_+. Only bonds with both end points in $\mathbb{E}_+$ enter $\mathcal{Y}$. The one-step locality in Proposition YM3_I:4.5 iterates: each finer block about an endpoint in a given block is contained in that block. Consequently

$V_i(b_k)$ for $k \ge n+2$ is a function of U on the bonds with end points in $B^{K-i}(x_{k-1}) \cup B^{K-i}(x_k)$, and the lowest of these end points have the height $(x_{n+1})_\nu - \frac12(a_i - a_K) = c + \frac12 a_K$; the bare transports involved join x_+ to x_{2n+1}; and every height stays below $c + (n+2)a_i < c + \frac{\ell}{2}$. *The reflected quantity.* We have $\theta x_{n+1+k} = x_{n-k}$, and block equivariance gives $V_i[\theta U](\langle x_{n+k}, x_{n+k+1}\rangle) = V_i(\langle x_{n+1-k}, x_{n-k}\rangle)$, whence $V_i[\theta U]([x_{n+1}, x_{2n+1}]) = V_i([x, x_n])^{-1}$. Combined with $\mathsf{L}[\theta U](p,q) = \mathsf{L}(\theta p, \theta q)$, this yields $Z^{(2)}(\theta U) = ({}^{\mathsf{L}(x_n,x)}Z^{(1)})^{-1}$ and $\mathcal{Y}(\theta U) = ({}^{\mathsf{L}(x_-,x)}Z^{(1)})^{-1}$. As Re is unchanged by conjugation and $\mathsf{L}(x_-, x_{n+1}) = U(b_x)\mathsf{L}(x_+, x_{n+1})$, we obtain $\operatorname{Re} Y = \operatorname{Re}[\mathcal{Y}(\theta U)^{-1} \cdot {}^{U(b_x)}\mathcal{Y}(U)]$. Split $\mathcal{Y} = \mathsf{c} + i\mathsf{S}$, where $\mathsf{c} = \operatorname{Re}\mathcal{Y}$ is real and gauge invariant and $\mathsf{S} = \operatorname{Im}\mathcal{Y}$; then $\mathcal{Y}^{-1} = \mathsf{c} - i\mathsf{S}$, and since S and its conjugates are traceless, $\operatorname{Re} Y = \mathsf{c}(\theta U)\mathsf{c}(U) + \langle \mathsf{S}(\theta U), {}^{U(b_x)}\mathsf{S}(U)\rangle$. Cauchy–Schwarz in the scalar reflection form, applied to 1 and c and using reflection invariance, gives $\mathbb{E}[\mathsf{c}(\theta U)\mathsf{c}(U)] \ge (\mathbb{E}\mathsf{c})^2$, and by Lemma 18.85 the second term has a non-negative mean. Put $w = \mathbb{E}\mathsf{c} = \mathbb{E}\operatorname{Re} Z^{(2)} = 1 - \frac12\sigma_i(n)^2 \in [-1,1]$; then $\|Y - \mathbf{1}\|_2^2 \le 2 - 2w^2 \le 4(1-w) = 2\sigma_i(n)^2$. *Induction.* If $\sigma_i(1) = 0$, the two inequalities give $\sigma_i(n) = 0$ for all admissible n; otherwise divide by $\sigma_i(1)$ and assume $\sigma_i(1) = 1$. The bound holds for $n = 0, 1, 2$, because $c_{\mathrm{d}}(\sqrt{2} - 1) = 2$ and $c_{\mathrm{d}}(\sqrt{3} - 1) \ge 2$. For $n \ge 3$ with $(n+1)a_i < \frac{\ell}{4}$ let $n' = \lfloor \frac{n-1}{2} \rfloor$; as $2n' + 2 \le n + 1$, both inequalities may be used, and $\sigma_i(n) \le \sqrt{2}\sigma_i(n') + 2 \le c_{\mathrm{d}}\sqrt{2n'+2} - \sqrt{2}c_{\mathrm{d}} + 2 = c_{\mathrm{d}}\sqrt{2n'+2} - c_{\mathrm{d}} \le c_{\mathrm{d}}(\sqrt{n+1} - 1)$. (b) On $\mathsf{G}_{i_*}^K$ (Lemma 18.84(a)) we have $\varpi(V_{i'}) < 2c_\rho\varepsilon_{[i']} \le \omega_M$ for $i_* < i' \le K$, the last bound by the choice of d_Θ, as $i' > i_* \ge D_1 \ge d_\Theta$; so Lemma 18.78(d) gives $|V_{i'-1}(c')V_{i'}[c']^{-1} - \mathbf{1}| \le 16c_\rho L^2\varepsilon_{[i']}$ for these i' and every bond c' of $\Lambda_{i'-1}$. *One step.* Let $i_* \le i - \mathfrak{t}' < i \le K$ with $1 \le \mathfrak{t}' \le \mathfrak{t}$, let $c \parallel e_\nu$ be a bond of $\Lambda_{i-\mathfrak{t}'}$, and let $V_{i'}[[c]]$ be the transport of $V_{i'}$ along the straight path of $L^{i'-i+\mathfrak{t}'}$ bonds of $\Lambda_{i'}$ from c_- to c_+. For $i - \mathfrak{t}' < i' \le i$, $V_{i'-1}[[c]]V_{i'}[[c]]^{-1}$ is a product of $L^{i'-1-i+\mathfrak{t}'}$ conjugates of factors $V_{i'-1}(c')V_{i'}[c']^{-1}$, hence within $16c_\rho L^2 L^{i'-1-i+\mathfrak{t}'}\varepsilon_{[i']}$ of $\mathbf{1}$. Summing over i', with $\varepsilon_{[i']} \le L^{(i-i')/2}\varepsilon_{[i]}$ and $\sum_{q\ge0} L^{-q/2} \le 1.384$, gives $|V_{i-\mathfrak{t}'}(c)V_i[[c]]^{-1} - \mathbf{1}| \le 23c_\rho L^{\mathfrak{t}'+1}\varepsilon_{[i]}$ on $\mathsf{G}_{i_*}^K$; off this event the left-hand side cannot exceed 2, and the event fails with probability at most R_{i_*}. Since $z_{i-\mathfrak{t}'}(c) = (V_{i-\mathfrak{t}'}(c)V_i[[c]]^{-1})\, Z_i(c_-; L^{\mathfrak{t}'})$ and $(L^{\mathfrak{t}'} + 1)a_i \le 2a_{i-\mathfrak{t}'} \le 2 < \frac{\ell}{4}$, part (a) gives $\sigma_{i-\mathfrak{t}'}(1) \le c_{\mathrm{d}}L^{\mathfrak{t}'/2}\sigma_i(1) + 23c_\rho L^{\mathfrak{t}'+1}\varepsilon_{[i]} + 2R_{i_*}^{1/2}$. In terms of $y_i = L^{i/2}\sigma_i(1)$ this reads $y_{i-\mathfrak{t}'} \le c_{\mathrm{d}}y_i + \mathsf{f}$, with f the bracket in the claim. *Chaining.* Descend from K, where $y_K = 0$, to i_* in $q = \lceil (K - i_*)/\mathfrak{t} \rceil$ steps, each of length at most $\mathfrak{t}$: $y_{i_*} \le \mathsf{f}(1 + c_{\mathrm{d}} + \cdots + c_{\mathrm{d}}^{q-1}) \le \frac{c_{\mathrm{d}}^q}{c_{\mathrm{d}}-1}\mathsf{f} \le 0.27\, c_{\mathrm{d}}^q \mathsf{f}$, the same event $\mathsf{G}_{i_*}^K$ being used at every step. (c) Here $\mathfrak{t} = 31000$, $q \le \frac{K}{\mathfrak{t}} + 1$ and $c_{\mathrm{d}}^{K/\mathfrak{t}} = L^{s\cdot\frac{1260}{31000}\log_L c_{\mathrm{d}}} \le L^{0.02496\,s} \le L^{s/40}$, as $L \ge 13$; $L^{i'/2}\varepsilon_{[i']} \le \mathsf{e}$; $L^{K/2}R_i^{1/2} \le \mathsf{A}_R^{1/2}L^{630s+3i/2}e^{-a_R i^2/2}$ with $i \ge \frac{s}{5} - 1$, which is at most $\frac12 L^{\mathfrak{t}/2+1}$ for large s; and $0.27\, c_{\mathrm{d}}(23c_\rho + 1) \le 32(c_\rho + 1)$. For large s also $\lfloor s/5 \rfloor \ge D_1$, so (b) applies with $i_* = i$. □

Lemma 18.88 (Defects stacked in a column transverse to the shift add up at most like independent ones)**.** Let $K > s > j \ge 0$, $\beta > 0$, $h = a_s e_\nu$, and $n \ge 1$ with $(n+2)a_j < \frac{\ell}{4}$. Take a bond $b_1 \perp e_\nu$ of Λ_j, its translates $b_k = b_1 + (k-1)a_j e_\nu$ with the lower ends $y_k = (b_k)_-$, a number $\eta > 0$, and the truncated defects $\hat\pi_k = \pi_j(b_k)\mathbf{1}\{|\pi_j(b_k)| \le \eta\}$, formed from $V_s = \mathcal{M}^{K-s}U$. Then $\|\sum_{k=1}^n {}^{\mathsf{L}(y_1,y_k)}\hat\pi_k\|_2 \le \eta\,(\sqrt{3n} + n\sqrt{2\sigma_s(1)})$. ■

Sketch of proof. Since conjugation is an isometry and $\mathsf{L}(y_1,y_k)^{-1}\mathsf{L}(y_1,y_l) = \mathsf{L}(y_k,y_l)$, we have $|\sum_k {}^{\mathsf{L}(y_1,y_k)}\hat\pi_k|^2 = \sum_{k,l}\langle \hat\pi_k, {}^{\mathsf{L}(y_k,y_l)}\hat\pi_l\rangle$. There are at most $3n$ pairs with $|k-l| \le 1$, each contributing at most η^2. Now let $l \ge k+2$ (the case $l \le k-2$ is symmetric), and let t_k denote the height of b_k. *The mirror.* We place it at the height $c = \frac12(t_k + t_l - a_s) \in \frac{a_K}{2}\mathbb{Z}$. Because $(l-k)a_j - a_s = a_s((l-k)L^{s-j} - 1)$ with L^{s-j} odd, the mirror is of the site type when $l-k$ is odd and of the bond type when $l-k$ is even. Its reflection is $\vartheta = \mathsf{r} \circ \mathrm{t}_h$, where r is the reflection at the height $\frac12(t_k + t_l) \in \frac{a_j}{2}\mathbb{Z}$; thus $\mathsf{r} \in \mathsf{Iso}_j$, $\vartheta \in \mathsf{Iso}_s$, $\mathsf{r}b_l = b_k$ and $\vartheta y_l = y_k - h$. Block equivariance gives $V_j[\vartheta U] = \mathsf{r}V_j'$, $V_j'[\vartheta U] = \mathsf{r}V_j$ and $V_s[\vartheta U] = \vartheta V_s$, so that $g[\vartheta U](x) = g(\mathsf{r}x)^{-1}$. Therefore $\mathsf{P}_j(b_l)[\vartheta U] = g(y_k)V_j(b_k)g(b_{k+})^{-1}V_j'(b_k)^{-1} = {}^{g(y_k)}(\mathsf{P}_j(b_k)^{-1})$, and Lemma 18.78(a) gives $\hat\pi_l \circ \vartheta = -{}^{g(y_k)}\hat\pi_k$, the truncation depending on the norm

only. Consequently $\langle\hat\pi_k, {}^{\mathsf{L}(y_k,y_l)}\hat\pi_l\rangle = -\langle\hat\pi_l\circ\vartheta, {}^{g(y_k)\mathsf{L}(y_k,y_l)}\hat\pi_l\rangle$. *Replacing g by a bare transport.* Since $g(y_k)\mathsf{L}(y_k,y_k-h) = z_s(\langle y_k-h,y_k\rangle)$, we get $|g(y_k)\mathsf{L}(y_k,y_l)-\mathsf{L}(y_k-h,y_l)| = |z_s(\langle y_k-h,y_k\rangle)-\mathbf{1}|$, a quantity of mean at most $\sigma_s(1)$; by Lemma 18.78(a), making this replacement changes the mean of the pairing by at most $2\sigma_s(1)\eta^2$. *Positivity.* Let $x_\pm$ be the sites of the column of the y_k next to the mirror, and $S = {}^{\mathsf{L}(x_+,y_l)}\hat\pi_l$, which is covariant at x_+ by Lemma 18.83(b). By the locality of the averaging, $\mathsf{P}_j(b_l)$ depends on U only through the bonds with end points in $B^{K-j}((b_l)_\pm)$, in the translates of these blocks by $-h$, and in $B^{K-s}((b_l)_\pm)$, $B^{K-s}((b_l)_\pm-h)$. All these end points have heights at least $t_l-a_s-\frac12(a_j-a_K)$, which is $\ge c+\frac12 a_K$ because $t_l-t_k\ge 2a_j\ge a_j+a_s$, and at most $t_l+\frac12 a_j < c+\frac{\ell}{2}$. Hence S meets the hypotheses of Lemma 18.85 for either type. Moreover $S(\vartheta U) = {}^{\mathsf{L}(x_-,y_k-h)}(\hat\pi_l\circ\vartheta)$ and $\mathsf{L}(y_k-h,x_-)U(b_x)\mathsf{L}(x_+,y_l) = \mathsf{L}(y_k-h,y_l)$, so $\langle S,S\rangle_\Sigma = \mathbb{E}\langle\hat\pi_l\circ\vartheta, {}^{\mathsf{L}(y_k-h,y_l)}\hat\pi_l\rangle \ge 0$. *Collecting.* For $|k-l|\ge 2$ this gives $\mathbb{E}\langle\hat\pi_k, {}^{\mathsf{L}(y_k,y_l)}\hat\pi_l\rangle \le 2\sigma_s(1)\eta^2$, and therefore $\|\sum_k {}^{\mathsf{L}(y_1,y_k)}\hat\pi_k\|_2^2 \le 3n\eta^2+2n^2\sigma_s(1)\eta^2$. □

Lemma 18.89 (Defects in a column along the shift, controlled through increments of a correlation of positive type)**.** Let $K>s>j\ge 0$, $\beta>0$, $h=a_se_\nu$, and $n\ge 1$ with $2(n+2)a_j<\frac{\ell}{4}$. Take a positively oriented bond $b_1\parallel e_\nu$ of Λ_j, $b_k=b_1+(k-1)a_je_\nu$ and $y_k=(b_k)_-$, and set $\mathfrak{a}_k=\operatorname{Im} z_j(b_k)$, $\mathfrak{a}_k^\flat(U)=\mathfrak{a}_k(\mathrm{t}_hU)$, $\tilde{\mathfrak{a}}_k = {}^{\mathsf{L}(y_k,y_k-h)}\mathfrak{a}_k^\flat$ and $\mathsf{v}=\mathbb{E}|\tilde{\mathfrak{a}}_1-\mathfrak{a}_1|^2$. Then $\|\sum_{k=1}^n {}^{\mathsf{L}(y_1,y_k)}(\tilde{\mathfrak{a}}_k-\mathfrak{a}_k)\|_2^2 \le n\,[5\mathsf{v}+7L^{-2(s-j)}\sigma_j(1)^2]$. Moreover, writing $\mathsf{P}_j^{\mathsf{L}}(b)=\mathsf{L}(b_-,b_--h)\,V_j'(b)\,\mathsf{L}(b_+-h,b_+)\,V_j(b)^{-1}$, the identity $\tilde{\mathfrak{a}}_k-\mathfrak{a}_k=\operatorname{Im}\mathsf{P}_j^{\mathsf{L}}(b_k)+\operatorname{Im}[(\mathsf{P}_j^{\mathsf{L}}(b_k)-\mathbf{1})(z_j(b_k)-\mathbf{1})]$ holds exactly, $|\tilde{\mathfrak{a}}_k-\mathfrak{a}_k|\le|\mathsf{P}_j^{\mathsf{L}}(b_k)-\mathbf{1}|$, and $|\mathsf{P}_j^{\mathsf{L}}(b)-\mathsf{P}_j(b)|\le|z_s(\langle b_--h,b_-\rangle)-\mathbf{1}|+|z_s(\langle b_+-h,b_+\rangle)-\mathbf{1}|$ for every bond b of Λ_j. ■

Sketch of proof. The identity. Fix $b=b_k$ and write $z=z_j(b)$. Since $V_j[\mathrm{t}_hU]=V_j'$ and $\mathsf{L}[\mathrm{t}_hU](p,q)=\mathsf{L}(p-h,q-h)$, we get $z^\flat = z\circ\mathrm{t}_h = V_j'(b)\mathsf{L}(b_+-h,b_--h)$; let $\tilde z = {}^{\mathsf{L}(b_-,b_--h)}z^\flat$. Along one column $\mathsf{L}(b_+-h,b_--h)\mathsf{L}(b_--h,b_-)\mathsf{L}(b_-,b_+)=\mathsf{L}(b_+-h,b_+)$, so $\tilde z z^{-1}=\mathsf{P}_j^{\mathsf{L}}(b)=:P$. Then $\tilde{\mathfrak{a}}-\mathfrak{a}=\operatorname{Im}(Pz-z)$, where $Pz-z=(P-\mathbf{1})+(P-\mathbf{1})(z-\mathbf{1})$, and $|\operatorname{Im}(Pz-z)|\le|P-\mathbf{1}|$. In P_j, compared with $\mathsf{P}_j^{\mathsf{L}}$, the factor $g(b_-)^{-1}$ stands in place of $\mathsf{L}(b_-,b_--h)$ and $g(b_+)$ in place of $\mathsf{L}(b_+-h,b_+)$; and $|g(x)-\mathsf{L}(x-h,x)|=|z_s(\langle x-h,x\rangle)-\mathbf{1}|$. *Shifted copies.* For $y\in a_K\mathbb{Z}$ let y be the site of the column at the height y, and $\mathfrak{a}^{(y)}(U)=\mathfrak{a}_1(\mathrm{t}_{(t_1-y)e_\nu}U)$, t_k being the height of y_k. Block equivariance gives $\mathfrak{a}^{(t_k)}=\mathfrak{a}_k$ and $\mathfrak{a}^{(t_k-a_s)}=\mathfrak{a}_k^\flat$. Each $\mathfrak{a}^{(y)}$ satisfies $|\mathfrak{a}^{(y)}|\le 1$, is covariant at y, and depends on U only at heights in $[y-\frac12(a_j-a_K),\,y+a_j+\frac12(a_j-a_K)]$. *Behaviour under reflections.* For $c\in\frac{a_K}{2}\mathbb{Z}$ let θ_c be the reflection at the height c, and $y^*=2c-y-a_j$. Then $\mathfrak{a}^{(y)}\circ\theta_c = -{}^{\mathsf{L}(\mathsf{y}^*+a_je_\nu,\mathsf{y}^*)}\mathfrak{a}^{(y^*)}$. To see this, reflect at the midpoint $c_1=t_1+\frac{a_j}{2}$ of b_1: $z_j(b_1)[\theta_{c_1}U]=V_j(b_1)^{-1}\mathsf{L}(b_{1-},b_{1+})=({}^{\mathsf{L}(b_{1+},b_{1-})}z_j(b_1))^{-1}$; and on heights, θ_c followed by the translation through t_1-y equals the translation through t_1-y^* followed by θ_{c_1}. *A correlation function.* For $T\in a_K\mathbb{Z}$ with $0\le T<\frac{\ell}{2}$, $C(T)=\mathbb{E}\langle\mathfrak{a}^{(y)}, {}^{\mathsf{L}(\mathsf{y},\mathsf{y}+Te_\nu)}\mathfrak{a}^{(y+T)}\rangle$ is independent of y, and $|C(T)|\le\sigma_j(1)^2$; let $v=-C$. *Positive type.* Let $c\in\frac{a_K}{2}\mathbb{Z}$, let $y_\alpha\in a_K\mathbb{Z}$ be finitely many heights with $c+\frac{a_j}{2}\le y_\alpha<c+\frac{\ell}{4}-a_j$, and let ξ_α be real. Then $S=\sum_\alpha\xi_\alpha\,{}^{\mathsf{L}(x_+,\mathsf{y}_\alpha)}\mathfrak{a}^{(y_\alpha)}$ meets the hypotheses of Lemma 18.85 at mirrors of both types: each $\mathfrak{a}^{(y_\alpha)}$ depends on U only at heights $\ge c+\frac12 a_K$, the transport $\mathsf{L}(x_+,\mathsf{y}_\alpha)$ climbs the column starting at x_+, whose height is $c+\frac12 a_K$ at a bond mirror and c at a site mirror, and all these heights stay below $c+\frac{\ell}{2}$; so every bond that enters S lies in $\mathsf{B}(\Sigma)$. By the reflection rule, $S_\alpha(\theta U)=-{}^{\mathsf{L}(x_-,\mathsf{y}_\alpha^*)}\mathfrak{a}^{(y_\alpha^*)}$, so that $\mathbb{E}\langle S_\alpha(\theta U), {}^{U(b_x)}S_\beta(U)\rangle = v(y_\alpha+y_\beta+a_j-2c)$; hence $\sum_{\alpha,\beta}\xi_\alpha\xi_\beta\,v(y_\alpha+y_\beta+a_j-2c)=\langle S,S\rangle_\Sigma\ge 0$. *Pairs of distinct bonds.* For $l>k$ and $T=t_l-t_k$, the pairing $D_{kl}=\mathbb{E}\langle\tilde{\mathfrak{a}}_k-\mathfrak{a}_k, {}^{\mathsf{L}(y_k,y_l)}(\tilde{\mathfrak{a}}_l-\mathfrak{a}_l)\rangle$ expands into four correlations, with the arguments T, T, $T+a_s$ and $T-a_s$; thus $D_{kl}=v(T+a_s)+v(T-a_s)-2v(T)$. Suppose $l-k\ge 3$, put $n_{kl}=(l-k-2)L^{s-j}$, so that $n_{kl}a_s=T-2a_j$, and $e(\gamma)=v(T+\gamma a_s)$ for $|\gamma|\le n_{kl}$. Given ξ supported in $[-\frac{n_{kl}}{2},\frac{n_{kl}}{2}]$ and in one class, choose $y_\circ\in a_K\mathbb{Z}$ for the class $\mathbb{Z}$ and $y_\circ\in a_K(\mathbb{Z}+\frac12)$ for the class $\mathbb{Z}+\frac12$ (recall that a_s/a_K is odd), and set $y_\alpha=y_\circ+\alpha a_s$ and $c=y_\circ+\frac12(a_j-T)$. Then $y_\alpha+y_\beta+a_j-2c=T+(\alpha+\beta)a_s$, $y_\alpha\ge c+\frac{a_j}{2}$, and $y_\alpha-c\le T-\frac32 a_j<\frac{\ell}{4}-a_j$ because $2T<\frac{\ell}{4}$. So

the positivity just established is precisely the hypothesis of Lemma 18.86, with both classes and both types of mirrors occurring. That lemma, together with $e(0) = v(T) \geq 0$ (positivity for a single α), yields $0 \leq D_{kl} \leq n_{kl}^{-2}[e(n_{kl}) + e(-n_{kl}) - 2e(0)] \leq 2n_{kl}^{-2}\sigma_j(1)^2$. *Summation.* By the Schwarz inequality and translation invariance, each of the at most $5n$ pairs with $|k-l| \leq 2$ contributes at most v; all remaining pairs together contribute at most $n \cdot 2\sum_{q\geq 1} 2q^{-2}L^{-2(s-j)}\sigma_j(1)^2 \leq 7nL^{-2(s-j)}\sigma_j(1)^2$. □

Lemma 18.90 (At a coarse depth the defect is, after a small gauge change and up to small errors, an average of finer defects along straight paths)**.** Let $D_g \leq d < D < j < s$ be integers, $\mathfrak{m} = j - D$, $N = L^{\mathfrak{m}}$, with

$$(\mathrm{Z}^\sharp) \qquad \mathsf{k}_2\mathsf{E}_s L^{-D} \leq \min\{c_*, \tfrac{\rho_L}{200}\}, \qquad \mathsf{k}_1(2+s)^2\varepsilon_{[s]} \leq \tfrac{\rho_L}{200}, \qquad \mathsf{k}_1(2+s)L^j\varepsilon_{[s]} \leq \mathsf{k}_2\mathsf{E}_s,$$

and put $\mathsf{H}_s = \mathsf{k}_2\mathsf{E}_s + \mathsf{k}_1(2+s)L^j\varepsilon_{[s]}$ with the j of this lemma; then $\mathsf{H}_s \leq 2\mathsf{k}_2\mathsf{E}_s$, and $L^i\bar\eta_i \leq \mathsf{H}_s$ for $i \leq j$. Let $h = \pm a_s e_\nu$, $V \in \mathsf{Gd}_{d,s}$, c_0 a bond of Λ_d, u and Φ_i, $d \leq i \leq s$, the objects of Lemma 18.82 at $j_0 = d$, $\mathcal{R}_i$ the set of the bonds of Λ_i with both end points in $B^{i-d}(c_{0-}) \cup B^{i-d}(c_{0+})$, and $E_i'(b) = \mathsf{u}(b_- - h)V_i'(b)\mathsf{u}(b_+ - h)^{-1}$ for $b \in \mathcal{R}_i$. Let i_1 be the least integer $\geq D_g$ with $\mathsf{k}_2\mathsf{E}_s L^{-i_1} \leq \min\{c_*, \frac{\rho_L}{200}\}$; then $i_1 \leq D$ and $L^{i_1} \leq L\max\{L^{D_g}, \mathsf{k}_2\mathsf{E}_s/\min\{c_*, \frac{\rho_L}{200}\}\}$.

(a) $E_i' = \mathcal{M}^{s-i}(e^{i\,\mathrm{t}_h\Phi_s})$ on $\mathcal{R}_i$, and $||E_i'(b) - e^{i\Phi_i(b)}| - |\mathsf{P}_i(b) - \mathbf{1}|| \leq 2C_g\varepsilon_{[s]}$ for $d \leq i \leq s$ and $b \in \mathcal{R}_i$. For $\max\{d, i_1\} \leq i \leq s$: $|E_i'(b) - e^{i\Phi_i(b)}| \leq \bar\eta_i + 2C_g\varepsilon_{[s]}$, $E_i' = e^{i\Phi_i'}$ on $\mathcal{R}_i$, and $\delta_i = \Phi_i' - \Phi_i$ has $|\delta_i| \leq 3\bar\eta_i$, $|\Phi_i'| \leq \rho_L$.

(b) For $b \in \mathcal{R}_j$: $|\delta_j(b) - {}^{\mathsf{u}(b_-)}\pi_j(b)| \leq \varrho^{(3)} = 3C_g\varepsilon_{[j]}\bar\eta_j + 5\bar\eta_j^3 + 2C_g\varepsilon_{[s]}$.

(c) Let $\zeta = \zeta_{\mathfrak{m}}(\delta_j)$ (Lemma 18.79(b)), defined at the sites of Λ_D that lie in $B^{D-d}(c_{0-}) \cup B^{D-d}(c_{0+})$, and $\tilde E_D(c) = e^{i\zeta(c_-)}E_D'(c)e^{-i\zeta(c_+)}$. Then $|\zeta| \leq 4.5L^{-D}\mathsf{H}_s$; $\tilde E_D = e^{i\tilde\Phi_D}$ on $\mathcal{R}_D$; and $\tilde\delta_D = \tilde\Phi_D - \Phi_D$ satisfies $|\tilde\delta_D(c) - \mathsf{M}(c)| \leq \varrho$ for $c \in \mathcal{R}_D$, where $\mathsf{M}(c) = L^{-3\mathfrak{m}}\sum_{x\in B^{\mathfrak{m}}(c_-)}\sum_{b\in[x,x+c_+-c_-]} {}^{\mathsf{u}(b_-)}\pi_j(b)$, the inner sum over the N bonds of a straight path of Λ_j, and $L^D\varrho \leq \mathsf{H}_s[(C_N+21)C_g\varepsilon_{[D]} + (C_N+100)L^{-D}\mathsf{H}_s] + 2C_gL^j\varepsilon_{[s]}$.

The objects u, Φ_i, Φ_i', ζ and $\tilde\delta_D$ can be chosen as Borel functions of V on $\mathsf{Gd}_{d,s}$. ■

Sketch of proof. (a) Write $\mathsf{u}' = \mathsf{u}(\cdot - h)$. For $b \in \mathcal{R}_s$ the bond $b - h$ lies in the box, and $(\mathrm{t}_hV)^{\mathsf{u}'}(b) = V^{\mathsf{u}}(b-h) = e^{i\Phi_s(b-h)}$; covariance and locality of the averaging then give $\mathcal{M}^{s-i}(e^{i\,\mathrm{t}_h\Phi_s})(b) = \mathsf{u}'(b_-)V_i'(b)\mathsf{u}'(b_+)^{-1} = E_i'(b)$. Let $\varsigma(x) = \mathsf{u}(x-h)g(x)\mathsf{u}(x)^{-1} = V^{\mathsf{u}}(\langle x-h, x\rangle)$, so that $|\varsigma(x) - \mathbf{1}| \leq C_g\varepsilon_{[s]}$. Using $V_i'(b) = g(b_-)\check V_i(b)g(b_+)^{-1}$ (Lemma 18.83(a)) one finds

$$E_i'(b) = \varsigma(b_-)\,{}^{\mathsf{u}(b_-)}\mathsf{P}_i(b)\,e^{i\Phi_i(b)}\,\varsigma(b_+)^{-1},$$

and the first inequality follows. If $\max\{d, i_1\} \leq i < s$, then $i \geq D_g$ and $\mathsf{k}_2L^{s-i}\varepsilon_{[s]}^2 = \mathsf{k}_2\mathsf{E}_sL^{-i} \leq c_*$, so Lemma 18.83(c) gives $|\mathsf{P}_i(b) - \mathbf{1}| \leq \bar\eta_i$; for $i = s$, $|\mathsf{P}_s(b) - \mathbf{1}| \leq \varpi(V) < 2\varepsilon_{[s]} \leq \bar\eta_s$ (Lemma 18.83(a)). Condition $(\mathrm{Z}^\sharp)$ gives $\bar\eta_i \leq \frac{\rho_L}{100}$; hence $|E_i' - \mathbf{1}| < 1$, the logarithm $\Phi_i' = -i\log E_i'$ exists, Lemma 18.78(b) gives $|\delta_i| \leq 2(\bar\eta_i + 2C_g\varepsilon_{[s]}) \leq 3\bar\eta_i$, and $|\Phi_i'| \leq \frac{\rho_L}{2} + \frac{3\rho_L}{100}$. (b) From the display, $|E_j'e^{-i\Phi_j} - {}^{\mathsf{u}(b_-)}\mathsf{P}_j(b)| \leq 2C_g\varepsilon_{[s]}$. Lemma 18.78(b) gives $|e^{i\Phi_j'}e^{-i\Phi_j} - e^{i\delta_j}| \leq |[\delta_j, \Phi_j]|/2 \leq |\delta_j||\Phi_j|$. Further, $|\operatorname{Im} e^{i\delta} - \delta| = |\delta| - \sin|\delta| \leq \frac{1}{6}|\delta|^3$. Finally Im is 1-Lipschitz and commutes with ${}^{\mathsf{u}(b_-)}$. (c) For $D < i \leq j$ part (a) applies, because $i \geq D \geq i_1$, and gives $\sup_{\mathcal{R}_i}|\Phi_i|, \sup_{\mathcal{R}_i}|\Phi_i'| \leq \rho_L$; Lemma 18.80(a) on $\mathcal{R}_{i-1}$ then gives $\delta_{i-1} = \mathbf{Q}\delta_i + r_i$ with $|r_i| \leq C_N(C_g\varepsilon_{[i]} + 3\bar\eta_i)\,3\bar\eta_i$. Iterating, and using Lemma 18.79(b), (c): $\delta_D = \mathbf{Q}^{\mathfrak{m}}\delta_j + \sum_{i=D+1}^{j}\mathbf{Q}^{i-1-D}r_i = \mathbf{S}^{\mathfrak{m}}\delta_j + \mathrm{d}\zeta + \rho^{(1)}$, where $|\rho^{(1)}| \leq \sum_{i=D+1}^{j} 4L^{i-1-D}\,3C_N(C_g\varepsilon_{[i]} + 3\bar\eta_i)\bar\eta_i$. With $L^i\bar\eta_i \leq \mathsf{H}_s$, $\sum_{i>D}\varepsilon_{[i]} \leq 0.62\varepsilon_{[D]}$ and $\sum_{i>D}L^{-i} = \frac{L^{-D}}{L-1}$ this gives $L^D|\rho^{(1)}| \leq C_N\mathsf{H}_s[C_g\varepsilon_{[D]} + L^{-D}\mathsf{H}_s]$. The value $\zeta(y)$ depends only on δ_j inside $B^{\mathfrak{m}}(y)$, and $|\zeta| \leq \frac{3}{2}(L^{\mathfrak{m}} - 1)\sup|\delta_j| \leq 4.5L^{\mathfrak{m}}\bar\eta_j \leq 4.5L^{-D}\mathsf{H}_s$. *Removing* $\mathrm{d}\zeta$ *by a gauge change.* Two applications of Lemma 18.78(b) give $|e^{i\zeta(c_-)}e^{i\Phi_D'(c)}e^{-i\zeta(c_+)} - e^{i(\Phi_D'(c) - (\mathrm{d}\zeta)(c))}| \leq |\zeta(c_-)||\Phi_D'(c)| + |\zeta(c_+)|(|\Phi_D'(c)| + |\zeta(c_-)|)$. All exponents having norm below 1.1, it follows that $\tilde\Phi_D = \Phi_D' - \mathrm{d}\zeta + \rho^{(2)}$ with $|\rho^{(2)}| \leq$

$2\sup|\zeta|(2\sup|\Phi'_D|+\sup|\zeta|)$, and, as $|\Phi'_D|\le C_g\varepsilon_{[D]}+3L^{-D}\mathsf{H}_s$, $L^D|\rho^{(2)}|\le 9\mathsf{H}_s[2C_g\varepsilon_{[D]}+10.5L^{-D}\mathsf{H}_s]$. *Combining.* We have $\tilde\delta_D=\mathbf{S}^{\mathfrak m}\delta_j+\rho^{(1)}+\rho^{(2)}$. The value $(\mathbf{S}^{\mathfrak m}\delta_j)(c)$ is a sum of $L^{3\mathfrak m}\cdot L^{\mathfrak m}$ values $\delta_j(b)$, each with the weight $L^{-3\mathfrak m}$; so (b) gives $|(\mathbf{S}^{\mathfrak m}\delta_j)(c)-\mathsf{M}(c)|\le L^{\mathfrak m}\varrho^{(3)}$, and $L^{D+\mathfrak m}\varrho^{(3)}\le \mathsf{H}_s(3C_g\varepsilon_{[D]}+5L^{-D}\mathsf{H}_s)+2C_gL^j\varepsilon_{[s]}$. *Measurability* follows from Lemma 18.82 and from that of the logarithm near $\mathbf{1}$. □

Lemma 18.91 (The mean of the defect on the diagonal)**.** Assume the one-torus setting; let s be large, $D,\mathfrak m,j,N,K$ on the diagonal, $D_g\le d<D$, c_0 a bond of Λ_d, $h=a_se_\nu$, and $\mathcal G=\{U\in\mathcal V_K:\mathcal M^{K-s}U\in\mathsf{Gd}_{d,s}\}$, the objects of Lemma 18.90 being formed from $V=\mathcal M^{K-s}U$ on $\mathcal G$. Then ($\mathsf{Z}^\sharp$) holds, and $X_D=\max_{c\in\mathcal R_D}\mathbb E[|\tilde\delta_D(c)|;\mathcal G]\le \mathsf{C}_7\,\mathsf{e}^4L^{-D}L^{-s/20}$ with a number C_7 formed from L and c_ρ. ■

Sketch of proof. Step 0. On the diagonal $D\ge\frac{s}{5}-1$ and $j\le\frac32D\le0.3s$. The quantities $\mathsf{k}_2\mathsf{E}_sL^{-D}\le\mathsf{k}_2\mathsf{e}^2L^{1-s/5}$, $\mathsf{k}_1(2+s)^2\varepsilon_{[s]}\le\mathsf{k}_1(2+s)^2\mathsf{e}L^{-s/2}$ and $\mathsf{k}_1(2+s)L^j\varepsilon_{[s]}\le\mathsf{k}_1(2+s)\mathsf{e}L^{-s/5}$ tend to 0, whereas $\mathsf{k}_2\mathsf{E}_s\ge\mathsf{k}_2A_0^2\mathsf{b}^{-1}$; so ($\mathsf{Z}^\sharp$) holds once s is large, and then $\mathsf{H}_s\le2\mathsf{k}_2\mathsf{e}^2$. *Step 1: reduction to columns.* Fix $c\in\mathcal R_D$. If the direction κ of c differs from ν, fix in $\mathsf{M}(c)$ the position along the straight path together with the two coordinates of x other than the height (N^3 choices); what remains is a sum over the N heights of x, namely $\Sigma=\sum_{k=1}^N{}^{\mathsf u(y_k)}\pi_j(b_k)$ over a column of bonds $b_k=b_1+(k-1)a_je_\nu\perp e_\nu$ with $y_k=(b_k)_-$. If $c\parallel e_\nu$, fix instead $x\in B^{\mathfrak m}(c_-)$; the sum along the path is again of the form Σ, now with $b_k\parallel e_\nu$. As $L^{-3\mathfrak m}N^3=1$, we get $\mathbb E[|\mathsf M(c)|;\mathcal G]\le\max\mathbb E[|\Sigma|;\mathcal G]$, where the maximum runs over all columns of N bonds of $\mathcal R_j$ of these two kinds. *Step 2: change of frame.* Put $\mathsf L^{\mathsf u}(y_1,y_k)=\mathsf u(y_1)\mathsf L(y_1,y_k)\mathsf u(y_k)^{-1}$. Then ${}^{\mathsf u(y_k)}X={}^{\mathsf L^{\mathsf u}(y_1,y_k)^{-1}\mathsf u(y_1)\mathsf L(y_1,y_k)}X$, and Lemma 18.78(a) gives $|\Sigma|\le|\sum_k{}^{\mathsf L(y_1,y_k)}\pi_j(b_k)|+2\sum_k|\mathsf L^{\mathsf u}(y_1,y_k)-\mathbf1||\pi_j(b_k)|$. Because $V_j^{\mathsf u}([y_1,y_k])\,\mathsf L^{\mathsf u}(y_1,y_k)^{-1}={}^{\mathsf u(y_1)}Z_j(y_1;k-1)$, and because on $\mathcal G$ we have $|V_j^{\mathsf u}([y_1,y_k])-\mathbf1|\le(k-1)C_g\varepsilon_{[j]}$ (the bonds of the column lie inside the box), we get $|\mathsf L^{\mathsf u}(y_1,y_k)-\mathbf1|\le|Z_j(y_1;k-1)-\mathbf1|+NC_g\varepsilon_{[j]}$. On $\mathcal G$, $|\pi_j(b)|\le|\mathsf P_j(b)-\mathbf1|\le\bar\eta_j$ by Lemma 18.83(c), whose hypotheses at the depth j follow from ($\mathsf{Z}^\sharp$); and $\mathbb E|Z_j(y_1;k-1)-\mathbf1|\le\sigma_j(k-1)\le c_{\mathrm d}\sqrt N\sigma_j(1)$ by Lemma 18.87(a). Hence the last sum has, on $\mathcal G$, a mean of at most $2N\bar\eta_j[c_{\mathrm d}\sqrt N\sigma_j(1)+NC_g\varepsilon_{[j]}]$. *Step 3: columns of bonds transverse to the shift.* On $\mathcal G$ the truncation at $\eta=\bar\eta_j$ changes nothing, $\pi_j(b_k)=\hat\pi_k$, and Lemma 18.88, whose hypothesis $(N+2)a_j<\frac{\ell}{4}$ is satisfied, gives $\mathbb E[|\sum_k{}^{\mathsf L(y_1,y_k)}\pi_j(b_k)|;\mathcal G]\le\bar\eta_j(\sqrt{3N}+N\sqrt{2\sigma_s(1)})$. *Step 4: columns of bonds along the shift.* Let $\zeta'_k=|z_s(\langle y_k-h,y_k\rangle)-\mathbf1|+|z_s(\langle y_{k+1}-h,y_{k+1}\rangle)-\mathbf1|$; then $\mathbb E\zeta'_k\le2\sigma_s(1)$ and $\mathbb E\zeta'^2_k\le4\sigma_s(1)^2$. Lemma 18.89 gives, on $\mathcal G$, $|\pi_j(b_k)-(\tilde{\mathfrak a}_k-\mathfrak a_k)|\le|\mathsf P_j(b_k)-\mathsf P_j^{\mathsf L}(b_k)|+|\mathsf P_j^{\mathsf L}(b_k)-\mathbf1||z_j(b_k)-\mathbf1|\le3\zeta'_k+\bar\eta_j|z_j(b_k)-\mathbf1|$, whose mean is at most $6\sigma_s(1)+\bar\eta_j\sigma_j(1)$. Moreover $\mathsf v\le2\mathbb E|\mathsf P_j(b_1)-\mathbf1|^2+2\mathbb E\zeta'^2_1\le2\bar\eta_j^2+8\frac{L}{L-1}R_j+8\sigma_s(1)^2$, using Lemma 18.83(c) on $\{\mathcal M^{K-s}U\in\mathsf{Gd}_{j,s}\}$ and Lemma 18.84(b) for the complement. Lemma 18.89, whose hypothesis $2(N+2)a_j<\frac{\ell}{4}$ is satisfied, together with $\sigma_j(1)\le2$, then gives $\mathbb E[|\sum_k{}^{\mathsf L(y_1,y_k)}\pi_j(b_k)|;\mathcal G]\le\sqrt N[\sqrt{10}\,\bar\eta_j+7R_j^{1/2}+7\sigma_s(1)+6L^{-(s-j)}]+N[6\sigma_s(1)+\bar\eta_j\sigma_j(1)]$. *Step 5: bookkeeping.* Lemma 18.90(c) and Steps 1–4, with $L^DN=L^j$ and $L^j\bar\eta_j\le\mathsf H_s$, give

$$L^DX_D\le\mathsf H_s\Big[\sqrt{\tfrac{10}{N}}+\sqrt{2\sigma_s(1)}+(2c_{\mathrm d}\sqrt N+1)\sigma_j(1)+2NC_g\varepsilon_{[j]}\Big]+L^j\Big[\tfrac{7}{\sqrt N}(R_j^{1/2}+\sigma_s(1)+L^{-(s-j)})+6\sigma_s(1)\Big]+L^D\varrho.$$

Using $\frac{s}{10}-1\le\mathfrak m\le\frac{D}{2}$, $j\le0.3s$ and Lemma 18.87(c), we have: $N^{-1/2}\le L^{1/2}L^{-s/20}$; $\sqrt{2\sigma_s(1)}\le(2\mathsf C_3\mathsf e)^{1/2}L^{-19s/80}$; $\sqrt N\sigma_j(1)\le\mathsf C_3\mathsf eL^{\mathfrak m/2+s/40-j/2}=\mathsf C_3\mathsf eL^{s/40-D/2}\le\mathsf C_3\mathsf eL^{1/2}L^{-3s/40}$; $NC_g\varepsilon_{[j]}\le C_g\mathsf eL^{(\mathfrak m-D)/2}\le C_g\mathsf eL^{1/4}L^{-s/20}$; $L^j\sigma_s(1)\le\mathsf C_3\mathsf eL^{-7s/40}$; $L^jL^{-(s-j)}\le L^{-2s/5}$; $L^jR_j^{1/2}\le A_R^{1/2}L^{5j/2}e^{-a_Rj^2/2}\le L^{-s}$ for large s; $\varepsilon_{[D]}\le\mathsf eL^{1/2}L^{-s/10}$; $L^{-D}\mathsf H_s\le2\mathsf k_2\mathsf e^2L^{1-s/5}$; $L^j\varepsilon_{[s]}\le\mathsf eL^{-s/5}$. So each term is bounded by a number formed from L and c_ρ, times $\mathsf e^4L^{-s/20}$. □

Lemma 18.92 (Going down the depths, first moments grow by at most the factor L per depth)**.** Keep the situation of Lemma 18.90, let $\mathbb P$ be a Borel probability measure on $\mathcal V_s$, regard V as

the random field with the law $\mathbb{P}$, and put $\mathcal{G} = \{V \in \mathsf{Gd}_{d,s}\}$, $X_D = \max_{c\in\mathcal{R}_D} \mathbb{E}_{\mathbb{P}}[|\tilde\delta_D(c)|;\mathcal{G}]$, and $C_G = 4\exp(0.015\,C_N)$. Then for every $\rho' > 0$

$$\mathbb{P}(\mathcal{G} \cap \{|\mathsf{P}_d(c_0) - \mathbf{1}| > \rho' + 9L^{-D}\mathsf{H}_s + 2C_g\varepsilon_{[s]}\}) \le C_G L^D X_D\Big[\frac{L^{-d}}{\rho'} + 12A_0^{-1}\mathsf{b}^{1/2}L^{\frac52 i_1}\Big].$$

■

Sketch of proof. Following the descent. For $d \le i \le D$ and $b \in \mathcal{R}_i$ let $\tilde E_i = \mathcal{M}^{D-i}(\tilde E_D)$; by the covariance, $\tilde E_i(b) = e^{i\zeta(b_-)}E'_i(b)e^{-i\zeta(b_+)}$. Let $\mathsf{x}_i(b) = |\tilde E_i(b) - e^{i\Phi_i(b)}|$. It differs from $|E'_i(b) - e^{i\Phi_i(b)}|$ by at most $2\sup|\zeta|$, and Lemma 18.90(a), (c) yields $|\mathsf{P}_d(c_0) - \mathbf{1}| \le \mathsf{x}_d(c_0) + 9L^{-D}\mathsf{H}_s + 2C_g\varepsilon_{[s]}$. *Thresholds.* Let $\varkappa_i = 20\bar\eta_i$ for $i_1 \le i \le D$ and $\varkappa_i = \varepsilon_{[i]}$ for $d \le i < i_1$. For $i_1 \le i \le D$, everywhere on $\mathcal{G}$, $\mathsf{x}_i \le \bar\eta_i + 2C_g\varepsilon_{[s]} + 9L^{-D}\mathsf{H}_s \le 20\bar\eta_i$, because $\mathsf{H}_s \le 2\mathsf{k}_2\mathsf{E}_s$ and $\mathsf{k}_2\mathsf{E}_sL^{-D} \le \bar\eta_i$. Set $\mathcal{G}_{D+1} = \mathcal{G}$ and $\mathcal{G}_i = \mathcal{G} \cap \{\mathsf{x}_{i'}(b) \le \varkappa_{i'}$ for all $b \in \mathcal{R}_{i'}$, $i \le i' \le D\}$; then $\mathcal{G}_i = \mathcal{G}$ for $i \ge i_1$, and $\mathcal{G}_i \subset \mathcal{G}_{i+1}$. On $\mathcal{G}_i$ and at each depth $i' \ge i$ we have $\tilde E_{i'} = e^{i\tilde\Phi_{i'}}$, the difference $\tilde\delta_{i'} = \tilde\Phi_{i'} - \Phi_{i'}$ satisfies $|\tilde\delta_{i'}| \le 2\varkappa_{i'}$ (Lemma 18.78(b)), and $\mathsf{m}_{i'} = \max\{\sup_{\mathcal{R}_{i'}}|\Phi_{i'}|, \sup_{\mathcal{R}_{i'}}|\tilde\Phi_{i'}|\} \le C_g\varepsilon_{[i']} + 2\varkappa_{i'} \le \rho_L$. In fact $\sum_{i'>d}(C_g\varepsilon_{[i']} + 2\varkappa_{i'}) \le \rho_L$, by ($\mathrm{Z}^\sharp$), by $\sum_{i'\ge i_1}\bar\eta_{i'} \le \mathsf{k}_1(2+s)^2\varepsilon_{[s]} + \frac{L}{L-1}\mathsf{k}_2\mathsf{E}_sL^{-i_1}$, and by $\sum_{i'>d}(C_g + 2)\varepsilon_{[i']} \le 0.62(C_g+2)\varepsilon_{[d]}$. *Recursion.* On $\mathcal{G}_{i+1}$, $d \le i < D$, Lemma 18.80(a) applied at the depths $i' > i$ produces $\tilde\Phi_i$ on $\mathcal{R}_i$ with $\tilde E_i = e^{i\tilde\Phi_i}$ and $\tilde\delta_i = \mathbf{Q}^{D-i}\tilde\delta_D + \sum_{i'=i+1}^D \mathbf{Q}^{i'-1-i}(q(\tilde\Phi_{i'}) - q(\Phi_{i'}))$, where $|q_c(\tilde\Phi_{i'}) - q_c(\Phi_{i'})| \le C_N\mathsf{m}_{i'}\sum_{b\in\mathsf{P}_c^+}|\tilde\delta_{i'}(b)|$ and $\#\mathsf{P}_c^+ \le 6L^3$. Let $X_i = \max_{b\in\mathcal{R}_i}\mathbb{E}[|\tilde\delta_i(b)|;\mathcal{G}_{i+1}]$. Since $\mathcal{G}_{i+1} \subset \mathcal{G}_{i'+1}$ for $i' \ge i$ and all integrands are non-negative, Lemma 18.79(c) gives $X_i \le 4L^{D-i}X_D + \sum_{i'=i+1}^D 4L^{i'-1-i}\,6L^3C_N(C_g\varepsilon_{[i']} + 2\varkappa_{i'})X_{i'}$. In terms of $Y_i = L^iX_i$ and $\kappa_{i'} = 24L^2C_N(C_g\varepsilon_{[i']} + 2\varkappa_{i'})$ this reads $Y_i \le 4Y_D + \sum_{i'>i}\kappa_{i'}Y_{i'}$, and a descending induction gives $Y_i \le 4Y_D\prod_{i<i'\le D}(1+\kappa_{i'}) \le 4Y_De^{\sum\kappa}$, where $\sum\kappa_{i'} \le 24L^2C_N\rho_L = 0.015\,C_N$. Hence $X_i \le C_GL^{D-i}X_D$ for $d \le i \le D$. *Existence of the logarithms.* For $d < i < i_1$, as $\mathsf{x}_i \le |\tilde\delta_i|$ on $\mathcal{G}_{i+1}$, Chebyshev's inequality and a union bound over the at most $6L^{3(i-d)}$ bonds of $\mathcal{R}_i$ give $\mathbb{P}(\mathcal{G}_{i+1}\setminus\mathcal{G}_i) \le 6L^{3(i-d)}X_i/\varepsilon_{[i]}$, and $\varepsilon_{[i]}^{-1} \le A_0^{-1}\mathsf{b}^{1/2}L^{i/2}$; adding up, $\mathbb{P}(\mathcal{G}\setminus\mathcal{G}_{d+1}) \le 12\,C_GA_0^{-1}\mathsf{b}^{1/2}L^DX_DL^{\frac52 i_1}$. *Conclusion.* $\mathbb{P}(\mathcal{G}\cap\{\mathsf{x}_d(c_0) > \rho'\}) \le \mathbb{P}(\mathcal{G}\setminus\mathcal{G}_{d+1}) + X_d/\rho'$; combine this with the bound for $|\mathsf{P}_d(c_0) - \mathbf{1}|$ found at the start. □

Lemma 18.93 (A shift by one fine spacing moves coarser block fields only slightly, outside a rare event)**.** Assume the one-torus setting and let $\nu \in \{1,2,3\}$. One can find numbers s_1 and $\mathsf{C}_A \ge 1$, formed from the constants, ℓ and b, with the following property. Whenever $s \ge s_1$ and d are integers with $D_1 \le d < \lfloor s/5\rfloor$, c is a bond of Λ_d, $\rho \in [L^{-s/6}, 2]$ and $h = \pm a_se_\nu$,

$$\mu(V_s \in \mathsf{Gd}_{d,s} \text{ and } |\mathsf{P}_d(c) - \mathbf{1}| > \rho) \le \mathsf{C}_A\,\rho^{-1}L^{-s/21},$$

where the defect is formed from V_s; and the same bound holds when the law μ_s of V_s is replaced by μ_s^K with $K = 1260s$. Consequently, for every $d \ge D_1$ and every $\rho > 0$, $\mu(\mathsf{Gd}_d \cap \{\mathrm{dist}_{\mathrm{orb}}((\mathrm{T}_hV_\bullet)_d, V_d) > \rho\}) \le 3\ell^3L^{3d}\mathsf{C}_A\rho^{-1}L^{-s/21}$ for all $s \ge s_1$ with $d < \lfloor s/5\rfloor$, which tends to 0 as $s \to \infty$. ■

Sketch of proof. Let s be large, let $D, \mathfrak{m}, j, N, K$ be the numbers of the diagonal, $D_1 \le d < D$, and $h = a_se_\nu$. The event in question is $\{V_s \in E\}$ for a Borel set $E \subset \mathcal{V}_s$ (Proposition YM3_I:4.5). Take the cutoff $K = 1260s$ and let $\mathbb{P}$ be the law μ_s^K of $V_s = \mathcal{M}^{K-s}U$; Lemma 18.91 gives ($\mathrm{Z}^\sharp$) and $L^DX_D \le \mathsf{C}_7\mathsf{e}^4L^{-s/20}$. When $\rho \ge L^{-s/6}$ and s is large, $9L^{-D}\mathsf{H}_s + 2C_g\varepsilon_{[s]} \le 18\mathsf{k}_2\mathsf{e}^2L^{1-s/5} + 2C_g\mathsf{e}L^{-s/2} \le \frac12 L^{-s/6} \le \frac{\rho}{2}$, so Lemma 18.92 with $\rho' = \frac{\rho}{2}$ gives $\mu_s^K(E) \le C_G\mathsf{C}_7\mathsf{e}^4L^{-s/20}[2\rho^{-1}L^{-d} + 12A_0^{-1}\mathsf{b}^{1/2}L^{\frac52 i_1}]$. Here $L^{i_1} \le \mathsf{Ce}^2$ with C formed from the constants and b, $1 \le 2\rho^{-1}$, $\mathsf{e} \le C_\mathsf{e}s^{\mathfrak{p}_0}$, and $s^{9\mathfrak{p}_0}L^{-s/20} \le \mathsf{C}'L^{-s/21}$. To pass from the cutoff to the limit, Corollary 2.8(b), (c) and eq. 2.xvii give, at $K = 1260s$ (so that $\lceil K/1260\rceil = s$) and for $K \ge K_{\mathrm{bf}}$, $|\mu_s(E) - \mu_s^K(E)| \le \mathsf{C}_{\mathrm{bf}}\ell^3\sum_{K'\ge K}K'^{\mathfrak{p}}L^{-K'/10}$ with $\mathfrak{p} = 2\mathfrak{p}_0 + \frac12$, and this is at most $\rho^{-1}L^{-s/21}$ when s is large. *The sign* $-$. The reflection $x_\nu \mapsto -x_\nu$ is a diagonal element of Iso_0. It preserves the Wilson measure and μ_s (by isometry invariance and Lemma 18.77(a)), commutes with $\mathcal{M}$, preserves ϖ and $\mathsf{Gd}_{d,s}$, and turns the covariant shift

through $a_s e_\nu$ into the one through $-a_s e_\nu$; the defects of the reflected field are those of the field at the reflected bonds, possibly reversed, and a reversal does not change $|\mathsf{P}-\mathbf{1}|$. *The last assertion.* By Lemma 18.83(a), $\mathrm{dist}_{\mathrm{orb}}(V'_{d,s}, V_d) \le \max_b |\mathsf{P}_d(b)-\mathbf{1}| \le 2$. The lattice Λ_d has $3\ell^3 L^{3d}$ positively oriented bonds, and $\mathsf{Gd}_d \subset \{V_s \in \mathsf{Gd}_{d,s}\}$. For $L^{-s/6} \le \rho \le 2$ the bound therefore follows from the first assertion by a union over bonds; for $\rho > 2$ the event is empty; and for $\rho < L^{-s/6}$ the right side exceeds 1, as $\mathsf{C}_A \ge 1$. □

Lemma 18.94 (Uniform control of all shifts shorter than a fine spacing)**.** Assume the one-torus setting. There is an integer $D_3 \ge D_1$, formed from the constants and b, such that for every $d \ge D_3$, every $\nu \in \{1,2,3\}$ and every $\rho > 0$:

$$\lim_{s'\to\infty} \sup_{t\in\mathbb{Q}_L,\ 0\le t<a_{s'}} \mu\big(\mathsf{Gd}_d \cap \{\mathrm{dist}_{\mathrm{orb}}((\mathrm{T}_{te_\nu}V_\bullet)_d, V_d) > \rho\}\big) = 0.$$

■

Sketch of proof. Parameters. Let $\kappa = 1$, $\lambda = L+1 \le L^{1.03}$, $\rho_* = \rho_{\mathrm{Lip}}(1)$ (Lemma 18.80(b)), $\delta(i) = \lfloor i/200 \rfloor$ and $\rho_i = \lambda^{-\delta(i)} L^{-i/84}$. Let D_3 be the least $d \ge D_1$ with $3\varepsilon_{[d]} < \omega_M$, $49L^2 \cdot 3 \cdot 0.62\,\varepsilon_{[d]} \le \frac12 \rho_*$ and $L^{-d/2}\mathsf{b}^{1/2} \le A_0$; the last condition gives $\lambda^{-i'} \le L^{-i'} \le \varepsilon_{[i']}$ for $i' \ge d$. Fix $d \ge D_3$ and choose s' so large that $s' \ge \max\{s_1, 200(d+1)\}$, $12L\sum_{i>s'} L^{-i/84} \le 1$ and $3L^{-s'/84} \le \frac12\rho_*$. For $i > s'$ one then has $D_1 \le d \le \delta(i) < \lfloor i/5 \rfloor$ and $L^{-i/6} \le L^{-0.0171\,i} \le \rho_i \le 2$, so that Lemma 18.93 is available with $(s,d,\rho) = (i,\delta(i),\rho_i)$. *Decomposing the shift.* Expand $t = \sum_{i=s'+1}^{S} k_i a_i$ in base L, $0 \le k_i \le L-1$, and carry out the $\sum_i k_i$ elementary shifts in the order of increasing i, the n-th one being through $a_{i_n}e_\nu$: $W^{(0)} = V_\bullet$ and $W^{(n+1)} = \mathrm{T}_{a_{i_n}e_\nu} W^{(n)}$. By Lemma 18.77(b) the final thread is $\mathrm{T}_{te_\nu}V_\bullet$, and each $W^{(n)}$ has the law μ. Let $\mathcal{E}_n$ be the event that (e1) $W^{(n)} \in \mathsf{Gd}_{\delta(i_n)}$, (e2) $W^{(n+1)} \in \mathsf{Gd}_{\delta(i_n)}$, and (e3) $|\mathsf{P}_{\delta(i_n)}(c) - \mathbf{1}| \le \rho_{i_n}$ at every bond c of $\Lambda_{\delta(i_n)}$, for the defects of the shift through $a_{i_n}e_\nu$ formed from $W^{(n)}$. Lemmas 18.84(b) and 18.93 give $\mu(\mathcal{E}_n^c) \le q_{i_n}$, where $q_i = 2\frac{L}{L-1}R_{\delta(i)} + 3\ell^3 L^{3\delta(i)}\mathsf{C}_A\rho_i^{-1}L^{-i/21} \le 2\frac{L}{L-1}R_{\delta(i)} + 3\ell^3\mathsf{C}_A L^{-i/65}$, because $\frac{3}{200} + \frac{1.03}{200} + \frac{1}{84} - \frac{1}{21} < -\frac{1}{65}$; and $\sum_i q_i < \infty$. *Claim:* on $\mathsf{Gd}_d \cap \bigcap_n \mathcal{E}_n$, for every n, (R_n) $\varpi(W^{(n)}_{i'}) < 2\varepsilon_{[i']} + 12\lambda^{-i'}\sum_{n'<n} L^{-i_{n'}/84}$ for all $i' \ge d$, and consequently $\varpi(W^{(n)}_{i'}) < 3\varepsilon_{[i']}$; and ($\mathrm{M}_n$) $\mathrm{dist}_{\mathrm{orb}}(W^{(n+1)}_{i'}, W^{(n)}_{i'}) \le 3\lambda^{-i'}L^{-i_n/84}$ for $d \le i' \le \delta(i_n)$. For $n = 0$, (R_0) says that $V_\bullet \in \mathsf{Gd}_d$. Suppose ($\mathrm{R}_n$) holds; write $i = i_n$, $W = W^{(n)}$, and let $\hat W_{i'} = \mathcal{M}^{i-i'}(\check W_i)$ denote the block fields of the covariantly shifted field at the depth i; by Lemma 18.83(a), $W^{(n+1)}_{i'}$ and $\hat W_{i'}$ differ by a gauge transformation. For $d \le i' < \delta(i)$ we may use Lemma 18.81(b) with $\kappa = 1$, $D' = \delta(i)$, $d' = i'$, $V_{D'} = W_{\delta(i)}$, $\tilde V_{D'} = \hat W_{\delta(i)}$ and $\eta = \rho_i$: its hypotheses hold, since $\varpi(W_{i''}) < 3\varepsilon_{[i'']} < \omega_M$, $49L^2\sum_{i''>i'} 3\varepsilon_{[i'']} \le \frac12\rho_*$, $|\hat W_{\delta(i)}(c) - W_{\delta(i)}(c)| = |\mathsf{P}_{\delta(i)}(c) - \mathbf{1}| \le \rho_i$ by (e3), and $3\lambda^{\delta(i)-i'}\rho_i \le 3L^{-i/84} \le \frac12\rho_*$. It yields $|\hat W_{i'}(c) - W_{i'}(c)| \le 3\lambda^{-i'}L^{-i/84}$ on every bond of $\Lambda_{i'}$; at $i' = \delta(i)$ the same bound is (e3); together this is (M_n). Each plaquette has four sides, so $\varpi(W^{(n+1)}_{i'}) = \varpi(\hat W_{i'}) \le \varpi(W_{i'}) + 12\lambda^{-i'}L^{-i/84}$ for $i' < \delta(i)$, while for $i' \ge \delta(i)$ the statement (R_{n+1}) is just (e2). Since each i occurs at most $L-1$ times among the i_n, $12\lambda^{-i'}\sum_{n'} L^{-i_{n'}/84} \le \lambda^{-i'} \le \varepsilon_{[i']}$. *Conclusion.* On $\mathsf{Gd}_d \cap \bigcap_n \mathcal{E}_n$ the triangle inequality for $\mathrm{dist}_{\mathrm{orb}}$ gives $\mathrm{dist}_{\mathrm{orb}}((\mathrm{T}_{te_\nu}V_\bullet)_d, V_d) \le 3\lambda^{-d}(L-1)\sum_{i>s'} L^{-i/84}$, which tends to 0 as $s' \to \infty$; and $\mu(\bigcup_n \mathcal{E}_n^c) \le (L-1)\sum_{i>s'} q_i \to 0$. Neither bound depends on t. □

Lemma 18.95 (The reflected correlation at a mirror is log-convex and convex)**.** Assume the one-torus setting; let (μ, c) be a mirror as in the notation, $\alpha' > 0$, $F \in \mathcal{A}(0,\alpha')$, and $I = \mathbb{Q}_L \cap [0, 2\alpha']$.

(a) Let $u \in \mathbb{Q}_L$, $c^* = c + \frac{u}{2}$, and $x, y \in \mathbb{Q}_L$ with $\frac{u}{2} \le x, y \le \alpha' + \frac{u}{2}$. Then $\mathcal{U}_x F$ and $\mathcal{U}_y F$ lie in $\mathcal{A}^{c^*}(0,0)$, and $\langle \mathcal{U}_x F, \mathcal{U}_y F\rangle_{c^*} = \varphi_F(x+y-u)$. In particular $\langle \mathcal{U}_{t_1}F, \mathcal{U}_{t_2}F\rangle_c = \varphi_F(t_1+t_2)$ for $t_1, t_2 \in \mathbb{Q}_L \cap [0,\alpha']$, and $0 \le \varphi_F \le \|F\|^2_{L^2(\mu)}$ on I.

(b) $\varphi_F(t)^2 \le \varphi_F(t-h)\,\varphi_F(t+h)$ whenever $t, h \in \mathbb{Q}_L$, $0 \le h \le t$ and $t + h \le 2\alpha'$.

(c) φ_F is convex on I and has a continuous extension to $(0, 2\alpha')$; the limit $\varphi_F(0+)$ exists and does not exceed $\varphi_F(0)$; and $\|\mathcal{U}_t F - F\|_c^2 \to \varphi_F(0) - \varphi_F(0+)$ as $t \downarrow 0$ in $\mathbb{Q}_L$.
(d) For $\alpha > 0$ and $F \in \mathcal{A}(\alpha, \alpha')$, the two moduli stated in Proposition 18.76(B2) hold.
(e) If $\varphi_F(0) = 0$, then φ_F vanishes on $\mathbb{Q}_L \cap [0, 2\alpha')$. If $\varphi_F(t_0) = 0$ for some $t_0 \in I$ with $t_0 > 0$, then φ_F vanishes on $\mathbb{Q}_L \cap (0, t_0]$.

■

Sketch of proof. (a) Choose j so large that $x, y, u \in a_j\mathbb{Z}$. Then the bonds of Λ_j on which $\mathcal{U}_x F$ depends have end points with $c + x + \frac{1}{2}a_j \le x_\mu \le c + \frac{\ell}{2} - \alpha' + x - \frac{1}{2}a_j$ (Lemma 18.77(c)); as $c + x \ge c^*$ and $c + \frac{\ell}{2} - \alpha' + x \le c^* + \frac{\ell}{2}$, these bonds lie in the window of $\mathcal{A}^{c^*}(0, 0)$, and the same holds for $\mathcal{U}_y F$. Lemma 18.77(c) also gives $\Theta_{c^*} = \Theta_c \mathcal{U}_{-u}$ and $\Theta_c \mathcal{U}_{x-u} = \mathcal{U}_{u-x}\Theta_c$, and μ is translation invariant (Lemma 18.77(b)). Hence $\langle \mathcal{U}_x F, \mathcal{U}_y F\rangle_{c^*} = \int \overline{\mathcal{U}_{u-x}\Theta_c F}\, \mathcal{U}_y F \, d\mu = \varphi_F(x + y - u)$. Taking $u = 0$ gives the second statement. Taking $u = x = y = t \in I$ gives $\varphi_F(t) = \|\mathcal{U}_t F\|^2_{c+t/2}$, which is ≥ 0 by Lemma 18.77(d) applied to the mirror at $c + \frac{t}{2} \in \frac{1}{2}\mathbb{Q}_L$, whatever its type; we argue in this way because $\frac{t}{2}$ need not belong to $\mathbb{Q}_L$. Finally $\varphi_F(t) \le \|\Theta F\|_2 \|\mathcal{U}_t F\|_2 = \|F\|_2^2$. (b) Write $p = t - h$ and $q = t + h$, and use (a) with $u = x = p$ and $y = t$, which is admissible. Since $x + y - u = t$, $2x - u = p$ and $2y - u = q$, the Schwarz inequality for $\langle \cdot, \cdot \rangle_{c^*}$ gives (b). (c) From (b) and $\sqrt{ab} \le \frac{1}{2}(a + b)$, on every grid $a_s\mathbb{Z} \cap [0, 2\alpha']$ the sequence $k \mapsto \varphi_F(ka_s)$ has non-negative second differences; any three points of I lie on a common grid, so φ_F is convex on I. Being convex and bounded on I, which is dense in $[0, 2\alpha']$, φ_F is locally Lipschitz on $I \cap (0, 2\alpha')$ and therefore has a continuous extension to $(0, 2\alpha')$; as its difference quotients increase, the limit $\varphi_F(0+)$ exists and is at most $\varphi_F(0)$. By (a), $\|\mathcal{U}_t F - F\|_c^2 = \varphi_F(2t) - 2\varphi_F(t) + \varphi_F(0)$. (d) Let v be convex on $\mathbb{Q}_L \cap [0, b]$ with $0 \le v \le \mathsf{m}$. Increasing difference quotients give $-\frac{\mathsf{m}}{x} \le \frac{v(x) - v(0)}{x} \le \frac{v(y) - v(x)}{y - x} \le \frac{v(b') - v(y)}{b' - y} \le \frac{\mathsf{m}}{b' - y}$ for $0 < x < y < b' \le b$ in $\mathbb{Q}_L$; letting b' increase to b, one gets $v(x + 2t) - 2v(x + t) + v(x) \le t\mathsf{m}(\frac{1}{b - x - 2t} + \frac{1}{x})$ whenever $x > 0$ and $x + 2t < b$. Now let $\alpha'' \in \mathbb{Q}_L \cap (0, \alpha]$ and $G = \mathcal{U}_{-\alpha''} F \in \mathcal{A}(0, \alpha' + \alpha'')$, so that $\|G\|_2 = \|F\|_2$, and apply this to $v = \varphi_G$ and $b = 2(\alpha' + \alpha'')$. By (a), $\|\mathcal{U}_t F - F\|_c^2$ is the second difference of v with the step t at the point $x = 2\alpha''$, where $b - x - 2t = 2\alpha' - 2t \ge \alpha'$ if $t \le \frac{\alpha'}{2}$; and $\|\mathcal{U}_{-t} F - F\|_c^2$ equals the second difference taken at $x = 2\alpha'' - 2t \ge \alpha''$ (when $2t \le \alpha''$), where $b - x - 2t = 2\alpha'$. Then let α'' increase to α. (e) If $\varphi_F(0) = 0$, then (b) with $h = t$ gives $\varphi_F = 0$ on $\mathbb{Q}_L \cap [0, \alpha']$. Next, suppose $\varphi_F = 0$ on $\mathbb{Q}_L \cap [0, z)$ with $0 < z < 2\alpha'$, and let $x \in \mathbb{Q}_L$ with $z \le x < \frac{1}{2}(z + 2\alpha')$; choosing $h \in \mathbb{Q}_L \cap (x - z, 2\alpha' - x)$ with $h \le x$, (b) gives $\varphi_F(x)^2 \le \varphi_F(x - h)\varphi_F(x + h) = 0$. So the zero set grows from $[0, z_k)$ to $[0, z_{k+1})$ with $z_{k+1} = \frac{1}{2}(z_k + 2\alpha')$, and $z_k \to 2\alpha'$. If instead $\varphi_F(t_0) = 0$, then for $\frac{1}{2}t_0 \le x < t_0$ the choice $h = t_0 - x$ in (b) gives $\varphi_F(x)^2 \le \varphi_F(2x - t_0)\varphi_F(t_0) = 0$. Since $\frac{1}{2}t_0$ may fail to lie in $\mathbb{Q}_L$, pick $t_1 \in \mathbb{Q}_L \cap [\frac{1}{2}t_0, \frac{2}{3}t_0]$ and repeat with t_1 in place of t_0; the intervals $[\frac{1}{2}t_k, t_k]$ overlap, and $t_k \le (\frac{2}{3})^k t_0$, so together they cover $(0, t_0]$. □

Lemma 18.96 (Near a bond mirror, the averaging forgets the first layer of fine bonds)**.** Let (μ, c), $c \in \frac{a_{d_0}}{2}\mathbb{Z}$, be a mirror of the bond type. For $j \ge d_0$ let $\ell_1^{(j)}$ denote the sites of Λ_j at the height $x_\mu = c + \frac{1}{2}a_j$, the first layer above the mirror, and $\mathcal{L}_j$ the bonds of Λ_j that have both end points in $\mathbb{E}_+$ and touch $\ell_1^{(j)}$. Put $\lambda_{\mathrm{w}} = 1 + \frac{2}{L} + \frac{L^2 - 1}{2L^2} < 1.654$ and $\lambda_{\mathrm{l}} = 1.8$; then $\lambda_{\mathrm{l}}/\sqrt{L} < \frac{1}{2}$.

(a) Let $i > d_0$ and let c' be a bond of Λ_{i-1} with both end points in $\mathbb{E}_+$. The coefficients of $(\mathbf{Q}A)(c') = \sum_b \mathsf{w}_{c'}(b) A(b)$ satisfy $\sum_{b \in \mathcal{L}_i} |\mathsf{w}_{c'}(b)| \le \lambda_{\mathrm{w}}$; and $\mathsf{P}_{c'}$ meets $\mathcal{L}_i$ only if $c' \in \mathcal{L}_{i-1}$.
(b) There is a number $\rho_{\mathrm{l}} \in (0, \frac{1}{4}\omega_M)$, formed from L alone, with the following property. Let $i > d_0$, let c' be a bond of Λ_{i-1} with both end points in $\mathbb{E}_+$, let $V, \tilde{V} \in \mathcal{V}_i$ and $\varpi', \delta \ge 0$. Suppose that $\tilde{V} = V$ on $\mathsf{P}_{c'} \setminus \mathcal{L}_i$, that $|\partial V(p) - \mathbf{1}| \le \varpi'$ for the plaquettes p of the double block of c', that $|\tilde{V} - V| \le \delta$ on $\mathsf{P}_{c'} \cap \mathcal{L}_i$, and that $\frac{\pi}{2}(3L\varpi' + \delta) \le \rho_{\mathrm{l}}$. Then $|\mathcal{M}(\tilde{V})(c') - \mathcal{M}(V)(c')| \le \lambda_{\mathrm{l}}\delta$.

(c) For $j > d_0$ and $V \in \mathcal{V}_j$ define $V^\flat \in \mathcal{V}_j$ by: $V^\flat = \mathbf{1}$ on the bonds $\langle x, x + a_j e_\mu\rangle$ with $x \in \ell_1^{(j)}$; $V^\flat(b) = V(b + a_j e_\mu)$ on the bonds b with both end points in $\ell_1^{(j)}$; $V^\flat(b) = V(b)$ on every other bond; reversed bonds receive the inverse values. Let $d_0 \le D < j$, $V_i = \mathcal{M}^{j-i}V$ and $V_i^\flat = \mathcal{M}^{j-i}V^\flat$. For real $\alpha' \ge 0$, the restriction $V_D^\flat|_{\mathsf{Bd}_D(0,\alpha')}$ is a Borel function of $V|_{\mathsf{Bd}_j(a_j,\alpha')}$. If $\varpi_i \ge \varpi(V_i)$ and $\frac{\pi}{2}(3L\varpi_i + \lambda_1^{j-i}\varpi_j) \le \rho_1$ for $D < i \le j$, then at every bond c' of Λ_D with both end points in $\mathbb{E}_+$, $V_D^\flat(c') = V_D(c')$ when $c' \notin \mathcal{L}_D$, and $|V_D^\flat(c') - V_D(c')| \le \lambda_1^{j-D}\varpi_j$ when $c' \in \mathcal{L}_D$.

(d) In the one-torus setting let $C_\lambda = \sup_{n\ge 0}(\lambda_1/\sqrt{L})^n(1+n)^{\mathfrak{p}_0}$, and let D_* be the least integer $D \ge \max\{d_\natural, d_0\}$ with $\pi(3L + C_\lambda)\sup_{i\ge D}\varepsilon_{[i]} \le \rho_1$. On Gd_D with $D \ge D_*$, for all $j > D$, $|(\mathcal{M}^{j-D}V_j^\flat)(c') - V_D(c')| \le 2\varepsilon_{[D]}(\lambda_1/\sqrt{L})^{j-D}(1+j-D)^{\mathfrak{p}_0}$ at every bond c' of Λ_D whose end points both lie in $\mathbb{E}_+$.

(e) In the one-torus setting, each $F \in \mathcal{A}(0,\alpha')$, $\alpha' \ge 0$, is the limit in $L^2(\mu)$ of functions $F_n \in \mathcal{A}_{j_n}(a_{j_n},\alpha')$ with $\sup|F_n| \le \sup|F|$; and each $F \in \mathcal{A}(\alpha,0)$, $\alpha \ge 0$, is such a limit of functions $F_n \in \mathcal{A}_{j_n}(\alpha, a_{j_n})$, with the same bound.

■

Sketch of proof. (a) Work in units of Λ_i and put $\mathsf{h} = \frac{1}{2}(L-1)$. For a path Γ let $N(\Gamma)$ count those of its bonds that belong to $\mathcal{L}_i$, in either orientation. The formula for $\mathbf{Q}$ gives $\sum_{b\in\mathcal{L}_i}|\mathsf{w}_{c'}(b)| \le L^{-3}\sum_{x\in B(c'_-)}[\bar N(c'_-,x) + N([x,x']) + \bar N(c'_+,x')]$, with $\bar N$ the average over the contour family. For $y \in \Lambda_{i-1}\cap\mathbb{E}_+$, the block $B(y)$ contains sites of $\ell_1^{(i)}$ exactly when $y \in \ell_1^{(i-1)}$, and these are then its L^2 sites with $n_\mu = -\mathsf{h}$; this proves the second assertion. On a contour every coordinate moves monotonically from 0 to n_κ. Hence a contour reaches the layer only if $n_\mu = -\mathsf{h}$; in that case its last step in the direction μ ends in the layer, the earlier steps stay off it, and all later steps run inside it, so that $N(\Gamma_\sigma) = 1 + \sum\{|n_\kappa| : \kappa \text{ comes after } \mu \text{ in } \sigma\}$. Every $\kappa \ne \mu$ with $n_\kappa \ne 0$ comes after μ in half of the orders; therefore $\bar N(y,x) = 1 + \frac{1}{2}\sum_{\kappa\ne\mu}|n_\kappa|$, and since $\sum_{|k|\le\mathsf{h}}|k| = \frac{1}{4}(L^2-1)$, $L^{-3}\sum_{x\in B(y)}\bar N(y,x) = \frac{1}{L} + \frac{L^2-1}{4L^2}$. When c' is parallel to the mirror, $N([x,x'])$ equals L for the L^2 sites with $n_\mu = -\mathsf{h}$ and 0 otherwise, which contributes 1; adding the two blocks, the total is at most $1 + \frac{2}{L} + \frac{L^2-1}{2L^2}$. When c' is perpendicular to the mirror with $c'_- \in \ell_1^{(i-1)}$, the segment $[x,x']$ contains one bond of the layer if $n_\mu = -\mathsf{h}$ and none otherwise, which contributes $\frac{1}{L}$, and the block of c'_+ contains no site of the layer. (b) We use the integer coordinates n of the proof of Lemma 18.80, attached to whichever of c', $\bar c'$ is positively oriented. In them the map $V|_{\mathsf{P}_{c'}} \mapsto \mathcal{M}(V)(c')$ depends only on the direction and the orientation of c', at every depth and on every side. By the nesting in the proof of Lemma 18.77(c), the double block of c' lies in $\mathbb{E}_+$, so that $\mathsf{P}_{c'}\cap\mathcal{L}_i$ consists of the bonds of $\mathsf{P}_{c'}$ that touch $\ell_1^{(i)}$; and by the proof of (a), the sites of the double block in $\ell_1^{(i)}$ are, for each end point y of c' in $\ell_1^{(i-1)}$, the L^2 sites of $B(y)$ with the smallest coordinate x_μ, and there are no others. In the coordinates n the set $\mathsf{P}_{c'}\cap\mathcal{L}_i$ therefore depends only on the direction and the orientation of c', on μ, and on which end points of c' lie in $\ell_1^{(i-1)}$, and not on the depth, the side or the height c. So there are finitely many cases, and ρ_1 is the smallest of the numbers obtained below for the individual cases. In one case, let $\mathsf{P}^+ \subset \mathsf{P}_{c'}$ be the subset of positively oriented bonds, let $E = \mathfrak{g}^{\mathsf{P}^+}$ with $|A|_\infty = \max_b|A(b)|$, and let $E_\mathcal{L} \subset E$ be the forms vanishing off $\mathcal{L}_i$. On $|A|_\infty < \frac{1}{4}\omega_M$ the map $\Psi(A) = \mathcal{M}(e^{iA})(c')$ is continuously differentiable (Lemma 18.80(a) and its proof), and $D\Psi(0)\delta A = i\sum_b \mathsf{w}_{c'}(b)\delta A(b)$ (Lemma YM3_I:4.6). Let $\Lambda(\rho) = \sup\{|D\Psi(A)\delta A| : |A|_\infty \le \rho,\ \delta A \in E_\mathcal{L},\ |\delta A|_\infty \le 1\}$. By (a), $\Lambda(0) \le \lambda_\mathrm{w} < \lambda_1$, and by compactness Λ is continuous at 0; so ρ_1 can be chosen with $\Lambda(\rho_1) \le (1-\rho_1)\lambda_1$.

Gauge fixing on the double block. Let ν' be the direction of c' and κ, κ' the two other directions; let o be the vertex of the double block whose coordinates are smallest, and write every site of the double block as $o + n_1 e_{\nu'} + n_2 e_\kappa + n_3 e_{\kappa'}$ with $0 \le n_1 \le 2L-1$ and $0 \le n_2, n_3 \le L-1$. Let Γ_x go from o first n_3 steps along $e_{\kappa'}$, then n_2 steps along e_κ, then n_1 steps along $e_{\nu'}$, and set

$u(x) = V(\Gamma_x)$ on the double block and $\mathbf{1}$ elsewhere. Then $V^u = \mathbf{1}$ on all bonds along $e_{\nu'}$, on the bonds along e_κ with $n_1 = 0$, and on the bonds along $e_{\kappa'}$ with $n_1 = n_2 = 0$. If b and $b + e_{\nu'}$ are bonds of a direction other than ν', the plaquette they span has its two remaining sides equal to $\mathbf{1}$, so $|V^u(b + e_{\nu'}) - V^u(b)| \le \varpi'$; walking back to the trivial bonds gives $|V^u - \mathbf{1}| \le 3L\varpi'$ on $\mathsf{P}_{c'}$. By Lemma 18.78(b), $V^u = e^{iA}$ and $\tilde V^u = e^{i\tilde A}$ on P^+ with $|A|_\infty, |\tilde A|_\infty \le \rho_1$, $\tilde A - A \in E_{\mathcal{L}}$ and $|\tilde A - A|_\infty \le (1-\rho_1)^{-1}\delta$. As the ball is convex, $|\Psi(\tilde A) - \Psi(A)| \le \Lambda(\rho_1)(1-\rho_1)^{-1}\delta \le \lambda_1\delta$; and $\Psi(A)$, $\Psi(\tilde A)$ come from $\mathcal{M}(V)(c')$, $\mathcal{M}(\tilde V)(c')$ through the same multiplications, by $u(c'_-)$ on the left and by $u(c'_+)^{-1}$ on the right (Proposition YM3_I:4.5). (c) *The first claim.* By locality and nesting, for $c' \in \mathsf{Bd}_D(0,\alpha')$ the value $V^\flat_D(c')$ depends on $V^\flat$ only at bonds $b \in \mathsf{Bd}_j(0,\alpha')$ inside the blocks $B^{j-D}(c'_\pm)$. For such b: if neither end point of b is in $\ell_1^{(j)}$, then $V^\flat(b) = V(b)$ and $b \in \mathsf{Bd}_j(a_j,\alpha')$; if b is perpendicular to the mirror with an end point in $\ell_1^{(j)}$, then $V^\flat(b) = \mathbf{1}$; and if b is contained in the first layer, then $V^\flat(b) = V(b + a_j e_\mu)$, the bond $b + a_j e_\mu$ connecting two sites one layer higher and still inside the same blocks, as these have $L^{j-D} \ge 2$ layers. *A gauge change that the coarser depths ignore.* Let $g(x) = V(\langle x, x + a_j e_\mu\rangle)^{-1}$ for $x \in \ell_1^{(j)}$, and $g = \mathbf{1}$ at all other sites. The heights of the sites of Λ_{j-1} lie in $c + a_{j-1}(\mathbb{Z} + \frac12)$, which does not contain $c + \frac12 a_j$; so $g = \mathbf{1}$ on Λ_{j-1}, and $\mathcal{M}^{j-i}(V^g) = V_i$ for $i < j$ (Proposition YM3_I:4.5). Put $V_j^\sharp = V^g$ and $V_i^\sharp = V_i$ for $i < j$. *Claim* (I_i), $D \le i \le j$: at each bond b of Λ_i with both end points in $\mathbb{E}_+$, $V_i^\flat(b) = V_i^\sharp(b)$ when $b \notin \mathcal{L}_i$, and $|V_i^\flat(b) - V_i^\sharp(b)| \le \lambda_1^{j-i}\varpi_j$ when $b \in \mathcal{L}_i$. For $i = j$: away from the layer $V^g = V = V^\flat$; on a bond leaving the layer perpendicularly, $V^g = \mathbf{1} = V^\flat$; and on a bond $b = \langle x, x + \mathsf{f}\rangle$ inside the layer, $V^g(b)V^\flat(b)^{-1}$ is conjugate to the transport of V around the plaquette with the corners x, $x + \mathsf{f}$, $x + \mathsf{f} + a_j e_\mu$, $x + a_j e_\mu$, so $|V^g(b) - V^\flat(b)| \le \varpi_j$. From i to $i-1$: if $c' \notin \mathcal{L}_{i-1}$, then $\mathsf{P}_{c'} \cap \mathcal{L}_i = \emptyset$ by (a), so $V_i^\flat = V_i^\sharp$ on $\mathsf{P}_{c'}$, and the averages coincide (Proposition YM3_I:4.5); if $c' \in \mathcal{L}_{i-1}$, apply (b) with $V = V_i^\sharp$, $\tilde V = V_i^\flat$, $\varpi' = \varpi_i$ (the plaquette variables of $V_i^\sharp$ are conjugate to those of V_i) and $\delta = \lambda_1^{j-i}\varpi_j$. The case ($\mathrm{I}_D$) is the second claim. (d) On Gd_D take $\varpi_i = 2\varepsilon_{[i]}$. For $i \ge 1$, since $\mathsf{b} \ge 1$, $\log L^j\mathsf{b} \le (1 + j - i)\log L^i\mathsf{b}$; therefore $\lambda_1^{j-i}\varepsilon_{[j]} \le \varepsilon_{[i]}(\lambda_1/\sqrt{L})^{j-i}(1 + j - i)^{\mathfrak{p}_0} \le C_\lambda\varepsilon_{[i]}$, and $\frac{\pi}{2}(3L\varpi_i + \lambda_1^{j-i}\varpi_j) \le \pi(3L + C_\lambda)\varepsilon_{[i]} \le \rho_1$ for $i \ge D_*$. So (c) applies. (e) Let $\epsilon > 0$ and $F \in \mathcal{A}(0,\alpha')$. By the nesting, $F = \mathsf{f}(V_D|_{\mathsf{Bd}_D(0,\alpha')})$ for every large D; take $D \ge D_*$ so large that $\mu(\mathsf{Thr} \setminus \mathsf{Gd}_D) \le \epsilon^2$ (Lemma 18.84(b)). For every finite Borel measure ν on a compact metrisable space, continuous functions are dense in $L^2(\nu)$; composing them with the radial retraction of $\mathbb{C}$ onto the disc of radius $\sup|\mathsf{f}|$ makes their modulus at most $\sup|\mathsf{f}|$ without increasing their distance to f. Take such a continuous f_ϵ with $\|F - \mathsf{f}_\epsilon(V_D|_{\mathsf{Bd}_D(0,\alpha')})\|_{L^2(\mu)} \le \epsilon$. Then $F_{\epsilon,j} = \mathsf{f}_\epsilon((\mathcal{M}^{j-D}V_j^\flat)|_{\mathsf{Bd}_D(0,\alpha')})$ belongs to $\mathcal{A}_j(a_j,\alpha')$ by (c), and on Gd_D it converges to $\mathsf{f}_\epsilon(V_D|_{\mathsf{Bd}_D(0,\alpha')})$ uniformly as $j \to \infty$, by (d) and the uniform continuity of f_ϵ. Hence $\limsup_j \|F_{\epsilon,j} - F\|_{L^2(\mu)} \le \epsilon + 2\sup|F|\,\epsilon$. For the second assertion use R: it maps $\mathcal{A}(\alpha,0)$ onto $\mathcal{A}(0,\alpha)$ and $\mathcal{A}_j(a_j,\alpha)$ onto $\mathcal{A}_j(\alpha,a_j)$, and it preserves μ (Lemma 18.77(b), (c)). □

Sketch of proof of Proposition 18.76. (A1). The statements about T_h and $\mathsf{r}^\bullet$ are Lemma 18.77(b). Since T_h preserves μ and T_{-h} inverts it on Thr, $\mathcal{U}_h$ is unitary on $L^2(\mu)$ and $\mathcal{U}_h\mathcal{U}_{h'} = \mathcal{U}_{h+h'}$. Let $v \in a_s\mathbb{Z}^3$ and let F be a bounded gauge-invariant Borel function on $\mathcal{V}_d$. Then $\mathcal{U}_v(F \circ \pi_d)$ equals $(F \circ \mathrm{t}_{-v}) \circ \pi_d$ if $d \ge s$, and $(F \circ \mathcal{M}^{s-d} \circ \mathrm{t}_{-v}) \circ \pi_s$ if $d < s$; both are bounded, Borel and gauge invariant, because $\mathrm{t}_{-v}(V^w) = (\mathrm{t}_{-v}V)^{w(\cdot+v)}$ and by Proposition YM3_I:4.5. So $\mathcal{U}_v$ and $\mathcal{U}_{-v}$ send $\mathcal{K}^{\mathrm{inv}}$ into itself. *(A2).* Fix F, bounded, gauge invariant and Borel on $\mathcal{V}_d$, together with $\epsilon > 0$ and $\nu \in \{1,2,3\}$. Choose $d' \ge \max\{d, D_3, d_\Sigma\}$ with $\frac{L}{L-1}R_{d'} \le \epsilon^2$, so that $\mu(\mathsf{Thr} \setminus \mathsf{Gd}_{d'}) \le \epsilon^2$ (Lemma 18.84(b)). The function $F' = F \circ \mathcal{M}^{d'-d}$ on $\mathcal{V}_{d'}$ is bounded, Borel and gauge invariant, and along threads $F(V_d) = F'(V_{d'})$ and $F((\mathrm{T}_{te_\nu}V_\bullet)_d) = F'((\mathrm{T}_{te_\nu}V_\bullet)_{d'})$. Pick a continuous Φ_0 on $\mathcal{V}_{d'}$ with $|\Phi_0| \le \sup|F|$ and $\|F' - \Phi_0\|_{L^2(\mu_{d'})} \le \epsilon$, and average it over gauge transformations: $\Phi(W) = \int \Phi_0(W^w)\,dw$, dw being the normalized Haar measure of the group of gauge transformations

of $\Lambda_{d'}$. Then Φ is a continuous gauge-invariant function, and $\|F'-\Phi\|_{L^2(\mu_{d'})}\le\epsilon$ because both $\mu_{d'}$ and F' are gauge invariant. Write ω for the modulus of continuity of Φ with respect to $\max_b|W'(b)-W(b)|$; gauge invariance gives $|\Phi(W')-\Phi(W)|\le\omega(\mathrm{dist}_{\mathrm{orb}}(W',W))$. Since $(\mathrm{T}_{te_\nu}V_\bullet)_{d'}$ has the law $\mu_{d'}$ (Lemma 18.77(b)), we obtain for every $\rho>0$

$$\|F((\mathrm{T}_{te_\nu}V_\bullet)_d)-F(V_d)\|_{L^2(\mu)}\le 2\epsilon+\omega(\rho)+2\sup|F|\,[\mu(\mathsf{Thr}\setminus\mathsf{Gd}_{d'})+\mu(\mathsf{Gd}_{d'}\cap\{\mathrm{dist}_{\mathrm{orb}}((\mathrm{T}_{te_\nu}V_\bullet)_{d'},V_{d'})>\rho\})]^{1/2}.$$

By Lemma 18.94, the upper limit as $s'\to\infty$ of the supremum of the left side over $t\in\mathbb{Q}_L\cap[0,a_{s'})$ is at most $2\epsilon+\omega(\rho)+2\sup|F|\,\epsilon$; now let $\rho\to0$ and then $\epsilon\to0$. Finally, unitarity gives $\|\mathcal{U}_{-w}\psi-\psi\|=\|\mathcal{U}_w\psi-\psi\|$ and $\|\mathcal{U}_{w+w'}\psi-\psi\|\le\|\mathcal{U}_w\psi-\psi\|+\|\mathcal{U}_{w'}\psi-\psi\|$, which yields the limit along all $v\in\mathbb{Q}_L^3$ with $|v|_\infty<a_{s'}$, $s'\to\infty$. *(A3).* Since the $\mathcal{U}_v$ are unitary, the vectors $\psi\in\mathcal{K}^{\mathrm{inv}}$ with $\|\mathcal{U}_v\psi-\psi\|\to0$ as $v\to0$ in $\mathbb{Q}_L^3$ form a closed subspace; by (A2) it contains a family whose linear hull is dense, so it is all of $\mathcal{K}^{\mathrm{inv}}$. As $\|\mathcal{U}_v\psi-\mathcal{U}_{v'}\psi\|=\|\mathcal{U}_{v-v'}\psi-\psi\|$, the map $v\mapsto\mathcal{U}_v\psi$ is uniformly continuous on $\mathbb{Q}_L^3/\ell\mathbb{Z}^3$, a dense subgroup of the compact group $\mathbb{R}^3/\ell\mathbb{Z}^3$; it therefore has exactly one continuous extension, and the extension inherits the homomorphism property and unitarity. For $k\in\frac{2\pi}{\ell}\mathbb{Z}^3$ let $P_k\psi=\ell^{-3}\int_{T_\ell}e^{-ik\cdot x}\,\mathcal{U}(x)\psi\,dx$, an integral of a continuous function. Then $\mathcal{U}(y)P_k\psi=e^{ik\cdot y}P_k\psi$, P_k restricts to the identity on $\mathcal{K}_k$, and P_k is self-adjoint because $\mathcal{U}(x)^*=\mathcal{U}(-x)$; hence P_k is the orthogonal projection onto $\mathcal{K}_k$, and distinct $\mathcal{K}_k$ are orthogonal. If ψ is orthogonal to all the $\mathcal{K}_k$, then for each ϕ the continuous function $x\mapsto\langle\phi,\mathcal{U}(x)\psi\rangle$ has all its Fourier coefficients $\langle\phi,P_k\psi\rangle$ equal to 0 and so vanishes identically; at $x=0$ this gives $\langle\phi,\psi\rangle=0$ for all ϕ, hence $\psi=0$. *(B1)* is Lemma 18.77(d). *(B4).* For a site mirror, $\mathcal{A}_j(0,0)=\mathcal{A}_j(\frac{a_j}{2},\frac{a_j}{2})$ (Lemma 18.77(c)). For a bond mirror, Lemma 18.96(e) approximates $F\in\mathcal{A}(0,0)$ by some $F'\in\mathcal{A}(a_j,0)$, and then F' by some $F''\in\mathcal{A}(a_j,a_{j'})$, with the stated bounds. The density of the classes follows, since $\|\cdot\|_c\le\|\cdot\|_{L^2(\mu)}$. *(B2).* The two moduli are Lemma 18.95(d). Let $F\in\mathcal{A}(0,\alpha')$ with $\alpha'>0$, $\tilde F\in\mathcal{A}(\alpha,\alpha')$ with $\alpha>0$, and $0\le t\le\frac{\alpha'}{2}$. Then $\mathcal{U}_t(F-\tilde F)\in\mathcal{A}(0,0)$ and, by (B1), $\|\mathcal{U}_t(F-\tilde F)\|_c\le\|F-\tilde F\|_{L^2(\mu)}$; hence $\|\mathcal{U}_tF-F\|_c\le2\|F-\tilde F\|_{L^2(\mu)}+\|\mathcal{U}_t\tilde F-\tilde F\|_c$. Lemma 18.96(e) for a bond mirror, and the choice $\tilde F=F$ for a site mirror, make the first term arbitrarily small, and the moduli send the second term to 0 as $t\downarrow0$. For $F\in\mathcal{A}(\alpha,0)$ we have $\|\mathcal{U}_{-t}F-F\|_c=\|\mathcal{U}_tRF-RF\|_c$, because $\langle RF,RF'\rangle_c=\int\overline{R\Theta F}\,RF'\,d\mu=\langle F,F'\rangle_c$ (Lemma 18.77(b), (c)). For $F\in\mathcal{A}(0,0)$ and both signs of t: given $\epsilon>0$, choose by (B4) some $\tilde F\in\mathcal{A}(\alpha,\alpha')$, $\alpha,\alpha'>0$, with $\|F-\tilde F\|_{L^2(\mu)}\le\epsilon$. For $|t|\le\min\{\alpha,\alpha'\}$ the function $\mathcal{U}_t\tilde F$ lies in $\mathcal{A}(0,0)$, and $\int\overline{\Theta F}(\mathcal{U}_tF-F)\,d\mu=\int\overline{\Theta F}(\mathcal{U}_t(F-\tilde F)-(F-\tilde F))\,d\mu+\langle F,\mathcal{U}_t\tilde F-\tilde F\rangle_c$; its modulus is at most $2\|F\|_{L^2(\mu)}\epsilon+\|F\|_{L^2(\mu)}\|\mathcal{U}_t\tilde F-\tilde F\|_c$, and the last norm tends to 0 by the moduli. *(B3).* By Lemma 18.95(a), $\|\mathcal{U}_tF\|_c^2=\varphi_F(2t)$ for $0<2t<2\alpha'$. If $\|F\|_c^2=\varphi_F(0)=0$, Lemma 18.95(e) gives $\varphi_F(2t)=0$. Conversely, if $\varphi_F(2t)=0$, the same item gives $\varphi_F=0$ on $\mathbb{Q}_L\cap(0,2t]$, hence $\varphi_F(0+)=0$; and $\varphi_F(0)=\varphi_F(0+)$ by (B2) and Lemma 18.95(c). *(B5).* We rely on the theorem of A. Klein and L. J. Landau, *Construction of a unique self-adjoint generator for a symmetric local semigroup*, J. Funct. Anal. 44 (1981), 121–137, in the following form. Let $\mathcal{H}$ be a Hilbert space and $T>0$, and for each real $\alpha\in[0,T]$ let S_α be a symmetric linear operator with domain $\mathcal{D}_\alpha\subset\mathcal{H}$, such that (i) $\mathcal{D}_\alpha\supset\mathcal{D}_\beta$ for $\alpha\le\beta$, and $\bigcup_{0<\alpha\le T}\mathcal{D}_\alpha$ is dense; (ii) for $\gamma\in[0,T]$ and $\chi\in\mathcal{D}_\gamma$ the function $\alpha\mapsto\langle\chi,S_\alpha\chi\rangle$ is continuous on $[0,\gamma]$; (iii) S_0 is the identity, $S_\beta\mathcal{D}_\alpha\subset\mathcal{D}_{\alpha-\beta}$ for $0\le\beta\le\alpha$, and $S_\alpha S_\beta=S_{\alpha+\beta}$ on $\mathcal{D}_{\alpha+\beta}$ for $\alpha+\beta\le T$. Then a unique self-adjoint operator H on $\mathcal{H}$ satisfies $\mathcal{D}_\alpha\subset\mathrm{Dom}(e^{-\alpha H})$ and $e^{-\alpha H}|_{\mathcal{D}_\alpha}=S_\alpha$ for all $\alpha\in[0,T]$. We also use three consequences of the spectral theorem, for a self-adjoint H and a vector ϕ with spectral measure ρ_ϕ: $\phi\in\mathrm{Dom}(e^{-tH})$ if and only if $\int e^{-2t\lambda}d\rho_\phi(\lambda)<\infty$; if $\phi\in\mathrm{Dom}(e^{-t_0H})$ with $t_0>0$, then $t\mapsto e^{-tH}\phi$ is norm continuous on $[0,t_0]$; and e^{-tH} is injective with range $\mathrm{Dom}(e^{tH})$, and $e^{tH}e^{-tH}\phi=\phi$. *Step 1: the vectors $\phi(F,\gamma)$.* Let $F\in\mathcal{A}(0,\alpha'_F)$ with $\alpha'_F>0$. By Lemma 18.95(a), $\|\mathcal{U}_tF-\mathcal{U}_{t'}F\|_c^2=\varphi_F(2t)-2\varphi_F(t+t')+\varphi_F(2t')$ for $t,t'\in\mathbb{Q}_L\cap[0,\alpha'_F)$, and by Lemma 18.95(c) and (B2) the function φ_F extends continuously to $[0,2\alpha'_F)$. Hence, for real $\gamma\in[0,\alpha'_F)$, the limit $\phi(F,\gamma)=\lim_{\substack{t\to\gamma\\ t\in\mathbb{Q}_L\cap[0,\alpha'_F)}}[\mathcal{U}_tF]$ exists in $\mathcal{K}_c$; it equals $[\mathcal{U}_tF]$ when $\gamma=t\in\mathbb{Q}_L$, depends continuously on γ in norm, and is independent of the

choice of α'_F. For two such functions F, G and times $t_1 \in \mathbb{Q}_L \cap [0, \alpha'_F)$, $t_2 \in \mathbb{Q}_L \cap [0, \alpha'_G)$, the number $\langle \mathcal{U}_{t_1} F, \mathcal{U}_{t_2} G\rangle_c = \int \overline{\Theta F}\, \mathcal{U}_{t_1+t_2} G \, d\mu$ depends only on $t_1 + t_2$. Approximating real numbers with $\gamma_1 + \gamma'_1 = \gamma_2 + \gamma'_2$ by $t_1, t'_1, t_2 \in \mathbb{Q}_L$ and setting $t'_2 = t_1 + t'_1 - t_2$ (with $t_2 \le t_1 + t'_1$ when $\gamma'_2 = 0$), one obtains a continuous function $\mathsf{U}_{F,G}$ on $[0, \alpha'_F + \alpha'_G)$ with $\langle \phi(F,\gamma), \phi(G,\gamma')\rangle = \mathsf{U}_{F,G}(\gamma + \gamma')$. *Step 2: domains and operators.* For real $\alpha \in [0, \frac{\ell}{2}]$ let $\mathcal{D}_\alpha$ consist of the finite linear combinations of the $\phi(F,\gamma)$ with $\alpha'_F > \alpha + \gamma$, and for $0 \le \beta \le \alpha$ and $\psi = \sum_i z_i \phi(F_i, \gamma_i) \in \mathcal{D}_\alpha$ let $S_\beta \psi = \sum_i z_i \phi(F_i, \gamma_i + \beta)$. This does not depend on how ψ is written. Indeed, with $\psi_x = \sum_i z_i \phi(F_i, \gamma_i + x)$, $0 \le x \le \alpha$, Step 1 gives $\langle \psi_x, \psi_y\rangle = w(x+y)$ with w continuous on $[0, 2\alpha]$, $w(2x) = \|\psi_x\|^2$ and $|w(x+y)|^2 \le w(2x) w(2y)$. If $\psi_0 = 0$, then w vanishes on $[0, \alpha]$; and if w vanishes on $[0, z]$, then it vanishes on $[0, \frac{z}{2} + \alpha]$. Hence $w = 0$ on $[0, 2\alpha]$, and $\psi_x = 0$ for all $x \le \alpha$. *Step 3: checking the hypotheses, with $T = \frac{\ell}{2}$.* (i) The $\mathcal{D}_\alpha$ decrease, and their union contains $[F] = \phi(F, 0)$ for every $F \in \bigcup_{\alpha' > 0} \mathcal{A}(0, \alpha')$, a dense set by (B4). (ii) $\langle \psi, S_\beta \psi\rangle = w(\beta)$. (iii) S_0 is the identity, $S_\beta \mathcal{D}_\alpha \subset \mathcal{D}_{\alpha-\beta}$, the semigroup law is immediate from the definition, and $\langle S_\beta \psi, \psi'\rangle = \sum_{i,k} \bar z_i z'_k \mathsf{U}_{F_i, F'_k}(\gamma_i + \beta + \gamma'_k) = \langle \psi, S_\beta \psi'\rangle$. The theorem provides $\mathfrak{h}_c$ with $e^{-\alpha \mathfrak{h}_c}|_{\mathcal{D}_\alpha} = S_\alpha$. If $\alpha' \le \frac{\ell}{2}$, $F \in \mathcal{A}(0, \alpha')$ and $t \in \mathbb{Q}_L \cap [0, \alpha')$, then $[F] \in \mathcal{D}_t$ and $e^{-t\mathfrak{h}_c}[F] = \phi(F, t) = [\mathcal{U}_t F]$. The constant function 1 involves no bond, lies in every $\mathcal{A}(0, \alpha')$ with $\alpha' < \frac{\ell}{2}$, and satisfies $\mathcal{U}_t 1 = 1$; so $e^{-t\mathfrak{h}_c}[1] = [1]$ for $0 \le t < \frac{\ell}{2}$, the spectral measure of $[1]$ is concentrated at 0, and $\mathfrak{h}_c[1] = 0$. If $\alpha' > \frac{\ell}{2}$, no site of any Λ_j obeys the two bounds that define $\mathsf{Bd}_j(0, \alpha')$, so every $F \in \mathcal{A}(0, \alpha')$ is a constant multiple of 1; then $\mathcal{U}_t F = F$, and $e^{-t\mathfrak{h}_c}[F] = [F]$ for every real $t \ge 0$ because $\mathfrak{h}_c[1] = 0$, which gives the identities of (B5) for such α', the one at $t = \alpha'$ included. *Step 4: uniqueness.* Let H' be self-adjoint with the property stated in (B5). For real $\gamma < \alpha'_F$ choose $t \in \mathbb{Q}_L$ with $\gamma < t < \alpha'_F$; the map $x \mapsto e^{-xH'}[F]$ is norm continuous on $[0, t]$ and equals $[\mathcal{U}_x F]$ at the points $x \in \mathbb{Q}_L$, so $e^{-\gamma H'}[F] = \phi(F, \gamma)$, and $e^{-\beta H'} \phi(F, \gamma) = \phi(F, \gamma + \beta)$ whenever $\gamma + \beta < \alpha'_F$. Thus $e^{-\alpha H'}|_{\mathcal{D}_\alpha} = S_\alpha$, and the uniqueness part of the theorem gives $H' = \mathfrak{h}_c$. *Step 5: the end point.* Let $\alpha' \in \mathbb{Q}_L$, $F \in \mathcal{A}(0, \alpha')$, and $t_n \uparrow \alpha'$ in $\mathbb{Q}_L$. Then $\mathcal{U}_{\alpha'} F \in \mathcal{A}(\alpha', 0)$, and (B2) gives $\|\mathcal{U}_{t_n} F - \mathcal{U}_{\alpha'} F\|_c = \|\mathcal{U}_{-(\alpha' - t_n)}(\mathcal{U}_{\alpha'} F) - \mathcal{U}_{\alpha'} F\|_c \to 0$. Hence $\int e^{-2t_n \lambda} d\rho_{[F]} = \|\mathcal{U}_{t_n} F\|_c^2$ stays bounded, Fatou's lemma gives $\int e^{-2\alpha' \lambda} d\rho_{[F]} < \infty$, and $e^{-t_n \mathfrak{h}_c}[F] \to e^{-\alpha' \mathfrak{h}_c}[F]$; consequently $e^{-\alpha' \mathfrak{h}_c}[F] = [\mathcal{U}_{\alpha'} F]$. *Step 6: negative times.* Let $F \in \mathcal{A}(\alpha, \alpha')$ with $\alpha, \alpha' > 0$, and $t \in \mathbb{Q}_L \cap (0, \alpha]$. Then $G = \mathcal{U}_{-t} F \in \mathcal{A}(\alpha - t, \alpha' + t) \subset \mathcal{A}(0, \alpha' + t)$ and $t < \alpha' + t$, so $[G] \in \mathrm{Dom}(e^{-t\mathfrak{h}_c})$ and $e^{-t\mathfrak{h}_c}[G] = [\mathcal{U}_t G] = [F]$. As the range of $e^{-t\mathfrak{h}_c}$ is the domain of $e^{t\mathfrak{h}_c}$ and $e^{t\mathfrak{h}_c} e^{-t\mathfrak{h}_c}[G] = [G]$, the class $[F]$ lies in the domain of $e^{t\mathfrak{h}_c}$, and $e^{t\mathfrak{h}_c}[F] = [\mathcal{U}_{-t} F]$. □

18.9. **The two minima of one unit of centre flux, and the energy of a pair of $\mathbb{Z}_2$ monopoles.** This subsection sets out two classical layers under the partition functions of the section. The first is one unit of centre flux through the plane 12 of a box: the action of the twisted fields of Lemma 11.9 vanishes on exactly two gauge orbits, each with the stabiliser $\{\pm\mathbf{1}\}$, which the change of sign of the bonds of the direction 3 across one plane exchanges; at them, on a cube of side l whose spacing is a, the second variation in physical units has, on the orthogonal complement of the gauge directions, the floor $a^{-2}\, 4 \sin^2 \frac{\pi a}{2l}$, a number that is at least $4l^{-2}$ at every spacing and tends to $\pi^2 l^{-2}$ as $a \to 0$; and on a box with $|N|$ sites and largest side $\bar N$, when every plaquette variable lies at a distance less than ε from $\mathbf{1}$ and $36\pi |N| \bar N^3 \varepsilon \le 1$, a bound on ε that shrinks as the box grows, the field is, up to a gauge transformation fixed up to its sign, one of the two minima times the exponential of an element of the Landau slice, and the set of these elements lies between two convex sets of the slice (Propositions 18.97 and 18.98); this is the description of the minima that the sketch of Proposition 11.14(a) uses, for a class with one twisted plane. The second is the point operator of a periodic box, the sum of the Wilson integrals over the sign fields whose monopoles are two given cubes, divided by the same sum over the closed sign fields. The least action of one $\mathbb{Z}_2$ monopole on $\mathbb{Z}^3$ is a number c_{mon}, attained at an abelian field, with $0.9960 < c_{\mathrm{mon}} \le \frac{\pi^2}{2} \mathcal{G}(0)$, $\mathcal{G}$ the Green function of $\mathbb{Z}^3$ (Proposition 18.101); the least action of a pair at the lattice vector v is $2c_{\mathrm{mon}} - \pi/(4|v|) + O(|v|^{-2})$

over all SU(2) fields (Proposition 18.103); and on the lattices $\Lambda_{K,\ell}$ of the torus T_ℓ, for every side $\ell = 2L^m$ and every label, the point operator of two distinct points, both centres of cubes of a single lattice of this family, is at most $\exp[-2c_{\mathrm{mon}}\beta + (192L+69)\beta^{3/4}(\log\beta)^{1/4}]$ at all large cutoffs, while for two cubes that differ by a lattice vector v_K with $|v_K| \to \infty$ and $|v_K|^6 \log\beta = o(\beta)$ as the cutoff K tends to infinity, its logarithm is $-2c_{\mathrm{mon}}\beta + \frac{\pi}{4}\beta/|v_K|$ up to $o(\beta/|v_K|)$ (Proposition 18.105). Propositions 18.99, 18.100, 18.102 and 18.104 hold the tools: Stokes inequalities for sets of cubes, abelian fields made from flows and the asymptotics of $\mathcal{G}$, the potential of one monopole at large distances, and the exact relations of the point operator on one box.

Twisted fields. In Propositions 18.97 and 18.98, $N = (N_1, N_2, N_3)$ is a box with all $N_\mu \geq 3$, $|N| = N_1N_2N_3$ and $\bar{N} = \max_\mu N_\mu$; the class is the one whose one twisted plane is 12, with the twist triple $\Omega = (i\sigma_1, i\sigma_2, \mathbf{1})$ of Lemma 11.9, the other classes with one twisted plane being reached by a permutation of the axes. $\mathcal{V}_N$ is the set of the twisted fields of Lemma 11.9, the maps U from the bonds of $\mathbb{Z}^3$ to G with $U(b + N_\mu e_\mu) = \Omega_\mu U(b)\Omega_\mu^{-1}$; $\mathscr{G}_N$ is the group of the maps $g\colon \mathbb{Z}^3 \to G$ with $g(x + N_\mu e_\mu) = \Omega_\mu g(x)\Omega_\mu^{-1}$, which act by $U^g(b) = g(b_-)U(b)g(b_+)^{-1}$; $\mathsf{B}_N = \prod_\mu \{0, \dots, N_\mu - 1\}$, and dU, dg are the products of the Haar probability measures over the bonds and the sites that begin in B_N; (x, μ) is the bond from x to $x + e_\mu$; $\partial U(p)$ is the ordered product around the oriented boundary of p, taking the inverse on a bond traversed backwards, and $A(U) = \sum_p (1 - \frac{1}{2}\mathrm{tr}\,\partial U(p))$, the sum over the $3|N|$ plaquettes based in B_N, is the action A' of Lemma 11.9; $\|\partial U - \mathbf{1}\|_\infty$ is the largest $|\partial U(p) - \mathbf{1}|$ over all plaquettes of $\mathbb{Z}^3$, $|\cdot|$ the operator norm, and it is attained at a plaquette based in B_N, since a translation by a period conjugates the plaquette variable. The map of the sketch of Lemma 11.9, which we call I and which multiplies $U(b)$ on the right by Ω_μ at the bonds b of the direction μ that begin in B_N and end outside it, is a bijection of $\mathcal{V}_N$ onto the periodic fields of the box N that carries dU to Haar measure, with $\mathrm{tr}\,\partial(\mathsf{I}U)(p) = \eta^{n_{12}}(p)\,\mathrm{tr}\,\partial U(p)$ for the sign field $\eta^{n_{12}}$ whose reversed column lies over the point $(N_1 - 1, N_2 - 1)$ of the plane 12, and with $\mathsf{I}(U^g) = (\mathsf{I}U)^{g|_{\mathsf{B}_N}}$; so $A_{\eta^{n_{12}}} \circ \mathsf{I} = A$, $\int e^{-\beta A} dU = Z[n_{12}]$, and every statement below on $\mathcal{V}_N$ is a statement on the class n_{12}. For $\varsigma \in \{+, -\}$ the field $R_\varsigma \in \mathcal{V}_N$ is $\varsigma\mathbf{1}$ at the bonds $(x, 3)$ with $x_3 \equiv N_3 - 1$ modulo N_3 and $\mathbf{1}$ at all other bonds; the flip is $U \mapsto R_- U$, the product bond by bond, that is the change of sign of the bonds of the direction 3 that cross one plane normal to 3; it keeps dU and every plaquette variable. $\mathcal{P}_3(U)(x) = U(x,3)U(x + e_3, 3) \cdots U(x + (N_3 - 1)e_3, 3)$ is the holonomy of the closed line through x in the direction 3. *Forms.* C^0, C^1 and C^2 are the spaces of the $\mathfrak{g}$-valued functions f of the sites, of the bonds, respectively of the plaquettes of $\mathbb{Z}^3$ that obey $f(\cdot + N_\mu e_\mu) = \Omega_\mu f(\cdot)\Omega_\mu^{-1}$; in each of them $\|f\|^2 = \sum |f|^2$, the sum running over the sites of B_N, over the bonds that begin there, respectively over the plaquettes whose base point lies there, with $|X|^2 = \frac{1}{2}\mathrm{tr}\,X^2$ and $\langle X, Y\rangle = \frac{1}{2}\mathrm{tr}\,XY$ on $\mathfrak{g}$, and $|f|_\infty = \max|f|$. $(\nabla\lambda)(b) = \lambda(b_+) - \lambda(b_-)$, ∇^* is its adjoint, $(dX)(p) = X(b_1) + X(b_2) - X(b_3) - X(b_4)$ where b_1, b_2 are the positive bonds on the path from the base of p along its first and second directions, and b_3, b_4 are the positive bonds on the path in the reverse order, so that $X \mapsto dX$ maps C^1 to C^2, and $\mathcal{H}_N = \ker\nabla^* \subset C^1$ is the Landau slice; for $X \in C^1$, $e^{iX} \in \mathcal{V}_N$. We put

$$\lambda_* = \min\{4\sin^2\tfrac{\pi}{2N_1},\, 4\sin^2\tfrac{\pi}{2N_2}\}, \qquad \Xi = \tfrac{\bar{N}}{2}(3|N|)^{1/2}, \qquad r_\Xi = \frac{1}{16\,\Xi}.$$

Proposition 18.97 (One unit of centre flux: the two minima and the floor of the second variation)**.** Let N be a box with all $N_\mu \geq 3$.

(a) $A(U) = 0$ if and only if $U = R_\varsigma^g$ for some $g \in \mathscr{G}_N$ and some $\varsigma \in \{+, -\}$.

(b) $\frac{1}{2}\mathrm{tr}\,\mathcal{P}_3 = \varsigma$ on the orbit of R_ς, so the two orbits are disjoint; the flip maps each of them onto the other; and the stabiliser of R_ς in $\mathscr{G}_N$ is $\{\pm\mathbf{1}\}$.

(c) The holonomies of the periodic field $\mathsf{I}R_\varsigma$ along the straight closed lattice paths from the origin in the directions 1, 2, 3 are $i\sigma_1$, $i\sigma_2$ and $\varsigma\mathbf{1}$.

(d) For $X \in C^1$, $\frac{d^2}{ds^2}A(e^{isX}R_\varsigma)\big|_{s=0} = \|dX\|^2$; the tangent space at R_ς of its orbit is ∇C^0, and its orthogonal complement in C^1 is $\mathcal{H}_N$.

(e) $\|dX\|^2 + \|\nabla^* X\|^2 \geq \lambda_* \|X\|^2$ for $X \in C^1$ and $\|\nabla\lambda\|^2 \geq \lambda_* \|\lambda\|^2$ for $\lambda \in C^0$, with equality in each at some element $\neq 0$; so ∇ is injective, $\dim \mathcal{H}_N = 6|N|$, $\|dX\|^2 \geq \lambda_* \|X\|^2 \geq 4\bar{N}^{-2}\|X\|^2$ on $\mathcal{H}_N$, and $\lambda_* \leq 1$.

(f) On the cube with N sites a side, of spacing a and side $l = Na$, the second variation at R_ς of the action $a^{-1}A$ in physical units, taken in the physical field X/a with a^3 times the lattice-sum inner product, is at least $a^{-2}\, 4\sin^2 \frac{\pi a}{2l} \geq 4l^{-2}$ on the orthogonal complement of the gauge directions, and $a^{-2}\, 4\sin^2 \frac{\pi a}{2l} \to \pi^2 l^{-2}$ as $a \to 0$ at fixed l; for every $j > -m$ the lattice $\Lambda_{j,\ell}$ of the torus T_ℓ is the cube of side ℓ with $N = 2L^{m+j} \geq 2L$, and on it this floor is at least $4\ell^{-2}$.

■

Sketch. (a)–(c). At every plaquette $\partial R_\varsigma(p) = \mathbf{1}$, since a plaquette holds either none of the bonds at which $R_\varsigma = \varsigma\mathbf{1}$ or two of them, run in opposite senses, and $\partial U^g(p)$ is conjugate to $\partial U(p)$; so $A = 0$ on the two orbits. Conversely, if $A(U) = 0$, all plaquette variables of $\mathbb{Z}^3$ are $\mathbf{1}$; two lattice paths with the same ends differ by moves across plaquettes and by backtrackings, so the holonomy $h(x)$ of U along any path from x to 0 is well defined, and $U(b) = h(b_-)h(b_+)^{-1}$. By the twisted periodicity of U the function $x \mapsto \Omega_\mu^{-1} h(x + N_\mu e_\mu)$ has the same increments as h along every bond, so it is $h(x)C_\mu$ with a constant $C_\mu \in G$, that is $h(x + N_\mu e_\mu) = \Omega_\mu h(x) C_\mu$; computing $h(x + N_\mu e_\mu + N_\nu e_\nu)$ in the two orders, with $\Omega_1\Omega_2 = -\Omega_2\Omega_1$ and $\Omega_3 = \mathbf{1}$, gives $C_1C_2 = -C_2C_1$ and $C_3C_j = C_jC_3$ for $j = 1, 2$. Two anticommuting elements of G are imaginary unit quaternions with orthogonal axes; as $\mathrm{Ad}\colon G \to \mathrm{SO}(3)$ is onto, there is $c \in G$ with $cC_jc^{-1} = -i\sigma_j = \Omega_j^{-1}$ for $j = 1, 2$, and an element that commutes with both is $\pm\mathbf{1}$, so $C_3 = \varsigma\mathbf{1}$. Then $h' = hc^{-1}$ has $h'(x + N_j e_j) = \Omega_j h'(x) \Omega_j^{-1}$ for $j = 1, 2$ and $h'(x + N_3 e_3) = \varsigma h'(x)$; with $s(x) = \varsigma^{\lfloor x_3/N_3 \rfloor}$ the map $g = sh'$ lies in $\mathscr{G}_N$, and $U(b) = s(b_-)s(b_+)\, g(b_-)g(b_+)^{-1} = R_\varsigma^g(b)$, since $s(b_-)s(b_+) = \varsigma$ exactly at the bonds where $R_\varsigma = \varsigma\mathbf{1}$. As $\Omega_3 = \mathbf{1}$, $\mathcal{P}_3(U^g)(x) = g(x)\mathcal{P}_3(U)(x)g(x)^{-1}$, so $\mathrm{tr}\,\mathcal{P}_3$ is gauge invariant, and $\mathcal{P}_3(R_\varsigma) = \varsigma\mathbf{1}$, as the closed line meets exactly one bond where $R_\varsigma = \varsigma\mathbf{1}$. $R_- R_\varsigma = R_{-\varsigma}$ and $R_- U^g = (R_- U)^g$, R_- being central. $R_\varsigma^g = R_\varsigma$ says $g(b_-) = g(b_+)$ at every bond, so g is constant, and $g = \Omega_j g \Omega_j^{-1}$ for $j = 1, 2$ leaves $g = \pm\mathbf{1}$. Along the direction μ from the origin, $\mathsf{I}R_\varsigma$ is $\mathbf{1}$ at $N_\mu - 1$ bonds and $R_\varsigma((N_\mu - 1)e_\mu, \mu)\, \Omega_\mu$ at the last one, which gives (c).

(d)–(f). As R_ς is central, $\partial(e^{isX} R_\varsigma)(p) = e^{isX(b_1)} e^{isX(b_2)} e^{-isX(b_3)} e^{-isX(b_4)} = \mathbf{1} + is\, dX(p) + O(s^2)$, and $1 - \frac{1}{2}\mathrm{tr}\, u = \frac{1}{2}|u - \mathbf{1}|^2$ for $u \in G$; so $A(e^{isX} R_\varsigma) = \frac{1}{2} s^2 \|dX\|^2 + O(s^3)$. The curve $s \mapsto R_\varsigma^{e^{is\lambda}}$ has the velocity $-\nabla\lambda$ at $s = 0$, and $(\nabla C^0)^\perp = \ker \nabla^*$. For (e): $\mathrm{Ad}(i\sigma_a)\sigma_c$ is σ_c for $c = a$ and $-\sigma_c$ for $c \neq a$, so the colours of $X = \sum_a X^a \sigma_a$ decouple, with $X^a(\cdot + N_\mu e_\mu) = (-1)^{\theta_\mu^a} X^a$, $\theta^1 = (0, 1, 0)$, $\theta^2 = (1, 0, 0)$, $\theta^3 = (1, 1, 0)$: the colour phases of Proposition 11.14 for the class n_{12}, divided by π. Such functions have the orthogonal basis $e^{ip\cdot x}$, $p_\mu \in \frac{2\pi}{N_\mu}(\mathbb{Z} + \frac{1}{2}\theta_\mu^a)$; with $k_\mu = e^{ip_\mu} - 1$ one has $\widehat{dX}_{\mu\nu} = k_\mu \hat{X}_\nu - k_\nu \hat{X}_\mu$, $\widehat{\nabla^* X} = \sum_\mu \bar{k}_\mu \hat{X}_\mu$ and $\widehat{\nabla\lambda}_\mu = k_\mu \hat{\lambda}$, and Lagrange's identity reads $\sum_{\mu<\nu} |k_\mu \hat{X}_\nu - k_\nu \hat{X}_\mu|^2 + |\sum_\mu \bar{k}_\mu \hat{X}_\mu|^2 = |k|^2 |\hat{X}|^2$ with $|k|^2 = \sum_\mu 4\sin^2 \frac{p_\mu}{2}$. Every θ^a has a $\mu \in \{1, 2\}$ with $\theta_\mu^a = 1$, and there $\frac{p_\mu}{2}$ lies at the distance $\geq \frac{\pi}{2N_\mu}$ from $\pi\mathbb{Z}$; so $|k|^2 \geq \lambda_*$ on every mode, which gives both inequalities. $\sin y \geq \frac{2y}{\pi}$ on $[0, \frac{\pi}{2}]$ gives $\lambda_* \geq 4\bar{N}^{-2}$, and $N_\mu \geq 3$ gives $\lambda_* \leq 1$. If $N_2 \geq N_1$, the field $X = \cos(\pi x_2/N_2)\, \sigma_1$ at the bonds of the direction 1 and 0 at the others lies in $\mathcal{H}_N$ and has $\|dX\|^2 = \lambda_* \|X\|^2$, and $\lambda = \cos(\pi x_2/N_2)\, \sigma_1$ has $\|\nabla\lambda\|^2 = \lambda_* \|\lambda\|^2$; if $N_1 > N_2$ the colour 2 with the axes 1, 2 exchanged serves. ∇ is injective on C^0, of the dimension $3|N|$, so ∇^* maps C^1, of the dimension $9|N|$, onto C^0, and $\dim \mathcal{H}_N = 6|N|$. For (f): in $\mathbf{A} = X/a$ the second variation of $a^{-1}A$ is $a^{-1}\|d(a\mathbf{A})\|^2 = a\|d\mathbf{A}\|^2$, while $(\mathbf{A}, \mathbf{A})_a = a^3 \|\mathbf{A}\|^2$; on $\mathcal{H}_N$ their quotient is at least $a^{-2}\lambda_*$, and on the cube $\lambda_* = 4\sin^2 \frac{\pi a}{2l} \geq 4a^2 l^{-2}$, with $a^{-2}\, 4\sin^2 \frac{\pi a}{2l} \to \pi^2 l^{-2}$; on $\Lambda_{j,\ell}$, $j > -m$, the side is $l = \ell$ and $N = 2L^{m+j} \geq 3$. □

Proposition 18.98 (Small plaquettes: two pieces, each between two convex sets of the slice)**.** Let N be a box with all $N_\mu \geq 3$ and $\varepsilon > 0$.

(a) If $\|\partial U-\mathbf{1}\|_\infty \le \varepsilon$ and $4\bar N^2\varepsilon \le 1$, there are $g\in\mathscr{G}_N$ and $\varsigma\in\{+,-\}$ with $\max_b |U^g(b)-R_\varsigma(b)| \le 3\bar N^2\varepsilon$ and $\varsigma\,\frac12\operatorname{tr}\mathcal{P}_3(U)(x) \ge 1-\frac12(3\bar N^2\varepsilon)^2 \ge \frac{23}{32}$ at every site x.

Let now $36\pi|N|\bar N^3\varepsilon\le 1$, and put $\mathcal{V}_{N,\varepsilon}=\{U\in\mathcal{V}_N : \|\partial U-\mathbf{1}\|_\infty<\varepsilon\}$, $\mathcal{V}^\varsigma_{N,\varepsilon}=\{U\in\mathcal{V}_{N,\varepsilon} : \varsigma\operatorname{tr}\mathcal{P}_3(U)(0)>0\}$, $\mathcal{S}_\varepsilon=\{X\in\mathcal{H}_N : |X|_\infty\le r_\Xi,\ \|\partial e^{iX}-\mathbf{1}\|_\infty<\varepsilon\}$ and, for $\rho>0$, $\mathcal{K}_\rho=\{X\in\mathcal{H}_N : \max_p|dX(p)|<\rho\}$, a convex set symmetric about 0.

(b) $\mathcal{V}_{N,\varepsilon}$ is the disjoint union of $\mathcal{V}^+_{N,\varepsilon}$ and $\mathcal{V}^-_{N,\varepsilon}$; both are open and carried onto themselves by $\mathscr{G}_N$, and the flip exchanges them.

(c) $\mathcal{S}_\varepsilon$ is open in $\mathcal{H}_N$, and on it $\max_p|dX(p)|<2\varepsilon$ and $|X|_\infty\le\|X\|<2\Xi\varepsilon<r_\Xi$.

(d) The map $\Psi_\varsigma\colon\mathscr{G}_N\times\mathcal{S}_\varepsilon\to\mathcal{V}^\varsigma_{N,\varepsilon}$, $\Psi_\varsigma(g,X)=(R_\varsigma e^{iX})^g$, is real-analytic and onto, and $\Psi_\varsigma(g,X)=\Psi_\varsigma(g',X')$ if and only if $X'=X$ and $g'=\pm g$; so, modulo gauge transformations, each of the two pieces $\mathcal{V}^\pm_{N,\varepsilon}$ is a copy of $\mathcal{S}_\varepsilon$.

(e) $\mathcal{K}_{\varepsilon(1-8\Xi^2\varepsilon)}\subset\mathcal{S}_\varepsilon\subset\mathcal{K}_{\varepsilon(1+32\Xi^2\varepsilon)}$, and $8\Xi^2\varepsilon=6\bar N^2|N|\varepsilon\le 0.018$.

■

Sketch. (a) *Two nearly anticommuting elements.* Let $C_1,C_2,C_3\in G$, $0\le\delta\le\frac14$, $|C_1C_2+C_2C_1|\le\delta$ and $|C_3C_j-C_jC_3|\le\delta$ for $j=1,2$. Write $C_j=\cos\vartheta_j+i\sin\vartheta_j\,n_j\cdot\sigma$ with $\sin\vartheta_j\ge0$, $|n_j|=1$, and $\nu=n_1\cdot n_2$. Expanding the scalar and vector parts of the anticommutator gives $\frac14|C_1C_2+C_2C_1|^2=\cos^2\vartheta_1+\sin^2\vartheta_1(\cos^2\vartheta_2+\sin^2\vartheta_2\,\nu^2)$, and the same holds with 1 and 2 exchanged; so $|\cos\vartheta_j|\le\frac{\delta}{2}$, $\sin^2\vartheta_j\ge\frac{63}{64}$ and $|\nu|\le0.508\delta$. A rotation $\mathrm{Ad}(c)$ that carries n_1 to e_1 and n_2 to $\nu e_1+(1-\nu^2)^{1/2}e_2$ gives $|cC_1c^{-1}-i\sigma_1|^2=2-2\sin\vartheta_1\le\frac{\delta^2}{2}$ and $|cC_2c^{-1}-i\sigma_2|^2=2-2\sin\vartheta_2(1-\nu^2)^{1/2}\le\frac{32}{63}\delta^2$. As $C_3C_j-C_jC_3=-2i\sin\vartheta_3\sin\vartheta_j\,(n_3\times n_j)\cdot\sigma$ and $\sum_j|n_3\times n_j|^2\ge1-|\nu|$, $\sin^2\vartheta_3\le0.582\delta^2$, and with ς the sign of $\cos\vartheta_3$, $|C_3-\varsigma\mathbf{1}|^2=2-2|\cos\vartheta_3|\le0.588\delta^2$. So $|cC_1c^{-1}-i\sigma_1|\le0.71\delta$, $|cC_2c^{-1}-i\sigma_2|\le0.72\delta$ and $|C_3-\varsigma\mathbf{1}|\le0.77\delta$. *The comb.* Let $\epsilon=\|\partial U-\mathbf{1}\|_\infty$. For $x\in\mathsf{B}_N$ let $h(x)$ be the holonomy of U along the path from 0 that makes x_1 steps e_1, then x_2 steps e_2, then x_3 steps e_3, and put $U'(b)=h(b_-)U(b)h(b_+)^{-1}$ at the bonds with both ends in B_N. Then $U'(x,3)=\mathbf{1}$, and $U'(x,2)$, $U'(x,1)$ are conjugate to the holonomies along the boundaries of ladders of x_3, respectively x_2+x_3, plaquettes; taking the plaquettes of a ladder away one at a time multiplies such a holonomy by a conjugate of a plaquette variable or of its inverse, so $|U'(x,2)-\mathbf{1}|\le x_3\epsilon$ and $|U'(x,1)-\mathbf{1}|\le(x_2+x_3)\epsilon$. *The seams.* For $x\in\mathsf{B}_N$ with $x_\mu=N_\mu-1$ and $x'=x+e_\mu-N_\mu e_\mu$ let $C_\mu(x)=h(x)U(x,\mu)\Omega_\mu h(x')^{-1}$, the value at the bond (x,μ) of $\mathsf{I}(U^{g_0})$, $g_0\in\mathscr{G}_N$ the extension of $h|_{\mathsf{B}_N}$; the plaquette variables of $\mathsf{I}(U^{g_0})$ lie within ϵ of $\eta^{n_{12}}(p)\mathbf{1}$. A plaquette of the periodic box through two neighbouring seam bonds (x,μ), $(x+e_\nu,\mu)$ with $x_\nu<N_\nu-1$ is not reversed, so $|C_\mu(x)-C_\mu(x+e_\nu)|\le\epsilon+|U'(x',\nu)-\mathbf{1}|+|U'(x,\nu)-\mathbf{1}|$. With $C_1=C_1(N_1-1,0,0)$, $C_2=C_2(0,N_2-1,0)$ and $C_3=C_3(0,0,N_3-1)$, moving on each seam first in the lower of its two free directions at the height 0 of the other and then in the other, the bounds of the comb give $|C_1(x)-C_1|\le(x_2+x_3)\epsilon$, $|C_2(x)-C_2|\le(x_1N_2+x_3)\epsilon$ and $|C_3(x)-C_3|\le(x_1+x_2)N_3\epsilon$, all at most $2\bar N(\bar N-1)\epsilon$. *The corners.* The reversed plaquette at $(N_1-1,N_2-1,0)$ gives $|C_1(x)C_2+C_2(x)C_1|\le\epsilon$ there, hence $|C_1C_2+C_2C_1|\le N_1N_2\epsilon$; the plaquettes of the planes 13 and 23 at the corners $(N_1-1,0,N_3-1)$ and $(0,N_2-1,N_3-1)$ give $|C_1C_3-C_3C_1|\le N_1N_3\epsilon$ and $|C_2C_3-C_3C_2|\le N_2N_3\epsilon$. With $\delta=\bar N^2\epsilon\le\frac14$ the first step gives c and ς, and the $g\in\mathscr{G}_N$ that extends $(ch)|_{\mathsf{B}_N}$ has $U^g=cU'c^{-1}$, within $2(\bar N-1)\epsilon$ of $\mathbf{1}$, at the inner bonds, and $U^g(x,\mu)=cC_\mu(x)c^{-1}\Omega_\mu^{-1}$, within $2\bar N(\bar N-1)\epsilon+0.77\bar N^2\epsilon\le3\bar N^2\epsilon$ of $R_\varsigma(x,\mu)$, at the seam bonds. The line through $(x_1,x_2,0)$ has $\mathcal{P}_3(U^g)=cC_3(x_1,x_2,N_3-1)c^{-1}$, within $3\bar N^2\epsilon\le\frac34$ of $\varsigma\mathbf{1}$, and $|u-\varsigma\mathbf{1}|^2=2-\varsigma\operatorname{tr}u$; $\operatorname{tr}\mathcal{P}_3$ is gauge invariant and reads x only through (x_1,x_2) modulo the periods.

(c), (e). Let $X\in\mathcal{H}_N$ with $|X|_\infty\le r_\Xi$ and $\|\partial e^{iX}-\mathbf{1}\|_\infty<\varepsilon$, and let $D=\max_p|dX(p)|$. By Proposition 18.97(e), as there are $3|N|$ plaquettes, $|X|_\infty\le\|X\|\le\lambda_*^{-1/2}\|dX\|\le\Xi D$. The plaquette variable u_p of e^{iX} is a product of four exponentials, and $|e^{iY}-\mathbf{1}-iY|\le\frac12|Y|^2$, $|e^{iY}-\mathbf{1}|\le|Y|$ and $|u_1\cdots u_4-\mathbf{1}-\sum_j(u_j-\mathbf{1})|\le\sum_{i<j}|u_i-\mathbf{1}||u_j-\mathbf{1}|$ for unitary u_j give $|u_p-\mathbf{1}-i\,dX(p)|\le$

$\frac12(\sum_{b\in p}|X(b)|)^2\le 8|X|_\infty^2$. So $D<\varepsilon+8r_\Xi\,\Xi D=\varepsilon+\frac12 D$, that is $D<2\varepsilon$ and $\|X\|<2\Xi\varepsilon$; and $32\Xi^2\varepsilon=24\bar N^2|N|\varepsilon\le\frac{24}{36\pi\bar N}<1$ gives $2\Xi\varepsilon<r_\Xi$, so the condition $|X|_\infty\le r_\Xi$ holds strictly on $\mathcal{S}_\varepsilon$, which is therefore open. The same bound gives $D<\varepsilon+8(2\Xi\varepsilon)^2$ on $\mathcal{S}_\varepsilon$; and for $X\in\mathcal{K}_{\rho'}$, $\rho'=\varepsilon(1-8\Xi^2\varepsilon)$, it gives $|X|_\infty\le\Xi\rho'<r_\Xi$ and $|u_p-\mathbf{1}|<\rho'(1+8\Xi^2\varepsilon)<\varepsilon$. Last, $8\Xi^2\varepsilon=6\bar N^2|N|\varepsilon\le\frac{6}{36\pi\bar N}\le 0.018$.

(b), (d). Let $\|\partial U-\mathbf{1}\|_\infty<\varepsilon$; as $4\bar N^2\varepsilon\le 1$, (a) gives g_0 and ς with $|U_1(b)-\mathbf{1}|\le 3\bar N^2\varepsilon$ for $U_1=R_\varsigma U^{g_0}$. Let $\mathsf{d}(u)\in[0,\pi]$ be the angle of $u\in G$, so that $u=e^{iY}$ with $|Y|=\mathsf{d}(u)$, and let g_1 minimise the continuous function $\Phi(g)=\sum_b\mathsf{d}(U_1^g(b))^2$, the sum over the bonds that begin in B_N, on the compact group $\mathscr{G}_N$. Every angle $\mathsf{d}(U_1^{g_1}(b))$ is at most $\Phi(g_1)^{1/2}\le\Phi(\mathbf{1})^{1/2}\le(3|N|)^{1/2}\frac{3\pi}{2}\bar N^2\varepsilon$, by $\mathsf{d}(u)\le\frac\pi2|u-\mathbf{1}|$, and this number is at most r_Ξ exactly when $36\pi|N|\bar N^3\varepsilon\le 1$, which we assume; so no $U_1^{g_1}(b)$ equals $-\mathbf{1}$, and at every bond we put $X=\frac1i\log U_1^{g_1}$, log being the branch on $G\setminus\{-\mathbf{1}\}$ with angle in $[0,\pi)$. Then $e^{iX}=U_1^{g_1}$, $|X(b)|=\mathsf{d}(U_1^{g_1}(b))$, $\|X\|^2=\Phi(g_1)$ and $|X|_\infty\le r_\Xi$; the intrinsic logarithm commutes with Ad, so $X\in C^1$. At $s=0$ the derivative of $\frac12\mathsf{d}(e^{is\lambda}e^{iY})^2$ is $\langle\lambda,Y\rangle$ and that of $\frac12\mathsf{d}(e^{iY}e^{-is\lambda})^2$ is $-\langle\lambda,Y\rangle$; so the stationarity of Φ at g_1 along $s\mapsto e^{is\lambda}g_1$ is $\langle\nabla^*X,\lambda\rangle=0$ for all $\lambda\in C^0$, that is $X\in\mathcal{H}_N$. Gauge transformations and the multiplication by R_ς keep $\|\partial U-\mathbf{1}\|_\infty$; so $X\in\mathcal{S}_\varepsilon$ and $U=(R_\varsigma e^{iX})^g$ with $g=(g_1g_0)^{-1}$: Ψ_ς is onto. For such U, $\frac12\mathrm{tr}\,\mathcal{P}_3(U)=\varsigma\frac12\mathrm{tr}\,\mathcal{P}_3(e^{iX})$ and $|\mathcal{P}_3(e^{iX})-\mathbf{1}|\le N_3r_\Xi\le\frac{1}{72}$, as $|N|\ge 27$; so $\mathrm{tr}\,\mathcal{P}_3(U)(0)$ does not vanish on $\mathcal{V}_{N,\varepsilon}$ and has the sign ς, which gives (b), the flip changing the sign of $\mathcal{P}_3$. *One to one.* Let $X,X'\in\mathcal{S}_\varepsilon$, $g\in\mathscr{G}_N$ and $e^{iX'(b)}=g(b_-)e^{iX(b)}g(b_+)^{-1}$ at all bonds. Then $|g(b_-)-g(b_+)|\le 2r_\Xi$. Writing $g(0)=\alpha+iw\cdot\sigma$, the bound $|\Omega_jg(0)\Omega_j^{-1}-g(0)|=|g(N_je_j)-g(0)|\le 2N_jr_\Xi$ reads $(w_2^2+w_3^2)^{1/2}\le\bar Nr_\Xi$ and $(w_1^2+w_3^2)^{1/2}\le\bar Nr_\Xi$, so $|w|\le\sqrt2\,\bar Nr_\Xi$; replacing g by $-g$, which acts in the same way, $\alpha\ge0$ and $|g(0)-\mathbf{1}|\le 2\bar Nr_\Xi$; every site is congruent modulo the periods to a site at most $\frac32\bar N$ steps from 0, so $|g-\mathbf{1}|_\infty\le 5\bar Nr_\Xi\le\frac{5}{72}$, and $\lambda=\frac1i\log g\in C^0$, taken at every site with the same intrinsic logarithm, has $|\lambda|_\infty\le 0.07$ and, by $|\lambda-\lambda'|\le|e^{i\lambda}-e^{i\lambda'}|/\cos 0.07$ on the ball $\{|\lambda|\le 0.07\}$, $|\nabla\lambda|_\infty\le 2.01r_\Xi$. Along $U_\tau=(e^{iX})^{e^{i\tau\lambda}}$, $0\le\tau\le1$, $|U_\tau(b)-\mathbf{1}|\le r_\Xi+2.01r_\Xi$, so $X_\tau=\frac1i\log U_\tau$ has $|X_\tau|_\infty\le 3.02r_\Xi$, $X_0=X$ and $X_1=X'$; and $\varphi(\tau)=\frac12\|X_\tau\|^2$ has $\varphi'(\tau)=-\langle\nabla^*X_\tau,\lambda\rangle$, which vanishes at $\tau=0$ and at $\tau=1$. With $T_Y=\int_0^1\mathrm{Ad}(e^{i\sigma Y})\,d\sigma$, the formulas $\frac{d}{d\tau}e^{iX_\tau}=i(T_{X_\tau}\dot X_\tau)e^{iX_\tau}$, $\dot U_\tau=i(\lambda(b_-)-\mathrm{Ad}(U_\tau)\lambda(b_+))U_\tau$ and $T_Y^{-1}(\mathrm{Ad}(e^{iY})-1)=i\,\mathrm{ad}\,Y$ give $\dot X_\tau=-T_{X_\tau}^{-1}\nabla\lambda-i[X_\tau,\lambda(b_+)]$, and

$$\varphi''(\tau)=\sum_b\big(\langle T_{X_\tau}^{-1}\nabla\lambda,\nabla\lambda\rangle+\langle i[X_\tau,\lambda(b_+)],\nabla\lambda\rangle\big)\ge(1-\tfrac12|X_\tau|_\infty^2)\|\nabla\lambda\|^2-2\sqrt3\,|X_\tau|_\infty\|\lambda\|\,\|\nabla\lambda\|\ge 0.92\,\|\nabla\lambda\|^2,$$

by $\langle T_Y^{-1}Z,Z\rangle\ge|Y|\cot|Y|\,|Z|^2$, $\|\lambda\|\le\frac{\bar N}{2}\|\nabla\lambda\|$ (Proposition 18.97(e)) and $\bar Nr_\Xi\le\frac{1}{72}$. As $\varphi'(0)=\varphi'(1)$, $\nabla\lambda=0$, so $\lambda=0$, $g=\pm\mathbf{1}$ and $X'=X$. The general case $\Psi_\varsigma(g,X)=\Psi_\varsigma(g',X')$ is this one with $g'^{-1}g$ in the place of g, as R_ς is central. □

Monopoles. From here on, on $\mathbb{Z}^3$, the lattice of Propositions 18.99–18.103, a unit cube is named by its centre $c\in\mathbb{Z}^3$, the closed cube being $c+[-\frac12,\frac12]^3$, so that the sites have half-integer coordinates. On a periodic box, the lattice of Propositions 18.104 and 18.105, the sites keep the integer coordinates of the periodic lattice of the box, each cube has the form $x+[0,1]^3$ with x a site, and for a cube c and $v\in\mathbb{Z}^3$ we write $c+v$ for the image of c under the translation by v; a set of cubes of a box is brought to $\mathbb{Z}^3$ by a translation that moves the midpoints of all its cubes to points of $\mathbb{Z}^3$, and brought back by the inverse translation. In both cases a plaquette is the common face of two neighbouring cubes, that is an edge $\{c,c'\}$ of the dual lattice; for $c\in\mathbb{Z}^3$, $|c|$ is the Euclidean length, $|c|_\infty$ and $|c|_1$ are the two other norms, and $\mathbb{B}_r=\{c\in\mathbb{Z}^3:|c|_\infty\le r\}$. For a finite set $\mathfrak{B}$ of cubes, $\partial\mathfrak{B}$ is the set of the plaquettes that are a face of exactly one cube of $\mathfrak{B}$, $\mathcal{P}^\circ(\mathfrak{B})$ the set of those that are a face of two cubes of $\mathfrak{B}$, and $\mathfrak{B}^\circ$ the set of the cubes of $\mathfrak{B}$ whose six neighbours lie in $\mathfrak{B}$; the closure of $\mathfrak{B}$ is the set of the bonds and the plaquettes of its cubes. For

a sign field η on the plaquettes, of $\mathbb{Z}^3$ or of a periodic box, $\delta\eta(c) = \prod_{p\subset\partial c}\eta(p)$ on the cubes, and $\mathfrak{m}(\eta) = \{c : \delta\eta(c) = -1\}$ is the set of the monopoles of η; the closed sign fields of the setting are those with $\mathfrak{m}(\eta) = \emptyset$. A configuration on a set P of plaquettes is a pair (U, η) of a field on the bonds of the plaquettes of P and a sign field on P; $\alpha_p \in [0, \pi]$ is given by $\cos\alpha_p = \frac{1}{2}\eta(p)t_p$, $t_p = \operatorname{tr}\partial U(p)$, so that $1 - \frac{1}{2}\eta(p)t_p = \mathsf{f}(\alpha_p)$ with $\mathsf{f}(t) = 1 - \cos t$; for a field U and a sign field η on the whole of $\mathbb{Z}^3$, $A_\eta(U) = \sum_p(1 - \frac{1}{2}\eta(p)t_p) \in [0, \infty]$, summed over every plaquette of $\mathbb{Z}^3$, is the action of eq. 11.i on that lattice; and $\alpha_p = d_G(\partial U(p), \eta(p)\mathbf{1})$, where $d_G(X, Y) = \arccos\frac{1}{2}\operatorname{tr}(X^*Y) \in [0, \pi]$ is the angle of X and Y as unit vectors of $\mathbb{R}^4 \supset G$, a metric that is invariant under left and right translations and under $X \mapsto X^{-1}$, with $d_G(\mathbf{1}, -\mathbf{1}) = \pi$. A flow is a real function j of the oriented edges of the dual lattice with $j(c' \to c) = -j(c \to c')$, and $\operatorname{div} j(c) = \sum_{c'\sim c} j(c \to c')$; for a function u on the cubes $\nabla u(c \to c') = u(c) - u(c')$, so that $\sum \nabla u\, j = \sum_c u \operatorname{div} j$, the first sum over the edges, when one of the two factors has a finite support or both decay fast enough; on a plaquette p a flow is read across p in the orientation fixed by the duality, and only $\cos j(p)$ and parities enter below. Last, $\mathsf{f}^*(y) = y\arcsin y - 1 + (1 - y^2)^{1/2}$ for $|y| \le 1$; so $\mathsf{f}(j) + \mathsf{f}^*(\sin j) = j\sin j$ for $|j| \le \frac{\pi}{2}$, and $(\mathsf{f}^*)' = \arcsin$.

Proposition 18.99 (Stokes inequalities for sets of cubes)**.** (a) A polygon is a closed lattice path; its sides are its steps, and its corners are the pairs of cyclically consecutive sides. Let finitely many polygons $w_1, \dots, w_F$ be given with a pairing of all their sides, two paired sides lying on one bond; let E be the number of pairs and V the number of the classes of corners for the equivalence generated by the rule that the corners next to two paired sides at the same end of their bond are equivalent. If the graph whose vertices are the polygons and whose edges are the pairs is connected and $V - E + F = 2$, then the polygons can be put in an order, and exponents $\epsilon_k = \pm 1$ chosen, independently of the field, so that every field U has $\prod_k g_k U(w_k)^{\epsilon_k} g_k^{-1} = \mathbf{1}$, the factors in that order, where $g_k = U(\zeta_k)$ is the product of U along a lattice path ζ_k; so for all signs s_k, $\sum_k d_G(U(w_k), s_k\mathbf{1}) \ge \pi$ if $\prod_k s_k = -1$, and $d_G(U(w_{k_0}), \prod_{k\ne k_0} s_k\mathbf{1}) \le \sum_{k\ne k_0} d_G(U(w_k), s_k\mathbf{1})$ for each k_0.

(b) A finite set R of cubes is good if $\sum_{p\in\partial R}\alpha_p \ge \pi$ for every configuration on ∂R with $\prod_{p\in\partial R}\eta(p) = -1$, that is with $\prod_{c\in R}\delta\eta(c) = -1$. We call a set Ω of cells of $\mathbb{Z}^2$ admissible when it is finite and non-empty, each of its rows is an interval, its non-empty rows occupy an interval, and each pair of consecutive non-empty rows shares a column; a set of cubes $\bigcup_{h_-\le h\le h_+}\Omega_h \times \{h\}$ for which every Ω_h and every $\Omega_h \cap \Omega_{h-1}$, $h_- < h \le h_+$, is admissible is called a generalised stack along the axis 3, and generalised stacks along the other axes are defined in the same way. Every generalised stack is good. Boxes and staircases are generalised stacks, a staircase being a finite set $R \ni 0$ that contains, along with any c in it, every c' each coordinate of which lies between 0 and the corresponding coordinate of c; and when $K \subset \mathbb{R}^3$ is compact, convex and non-empty, the set $\mathsf{R}(K)$ of all cubes meeting K is a generalised stack.

(c) Let (U, η) be given on the plaquettes of $\mathbb{Z}^3$, or on $\mathcal{P}^\circ(\mathfrak{B})$ for a finite set $\mathfrak{B}$ of cubes; let μ be a finite positive measure on a family of good sets R, contained in $\mathfrak{B}^\circ$ in the second case, each with $\prod_{c\in R}\delta\eta(c) = -1$, and let $y_p = \mu\{R : p \in \partial R\} \le \frac{1}{2}$ for all p. Then $\sum_p \mathsf{f}(\alpha_p) \ge \pi\,\mu(\text{all}) - \sum_p \mathsf{f}^*(y_p)$, the sums over all plaquettes, respectively over $\mathcal{P}^\circ(\mathfrak{B})$. ∎

Sketch. (a) If a side of w on the bond b is paired with a side of another polygon w', rotate and reverse the two so that $w = \mu b$ and $w' = b^{-1}\mu'$; the polygon $\mu\mu'$ has the holonomy $U(w)U(w')$, keeps the other pairs, and replaces the two pairs of equivalent corners at the ends of b by one corner at each end: F and E drop by one and V stays. Merging along a spanning tree of the graph of the polygons leaves one polygon $\hat{w}$ whose $2m$ sides are paired among themselves, $m = E - F + 1 = V - 1$, and whose holonomy is a product of conjugates of the $U(w_k)^{\pm 1}$, each k once; a rotation of a polygon

conjugates its holonomy by $U(\zeta)$ for a path ζ of some of its sides, and a reversal inverts it, so the order of the factors and their exponents come from the merging alone, and each conjugating element is $U(\zeta_k)$ for a path ζ_k made of sides of the polygons. In the graph $\hat\Gamma$ whose vertices are the classes of corners and whose edges are the pairs, a side joins the classes of the corners at its two ends, and $\hat w$ passes through all of them; so $\hat\Gamma$ is connected with V vertices and $V-1$ edges, a tree. At a leaf, every corner of that class is formed by the only pair $\{s,s'\}$ at it; hence s and s' follow one another in $\hat w$, lie on a single bond, and their meeting point is the site of that corner, so that $\hat w$ goes along a bond and straight back; erasing these two steps leaves the holonomy unchanged and takes the leaf away. By induction down to $m=1$, where $\hat w$ is one bond run there and back, $U(\hat w)=\mathbf{1}$. Solving the relation for one factor, the invariance of d_G under translations and $X\mapsto X^{-1}$, $d_G(XY,ss'\mathbf{1})\le d_G(X,s\mathbf{1})+d_G(Y,s'\mathbf{1})$ for signs s,s', and $d_G(\mathbf{1},-\mathbf{1})=\pi$ give the inequalities.

(b) *In a plane.* Let Ω be admissible. Because consecutive rows overlap, it never happens that two cells of Ω touch only at a corner while neither of the other two cells sharing that corner is present; the union of its closed cells, built up row by row with each new row meeting the union of the earlier ones in an interval of edges, has (vertices) − (edges) + (cells) = 1; and the edges lying on exactly one cell make up a single simple closed path $\partial\Omega$, which climbs along the right ends of the rows and descends along their left ends. Let $\Omega''\subset\Omega$ be admissible or empty, in a lattice plane of $\mathbb{Z}^3$. The polygons $\partial\Omega$, $\partial\Omega''$ and the boundaries of the plaquettes of $\Omega\setminus\Omega''$, with the pairing forced by the edges, form a connected complex in which the corners at one lattice vertex form one class whenever there are any; counting, $V-E+F=[V(\Omega)-E(\Omega)+|\Omega|]-[V_{\rm in}(\Omega'')-E_{\rm in}(\Omega'')+|\Omega''|]+2=1-1+2$ when $\Omega''\neq\emptyset$, the vertices and edges inner to Ω'' being those that carry no corner and no pair; when $\Omega''=\emptyset$ the complex consists of $\partial\Omega$ and the boundaries of the plaquettes of Ω, and $V-E+F=V(\Omega)-E(\Omega)+|\Omega|+1=2$. By (a), for every sign s, $d_G(U(\partial\Omega),s\varpi\mathbf{1})\le d_G(U(\partial\Omega''),s\mathbf{1})+\mathsf{s}$ and $d_G(U(\partial\Omega''),s\varpi\mathbf{1})\le d_G(U(\partial\Omega),s\mathbf{1})+\mathsf{s}$, with $\varpi=\prod_{\Omega\setminus\Omega''}\eta(p)$, $\mathsf{s}=\sum_{\Omega\setminus\Omega''}\alpha_p$ and $U(\partial\emptyset)=\mathbf{1}$. *A stack.* ∂R is made of the horizontal plaquettes over $\Omega_h\triangle\Omega_{h-1}$ between the layers $h-1$ and h, with $\Omega_{h_+ +1}=\Omega_{h_- -1}=\emptyset$, and of the bands of vertical plaquettes of each layer h over the edges of $\partial\Omega_h$. A band with the two copies of $\partial\Omega_h$ on its upper and lower planes is a complex as in (a) with $V-E+F=2n-3n+(n+2)=2$, n the length of $\partial\Omega_h$. Going down from the top faces, through each band, and between consecutive layers from $\partial\Omega_h$ to $\partial(\Omega_h\cap\Omega_{h-1})$ and on to $\partial\Omega_{h-1}$ by the inequalities in a plane, each plaquette of ∂R is used once, and the lower copy of $\partial\Omega_{h_-}$ comes within $\sum_{\partial R\setminus\text{bottom}}\alpha_p$ of one sign and within $\sum_{\text{bottom}}\alpha_p$ of the other, the product of the two signs being $\prod_{\partial R}\eta(p)=-1$; so $\sum_{\partial R}\alpha_p\ge\pi$. *Examples.* A staircase of $\mathbb{Z}^2$ is admissible, and two staircases meet in a staircase; so staircases of $\mathbb{Z}^3$, and boxes, are generalised stacks. For a compact convex $K'\subset\mathbb{R}^2$ the row y of $\mathsf{R}_2(K')$, the cells that meet K', is the set of the integers in $[\alpha-\frac12,\beta+\frac12]$, $[\alpha,\beta]$ the projection to the first axis of $K'\cap\{|x_2-y|\le\frac12\}$, and a segment between points of K' in two consecutive rows crosses the line between them in a point of K', which lies in a cell of each row; and $\mathsf{R}(K)$ has the layers $\Omega_h=\mathsf{R}_2(\pi_{12}(K\cap\{|x_3-h|\le\frac12\}))$, with $\Omega_h\cap\Omega_{h-1}=\mathsf{R}_2(\pi_{12}(K\cap\{x_3=h-\frac12\}))$ by the same crossing over one cell.

(c) For $0\le y\le\frac12$ and $0\le\alpha\le\pi$, $\mathsf{f}(\alpha)\ge y\alpha-\mathsf{f}^*(y)$: with $y=\sin j$, $0\le j\le\frac{\pi}{6}$, the difference $\mathsf{f}(\alpha)-\mathsf{f}(j)-(\alpha-j)\sin j$ vanishes at j, falls on $[0,j]$, rises on $[j,\pi-j]$, falls on $[\pi-j,\pi]$, and is $1+\cos j-(\pi-j)\sin j\ge0.55$ at π. Summing with $y=y_p$, and $\sum_p y_p\alpha_p=\int\mu(dR)\sum_{p\in\partial R}\alpha_p\ge\pi\mu(\text{all})$ by (b) and the definition of a good set, give the claim; for $R\subset\mathfrak{B}^\circ$, $\partial R\subset\mathcal{P}^\circ(\mathfrak{B})$. □

Proposition 18.100 (Abelian fields from flows; the Green function)**.** (a) Let j be a flow on $\mathbb{Z}^3$ and γ an integer flow with $\operatorname{div} j=\pi\operatorname{div}\gamma$. There is a real function ϕ of the bonds such that the field $U(b)=e^{i\phi(b)\sigma_3/2}$ and the sign field $\eta(p)=(-1)^{\gamma(p)}$ have $\frac12\eta(p)t_p=\cos j(p)$ at every plaquette; then $\mathfrak{m}(\eta)=\{c:\operatorname{div}\gamma(c)\text{ odd}\}$ and $A_\eta(U)=\sum_p\mathsf{f}(j(p))$. If $j-\pi\gamma$ vanishes off the plaquettes of a box of sites, ϕ may be taken 0 off the bonds of that box, so that $U=\mathbf{1}$ there.

(b) Every closed sign field on the plaquettes of $\mathbb{Z}^3$ is $d\gamma$ for a sign field γ on the bonds; so $\inf\{A_\eta(U) : \mathfrak{m}(\eta) = M\}$, over the fields on $\mathbb{Z}^3$, is the same for every sign field η with the monopoles M.

(c) Let $\lambda(k) = \sum_\mu (2 - 2\cos k_\mu)$ and $\mathcal{G}(c) = (2\pi)^{-3} \int_{[-\pi,\pi]^3} e^{ik\cdot c} \lambda(k)^{-1} dk$. $\mathcal{G}$ is the one function on $\mathbb{Z}^3$ with $\sum_{c' \sim c} (\mathcal{G}(c) - \mathcal{G}(c')) = \delta_{c,0}$ that tends to 0 at infinity. For every $n \geq 0$ there is C_n with $|\nabla_{e^{(1)}} \cdots \nabla_{e^{(n)}} (\mathcal{G} - \mathcal{G}_\mathrm{c})(c)| \leq C_n |c|^{-3-n}$ for every choice of $e^{(1)}, \dots, e^{(n)}$ among the six lattice unit vectors $\pm e_\mu$ and every $c \in \mathbb{Z}^3$ with $|c| \geq 2n + 2$, where $\mathcal{G}_\mathrm{c}(x) = \frac{1}{4\pi|x|}$ and $\nabla_e F(c) = F(c + e) - F(c)$; so there is an absolute $C_\mathcal{G}$ with $|\mathcal{G}(c) - \frac{1}{4\pi|c|}| \leq C_\mathcal{G} |c|^{-3}$, $|\nabla \mathcal{G}| \leq C_\mathcal{G} |c|^{-2}$ and $|\nabla \nabla \mathcal{G}| \leq C_\mathcal{G} |c|^{-3}$ at all $c \neq 0$; and $\sum (\nabla \mathcal{G})^2 = \mathcal{G}(0)$, the sum over the edges.

■

Sketch. (a) Through the duality between the plaquettes of $\mathbb{Z}^3$ and the edges of the dual lattice, oriented so that the coboundary of a real function Θ of the plaquettes, read on a cube, is the divergence of the corresponding flow, put $\Theta = 2(j - \pi\gamma)$; then $d\Theta = 2(\operatorname{div} j - \pi \operatorname{div} \gamma) = 0$. A closed real function of the plaquettes of $\mathbb{Z}^3$ is $d\phi$ for a real function ϕ of the bonds: put $\phi = 0$ on the bonds of the direction 3, fix ϕ on the plane $x_3 = 0$ by summing Θ over the plaquettes of that plane along rows, and continue it upwards and downwards by summing Θ over the vertical plaquettes; $d\phi - \Theta$ is then closed and vanishes on all vertical plaquettes and on the plane $x_3 = 0$, so it vanishes. The abelian field $U = e^{i\phi\sigma_3/2}$ has $\partial U(p) = e^{i(d\phi)(p)\sigma_3/2}$, so $\frac{1}{2} t_p = \cos(j(p) - \pi\gamma(p)) = (-1)^{\gamma(p)} \cos j(p)$, and $\delta\eta(c) = (-1)^{\operatorname{div}\gamma(c)}$. If Θ vanishes off the plaquettes of a box of sites, sum from below instead: $\phi = 0$ on the bonds of the direction 3 and, on the bond (ξ, τ) of the direction $\nu \in \{1, 2\}$, minus the sum of Θ over the vertical plaquettes of the direction ν over ξ below the height τ; this vanishes below the box and off the columns over it, and at the height τ_+ of the highest layer of sites of the box and at every greater height it is one and the same closed function of the plane, which vanishes off the projection of the box and is therefore the gradient of a function $\varkappa$ of the plane that vanishes off that projection, whose complement is connected; subtracting the gradient of the function that is $\varkappa(\xi)$ at the sites (ξ, τ) with $\tau \geq \tau_+$ and 0 at the others leaves the same $d\phi$, makes ϕ vanish on the horizontal bonds at the heights $\geq \tau_+$, and alters it on the vertical bonds only between the heights $\tau_+ - 1$ and τ_+ over the projection, which are bonds of the box; so ϕ then vanishes off the bonds of the box. (b) The same construction with signs in the place of real numbers gives the first claim, and $U \mapsto \gamma U$ keeps the Haar measure, with $A_{\eta\, d\gamma}(U) = A_\eta(\gamma U)$.

(c) $\lambda \geq \frac{4}{\pi^2} |k|^2$ on the cube $[-\pi, \pi]^3$, so λ^{-1} is integrable, $\sum_{c' \sim c} (\mathcal{G}(c) - \mathcal{G}(c')) = \delta_{c,0}$, and $\mathcal{G} \to 0$ by the Riemann–Lebesgue lemma; the difference of two such functions is harmonic and tends to 0, so a positive maximum or a negative minimum would be attained and would spread along a line to infinity. For the expansion fix $\chi \in C_c^\infty(\mathbb{R}^3)$ with $\chi = 1$ on $\{|k| \leq 1\}$ and $\chi = 0$ on $\{|k| \geq 2\}$, and write $\mathcal{G} = \mathcal{G}_1 + \mathcal{G}_2 + \mathcal{G}_3$ with the integrands $\chi |k|^{-2}$, $\chi \mathsf{r}$ and $(1 - \chi)\lambda^{-1}$, where $\mathsf{r} = \lambda^{-1} - |k|^{-2} = \mathsf{q}/(\lambda |k|^2)$ and $\mathsf{q} = |k|^2 - \lambda$. For real m let $\mathcal{S}^m$ be the set of the smooth functions F on $\{0 < |k| < \pi\}$ with $|\partial^\alpha F| \leq A_\alpha |k|^{m - |\alpha|}$ for all α. Then $\mathcal{S}^m \mathcal{S}^{m'} \subset \mathcal{S}^{m+m'}$, by the Leibniz rule, and $\mathcal{S}^m \subset \mathcal{S}^{m'}$ for $m \geq m'$, as $|k| < \pi$; for an integer $m \geq 0$, every function smooth near the closed ball that vanishes at 0 to the order m lies in $\mathcal{S}^m$, by Taylor's formula; $|k|^{-2} \in \mathcal{S}^{-2}$ and $|k|^{-4} \in \mathcal{S}^{-4}$, by homogeneity; and $1/F \in \mathcal{S}^0$ for every $F \in \mathcal{S}^0$ bounded below by a positive constant, by induction on $|\alpha|$ in $\partial^\alpha (F \cdot F^{-1}) = 0$. As q vanishes at 0 to the fourth order, $\mathsf{q} \in \mathcal{S}^4$; so $\mathsf{q}|k|^{-4} \in \mathcal{S}^0$ and $\lambda/|k|^2 = 1 - \mathsf{q}|k|^{-2} \in \mathcal{S}^0$, and since $\lambda/|k|^2 \geq \frac{4}{\pi^2}$, also $|k|^2/\lambda \in \mathcal{S}^0$; hence $\mathsf{r} = (\mathsf{q}|k|^{-4})(|k|^2/\lambda) \in \mathcal{S}^0$. For $m > -3$, an integer $M > m + 3$ and F supported in $\{|k| \leq 2\}$ with $|\partial^\alpha F| \leq A |k|^{m - |\alpha|}$ for $|\alpha| \leq M$, one has $|\int F e^{ik\cdot x} dk| \leq C(m, M) A |x|^{-3-m}$: split F with $\chi(|x|k)$; the part near 0 is at most $A \int_{|k| \leq 2/|x|} |k|^m dk$, and in the rest integrate by parts M times in a coordinate with $|x_\mu| \geq |x|/\sqrt{3}$. Applied to $(ik)^\gamma \chi \mathsf{r}$ with $m = |\gamma|$, this gives $|\partial^\gamma \mathcal{G}_2(x)| \leq C_\gamma |x|^{-3-|\gamma|}$ on $\mathbb{R}^3 \setminus \{0\}$. $(1 - \chi)\lambda^{-1}$ continues to a smooth periodic function, so on $\mathbb{Z}^3$, where $e^{ik\cdot c}$ is periodic

in k, $\mathcal{G}_3$ and all its finite differences decay faster than every power, by integration by parts on the torus. And $\mathcal{G}_{\mathrm{c}}(x) = \lim_{\varepsilon\to 0}(2\pi)^{-3}\int |k|^{-2}e^{-\varepsilon|k|^2}e^{ik\cdot x}dk$, by $|k|^{-2}e^{-\varepsilon|k|^2} = \int_\varepsilon^\infty e^{-t|k|^2}dt$ and $\int_0^\infty (4\pi t)^{-3/2}e^{-|x|^2/4t}dt = \frac{1}{4\pi|x|}$; the part with $1-\chi$, whose symbol bounds hold uniformly in $\varepsilon\in(0,1]$, decays with all its derivatives faster than every power of $|x|$, and so does $\mathcal{G}_{\mathrm{c}}-\mathcal{G}_1$. Hence $\mathcal{G}-\mathcal{G}_{\mathrm{c}} = \mathcal{G}_2+\mathcal{G}_3-(\mathcal{G}_{\mathrm{c}}-\mathcal{G}_1)$ on $\mathbb{Z}^3\setminus\{0\}$, and a finite difference of order n at c is the mean of the corresponding derivative over a cube of points at the distance $\geq |c|/2$ from 0 when $|c|\geq 2n+2$. The bounds on $\mathcal{G}$ follow with $|\partial^\gamma \mathcal{G}_{\mathrm{c}}|\leq C_\gamma |x|^{-1-|\gamma|}$, and a larger constant covers the finitely many $c\neq 0$ with $|c|<8$. Last, summation by parts over growing boxes, with $\mathcal{G}\leq C|c|^{-1}$ and $|\nabla\mathcal{G}|\leq C|c|^{-2}$, gives $\sum(\nabla\mathcal{G})^2 = \sum_c \mathcal{G}(c)\delta_{c,0} = \mathcal{G}(0)$. □

Proposition 18.101 (One monopole)**.** For $r\geq 1$ let $c_{\mathrm{mon}}(r)$ be the least value of $\sum_{p\in\mathcal{P}^\circ(\mathbb{B}_r)}(1-\frac{1}{2}\eta(p)t_p)$ over the configurations on the plaquettes of the closure of $\mathbb{B}_r$ with $\delta\eta(0)=-1$ and $\delta\eta(c)=1$ for $c\in\mathbb{B}_{r-1}\setminus\{0\}$, and let $c_{\mathrm{mon}} = \inf A_\eta(U)$ over the fields U on $\mathbb{Z}^3$ and the sign fields η on its plaquettes with $\mathfrak{m}(\eta)=\{0\}$, A_η the sum over all plaquettes. Let Γ_r be the graph with the vertices $\mathbb{B}_r$ and the edges $\mathcal{P}^\circ(\mathbb{B}_r)$, $\mathcal{F}_r$ the set of the flows j on Γ_r with $\operatorname{div} j = \pi\delta_0$ on $\mathbb{B}_{r-1}$, and $F_r(j) = \sum \mathsf{f}(j(p))$.

(a) $c_{\mathrm{mon}}(r) = \min_{\mathcal{F}_r} F_r$, and $c_{\mathrm{mon}}(r)$ is attained at a field with values in $\{e^{i\varphi\sigma_3/2} : \varphi\in\mathbb{R}\}$.

(b) There are a minimiser j_r^* of F_r on $\mathcal{F}_r$ and a function $u_r\geq 0$ on $\mathbb{Z}^3$, equal to 0 off $\mathbb{B}_{r-1}$, with $j_r^* = \arcsin\nabla u_r$ and $\sum_{c'\sim c}\arcsin(u_r(c)-u_r(c')) = \pi\delta_{c,0}$ for $c\in\mathbb{B}_{r-1}$; u_r is invariant under the 48 isometries of $\mathbb{Z}^3$ that fix 0 and does not increase when one $|c_i|$ increases, so the sets $\{u_r>s\}$, $0\leq s<u_r(0)$, are staircases; and $|j_r^*|\leq\frac{\pi}{6}$, so that $|\nabla u_r|\leq\frac{1}{2}$, with the outward flow $\frac{\pi}{6}$ through each face of the cube 0.

(c) $c_{\mathrm{mon}}(r)$ increases to c_{mon}; c_{mon} is attained at an abelian field, and it is the same for every sign field with the one monopole 0.

(d) $c_{\mathrm{mon}}(1) = 6(1-\cos\frac{\pi}{6})$, and $0.9960 < \sum_{r\geq 0} n_r\,\mathsf{f}(\pi/n_r)\leq c_{\mathrm{mon}}\leq\frac{\pi^2}{2}\mathcal{G}(0)$, with $n_r = 6(2r+1)^2$ and $\mathcal{G}$ of Proposition 18.100(c).

(e) For $3\leq r<r'$, $0\leq c_{\mathrm{mon}}(r')-c_{\mathrm{mon}}(r)\leq 6.25/\lfloor r/3\rfloor\leq 32/r$; so $c_{\mathrm{mon}}-c_{\mathrm{mon}}(r)\leq 32/r$ for $r\geq 3$.

(f) u_r increases with r to a function u_∞ with the symmetry and the monotonicity of (b), $0\leq u_\infty\leq u_\infty(0)$ and $u_\infty(c)\leq 1.99/\lfloor|c|_\infty/3\rfloor$ for $|c|_\infty\geq 3$; $j_\infty = \arcsin\nabla u_\infty$ is a flow on $\mathbb{Z}^3$ with $|j_\infty|\leq\frac{\pi}{6}$, $\operatorname{div} j_\infty = \pi\delta_0$ and $\sum_p \mathsf{f}(j_\infty(p)) = c_{\mathrm{mon}}$.

■

Sketch. (a), (b). *Flows give fields.* For $j\in\mathcal{F}_r$ lead the amount $-\operatorname{div} j(c)$ from each cube c of $\mathbb{B}_r\setminus\mathbb{B}_{r-1}$ straight outwards to infinity, along $\pm e_i$ for the first i with $c_i=\pm r$; these rays are disjoint and use no edge of $\mathcal{P}^\circ(\mathbb{B}_r)$, and the continued flow has the divergence $\pi\delta_0$ on $\mathbb{Z}^3$. Proposition 18.100(a) with γ the unit flow along $0, e_3, 2e_3, \dots$ gives an abelian field with the one monopole 0 whose restriction to the closure of $\mathbb{B}_r$ is admitted in $c_{\mathrm{mon}}(r)$ with the value $F_r(j)$; so $c_{\mathrm{mon}}(r)\leq\inf_{\mathcal{F}_r} F_r$. *A convex problem.* Let $\tilde{\mathsf{f}}$ be the even C^2 function equal to f on $[-1,1]$ and to $\mathsf{f}(1)+(|t|-1)\sin 1+\frac{1}{2}(|t|-1)^2\cos 1$ beyond; $\tilde{\mathsf{f}}''\geq\cos 1>0.54$ and $\tilde{\mathsf{f}}\geq\mathsf{f}$. On the non-empty affine space $\mathcal{F}_r$ the strictly convex and coercive $\tilde{F}_r = \sum\tilde{\mathsf{f}}(j(p))$ has one minimiser j_r^*, invariant under the 48 isometries. Its first variation vanishes on the flows without divergence on $\mathbb{B}_{r-1}$, which form the orthogonal complement of the gradients of the functions supported in $\mathbb{B}_{r-1}$; so $\tilde{\mathsf{f}}'(j_r^*) = \nabla u_r$ with u_r supported in $\mathbb{B}_{r-1}$, and $\sum_{c'\sim c} g(u_r(c)-u_r(c')) = \pi\delta_{c,0}$ on $\mathbb{B}_{r-1}$, $g = (\tilde{\mathsf{f}}')^{-1}$ strictly increasing. *Sign and moving planes.* At a negative minimum of u_r all terms of the equation are ≤ 0 while their sum is ≥ 0, so the neighbours share the value, and walking in one direction one leaves $\mathbb{B}_{r-1}$: so $u_r\geq 0$. Let σ be an isometry of $\mathbb{Z}^3$ and H a set of cubes with $0\notin H$, $H+e\subset H$ for a unit vector e, $\sigma(H\cap\mathbb{B}_{r-1})\subset\mathbb{B}_{r-1}$, and such that every neighbour $c'\notin H$ of a cube $c\in H$ has $w(c')=0$ or $w(c')=-w(c)$, where $w = u_r\circ\sigma - u_r$. Then $w\geq 0$ on H: off $\mathbb{B}_{r-1}$ this is $u_r\geq 0$; at a negative minimum of w on $H\cap\mathbb{B}_{r-1}$, the equation at σc has the right member ≥ 0, the one at c the right member 0, and the arguments of g differ

by $w(c)-w(c')\le 0$, strictly where $c'\notin H\cap\mathbb{B}_{r-1}$; so all differences vanish, and the minimum spreads in the direction e out of $\mathbb{B}_{r-1}$, which is absurd. For $\sigma(c)=(2k+1-c_1,c_2,c_3)$, $k\ge 0$, $H=\{c_1\ge k+1\}$, $e=e_1$, the neighbour of $c\in H$ outside H is σc; this gives $u_r(c-e_1)\ge u_r(c)$ for $c_1\ge 1$, and with the symmetries the monotonicity. *The size of the flow.* For an edge p from c to c' with $u_r(c)>u_r(c')$ and $s\in[u_r(c'),u_r(c))$, the set $R_s=\{u_r>s\}\subset\mathbb{B}_{r-1}$ holds 0, so the outflow $\pi=\sum_{\partial R_s}j_r^*$ is a sum of positive terms; R_s is invariant under the 48 isometries, which carry p to at least six plaquettes of ∂R_s with the same flow; so $6j_r^*(p)\le\pi$. Hence $\tilde{\mathsf{f}}=\mathsf{f}$ and $g=\arcsin$ at j_r^*, $|\nabla u_r|=\sin|j_r^*|\le\frac12$, and by symmetry each face of the cube 0 carries $\frac{\pi}{6}$. *Every field costs as much.* Let (U,η) be admitted in $c_{\mathrm{mon}}(r)$. By the tangent inequality in the sketch of Proposition 18.99(c), $\mathsf{f}(\alpha_p)\ge\mathsf{f}(|j_r^*(p)|)+(\alpha_p-|j_r^*(p)|)|\nabla u_r(p)|$; summing, $\sum|\nabla u_r||j_r^*|=\sum\nabla u_r\,j_r^*=\pi u_r(0)$, and by the coarea formula $\sum_p|\nabla u_r(p)|\alpha_p=\int_0^{u_r(0)}\sum_{p\in\partial R_s}\alpha_p\,ds\ge\pi u_r(0)$, since each R_s is a staircase in $\mathbb{B}_{r-1}$ that holds the one monopole 0, good by Proposition 18.99(b), with $\partial R_s\subset\mathcal{P}^\circ(\mathbb{B}_r)$. So the value of (U,η) is at least $F_r(j_r^*)$; with the first step, $c_{\mathrm{mon}}(r)=F_r(j_r^*)=\min_{\mathcal{F}_r}F_r$, attained at the abelian field of j_r^*.

(c), (f). A configuration admitted at $r+1$, or on $\mathbb{Z}^3$ with the one monopole 0, restricts to one admitted at r with no larger value: $c_{\mathrm{mon}}(r)\le c_{\mathrm{mon}}(r+1)\le c_{\mathrm{mon}}$. The comparison principle, that $u_1\ge u_2$ when $\sum_{c'\sim c}g(u_1(c)-u_1(c'))\ge\sum_{c'\sim c}g(u_2(c)-u_2(c'))$ on a finite set $\mathcal{D}$ and $u_1\ge u_2$ off $\mathcal{D}$, follows by the same spreading of a negative minimum of u_1-u_2; with $\mathcal{D}=\mathbb{B}_{r-1}$ it gives $u_r\le u_{r'}$ for $r<r'$. As $\mathsf{f}(j)\ge 0.488j^2$ on $[0,\frac{\pi}{6}]$, $\pi u_r(0)=\sum\nabla u_r\,j_r^*\le\sum(j_r^*)^2\le 2.1\,c_{\mathrm{mon}}$, so u_r increases to a bounded u_∞; the equation at each cube passes to the limit, so $j_\infty=\arcsin\nabla u_\infty$ has $\operatorname{div}j_\infty=\pi\delta_0$, and by Fatou's lemma $\sum\mathsf{f}(j_\infty)\le\lim c_{\mathrm{mon}}(r)$. Proposition 18.100(a) turns j_∞ into an abelian field with the one monopole 0 and the action $\sum\mathsf{f}(j_\infty)$, so $c_{\mathrm{mon}}\le\sum\mathsf{f}(j_\infty)\le\lim c_{\mathrm{mon}}(r)\le c_{\mathrm{mon}}$; by Proposition 18.100(b), c_{mon} does not depend on the sign field. The bound on u_∞ is that of the proof of (e) as $r'\to\infty$, with $\frac{100}{16\pi}<1.99$, together with the monotonicity.

(d) At $r=1$ the potential is $u_1=\frac12\delta_0$ and the flow is $\frac{\pi}{6}$ through each face of the cube 0. The surfaces $\partial\mathbb{B}_r$, $r\ge 0$, are disjoint, each with n_r plaquettes, and each $\mathbb{B}_r$ is good and holds the one monopole; with $y=\sin\frac{\pi}{n_r}\le\frac12$ the tangent inequality gives $\sum_{\partial\mathbb{B}_r}\mathsf{f}(\alpha_p)\ge\pi y-n_r\mathsf{f}^*(y)=n_r\mathsf{f}(\pi/n_r)$, and summing over r bounds every action with the one monopole 0 from below. Numerically $n_0\mathsf{f}(\frac{\pi}{6})=0.803848$, and for $r\ge 1$, $n_r\mathsf{f}(\pi/n_r)\ge\frac{\pi^2}{2n_r}(1-\frac{\pi^2}{12n_r^2})$, with $\sum_{r\ge1}\frac{\pi^2}{2n_r}=\frac{\pi^2}{12}(\frac{\pi^2}{8}-1)=0.192211$ and a correction below $3\cdot10^{-5}$. From above, the flow $\pi\nabla\mathcal{G}$ has the divergence $\pi\delta_0$ by Proposition 18.100(c), and $\mathsf{f}(t)\le\frac12t^2$ gives its abelian field the action $\le\frac{\pi^2}{2}\sum(\nabla\mathcal{G})^2=\frac{\pi^2}{2}\mathcal{G}(0)$.

(e) Let $3\le r<r'$, $u=u_{r'}$, $s=u(re_1)$ and $\rho'=\lfloor r/3\rfloor$. *A dual bound.* For v supported in $\mathbb{B}_{r-1}$ and $j\in\mathcal{F}_r$, Young's inequality with the even convex conjugate $\tilde{\mathsf{f}}^*$, which does not decrease in $|y|$, gives $\tilde F_r(j)\ge\sum[j\nabla v-\tilde{\mathsf{f}}^*(\nabla v)]=\pi v(0)-\sum\tilde{\mathsf{f}}^*(\nabla v)$; as $c_{\mathrm{mon}}(r)=\tilde F_r(j_r^*)=\min_{\mathcal{F}_r}\tilde F_r$, this bounds $c_{\mathrm{mon}}(r)$ from below, with equality at r' for $v=u$. With $v=(u-s)^+$, supported in $\mathbb{B}_{r-1}$ by the monotonicity, $|\nabla v|\le|\nabla u|$ and $v(0)=u(0)-s$: $c_{\mathrm{mon}}(r)\ge c_{\mathrm{mon}}(r')-\pi s$. *A floor near* 0. The reflections $\sigma(c)=(c_2+k,c_1-k,c_3)$, $k\ge0$, with $H=\{c_1-c_2\ge k+1\}$ and $e=e_1$ meet the conditions of the moving planes at r', the neighbours outside H lying on the plane fixed by σ; so $u(c_1-1,c_2+1,c_3)\ge u(c)$ when $c_1-c_2\ge1$. Stepping from $(r,0,0)$ to $(r-b,b,0)$ and then, with the axes 1 and 3, to $(r-b-q,b,q)$, for integers $b\ge q\ge0$ with $r-b-q\ge b$, the first coordinate exceeding the growing one before each step, and using the symmetries and the monotonicity, $u\ge s$ on $\{|c|_1\le r\}\supset\mathbb{B}_{\rho'}$. *A capacity bound.* Let $\bar u=\min(u,s)$; on each edge $\nabla\bar u$ has the sign of ∇u and $|\nabla\bar u|\le|\nabla u|\le|j_{r'}^*|$, so $\|\nabla\bar u\|^2\le\sum\nabla\bar u\,j_{r'}^*=\pi\bar u(0)=\pi s$; for every flow k whose divergence is ≥0, vanishes off $\mathbb{B}_{\rho'}$ and has the sum 1, $s=\sum\bar u\operatorname{div}\mathsf{k}=\sum\nabla\bar u\,\mathsf{k}\le(\pi s)^{1/2}\|\mathsf{k}\|$, so $s\le\pi\|\mathsf{k}\|^2$. Take for k the flux of the field $x/4\pi|x|^3$ through the plaquettes off $\mathcal{P}^\circ(\mathbb{B}_{\rho'})$, and 0 on $\mathcal{P}^\circ(\mathbb{B}_{\rho'})$; its divergence is 0 off $\mathbb{B}_{\rho'}$ and, on $\mathbb{B}_{\rho'}$, the outward flux through the outer faces, of the sum 1; the $72\varrho_n^2+48\varrho_n+12$ plaquettes of $\mathcal{P}^\circ(\mathbb{B}_{n+1})\setminus\mathcal{P}^\circ(\mathbb{B}_n)$ lie at the distance $\ge\varrho_n=n+\frac12$ from 0 and carry at most $(4\pi\varrho_n^2)^{-1}$

each, so, with $\sum_{n\ge\rho'}\varrho_n^{-m}\le\int_{\rho'}^\infty y^{-m}dy$, $\|\mathsf{k}\|^2\le\frac{1}{16\pi^2}(\frac{72}{\rho'}+\frac{24}{\rho'^2}+\frac{4}{\rho'^3})\le\frac{100}{16\pi^2\rho'}$ and $\pi s\le 6.25/\rho'$; and $\lfloor r/3\rfloor\ge r/5$ for $r\ge 3$. □

Proposition 18.102 (The potential of one monopole at large distances)**.** Let u_∞ and j_∞ be as in Proposition 18.101(f), and $\mathsf{h}=j_\infty-\nabla u_\infty$. There is an absolute constant C such that, for every $c\ne 0$ and every edge with an end at c:

(a) $|u_\infty(c)-\pi\mathcal{G}(c)|\le C|c|^{-3}$, and so $|u_\infty(c)-\frac{1}{4|c|}|\le C|c|^{-3}$;
(b) $|\nabla u_\infty|\le C(1+|c|)^{-2}$, at every edge;
(c) $|\mathsf{h}|\le 0.19\,|\nabla u_\infty|^3\le C(1+|c|)^{-6}$, at every edge;
(d) $c_{\rm mon}=\pi u_\infty(0)-\sum_p \mathsf{f}^*(\nabla u_\infty(p))$.

■

Sketch. (c) $\arcsin y-y\le 0.19y^3$ on $[0,\frac12]$, and $|\nabla u_\infty|\le\frac12$. (d) $\mathsf{f}(j)+\mathsf{f}^*(\sin j)=j\sin j$, and $\sum j_\infty\nabla u_\infty=\pi u_\infty(0)$ by summation by parts over $\mathbb{B}_r$, whose boundary term is $\le Cr^2\cdot r^{-1}\cdot r^{-2}$ by (b) and Proposition 18.101(f); and $\sum\mathsf{f}(j_\infty)=c_{\rm mon}$. *The decay of* h. For $\rho\ge 3$ every edge off $\mathcal{P}^\circ(\mathbb{B}_\rho)$ has both ends at $|\cdot|_\infty\ge\rho$, where $u_\infty\le 10/\rho$, so $|\nabla u_\infty|\le 10/\rho$ there; the restriction of j_∞ to Γ_ρ lies in $\mathcal{F}_\rho$, so $\sum_{\rm off}\mathsf{f}(j_\infty)\le c_{\rm mon}-c_{\rm mon}(\rho)\le 32/\rho$ by Proposition 18.101(a), (e), and $\sum_{\rm off}|\nabla u_\infty|^2\le 68/\rho$; so $\sum_{\rm off}|\mathsf{h}|\le 130\rho^{-2}$, and h is summable. *A representation.* Let $\psi(c)=\pi\mathcal{G}(c)-\sum_{\mathsf{e}}(\nabla\mathcal{G}(c-\cdot))_{\mathsf{e}}\,\mathsf{h}_{\mathsf{e}}$, the sum over the edges $\mathsf{e}=(c_1\to c_2)$ with $(\nabla\mathcal{G}(c-\cdot))_{\mathsf{e}}=\mathcal{G}(c-c_1)-\mathcal{G}(c-c_2)$; it is well defined, tends to 0 at infinity, and $\sum_{c'\sim c}(\psi(c)-\psi(c'))=\pi\delta_{c,0}-\operatorname{div}\mathsf{h}=\operatorname{div}\nabla u_\infty$; so $u_\infty-\psi$ is harmonic and tends to 0, and $u_\infty=\psi$. With $\rho=\lfloor|c|_\infty/2\rfloor$, by Proposition 18.100(c) the edges of $\mathcal{P}^\circ(\mathbb{B}_\rho)$ contribute at most $C|c|^{-2}\|\mathsf{h}\|_1$ to $\psi-\pi\mathcal{G}$ and $C|c|^{-3}\|\mathsf{h}\|_1$ to its increments, and the other edges at most $C\rho^{-2}$; so $|u_\infty-\pi\mathcal{G}|\le C|c|^{-2}$ and $|\nabla u_\infty|\le C|c|^{-2}$, which is (b), and then $|\mathsf{h}_{\mathsf{e}}|\le C(1+|c_1|)^{-6}$. *The next order.* u_∞ is even, so $\mathsf{h}_{-\mathsf{e}}=\mathsf{h}_{\mathsf{e}}$ for $-\mathsf{e}=(-c_1\to-c_2)$, and the sum in ψ is $\frac12\sum_{\mathsf{e}}\mathsf{h}_{\mathsf{e}}\mathsf{g}_{\mathsf{e}}$ with $\mathsf{g}_{\mathsf{e}}=\nabla_e\mathcal{G}(c-c_1-e)-\nabla_e\mathcal{G}(c+c_1)$, $c_2=c_1+e$: a difference of the values of $\nabla_e\mathcal{G}$ at two points joined by a monotone lattice path of at most $4|c_1|+1$ steps. For $|c|\ge 16$ and $|c_1|\le|c|/8$ that path stays at the distance $\ge|c|/2$ from 0, so $|\mathsf{g}_{\mathsf{e}}|\le C(4|c_1|+1)|c|^{-3}$, which is summable against $(1+|c_1|)^{-6}$; for $|c|/8<|c_1|\le 4|c|$, $|\mathsf{h}_{\mathsf{e}}|\le C|c|^{-6}$ against $\sum_{|z|\le 5|c|+1}(1+|z|)^{-2}\le C|c|$; and for $|c_1|>4|c|$ the terms are at most $C|c_1|^{-8}$. So the sum is at most $C|c|^{-3}$, and Proposition 18.100(c) gives (a); a larger constant covers $|c|<16$. □

Proposition 18.103 (The least action of a pair of monopoles)**.** For $v\in\mathbb{Z}^3\setminus\{0\}$ let $E_{\rm pair}(v)=\inf A_\eta(U)$ over the fields on $\mathbb{Z}^3$ and the sign fields with $\mathfrak{m}(\eta)=\{0,v\}$; let $E^{\rm ab}_{\rm pair}(v)=\inf\sum_p\mathsf{f}(J(p))$ over the flows J with $\operatorname{div}J=\pi(\delta_0-\delta_v)$; and, for a finite set $\mathfrak{B}$ of cubes with $0,v\in\mathfrak{B}^\circ$, let $E_{\rm pair}(v;\mathfrak{B})$ be the least value of $\sum_{p\in\mathcal{P}^\circ(\mathfrak{B})}(1-\frac12\eta(p)t_p)$ over the configurations on the plaquettes of the closure of $\mathfrak{B}$ with $\delta\eta=-1$ at 0 and at v and $\delta\eta=1$ at the other cubes of $\mathfrak{B}^\circ$. There are absolute constants C and t_0 such that:

(a) for all $v\ne 0$, $E_{\rm pair}(v)\le E^{\rm ab}_{\rm pair}(v)\le\sum_p\mathsf{f}(j_\infty(p)-j_\infty(p-v))\le 2c_{\rm mon}-\pi u_\infty(v)+C|v|^{-2}$, where $p-v$ is the plaquette p moved by $-v$;
(b) for $|v|\ge t_0$, $\varrho\ge 2|v|$ and every finite $\mathfrak{B}$ with $\mathfrak{B}^\circ\supset\mathbb{Z}^3\cap(\{|x|<\varrho\}\cup\{|x-v|<\varrho\})$, $E_{\rm pair}(v;\mathfrak{B})\ge 2c_{\rm mon}-\pi u_\infty(v)-C|v|^{-2}-\pi|v|/\varrho^2$; and $E_{\rm pair}(v)\ge 2c_{\rm mon}-\pi u_\infty(v)-C|v|^{-2}$ for $|v|\ge t_0$, the infimum being over all SU(2) fields;
(c) for all $v\ne 0$, $|E_{\rm pair}(v)-2c_{\rm mon}+\frac{\pi}{4|v|}|\le C|v|^{-2}$ and $0\le E^{\rm ab}_{\rm pair}(v)-E_{\rm pair}(v)\le C|v|^{-2}$;
(d) for $t=|v|$ and every integer $R\ge 4t+8$ there is a flow J'' that vanishes off $\mathcal{P}^\circ(\mathbb{B}_R)$, with $\operatorname{div}J''=\pi(\delta_0-\delta_v)$ and $\sum\mathsf{f}(J''(p))\le 2c_{\rm mon}-\pi u_\infty(v)+C(t^{-2}+R^{-1})$.

■

Sketch. Signs. $t=|v|$, $u_1=u_\infty$, $u_2=u_\infty(\cdot-v)$, $a=\nabla u_1$, $b=\nabla u_2$, $j_i=\arcsin\nabla u_i$, $\mathsf{h}_i=j_i-\nabla u_i$, $\mathsf{U}=u_1-u_2$, and $\iota(c)=v-c$, so that $u_1\circ\iota=u_2$ and $\mathsf{U}\circ\iota=-\mathsf{U}$, u_∞ being even; $\mathcal{N}_1$ is the set of the edges with both ends in $\{|c|\le|c-v|\}$ and $\mathcal{N}_2$ the set of the others, whose ends lie at the

distance $\geq \frac{t}{2}-1$ from 0. By Proposition 18.102, $|b| \leq C(1+t)^{-2}$ on $\mathcal{N}_1$ and $|a| \leq C(1+t)^{-2}$ on $\mathcal{N}_2$. *Two sums.* Summation by parts gives $\sum j_1 b = \pi u_2(0) = \pi u_\infty(v)$; and $\sum |\mathsf{h}_1||b| + \sum |\mathsf{h}_2||a| \leq Ct^{-2}$, by the summability of h on $\mathcal{N}_1$, by $|\mathsf{h}_1| \leq C(1+|c|)^{-6}$ on $\mathcal{N}_2$, and by ι.

(a) $J = j_1 - j_2$ has the divergence $\pi(\delta_0 - \delta_v)$, and $\mathsf{f}(x-x') = \mathsf{f}(x)+\mathsf{f}(x')-\mathsf{f}(x)\mathsf{f}(x') - \sin x \sin x' \leq \mathsf{f}(x) + \mathsf{f}(x') - \sin x \sin x'$; so $\sum \mathsf{f}(J) \leq 2c_{\mathrm{mon}} - \sum ab$, and $\sum ab = \sum (j_1 - \mathsf{h}_1)b \geq \pi u_\infty(v) - Ct^{-2}$. Proposition 18.100(a), with γ the unit flow along a dual path from 0 to v, gives $E_{\mathrm{pair}} \leq E^{\mathrm{ab}}_{\mathrm{pair}}$.

(b) *The dual value of* U. By Taylor's formula with $(\mathsf{f}^*)'' = (1-y^2)^{-1/2}$, $\mathsf{f}^*(x-x') \leq \mathsf{f}^*(x)+\mathsf{f}^*(x') - x' \arcsin x + C(x^2+x'^2)x'^2$ for $|x|, |x'| \leq \frac{1}{2}$; used with $(x,x') = (a,b)$ on $\mathcal{N}_1$ and $(x,x') = (b,a)$ on $\mathcal{N}_2$, with $j_2 a - j_1 b = \mathsf{h}_2 a - \mathsf{h}_1 b$, the two sums and Proposition 18.102(d), it gives

$$\mathcal{D}(\mathsf{U}) := \pi(\mathsf{U}(0) - \mathsf{U}(v)) - \sum_p \mathsf{f}^*(\nabla \mathsf{U}(p)) \geq 2c_{\mathrm{mon}} - \pi u_\infty(v) - Ct^{-2}.$$

Two families of good sets. Let $\rho = t^{2/3}$, $w_0 = \frac{1}{4t}$, $s_a = \frac{1}{4\rho}$, $s_b = \frac{1}{8\rho}$, and $\psi(x) = \frac{1}{4|x|} - \frac{1}{4|x-v|}$ on $\mathbb{R}^3$. For $s > 0$ the set $C_s = \{0\} \cup \{\psi \geq s\}$ is compact, convex and contained in $\{|x| < |x-v|\}$: if the gradient of ψ is orthogonal to a unit vector e, that is $(e \cdot x)/|x|^3 = (e \cdot (x-v))/|x-v|^3 = \lambda$, then $4e^{\mathsf{T}} \nabla^2 \psi\, e = -3\lambda^2(|x-v| - |x|) - (|x|^{-3} - |x-v|^{-3}) < 0$, so on a segment between two points of C_s the function ψ has no interior minimum below s; and for $\varrho \geq 2|v|$ and $s > |v|/2\varrho^2$, $C_s \subset \{|x| < \varrho\}$, as $\psi(x) \leq |v|/2|x|^2$ for $|x| \geq 2|v|$. Let $K_s = \{x : x + [-\frac{1}{2}, \frac{1}{2}]^3 \subset C_s\}$, compact and convex, $R_s = \mathsf{R}(K_s)$, a set of cubes inside C_s that decreases in s, and $u^\flat(c) = \sup\{s : c \in R_s\}$; then $R_s = \{u^\flat > s\}$ for all but countably many s, and $0 \leq u^\flat \leq \psi^+$. On the unit cube $\prod_i [c_i, c_i + \varsigma_i]$, ς_i the sign of $\partial_i \psi(c)$, the first order term of ψ about c is ≥ 0 and the second is $\geq -\frac{3}{2} \sup \|\nabla^2 \psi\| \geq -6(|c|^{-3} + |c-v|^{-3})$; so $\psi^+(c) - u^\flat(c) \leq 6(|c|^{-3} + |c-v|^{-3})$ for $|c|, |c-v| \geq 4$. For $0 < s \leq s_a$ and t large, $0 \in R_s$, $v \notin R_s$, and R_s is good by Proposition 18.99(b). Next, with $\mathsf{a} = (u_\infty - w_0)^+$ and $s_{\mathrm{top}} = u_\infty(0) - w_0$, the sets $T_s = \{\mathsf{a} > s\}$, $0 < s < s_{\mathrm{top}}$, are staircases by Proposition 18.101(f), so good, and by Proposition 18.102(a) $T_s \subset \{|c| < 3\rho\}$, so $v \notin T_s$, for $s \geq s_b$. *The measure.* Let $\theta(s) = \min\{1, \max\{0, (s-s_b)/(s_a - s_b)\}\}$, of the Lipschitz constant 8ρ, $\Theta(s) = \int_0^s \theta$ and $\bar{\Theta}(s) = s - \Theta(s)$; let $\mu^+ = \int_0^{s_{\mathrm{top}}} [\theta(s)\delta_{T_s} + (1-\theta(s))\delta_{R_s}]\, ds$ and $\mu = \mu^+ + \iota_* \mu^+$. Every set charged by μ is good and holds exactly one of 0 and v, so it has $\prod_{c \in R} \delta\eta(c) = -1$ whenever $\mathfrak{m}(\eta) = \{0, v\}$; $\mu(\mathrm{all}) = 2s_{\mathrm{top}}$; and by the coarea formula $y_p = \mu\{p \in \partial R\} = y_p^0 + y_{\iota p}^0$ with $y_p^0 = |\nabla \Theta(\mathsf{a})(p)| + |\nabla \bar{\Theta}(u^\flat)(p)|$. Put $\tilde{u}_0 = \Theta(\mathsf{a}) + \bar{\Theta}(u^\flat)$, $\tilde{u} = \tilde{u}_0 - \tilde{u}_0 \circ \iota$ and $\mathsf{r} = \tilde{u} - \mathsf{U}$. *Three zones.* On $\{|c|_\infty \leq \rho/4\}$, for large t, $u_\infty \geq 0.55/\rho$ and the unit cube at c lies in C_{s_a}, so $\mathsf{a} \geq s_a$ and $u^\flat \geq s_a$, and $\tilde{u}_0 = u_\infty - w_0$, as $\Theta(s) = s - \frac{1}{2}(s_a + s_b)$ and $\bar{\Theta}(s) = \frac{1}{2}(s_a + s_b)$ for $s \geq s_a$; on $\{|c| \geq 3\rho\}$, a and $u^\flat$ lie below s_b, so $\tilde{u}_0 = u^\flat$, which vanishes where $|c| \geq |c-v|$; hence $\tilde{u} = \tilde{u}_0$ on $\{|c| \leq |c-v|\}$ and $\tilde{u} = -\tilde{u}_0 \circ \iota$ on the other side. *The defect.* In the inner zone $\mathsf{r} = u_2 - w_0$ and $|\nabla \mathsf{r}| = |b| \leq Ct^{-2}$ on $C\rho^3$ edges; where $|c| \geq \rho/8$ and $|c| \leq |c-v|$, $|u^\flat - \mathsf{U}| \leq C|c|^{-3}$ by the bound on $\psi^+ - u^\flat$ and Proposition 18.102(a), which gives $\sum |\nabla \mathsf{r}|^2 \leq C\rho^{-3}$ over the outer zone; in the middle zone $\Theta(\mathsf{a}) - \Theta(u^\flat) = (\mathsf{a} - u^\flat)\mathsf{m}$ with $\mathsf{m} \in [0,1]$ of increments $\leq 8\rho \max(|\nabla \mathsf{a}|, |\nabla u^\flat|) \leq C\rho^{-1}$, $|\mathsf{a} - u^\flat| \leq C\rho^{-3} + C\rho t^{-2} \leq Ct^{-4/3}$ and $|\nabla(\mathsf{a} - u^\flat)| \leq Ct^{-2}$, so $|\nabla \mathsf{r}| \leq Ct^{-2}$ on $C\rho^3$ edges. As $\rho^3 = t^2$, $\|\nabla \mathsf{r}\|^2 \leq Ct^{-2}$. *From* y *to* $\nabla \tilde{u}$. $y_p = |\nabla \tilde{u}(p)|$ except on edges of the middle zone where $\nabla \Theta(\mathsf{a})$ and $\nabla \bar{\Theta}(u^\flat)$ have opposite signs, and there both are at most $|\nabla(\mathsf{a} - u^\flat)| \leq Ct^{-2}$; and $y_p \leq \frac{1}{2}$. So $\sum \mathsf{f}^*(y_p) \leq \sum \mathsf{f}^*(\nabla \tilde{u}) + Ct^{-2}$. *The end.* By Proposition 18.99(c), every (U, η) on $\mathbb{Z}^3$ with $\mathfrak{m}(\eta) = \{0, v\}$ has $A_\eta(U) \geq 2\pi s_{\mathrm{top}} - \sum \mathsf{f}^*(y_p)$. With $\mathsf{f}^*(x+x') \leq \mathsf{f}^*(x) + x' \arcsin x + x'^2$ for $|x|, |x+x'| \leq 0.6$, summation by parts, $\arcsin(a-b) = j_1 - j_2 - \kappa$ with $|\kappa| \leq C \max(a^2, b^2) \min(|a|, |b|)$ and so $\|\kappa\|_2 \leq Ct^{-2}$, and $\mathsf{r}(0) = -\mathsf{r}(v) = u_\infty(v) - w_0$, one gets $\sum \mathsf{f}^*(\nabla \tilde{u}) \leq \sum \mathsf{f}^*(\nabla \mathsf{U}) + 2\pi(u_\infty(v) - w_0) + Ct^{-2}$, hence $A_\eta(U) \geq \mathcal{D}(\mathsf{U}) - Ct^{-2}$. For the box keep in μ^+ the values $s > t/2\varrho^2$ alone: by the ball bound for C_s and $T_s \subset \{|c| < 3\rho\}$ all sets then lie in $\{|x| < \varrho\}$, those of $\iota_* \mu^+$ in $\{|x - v| < \varrho\}$, so in $\mathfrak{B}^\circ$; $\pi\mu(\mathrm{all})$ drops by $\pi t/\varrho^2$, while y_p decreases and f^* increases on $[0, \frac{1}{2}]$. A field on $\mathbb{Z}^3$ restricts to the closure of every box, which gives the bound on $E_{\mathrm{pair}}(v)$ as $\varrho \to \infty$.

(c) This is (a), (b) and Proposition 18.102(a) for $|v| \ge t_0$; for $|v| < t_0$, $0 \le E_{\text{pair}} \le E^{\text{ab}}_{\text{pair}} \le 2c_{\text{mon}} + C$.

(d) Let $\chi(c) = \min\{1, \max\{0, 2 - 2|c|_\infty/R\}\}$, equal to 1 on $\mathbb{B}_{R/2} \ni 0, v$ and to 0 off $\mathbb{B}_{R-1}$, let χ_p be its mean over the two ends of p, and $J^\chi = \chi_p J$ with $J = j_1 - j_2$; J^χ vanishes off $\mathcal{P}^\circ(\mathbb{B}_R)$. Its divergence is $\chi \operatorname{div} J + \omega'$ with $\omega'(c) = \frac12 \sum_{c' \sim c} (\chi(c') - \chi(c)) J(c \to c')$, carried by the shell $\{R/2 - 1 \le |c|_\infty \le R\}$, where $|c - v| \ge R/4 + 1$ and $|J| \le CR^{-2}$; so $|\omega'| \le CR^{-3}$, $\|\omega'\|_2^2 \le CR^{-3}$, $\|\omega'\|_1 \le C$, and $\sum \omega' = 0$. The flow k of least norm on Γ_R with $\operatorname{div} \mathsf{k} = -\omega'$ is a gradient $\nabla\varphi$, and $\|\mathsf{k}\|^2 = -\sum(\varphi - \bar\varphi)\omega'$; the Poincaré inequality $\|\varphi - \bar\varphi\| \le (3/2)^{1/2}(2R+1)\|\nabla\varphi\|$ on the box, by paths that adjust the coordinates in turn, each edge lying on at most $(2R+1)^4$ of them, gives $\|\mathsf{k}\|^2 \le C/R$. Then $J'' = J^\chi + \mathsf{k}$ has the divergence $\pi(\delta_0 - \delta_v)$, and by $\mathsf{f}(x + x') \le \mathsf{f}(x) + x' \sin x + \frac12 x'^2$ and $\mathsf{f}(\chi_p J) \le \mathsf{f}(J)$, $\sum \mathsf{f}(J'') \le \sum \mathsf{f}(J) + \sum \sin(\chi_p J)\, \mathsf{k} + \frac12 \|\mathsf{k}\|^2$; writing $\sin(\chi_p J) = \nabla \mathsf{U} + \mathsf{e}$, one has $\mathsf{e} = -a(1 - \cos j_2) + b(1 - \cos j_1)$ where $\chi_p = 1$ and $|\mathsf{e}| \le CR^{-2}$ elsewhere, so $\|\mathsf{e}\|_2 \le Ct^{-2} + CR^{-1/2}$, and $\sum \nabla \mathsf{U}\, \mathsf{k} = -\sum \mathsf{U} \omega'$ with $|\mathsf{U}| \le C/R$ on the shell; with (a) this is the claim. □

Proposition 18.104 (The point operator on one box)**.** Let N be a box with all N_μ even and ≥ 4, and $\beta \ge 0$. For a set M of cubes of the box let $\mathsf{Z}(M) = \sum_{\eta:\, \mathfrak{m}(\eta) = M} Z_\beta[\eta; 1]$, the sum over the sign fields on the plaquettes of the box, Z_β as in eq. 11.i, and $\mathsf{D}(M) = \mathsf{Z}(M)/\mathsf{Z}(\emptyset)$.

(a) $|\mathfrak{m}(\eta)|$ is even for every η, and every even set of cubes is an $\mathfrak{m}(\eta)$. For every sign field η, $\mathsf{Z}(\mathfrak{m}(\eta)) = 2^{2|N|-2} \sum_n Z_\beta[\eta\eta^n; 1]$, the sum over the eight classes; so $\mathsf{D}(\mathfrak{m}(\eta)) = \sum_n Z_\beta[\eta\eta^n; 1] / \sum_n Z[n]$, $\mathsf{D}(M) > 0$ exactly for $|M|$ even, D is invariant under the isometries of the box, and $Z_\beta[\eta; 1]/Z[0] \le 8\, \mathsf{D}(\mathfrak{m}(\eta))$.

(b) (Site mirrors.) Let θ be the reflection in the two planes $x_\mu = h$ and $x_\mu = h + \frac12 N_\mu$ through sites, and $M = M_+ \cup M_-$ with $M_\pm$ in the two closed halves that they bound. Then $\mathsf{Z}(M_+ \cup M_-)^2 \le \mathsf{Z}(M_+ \cup \theta M_+)\, \mathsf{Z}(M_- \cup \theta M_-)$.

(c) (Chessboard.) Let $N_\mu = 2n_\mu \mathsf{l}$ with integers $n_\mu, \mathsf{l} \ge 1$, let the blocks $\prod_\mu [k_\mu \mathsf{l}, (k_\mu + 1)\mathsf{l}]$ be named by $k \in \mathfrak{B} = \prod_\mu \mathbb{Z}/2n_\mu$, and let τ_k be the map of the block 0 onto the block k that in the direction μ is $x_\mu \mapsto k_\mu \mathsf{l} + x_\mu$ for even k_μ and $x_\mu \mapsto (k_\mu + 1)\mathsf{l} - x_\mu$ for odd k_μ. For a map $\mathcal{A}$ from $\mathfrak{B}$ to the sets of cubes of the block 0 put $M(\mathcal{A}) = \bigcup_k \tau_k \mathcal{A}(k)$, and for one such set P put $\|P\| = \mathsf{D}(M(\mathcal{A} \equiv P))^{1/|\mathfrak{B}|}$, $\mathcal{A} \equiv P$ the constant map. Then $\mathsf{D}(M(\mathcal{A})) \le \prod_k \|\mathcal{A}(k)\|$.

(d) For $\beta \ge 1$, $\log Z[0] \ge -|N|(\frac92 \log \beta + 29.4)$; and on a cube box every plaquette has the mean $\bar a = \langle 1 - \frac12 t_p \rangle \le (3 \log \beta + 19.6)/\beta$ under the periodic measure.

(e) (A triangular map.) On a cube box with N sites a side and $\beta \ge 0$, let Q be a box of sites with $H_\mu + 1 \le N - 1$ sites in the direction μ, V a field with $V(b) = \mathbf{1}$ unless b is a bond of Q that lies in no plaquette leaving Q, and η a sign field equal to 1 off the plaquettes of Q. Then, with $\bar a$ the mean plaquette and $|Q|$ the number of the sites of Q, $\log(Z_\beta[\eta; 1]/Z[0]) \ge -\beta A_\eta(V) - 48\, \beta \bar a\, |Q|\, (H_1 + H_2)^2$.

■

Sketch. (a) $\prod_c \delta\eta(c) = 1$, each plaquette being a face of two cubes; the sign field that is -1 on the plaquettes pierced by a dual path from c to c' has the monopoles c and c', and products of such fields give every even set. As $\mathfrak{m}(\eta\eta') = \mathfrak{m}(\eta) \triangle \mathfrak{m}(\eta')$, the sign fields with the monopoles $\mathfrak{m}(\eta)$ are the ηs with s closed; the closed sign fields are the disjoint union of the eight classes $[n]$ of the setting of Section 11.1, and $[n] \ni \eta^n$ consists of the $2^{2|N|-2}$ sign fields $\eta^n d\gamma$, γ a sign field on the bonds. Both facts are cellular cohomology of the torus with coefficients in $\mathbb{Z}_2$: every closed sign field of the class 0 has the form $d\gamma$, and every $d\gamma$ lies in the class 0, a bond lying in none or in two plaquettes of a lattice plane, so that $[n] = \eta^n[0]$, products over a plane being multiplicative; exactly $2^{|N|+2}$ sign fields γ have $d\gamma = 1$, since their products along three straight closed lines, one in each direction, take all eight values, and two of them with the same products differ by a field $\sigma(b_-)\sigma(b_+)$, σ one of the $2^{|N|}$ sign functions of the sites, with σ and $-\sigma$ giving the same field; dividing $2^{3|N|}$, the number of the sign fields on the $3|N|$ bonds, by $2^{|N|+2}$ gives the number of the distinct $d\gamma$. And $U \mapsto \gamma U$ gives

$Z_\beta[\eta\eta^n d\gamma;1]=Z_\beta[\eta\eta^n;1]$. An isometry of the box permutes the cells and keeps the Haar measure and the traces. By Theorem AG(1), $Z[n]\le Z[0]$, so $\sum_n Z[n]\le 8Z[0]$ and $\mathsf{D}(\mathfrak{m}(\eta))\ge Z_\beta[\eta;1]/8Z[0]$.

(b) Every cell lies in one of the two closed halves $\Lambda_\pm$, and the cells in both lie in the two planes, where θ fixes them with their orientations. With $s_c=-1$ for $c\in M$ and 1 else, $\mathsf{Z}(M)$ is the sum over the sign fields of the integral of $\prod_p e^{-\beta(1-\frac12\eta(p)t_p)}\prod_c \mathbf{1}[\delta\eta(c)=s_c]$; this weight is $W_0(\mathcal{X}_0)\,G_{M_+}(\mathcal{X}_+,\mathcal{X}_0)\,G_{\theta M_-}(\theta^*\mathcal{X}_-,\mathcal{X}_0)$, where $\mathcal{X}_0$ are the bond and plaquette variables in the planes, $\mathcal{X}_\pm$ those of the other cells of $\Lambda_\pm$, $W_0>0$ is the product over the plaquettes in the planes, and $G_{M'}$ is the product over the other plaquettes and over all cubes of Λ_+, with the signs of M'; θ^*, the pull back by θ, carries the Haar and counting measures of $\mathcal{X}_-$ to those of $\mathcal{X}_+$. Integrating out $\mathcal{X}_\pm$, $\mathsf{Z}(M_+\cup M_-)=\int W_0\,g_{M_+}g_{\theta M_-}\,d\mathcal{X}_0$ with bounded $g_{M'}\ge0$ and $\int W_0 g_{M'}^2\,d\mathcal{X}_0=\mathsf{Z}(M'\cup\theta M')$; the Schwarz inequality ends the argument.

(c) The planes $x_\mu=i\mathsf{l}$ and $x_\mu=(i+n_\mu)\mathsf{l}$ are a pair of site mirrors whose reflection θ maps the block k to the block θk with $(\theta k)_\mu=2i-1-k_\mu$ and has $\theta\circ\tau_k=\tau_{\theta k}$. Put $\phi(\mathcal{A})=\mathsf{Z}(M(\mathcal{A}))/\prod_k\|\mathcal{A}(k)\|$, and for such a mirror let $\mathcal{A}^\pm$ be $\mathcal{A}$ on the half $\pm$, continued by $\mathcal{A}^\pm(\theta k)=\mathcal{A}(k)$; by (b), $\phi(\mathcal{A})^2\le\phi(\mathcal{A}^+)\phi(\mathcal{A}^-)$, and $\phi(\mathcal{A}\equiv P)=\mathsf{Z}(\emptyset)$ for every P, $|\mathfrak{B}|$ being even, so that $\|P\|>0$. Among the finitely many maps with values in the range of a given $\mathcal{A}$ the maximisers of ϕ are closed under $\mathcal{A}\mapsto\mathcal{A}^\pm$; a maximiser with a longest run of equal slabs in the direction 1, if it were not constant in that direction, would be reflected at the mirror at one end of the run into a maximiser that is constant in that direction or has a longer run; the same in the directions 2 and 3, whose reflections keep the constancy already reached, gives a constant maximiser; so $\max\phi=\mathsf{Z}(\emptyset)$.

(d) Let every bond lie within the angle $\beta^{-1/2}$ of $\mathbf{1}$, a set of Haar measure $\frac{2}{\pi}\int_0^{\beta^{-1/2}}\sin^2\varphi\,d\varphi\ge\frac{8}{15\pi}\beta^{-3/2}$ for each bond; then $|\partial U(p)-\mathbf{1}|\le4\beta^{-1/2}$ and $1-\frac12 t_p\le8/\beta$, and the $3|N|$ bonds and $3|N|$ plaquettes give $\log Z[0]\ge-3|N|(\frac32\log\beta+\log\frac{15\pi}{8})-24|N|$, with $3\log\frac{15\pi}{8}+24\le29.4$. The derivative of $\log Z[0]$ in β is minus the mean action, which does not increase, $\log Z[0]$ being convex in β; so $\frac{\beta}{2}\langle A\rangle_\beta\le\log Z_{\beta/2}[0]-\log Z_\beta[0]\le|N|(\frac92\log\beta+29.4)$, as $Z\le1$; on a cube box the isometries make all $3|N|$ plaquettes have one mean.

(e) In Q take the tree T of the bonds of the direction 3 on the line through a corner x_0, the bonds of the direction 2 in the plane of the directions 2, 3 through x_0, and all bonds of the direction 1; let $P_x(U)$ be the holonomy along T from x_0 to x and $W(b)=P_{b_-}U(b)P_{b_+}^{-1}$, which is $\mathbf{1}$ on T. The map $\Phi(U)(b)=U(b)P_{b_+}^{-1}V(b)P_{b_+}$ at the bonds of Q, $\Phi(U)=U$ elsewhere, is at the bonds of T, ordered from x_0, a left translation of $U(b)$ by a function of earlier bonds, and at the other bonds a right translation by a function of the bonds of T; so it keeps the Haar measure, and $Z_\beta[\eta;1]=Z[0]\langle e^{-\beta(A_\eta\circ\Phi-A)}\rangle\ge Z[0]e^{-\beta\langle A_\eta\circ\Phi-A\rangle}$ by Jensen's inequality, $\langle\cdot\rangle$ the periodic mean. As $\Phi(U)$ is a gauge transform of the bondwise product WV on Q, a plaquette whose bonds all have $V=\mathbf{1}$ and whose sign is 1 keeps its term, and the at most $3|Q|$ other plaquettes have $\partial(WV)(p)$ equal to a product of eight unitary factors that differ from those of $\partial V(p)$ by $\omega_i=W(b)^{\pm1}-\mathbf{1}$ at four places. A global conjugation keeps the periodic measure and conjugates every $W(b)$, so $\langle W(b)^{\pm1}\rangle$ is a multiple of $\mathbf{1}$ and $\langle\omega_i\rangle=-\frac12\langle|\omega_i|^2\rangle\mathbf{1}$; expanding to the second order, the mean of each such term exceeds its value at V by at most $2\sum_{b\in p}\langle|W(b)-\mathbf{1}|^2\rangle$. $W(b)$ is the holonomy along the boundary of a ladder of at most H_1+H_2 plaquettes, so $|W(b)-\mathbf{1}|\le\sum_{\text{ladder}}|\partial U(p')-\mathbf{1}|$ and $\langle|W(b)-\mathbf{1}|^2\rangle\le2\bar a(H_1+H_2)^2$; dropping the terms $-(1-\frac12 t_p)\le0$ of $-A$ gives $\langle A_\eta\circ\Phi-A\rangle\le A_\eta(V)+3|Q|\cdot4\cdot2\cdot2\bar a(H_1+H_2)^2$. □

Proposition 18.105. *The point operator at large inverse coupling: the self-energy and the Coulomb term.*

(a) Let N be a cube box with $N=2n\mathsf{l}$ sites a side, $\mathsf{l}=2r+1$, $r\ge1$, $\beta\ge1$, and let $x\ne y$ be the central cubes of two blocks of side l. Then $\mathsf{D}(\{x,y\})\le8^{1/4}\exp[-2\beta c_{\text{mon}}(r)+\mathsf{l}^3(9\log\beta+58.8)]$.

(b) Let $\ell=2L^m$, $b>0$, $K_0\ge0$, and let $x\ne y$ be two points of T_ℓ that are centres of cubes of $\Lambda_{K_0,\ell}$; for $K\ge K_0$ let x_K,y_K be the cubes of $\Lambda_{K,\ell}$ with these centres, $\beta=L^Kb$, and

$D_K(x,y) = \mathsf{D}(\{x_K, y_K\})$ on $\Lambda_{K,\ell}$. There is K_1, formed from L, K_0 and b, such that for all $K \ge K_1$

$$\log D_K(x,y) \le -2c_{\mathrm{mon}}\beta + (192L+69)\,\beta^{3/4}(\log\beta)^{1/4};$$

so $\limsup_K \beta^{-1}\log D_K(x,y) \le -2c_{\mathrm{mon}}$; and the same holds for $Z_\beta[\eta;1]/Z[0]$, for every sign field η on $\Lambda_{K,\ell}$ with $\mathfrak{m}(\eta) = \{x_K, y_K\}$, with $\log 8$ added to the right member.

(c) Let N be a cube box with N sites a side, N even, $\beta \ge 1$, $v \in \mathbb{Z}^3 \setminus \{0\}$, $t = |v|$, c a cube, and C, t_0 the constants of Proposition 18.103. For every integer $R \ge 4t+8$ with $N \ge 2R+6$, the sign field η that is -1 exactly on the plaquettes pierced by a shortest dual path from c to $c+v$ has $\log(Z_\beta[\eta;1]/Z[0]) \ge -\beta[2c_{\mathrm{mon}} - \pi u_\infty(v) + C(t^{-2}+R^{-1})] - 48(2R+4)^3(4R+6)^2(3\log\beta + 19.6)$. For $t \ge t_0$, $\varrho \ge 2t$ and $N = 2n\mathsf{l}$ with $\mathsf{l} \ge t + 2\varrho + 5$, $\log \mathsf{D}(\{c, c+v\}) \le -\beta[2c_{\mathrm{mon}} - \pi u_\infty(v) - Ct^{-2} - \pi t/\varrho^2] + \mathsf{l}^3(\frac{9}{2}\log\beta + 29.4) + 1$.

(d) On $\Lambda_{K,\ell}$, for every $\ell = 2L^m$ and every $b > 0$, let $D_K(v) = \mathsf{D}(\{c, c+v\})$, which does not depend on the cube c. For every sequence $v_K \in \mathbb{Z}^3$ with $|v_K| \to \infty$ and $|v_K|^6 \log\beta/\beta \to 0$,

$$\log D_K(v_K) = -2c_{\mathrm{mon}}\beta + \frac{\pi}{4}\,\frac{\beta}{|v_K|} + o\Big(\frac{\beta}{|v_K|}\Big),$$

uniformly in the direction of v_K; in the physical distance $R_K = |v_K|a_K$ this reads $\log(e^{2c_{\mathrm{mon}}\beta} D_K(v_K)) = \frac{\pi}{4}\frac{b}{R_K}(1+o(1))$. The same holds for $Z_\beta[\eta;1]/Z[0]$ with η the sign field of a shortest dual path from c to $c+v_K$.

■

Sketch. (a) With $\mathcal{A}$ equal to the central cube at the blocks of x and of y and empty elsewhere, $M(\mathcal{A}) = \{x,y\}$, as τ_k maps the central cube of the block 0 to that of the block k, l being odd; Proposition 18.104(c) gives $\mathsf{D}(\{x,y\}) \le \|P\|^2 = \mathsf{D}(\mathfrak{C})^{2/|\mathfrak{B}|}$, P the central cube and $\mathfrak{C}$ the set of all central cubes. For $\mathfrak{m}(\eta) = \mathfrak{C}$ the restriction of (U,η) to each block, moved onto the closure of $\mathbb{B}_r$, is admitted in $c_{\mathrm{mon}}(r)$, and the sets $\mathcal{P}^\circ$ of different blocks are disjoint; so $Z_\beta[\eta;1] \le e^{-\beta|\mathfrak{B}|c_{\mathrm{mon}}(r)}$, and by Proposition 18.104(a), (d), $\mathsf{D}(\mathfrak{C}) \le 8e^{-\beta|\mathfrak{B}|c_{\mathrm{mon}}(r)}/Z[0] \le 8\exp[-\beta|\mathfrak{B}|c_{\mathrm{mon}}(r) + |\mathfrak{B}|\mathsf{l}^3(\frac{9}{2}\log\beta + 29.4)]$, with $|\mathfrak{B}| \ge 8$.

(b) The centre of a cube of $\Lambda_{K_0,\ell}$ is in lattice units $(k'+\frac12)L^{K-K_0} = (k+\frac12)L^j$ with $2k+1 = (2k'+1)L^{K-K_0-j}$; so for $1 \le j \le K-K_0$ the cubes x_K, y_K are central cubes of blocks of side L^j, and $N/L^j = 2L^{m+K-j}$ is even. Let $Y = (\beta/\log\beta)^{1/4}$ and $L^j \le Y < L^{j+1}$; for $K \ge K_1$, $\log\beta \ge 1$ and $1 \le j \le K-K_0$. Then $r = \frac{L^j-1}{2}$ satisfies $r \ge \frac{L^j}{3}$ because $L^j \ge 3$, and $r \ge 6$ because $L^j \ge L \ge 13$; and by Proposition 18.101(e) $2\beta(c_{\mathrm{mon}} - c_{\mathrm{mon}}(r)) \le 192\beta/L^j \le 192L\beta/Y$, while $L^{3j}(9\log\beta + 58.8) \le 68\,Y^3\log\beta$; and $\beta/Y = Y^3\log\beta = \beta^{3/4}(\log\beta)^{1/4}$, $\frac14\log 8 < 1$. The last sentence is Proposition 18.104(a).

(c) *Below.* Let J'' be the flow of Proposition 18.103(d) moved to c, and γ the unit flow along the shortest dual path, which stays in $c + \mathbb{B}_t$. By Proposition 18.100(a) there is an abelian field V on $\mathbb{Z}^3$, equal to $\mathbf{1}$ off the bonds of the box of the $(2R+2)^3$ sites of the cubes of $c+\mathbb{B}_R$, with $A_\eta(V) = \sum \mathsf{f}(J'')$; as $2R+2 < N$, it is placed on the periodic box without change of its action. Proposition 18.104(e), with Q that box enlarged by one layer, of $2R+4 \le N-1$ sites a side, and $H_1 = H_2 = 2R+3$, together with Proposition 18.104(d), gives the bound. *Above.* Let $\mathfrak{B}_v = \prod_i[\min(0,v_i) - \lceil\varrho\rceil - 1, \max(0,v_i) + \lceil\varrho\rceil + 1]$, with at most $t + 2\varrho + 5 \le \mathsf{l}$ cubes a side, placed with c so that $c+\mathfrak{B}_v$ lies in one block; $\mathfrak{B}_v^\circ$ holds the cubes within ϱ of 0 or of v. Proposition 18.104(c), with $\mathcal{A}$ equal to $\{c, c+v\}$ at that block and empty elsewhere, gives $\mathsf{D}(\{c,c+v\}) \le \|\{c,c+v\}\|$. For $\mathfrak{m}(\eta) = M(\mathcal{A} \equiv \{c,c+v\})$ the restriction of (U,η) to $\tau_k(c+\mathfrak{B}_v)$, carried back to $c+\mathfrak{B}_v$ by τ_k, which keeps the Haar measure and the traces, has among the cubes of $c+\mathfrak{B}_v^\circ$ the monopoles c and $c+v$ alone, so after the translation that takes c to the cube 0 of $\mathbb{Z}^3$ it is admitted in $E_{\mathrm{pair}}(v;\mathfrak{B}_v)$; the sets $\mathcal{P}^\circ(\tau_k(c+\mathfrak{B}_v))$ of different blocks are disjoint, so $Z_\beta[\eta;1] \le e^{-\beta|\mathfrak{B}|E_{\mathrm{pair}}(v;\mathfrak{B}_v)}$, and Proposition 18.103(b) and Proposition 18.104(a), (d) end as in (a), with $8^{1/|\mathfrak{B}|} < e$.

(d) Let $t = |v_K|$, $\varepsilon = t^6 \log\beta/\beta \to 0$, $\lambda = \varepsilon^{-1/6}$, $R = \lceil \lambda t \rceil$, $\varrho = \lambda t$, and $\mathsf{l} = L^j$ with $L^{j-1} < t + 2\varrho + 5 \le L^j$. Then $\beta t^{-2} = o(\beta/t)$, $\beta/R \le \varepsilon^{1/6}\beta/t$, $R^5 \log\beta \le 32\,\varepsilon^{1/6}\beta/t$, $\beta t/\varrho^2 = \varepsilon^{1/3}\beta/t$ and $\mathsf{l}^3 \log\beta \le (4L\lambda t)^3 \log\beta = 64L^3\varepsilon^{1/2}t^{-2}\beta/t$; for large K, $R \ge 4t + 8$, $N \ge 2R + 6$, $t \ge t_0$, and $j \le m + K$, so that N/l is even. By Proposition 18.102(a), $\pi u_\infty(v_K) = \frac{\pi}{4t} + O(t^{-3})$. The inequality $\mathsf{D} \ge Z_\beta[\eta; 1]/8Z[0]$ of Proposition 18.104(a) carries the lower bound of (c) from η to D, and the same inequality carries the upper bound of (c) from D to η; $\log 8 = o(\beta/t)$. All constants are absolute, so the error does not depend on the direction; and $\beta/|v_K| = b/R_K$. □

18.10. **The two-point function of a limit and of its components: the Källén–Lehmann measure, the law r^{-6} at a point and the growth M^5.** Fix a frame of Definition 13.1 and a reference coupling $0 < g \le \gamma$. Let (K_j, β_j, ν_j) be a converging Gibbs sequence, with limit σ and canonical decomposition $(\mathsf{X}, \lambda, (\sigma_\xi)_{\xi\in\mathsf{X}})$ in the sense of Definition 13.4(2). We use the scalar reconstruction, canonical decomposition and clustering of the components from Thms. YM3_I:AL and YM3_I:AP. Write $\bar c_g$ for the common bound on the one-point constants and $C^g_{\mathrm{rad}} = C^g_\wp + \bar c_g$ for the common point-kernel constant in that reconstruction. For $g \le \gamma_W$ we use the separated two-point law of Thm. YM3_I:C, with the common limiting label, thresholds and tolerances there. In particular that theorem gives the same estimates on σ and on every component. A volume-first limit has the centred functional of its defining Gibbs sequence and the same connected functions at orders $n \ge 2$. Proposition 13.25 writes the radial kernel of σ and of every σ_ξ as a constant plus a superposition of the Yukawa kernels $e^{-mr}/(4\pi r)$ with a positive measure ρ, written ρ_ξ for σ_ξ. We identify this constant, to which the kernel tends as $r \to \infty$ and which we call the constant at infinity: it is $\mathfrak{c}_\xi^2$ for σ_ξ and $\int \mathfrak{c}_\xi^2\, d\lambda$ for σ. In a component the kernel $\mathbf{s}^{\mathrm c}_\xi$ of the connected function of two points is therefore the superposition itself, completely monotone together with $r\,\mathbf{s}^{\mathrm c}_\xi(r)$, and from this form we obtain the convexity of $\log(r\,\mathbf{s}^{\mathrm c}_\xi(r))$ when $\rho_\xi \ne 0$, the bound $\mathbf{s}^{\mathrm c}_\xi(r) \le (r_0/r)\,\mathbf{s}^{\mathrm c}_\xi(r_0)$ for $0 < r_0 \le r$, the identity of $\rho_\xi(\{0\})/(4\pi)$ with the constant of the decay $|v|^{-1}$ at two points, and the bound $\rho_\xi([0,\mathsf{M}]) \le 1024\pi e\,(C^g_{\mathrm{rad}})^2\mathsf{M}^7$ for $\mathsf{M} \ge \frac12$, C^g_{rad} being the common reconstruction constant just specified; the connected functions of every order have real-analytic kernels at distinct points. Below the ceiling γ_W we show that r^6 times the connected kernel tends to $\mathsf{c}_2\mathsf{b}^{-2} = 9/(16\pi^2\mathsf{b}^2)$ as $r \to 0$, b the limit of the labels; that the kernel less its constant at infinity, which in a component is the connected kernel, once multiplied by $r^6\mathsf{b}^2/\mathsf{c}_2$, lies for small r between a lower and an upper member, neither of which depends on the sequence, the decomposition or the component; that $\rho([0,\mathsf{M}]) \sim \frac{3}{160\pi}\mathsf{b}^{-2}\mathsf{M}^5$ and $\mu^E([0,\mathsf{M}]) \sim \frac{\mathsf{c}_2}{720}\mathsf{b}^{-2}\mathsf{M}^6$ as $\mathsf{M} \to \infty$, uniformly in the sequence, the decomposition and the functional, limit or component, μ^E being the measure whose Laplace transform is the kernel less its constant at infinity; and that the Hamiltonian of the reconstruction is unbounded and its Hilbert space infinite-dimensional.

Definition 18.106. *The constant at infinity, the two parts of the kernel, the label, the energy of one field.*

(1) σ' denotes σ or a component σ_ξ, and $\mathfrak{c}'$ its one-point constant: $\mathfrak{c}' = 0$ for σ, because $S^\sigma_1 = 0$ (Thm. YM3_I:AP), and $\mathfrak{c}' = \mathfrak{c}_\xi$ for σ_ξ (Definition 13.4 (2)). $\mathbf{s}$ is the radial kernel of σ' (Definition 13.4 (3)), and $\kappa' = \lim_{r\to\infty}\mathbf{s}(r)$ and ρ are the number and the measure of Proposition 13.25 (a), (b), so that $\mathbf{s}(r) = \kappa' + \int e^{-mr}(4\pi r)^{-1}\, d\rho(m)$ for $r > 0$; we call κ' the *constant at infinity* and ρ the *Källén–Lehmann measure* of σ'; where the functional matters we write $\mathbf{s}_\sigma, \kappa'_\sigma, \rho_\sigma$ and $\mathbf{s}_\xi, \kappa'_\xi, \rho_\xi$, and we put the same subscripts on the objects that are formed from them below.

(2) The *Källén–Lehmann part* of the kernel is $\mathbf{s}^{\mathrm{KL}} = \mathbf{s} - \kappa'$, so that $4\pi r\,\mathbf{s}^{\mathrm{KL}}(r) = \int e^{-mr}\, d\rho(m)$, and the *connected kernel* is $\mathbf{s}^{\mathrm c} = \mathbf{s} - \mathfrak{c}'^2$. By the two-entry cumulant formula, $S^{\sigma'}_2(f,h) = \sigma'(f,h) - \sigma'((f))\,\sigma'((h))$, and $\sigma'((f)) = \mathfrak{c}'\int f$; so $S^{\sigma'}_2(f,h) = \iint f(x)h(y)\,\mathbf{s}^{\mathrm c}(|x-y|)\,dx\,dy$ for all $(f,h) \in \mathfrak{S}_2(\mathbb{R}^3)$. For the limit, $\mathbf{s}^{\mathrm c}_\sigma = \mathbf{s}_\sigma$.

(3) By Proposition 13.25 (a), $\mathbf{s}$ is completely monotone and non-increasing with the limit κ'; so $\mathbf{s}^{\mathrm{KL}} \geq 0$ is completely monotone, and by Bernstein's theorem there is exactly one positive Borel measure μ^E on $[0,\infty)$ with $\mathbf{s}^{\mathrm{KL}}(r) = \int e^{-rE}\, d\mu^E(E)$ for all $r > 0$, the *energy measure* of σ'.

(4) Let $0 < g \leq \gamma_W$, where γ_W is the ceiling in Thm. YM3_I:C. By that theorem the labels $a_{K_j}\beta_j$ converge to a positive number b, the *label* of the sequence. With the constant $\mathsf{c}_2 = \frac{9}{16\pi^2}$ of Thm. YM3_I:C we put $\mathsf{A}_{\mathsf{b}} = 4\pi\mathsf{c}_2\mathsf{b}^{-2} = \frac{9}{4\pi\mathsf{b}^2}$, and for $r > 0$ we put $y^{\mathrm{c}}(r) = r^6\, \mathbf{s}^{\mathrm{c}}(r)\, \mathsf{b}^2/\mathsf{c}_2$ and $y(r) = r^6\, \mathbf{s}^{\mathrm{KL}}(r)\, \mathsf{b}^2/\mathsf{c}_2$. For $0 < \delta \leq \frac{1}{2}$ let $\vartheta_\delta = \frac{32\pi}{105}\, \delta^3 \in (0, \frac{1}{8})$ and $a_\delta = \left(\frac{3+2\delta}{3-2\delta}\right)^6 \in (1, 64]$; with the threshold $\mathsf{d}_0(g,\vartheta)$ and the tolerance $\bar\varepsilon_{g,\vartheta}$ of Thm. YM3_I:C, let $r_\delta = (3-2\delta)\, \mathsf{d}_0(g,\vartheta_\delta)$, and $\varepsilon_\delta(r) = \bar\varepsilon_{g,\vartheta_\delta}(r/(3-2\delta))$ for $0 < r \leq r_\delta$. By Thm. YM3_I:C, ε_δ is non-decreasing, $\varepsilon_\delta(r) \leq \frac{1}{3}$, $\varepsilon_\delta(r) \to 0$ as $r \to 0$, and r_δ and ε_δ are formed from the frame, g and δ alone; they depend on no sequence, decomposition or component.

(5) For $m \geq 0$ and $\mathsf{q} \in \mathbb{R}^2$ let $\omega_m(\mathsf{q}) = (m^2 + |\mathsf{q}|^2)^{1/2}$, and for a real $h \in C^1_c(\mathbb{E}_+)$, writing $y = (y_\perp, y_3)$, let $\hat h_m(\mathsf{q}) = \int h(y)\, e^{-\omega_m(\mathsf{q})y_3 + i\mathsf{q}\cdot y_\perp}\, dy$. In $\mathcal{H}(\sigma', e_3)$ let $\Omega = [\varnothing]$, let P_0 be the orthogonal projection onto $\ker H$, and, with the vector ψ_h and the measure μ_h of Definition 13.4 (4), let $\mu_h^H(B) = \mu_h(B \times \mathbb{R}^2)$ for Borel sets $B \subset [0,\infty)$. Since $H = \int E\, d\mathcal{P}(E,\mathsf{q})$, μ_h^H is the spectral measure of H in the vector ψ_h: $\mu_h^H(B) = \|\mathbf{1}_B(H)\psi_h\|^2$, its mass is $\|\psi_h\|^2$, and $\int e^{-tE}\, d\mu_h^H(E) = \langle \psi_h, e^{-tH}\psi_h\rangle$ for $t \geq 0$ by the spectral theorem.

■

Lemma 18.107 (Laplace transforms of positive measures; Karamata's theorem)**.** Let $\mathfrak{m}$ be a positive Borel measure on $[0,\infty)$ with $\mathcal{L}_{\mathfrak{m}}(r) = \int e^{-mr}\, d\mathfrak{m}(m) < \infty$ for every $r > 0$.

(a) $\mathcal{L}_{\mathfrak{m}}$ is completely monotone on $(0,\infty)$; $\mathfrak{m}$ is the only positive Borel measure on $[0,\infty)$ whose Laplace transform is $\mathcal{L}_{\mathfrak{m}}$; $\mathcal{L}_{\mathfrak{m}}(r) \to \mathfrak{m}(\{0\})$ as $r \to \infty$; and $\mathfrak{m}([0,\mathsf{M}]) \leq e\, \mathcal{L}_{\mathfrak{m}}(1/\mathsf{M})$ for every $\mathsf{M} > 0$.

(b) Either $\mathfrak{m} = 0$, or $\mathcal{L}_{\mathfrak{m}} > 0$ on $(0,\infty)$ and $\log \mathcal{L}_{\mathfrak{m}}$ is convex and non-increasing on $(0,\infty)$.

(c) Let $\alpha > 0$, and let $\mathfrak{F}$ be a set of pairs $(\mathfrak{m}, A)$ of such measures and real numbers $A > 0$ such that $\sup_{(\mathfrak{m},A)\in\mathfrak{F}} |r^\alpha \mathcal{L}_{\mathfrak{m}}(r)/A - 1| \to 0$ as $r \downarrow 0$. Then $\sup_{(\mathfrak{m},A)\in\mathfrak{F}} |\Gamma(\alpha+1)\, \mathsf{M}^{-\alpha}\, \mathfrak{m}([0,\mathsf{M}])/A - 1| \to 0$ as $\mathsf{M} \to \infty$.

■

Sketch of proof. (a) For $r \geq r_0 > 0$ and an integer $k \geq 0$, $m^k e^{-mr} \leq (2k/(er_0))^k\, e^{-mr_0/2}$, a function that $\mathfrak{m}$ integrates; differentiation under the integral sign gives $(-1)^k \mathcal{L}_{\mathfrak{m}}^{(k)}(r) = \int m^k e^{-mr}\, d\mathfrak{m}(m) \geq 0$. The uniqueness is that of the measure in Bernstein's theorem. As $r \to \infty$, $e^{-mr} \to \mathbf{1}_{\{0\}}(m)$, dominated by e^{-m} once $r \geq 1$; and since $e^{-m/\mathsf{M}} \geq e^{-1}$ for $0 \leq m \leq \mathsf{M}$, $\mathcal{L}_{\mathfrak{m}}(1/\mathsf{M}) \geq e^{-1}\mathfrak{m}([0,\mathsf{M}])$.

(b) If $\mathfrak{m} \neq 0$, the positivity of e^{-mr} gives $\mathcal{L}_{\mathfrak{m}} > 0$. For $r_1, r_2 > 0$ and $0 < t < 1$, Hölder's inequality with the exponents $1/t$ and $1/(1-t)$, applied to e^{-tmr_1} and $e^{-(1-t)mr_2}$, gives $\mathcal{L}_{\mathfrak{m}}(tr_1 + (1-t)r_2) \leq \mathcal{L}_{\mathfrak{m}}(r_1)^t\, \mathcal{L}_{\mathfrak{m}}(r_2)^{1-t}$, which is the convexity of $\log \mathcal{L}_{\mathfrak{m}}$; by (a) it is non-increasing.

(c) *Step 1: two positive functionals.* For a bounded Borel function G on $[0,1]$, a pair $(\mathfrak{m}, A) \in \mathfrak{F}$ and $r > 0$ put

$$\Phi_r(G) = \frac{r^\alpha}{A} \int e^{-mr}\, G(e^{-mr})\, d\mathfrak{m}(m), \qquad \Phi_0(G) = \frac{1}{\Gamma(\alpha)} \int_0^\infty e^{-t}\, G(e^{-t})\, t^{\alpha-1}\, dt.$$

Both are linear and monotone in G, a pointwise inequality $G_1 \leq G_2$ giving $\Phi(G_1) \leq \Phi(G_2)$, and $\Phi_0(1) = 1$ by the integral of the Gamma function.

Step 2: polynomials. For an integer $k \geq 0$, $\Phi_r(x^k) = (k+1)^{-\alpha}\, \big((k+1)r\big)^\alpha \mathcal{L}_{\mathfrak{m}}\big((k+1)r\big)/A$, which tends to $(k+1)^{-\alpha}$ as $r \downarrow 0$, uniformly on $\mathfrak{F}$; and $\Phi_0(x^k) = \Gamma(\alpha)^{-1} \int_0^\infty e^{-(k+1)t} t^{\alpha-1}\, dt = (k+1)^{-\alpha}$. Hence $\Phi_r(P) \to \Phi_0(P)$ uniformly on $\mathfrak{F}$ for every polynomial P.

Step 3: an indicator between two continuous functions. Let $G_*(x) = x^{-1}$ for $e^{-1} \leq x \leq 1$ and $G_*(x) = 0$ for $0 \leq x < e^{-1}$. Then $e^{-t} G_*(e^{-t}) = \mathbf{1}_{[0,1]}(t)$, so that $\Phi_r(G_*) = r^\alpha\, \mathfrak{m}([0,1/r])/A$ and

$\Phi_0(G_*) = \Gamma(\alpha)^{-1}\int_0^1 t^{\alpha-1}\,dt = \Gamma(\alpha+1)^{-1}$. Let $0<\epsilon<1$. The function G_+ coincides with x^{-1} on $[e^{-1},1]$, vanishes on $[0,e^{-1-\epsilon}]$ and is affine on $[e^{-1-\epsilon},e^{-1}]$; the function G_- coincides with x^{-1} on $[e^{-1+\epsilon},1]$, vanishes on $[0,e^{-1}]$ and is affine on $[e^{-1},e^{-1+\epsilon}]$. Both are continuous and enclose G_*, $G_- \le G_* \le G_+$, because on $[e^{-1},e^{-1+\epsilon}]$ the values of G_- do not exceed $e^{1-\epsilon} \le x^{-1}$; and $xG_+(x) \le e^{-1}\cdot e = 1$ on $[e^{-1-\epsilon},e^{-1}]$. So $e^{-t}G_+(e^{-t}) \le \mathbf{1}_{[0,1+\epsilon]}(t)$ and $e^{-t}G_-(e^{-t}) \ge \mathbf{1}_{[0,1-\epsilon]}(t)$, whence $\Phi_0(G_+) \le (1+\epsilon)^\alpha/\Gamma(\alpha+1)$ and $\Phi_0(G_-) \ge (1-\epsilon)^\alpha/\Gamma(\alpha+1)$. By Weierstrass' approximation theorem there are polynomials $P_\pm$, depending on ϵ alone, with $G_+ \le P_+ \le G_+ + 2\epsilon$ and $G_- - 2\epsilon \le P_- \le G_-$ on $[0,1]$.

Step 4: the squeeze. By monotony $\Phi_r(P_-) \le r^\alpha\,\mathfrak{m}([0,1/r])/A \le \Phi_r(P_+)$, while $\Phi_0(P_+) \le (1+\epsilon)^\alpha/\Gamma(\alpha+1)+2\epsilon$ and $\Phi_0(P_-) \ge (1-\epsilon)^\alpha/\Gamma(\alpha+1)-2\epsilon$. Step 2 gives $r_\epsilon>0$ with $|\Phi_r(P_\pm)-\Phi_0(P_\pm)| \le \epsilon$ for $0<r\le r_\epsilon$ and every pair of $\mathfrak{F}$; with $\mathsf{M}=1/r$,

$$\frac{(1-\epsilon)^\alpha}{\Gamma(\alpha+1)} - 3\epsilon \le \frac{\mathfrak{m}([0,\mathsf{M}])}{A\,\mathsf{M}^\alpha} \le \frac{(1+\epsilon)^\alpha}{\Gamma(\alpha+1)} + 3\epsilon \qquad (\mathsf{M}\ge 1/r_\epsilon,\ (\mathfrak{m},A)\in\mathfrak{F}),$$

and ϵ is arbitrary. □

Lemma 18.108 (One field in the direction e_3)**.** Let σ' be σ or a component, and let $h \in C^1_c(\mathbb{E}_+)$ be real, with $h=0$ on $\{y_3<a\}$ for a number $a>0$.

(a) For every $t\ge 0$, all the integrals converging absolutely,

$$\langle\psi_h, e^{-tH}\psi_h\rangle = \kappa'\Big(\int h\Big)^2 + \int_{[0,\infty)} d\rho(m)\int_{\mathbb{R}^2} e^{-t\omega_m(\mathsf{q})}\,\frac{|\hat h_m(\mathsf{q})|^2}{2\,\omega_m(\mathsf{q})}\,\frac{d^2\mathsf{q}}{(2\pi)^2}.$$

(b) $\mu_h^H = \kappa'\big(\int h\big)^2\delta_0 + \mu_h^{\mathrm{sh}}$, where $\mu_h^{\mathrm{sh}}(B) = \int d\rho(m)\int \mathbf{1}_B(\omega_m(\mathsf{q}))\,|\hat h_m(\mathsf{q})|^2\,(2\omega_m(\mathsf{q}))^{-1}\,(2\pi)^{-2}\,d^2\mathsf{q}$ for Borel sets $B\subset[0,\infty)$.

(c) Let $h\ge 0$ and $h\ne 0$. For every $\mathsf{M}\ge 0$ with $\rho((\mathsf{M},\infty))>0$, $\mathbf{1}_{(\mathsf{M},\infty)}(H)\,\psi_h \ne 0$. If $\rho((\mathsf{M},\infty))>0$ for every $\mathsf{M}\ge 0$, then H is unbounded and $\mathcal{H}(\sigma',e_3)$ has infinite dimension.

■

Sketch of proof. Step 1: the Yukawa kernel as an integral over a plane. For $c,\omega>0$, $m\ge 0$, $t>0$ and $w\in\mathbb{R}^2$ we use the classical integrals

$$\int_0^\infty \frac{e^{-c^2/(4t)-\omega^2 t}}{(4\pi t)^{1/2}}\,dt = \frac{e^{-c\omega}}{2\omega}, \qquad \int_0^\infty \frac{e^{-c^2/(4t)-m^2 t}}{(4\pi t)^{3/2}}\,dt = \frac{e^{-mc}}{4\pi c}, \qquad \int_{\mathbb{R}^2} e^{i\mathsf{q}\cdot w - t|\mathsf{q}|^2}\,\frac{d^2\mathsf{q}}{(2\pi)^2} = \frac{e^{-|w|^2/(4t)}}{4\pi t}.$$

Let $\tau>0$ and $z=(w,\tau)$. Express $e^{-\tau\omega_m(\mathsf{q})}/(2\omega_m(\mathsf{q}))$ by the first integral at $c=\tau$, $\omega=\omega_m(\mathsf{q})$ (for $\mathsf{q}\ne 0$ if $m=0$, a null set being left out), integrate in q before t by the third, and apply the second at $c=|z|$; as $(4\pi t)^{-1/2}(4\pi t)^{-1} = (4\pi t)^{-3/2}$, this gives

$$\frac{e^{-m|z|}}{4\pi|z|} = \int_{\mathbb{R}^2} e^{i\mathsf{q}\cdot w}\,\frac{e^{-\tau\omega_m(\mathsf{q})}}{2\,\omega_m(\mathsf{q})}\,\frac{d^2\mathsf{q}}{(2\pi)^2}.$$

The exchange of the two integrations is Fubini's theorem: at $w=0$ every function in the computation is positive, so by Tonelli's theorem the integral of the modulus of the integrand is $e^{-m\tau}/(4\pi\tau)<\infty$.

Step 2: (a). By Definition 13.4 (4), $\langle\psi_h,e^{-tH}\psi_h\rangle = \langle[(h)],[(\tau_{te_3}h)]\rangle = \sigma'(\theta h,\tau_{te_3}h)$, where $\theta h = h\circ\theta$ is supported in $\{x_3\le -a\}$ and $\tau_{te_3}h$ in $\{x_3\ge a+t\}$. The radial kernel (Definition 13.4 (3)), the form of Proposition 13.25 (b) and the substitution $x\mapsto\theta x$, $y\mapsto y+te_3$ give

$$\sigma'(\theta h,\tau_{te_3}h) = \kappa'\Big(\int h\Big)^2 + \int d\rho(m)\iint h(x)h(y)\,\frac{e^{-m|z|}}{4\pi|z|}\,dx\,dy, \qquad z=(x_\perp-y_\perp,\ x_3+y_3+t),$$

the order of $d\rho$ and $dx\,dy$ being free by Fubini's theorem, as the modulus of the integrand is integrable: $|z|\ge 2a$ on the supports, and $\int e^{-2am}\,d\rho(m)<\infty$. Insert Step 1 at $w=x_\perp-y_\perp$ and $\tau=x_3+y_3+t\ge 2a$: the modulus of the integrand in (m,x,y,q) has the integral $\int d\rho(m)\iint|h(x)h(y)|\,e^{-m\tau}(4\pi\tau)^{-1}\,dx\,dy \le (8\pi a)^{-1}\|h\|_{L^1}^2\int e^{-2am}\,d\rho(m)$, so Fubini's

theorem lets us integrate in x and y first; h being real, $\int h(x)\, e^{i\mathsf{q}\cdot x_\perp - x_3\omega_m(\mathsf{q})}\, dx = \hat h_m(\mathsf{q})$ and $\int h(y)\, e^{-i\mathsf{q}\cdot y_\perp - y_3\omega_m(\mathsf{q})}\, dy = \overline{\hat h_m(\mathsf{q})}$, which gives (a).

Step 3: (b). The measure ρ is σ-finite. Assign the value 0 to the integrand defining μ_h^{sh} at $(m,\mathsf{q}) = (0,0)$. For every Borel set B the resulting integrand $\mathbf{1}_B(\omega_m(\mathsf{q}))\,|\hat h_m(\mathsf{q})|^2/(2\omega_m(\mathsf{q}))$ is nonnegative and Borel, so μ_h^{sh} is a positive Borel measure. By Tonelli's theorem the right member of (a) is $\int e^{-tE}\, d(\kappa'(\int h)^2\delta_0 + \mu_h^{\mathrm{sh}})(E)$, equal to $\|\psi_h\|^2 < \infty$ at $t = 0$. The left member is $\int e^{-tE}\, d\mu_h^H(E)$ (Definition 18.106 (5)). Two positive Borel measures on $[0,\infty)$ whose Laplace transforms are finite and equal coincide (Lemma 18.107 (a)).

Step 4: (c). Put $\varpi_h(m) = \int |\hat h_m(\mathsf{q})|^2\, (2\omega_m(\mathsf{q}))^{-1}(2\pi)^{-2}\, d^2\mathsf{q}$. For $m > \mathsf{M}$, $\omega_m(\mathsf{q}) \geq m > \mathsf{M}$ for every q; so by (b) $\|\mathbf{1}_{(\mathsf{M},\infty)}(H)\psi_h\|^2 = \mu_h^H((\mathsf{M},\infty)) \geq \int_{(\mathsf{M},\infty)} \varpi_h\, d\rho$. As $h \geq 0$ and $h \neq 0$, the function $\mathsf{q} \mapsto \hat h_m(\mathsf{q})$ is continuous with $\hat h_m(0) = \int h(y)\, e^{-my_3}\, dy > 0$; so $\varpi_h > 0$, and the last integral is positive when $\rho((\mathsf{M},\infty)) > 0$. If this is so for every M, the spectral projection $\mathbf{1}_{(\mathsf{M},\infty)}(H)$ is not 0 for any M, whereas $\mathbf{1}_{(\|H\|,\infty)}(H) = 0$ for a bounded H; so H is unbounded. Moreover $\mu_h^H((\mathsf{M}',\mathsf{M}''])$ increases to $\mu_h^H((\mathsf{M}',\infty)) > 0$ as $\mathsf{M}'' \to \infty$, so there are numbers $0 = \mathsf{M}_0 < \mathsf{M}_1 < \mathsf{M}_2 < \cdots$ with $\mu_h^H((\mathsf{M}_k,\mathsf{M}_{k+1}]) > 0$; the vectors $\mathbf{1}_{(\mathsf{M}_k,\mathsf{M}_{k+1}]}(H)\,\psi_h$, $k \geq 0$, are non-zero and pairwise orthogonal, and $\mathcal{H}(\sigma', e_3)$ has infinite dimension. □

Lemma 18.109 (The constants at infinity; the kernel of the limit)**.** (a) For every $\xi \in \mathsf{X}$ the constant at infinity of σ_ξ is $\kappa'_\xi = \mathfrak{c}_\xi^2$.

(b) The constant at infinity of σ is $\kappa'_\sigma = \int_{\mathsf{X}} \mathfrak{c}_\xi^2\, d\lambda(\xi)$, and $\kappa'_\sigma \leq \bar c_g^2$.

(c) At each $r > 0$, $\xi \mapsto \mathbf{s}_\xi^{\mathrm{c}}(r)$ is Borel on X, and its integral against λ is $\mathbf{s}_\sigma^{\mathrm{KL}}(r)$: $\mathbf{s}_\sigma^{\mathrm{KL}}(r) = \int_{\mathsf{X}} \mathbf{s}_\xi^{\mathrm{c}}(r)\, \lambda(d\xi)$.

■

Sketch of proof. Step 1: one field at large times. Let σ' be σ or σ_ξ, and let $h \in C_c^1(\mathbb{E}_+)$ be real with $h \geq 0$, $\int h > 0$ and $h = 0$ on $\{y_3 < a\}$, $a > 0$. In $\mathcal{H}(\sigma', e_3)$, $\langle \psi_h, e^{-tH}\psi_h\rangle = \sigma'(\theta h, \tau_{te_3} h)$ (Definition 13.4 (4)), and the radial kernel (Definition 13.4 (3)) with the substitution $x \mapsto \theta x$, $y \mapsto y + te_3$ turns this into $\iint h(x)h(y)\, \mathbf{s}(|z_t|)\, dx\, dy$, where $z_t = (x_\perp - y_\perp, x_3 + y_3 + t)$ and $|z_t| \geq 2a + t$ on the supports. By Proposition 13.25 (a), $\mathbf{s}$ is non-increasing with the limit κ'; dominated convergence gives $\langle \psi_h, e^{-tH}\psi_h\rangle \to \kappa'(\int h)^2$ as $t \to \infty$. By the spectral theorem $e^{-tH} \to P_0$ strongly as $t \to \infty$; hence $\kappa'(\int h)^2 = \langle \psi_h, P_0\psi_h\rangle = \|P_0\psi_h\|^2$.

Step 2: (a). In $\mathcal{H}(\sigma_\xi, e_3)$ the kernel of H is $\mathbb{C}\,\Omega$ (Thm. YM3_I:AP), $\|\Omega\|^2 = \sigma_\xi(\varnothing) = 1$, and $\langle \Omega, \psi_h\rangle = \sigma_\xi(\theta\varnothing \cdot (h)) = \sigma_\xi((h)) = \mathfrak{c}_\xi \int h$ (Definition 13.4 (2), (4)). So $\|P_0\psi_h\|^2 = |\langle \Omega, \psi_h\rangle|^2 = \mathfrak{c}_\xi^2(\int h)^2$, and Step 1 gives $\kappa'_\xi = \mathfrak{c}_\xi^2$.

Step 3: the kernel of the limit; (b) and (c). Let $r > 0$. Choose $x_0, y_0 \in \mathbb{R}^3$ at the distance r and, for each integer $n > 4/r$, non-negative C^1 functions f_n, h_n, neither of them 0, whose supports lie in the closed balls of radius $1/n$ centred at x_0 and at y_0; the pair (f_n, h_n) belongs to $\mathfrak{S}_2(\mathbb{R}^3)$, and the distance of a point of $\operatorname{supp} f_n$ from a point of $\operatorname{supp} h_n$ lies in $[r - \frac{2}{n}, r + \frac{2}{n}]$. For σ'' equal to σ or to a component let $F_n(\sigma'') = \sigma''(f_n, h_n)/(\int f_n \int h_n)$. By Definition 13.4 (3), $F_n(\sigma'')$ is an average, with non-negative weights, of the radial kernel $\mathbf{s}_{\sigma''}$ over $[r - \frac{2}{n}, r + \frac{2}{n}]$, and that kernel is continuous and non-increasing (Proposition 13.25 (a)); so $\mathbf{s}_{\sigma''}(r + \frac{2}{n}) \leq F_n(\sigma'') \leq \mathbf{s}_{\sigma''}(r - \frac{2}{n})$, and $F_n(\sigma'') \to \mathbf{s}_{\sigma''}(r)$ as $n \to \infty$. By continuity of evaluations in the canonical decomposition every $\xi \mapsto F_n(\sigma_\xi)$ is a continuous function on X, and their pointwise limit $\xi \mapsto \mathbf{s}_\xi(r)$ is therefore Borel; and the barycentre identity gives $F_n(\sigma) = \int F_n(\sigma_\xi)\, \lambda(d\xi)$. Hence $\int \mathbf{s}_\xi(r + \frac{2}{n})\, \lambda(d\xi) \leq F_n(\sigma) \leq \int \mathbf{s}_\xi(r - \frac{2}{n})\, \lambda(d\xi)$. As n grows, $\mathbf{s}_\xi(r + \frac{2}{n})$ increases to $\mathbf{s}_\xi(r)$, and monotone convergence gives $\int \mathbf{s}_\xi(r)\, \lambda(d\xi) \leq \mathbf{s}_\sigma(r)$, at every $r > 0$; in particular $\xi \mapsto \mathbf{s}_\xi(r/2)$ is λ-integrable. As n grows, $\mathbf{s}_\xi(r - \frac{2}{n})$ decreases to $\mathbf{s}_\xi(r)$ and stays below $\mathbf{s}_\xi(r/2)$, and dominated convergence gives the reverse inequality: $\mathbf{s}_\sigma(r) = \int_{\mathsf{X}} \mathbf{s}_\xi(r)\, \lambda(d\xi)$ for every $r > 0$. As $r \to \infty$, $\mathbf{s}_\xi(r)$ decreases to $\kappa'_\xi = \mathfrak{c}_\xi^2$ by (a), and for $r \geq 1$ it stays below the

integrable $\mathbf{s}_\xi(1)$; dominated convergence gives $\kappa'_\sigma = \int \mathfrak{c}_\xi^2\, d\lambda$. By Thm. YM3_I:AP, $|\mathfrak{c}_\xi| \le \bar{c}_g$ and $\xi \mapsto \mathfrak{c}_\xi$ is continuous; with $\lambda(\mathsf{X}) = 1$ the first gives the bound of (b). Finally $\xi \mapsto \mathbf{s}^{\mathrm{c}}_\xi(r) = \mathbf{s}_\xi(r) - \mathfrak{c}_\xi^2$ is a Borel function, and $\mathbf{s}^{\mathrm{KL}}_\sigma(r) = \mathbf{s}_\sigma(r) - \kappa'_\sigma = \int (\mathbf{s}_\xi(r) - \mathfrak{c}_\xi^2)\, \lambda(d\xi)$, which is (c). □

Proposition 18.110 (The connected kernel of a component: Källén–Lehmann form, log-convexity, the weight of the mass 0)**.** Under the statements granted at the head of this subsection, let $0 < g \le \gamma$ and $\xi \in \mathsf{X}$.

(a) The connected function of two points of σ_ξ is $S_2^{\sigma_\xi}(f,h) = \iint f(x)h(y)\, \mathbf{s}^{\mathrm{c}}_\xi(|x-y|)\, dx\, dy$ on $\mathfrak{S}_2(\mathbb{R}^3)$, with $\mathbf{s}^{\mathrm{c}}_\xi(r) = \int_{[0,\infty)} e^{-mr}(4\pi r)^{-1}\, d\rho_\xi(m)$ for all $r > 0$; ρ_ξ is the only positive Borel measure on $[0,\infty)$ for which this identity is true for all $r > 0$, and $\mathbf{s}^{\mathrm{c}}_\xi = \mathbf{s}^{\mathrm{KL}}_\xi$.

(b) $\mathbf{s}^{\mathrm{c}}_\xi$ and $r \mapsto r\, \mathbf{s}^{\mathrm{c}}_\xi(r)$ are completely monotone on $(0,\infty)$. Either $\rho_\xi = 0$ and $\mathbf{s}^{\mathrm{c}}_\xi = 0$, or $r\, \mathbf{s}^{\mathrm{c}}_\xi(r) > 0$ for every $r > 0$ and $r \mapsto \log(r\, \mathbf{s}^{\mathrm{c}}_\xi(r))$ is convex and non-increasing on $(0,\infty)$.

(c) $\mathbf{s}^{\mathrm{c}}_\xi(r) \le \frac{r_0}{r}\, \mathbf{s}^{\mathrm{c}}_\xi(r_0)$ for $0 < r_0 \le r$.

(d) As $r \to \infty$, $4\pi r\, \mathbf{s}^{\mathrm{c}}_\xi(r)$ tends to $\rho_\xi(\{0\})$.

■

Sketch of proof. Step 1: (a). The constant at infinity of σ_ξ is $\kappa'_\xi = \mathfrak{c}_\xi^2$ (Lemma 18.109 (a)); so $\mathbf{s}^{\mathrm{c}}_\xi = \mathbf{s}_\xi - \kappa'_\xi = \mathbf{s}^{\mathrm{KL}}_\xi$, and Definition 18.106 (2) with Proposition 13.25 (b) gives the formula and the uniqueness.

Step 2: (b)–(d). In the notation of Lemma 18.107, $4\pi r\, \mathbf{s}^{\mathrm{c}}_\xi(r) = \mathcal{L}_{\rho_\xi}(r)$; by clauses (a) and (b) of that lemma it is completely monotone, identically 0 if $\rho_\xi = 0$, and otherwise positive with a convex and non-increasing logarithm; $\mathbf{s}^{\mathrm{c}}_\xi = \mathbf{s}^{\mathrm{KL}}_\xi$ is completely monotone by Definition 18.106 (3). As $r\, \mathbf{s}^{\mathrm{c}}_\xi(r)$ is non-increasing, $r\, \mathbf{s}^{\mathrm{c}}_\xi(r) \le r_0\, \mathbf{s}^{\mathrm{c}}_\xi(r_0)$ for $r \ge r_0$, which is (c); and (d) is Lemma 18.107 (a), or Proposition 13.25 (c) with $\kappa'_\xi = \mathfrak{c}_\xi^2$. □

Proposition 18.111 (The law at a point; the growth of the Källén–Lehmann measure and of the energy measure)**.** Under the statements granted at the head of this subsection, let $0 < g \le \gamma$. For every $\xi \in \mathsf{X}$ the connected function of two points of σ_ξ has the kernel $\mathbf{s}^{\mathrm{c}}_\xi(|x-y|)$, where $\mathbf{s}^{\mathrm{c}}_\xi(r) = \int e^{-mr}(4\pi r)^{-1}\, d\rho_\xi(m)$ with exactly one positive Borel measure ρ_ξ on $[0,\infty)$, and both $\mathbf{s}^{\mathrm{c}}_\xi$ and $r\, \mathbf{s}^{\mathrm{c}}_\xi(r)$ are completely monotone. Let now $0 < g \le \gamma_W$, let b be the label of the sequence (Definition 18.106 (4)), and let σ' be σ or a component.

(a) *The law at a point.* For $0 < \delta \le \frac{1}{2}$ and $0 < r \le r_\delta$

$$a_\delta^{-1}(1 - \varepsilon_\delta(r)) \le y(r) \le a_\delta(1 + \varepsilon_\delta(r)), \qquad |y(r) - 1| \le a_\delta(1 + \varepsilon_\delta(r)) - 1;$$

for a component $y = y^{\mathrm{c}}$. For the limit and for every component, $r^6 \mathbf{s}^{\mathrm{c}}(r) \to \mathsf{c}_2 \mathsf{b}^{-2} = \frac{9}{16\pi^2 \mathsf{b}^2}$ as $r \to 0$.

(b) *Uniformity.* For every $\eta > 0$ there is $r(\eta) > 0$, formed from the frame, g and η alone, such that $|y^{\mathrm{c}}(r) - 1| \le \eta$ and $|y(r) - 1| \le \eta$ for $0 < r \le r(\eta)$, for every convergent Gibbs sequence at g, every canonical decomposition of its limit, every component and the limit itself.

(c) *The growth.* As $\mathsf{M} \to \infty$

$$\rho([0,\mathsf{M}]) \sim \frac{4\pi \mathsf{c}_2}{\Gamma(6)}\, \mathsf{b}^{-2}\mathsf{M}^5 = \frac{3}{160\pi}\, \mathsf{b}^{-2}\mathsf{M}^5, \qquad \mu^E([0,\mathsf{M}]) \sim \frac{\mathsf{c}_2}{\Gamma(7)}\, \mathsf{b}^{-2}\mathsf{M}^6 = \frac{\mathsf{c}_2}{720}\, \mathsf{b}^{-2}\mathsf{M}^6,$$

and uniformly: the suprema of $|\frac{160\pi}{3}\mathsf{b}^2\mathsf{M}^{-5}\rho([0,\mathsf{M}]) - 1|$ and of $|\frac{720}{\mathsf{c}_2}\mathsf{b}^2\mathsf{M}^{-6}\mu^E([0,\mathsf{M}]) - 1|$ over the convergent Gibbs sequences at g, the canonical decompositions of their limits, the components and the limits tend to 0 as $\mathsf{M} \to \infty$. Moreover $d\mu^E(E) = \frac{1}{4\pi}\rho([0,E])\, dE$.

(d) $\rho([0,\infty)) = \infty$; and for every $C > 1$ there is M_C, formed from the frame, g and C alone, with $\rho((\mathsf{M}, C\mathsf{M}]) > 0$ for all $\mathsf{M} \ge \mathsf{M}_C$ and all these σ'.

■

Sketch of proof. Step 0: the first sentence is Proposition 18.110 (a), (b).

Step 1: narrow pairs. Let $0 < \delta \le \frac12$, $\mathsf{d} > 0$, and $x_0, y_0 \in \mathbb{R}^3$ with $|x_0 - y_0| = 3\mathsf{d}$; let $\varphi(u) = (1-|u|^2)^2$ for $|u| \le 1$ and $\varphi(u) = 0$ for $|u| > 1$, and put $f(x) = \varphi((x-x_0)/(\delta\mathsf{d}))$ and $h(y) = \varphi((y-y_0)/(\delta\mathsf{d}))$. These are non-negative functions of class C^1 with $\|f\|_\infty = \|h\|_\infty = 1$; each is supported by the closed ball of radius $\delta\mathsf{d} \le \mathsf{d}$ about its centre, and the two balls lie at the distance $(3-2\delta)\mathsf{d}$, a number of $[2\mathsf{d}, 3\mathsf{d})$; $\int f = \int h = (\delta\mathsf{d})^3 \int \varphi = \vartheta_\delta\, \mathsf{d}^3$, as $\int \varphi = 4\pi \int_0^1 (1-s^2)^2 s^2\, ds = \frac{32\pi}{105}$; and $\operatorname{Lip} f = \operatorname{Lip} h = (\delta\mathsf{d})^{-1} \max_{0\le s\le 1} 4s(1-s^2) = \frac{8}{3\sqrt3\,\delta\mathsf{d}} \le \frac{1}{\vartheta_\delta \mathsf{d}}$, because $\vartheta_\delta \cdot \frac{8}{3\sqrt3\,\delta} = \frac{256\pi}{315\sqrt3}\,\delta^2 < \frac25$. So the test-pair conditions of Thm. YM3_I:C are satisfied with $\vartheta = \vartheta_\delta \in (0,1)$, and $(f,h) \in \mathfrak{T}^1_{\mathbb{R}^3}(\mathsf{d};\vartheta_\delta) \subset \mathfrak{S}_2(\mathbb{R}^3)$.

Step 2: the law on narrow pairs in a component. Let $\xi \in \mathsf{X}$. Thm. YM3_I:C at $\vartheta = \vartheta_\delta$ gives, for $0 < \mathsf{d} \le \mathsf{d}_0(g,\vartheta_\delta)$ and the pair of Step 1, $S_2^{\sigma_\xi}(f,h) = \mathsf{c}_2 \mathsf{b}^{-2} \mathcal{K}_{\text{free}}(f,h)(1+\eta_\xi)$ with $|\eta_\xi| \le \bar\varepsilon_{g,\vartheta_\delta}(\mathsf{d})$, where $\mathcal{K}_{\text{free}}(f,h) = \iint f(x)h(y)|x-y|^{-6}\,dx\,dy$ is the free kernel in Thm. YM3_I:C. For $x \in \operatorname{supp} f$ and $y \in \operatorname{supp} h$, $(3-2\delta)\mathsf{d} \le |x-y| \le (3+2\delta)\mathsf{d}$. Since f and h are non-negative and $\mathbf{s}^{\mathrm{c}}_\xi = \mathbf{s}_\xi - \mathfrak{c}_\xi^2$ is non-increasing (Proposition 13.25 (a)), Definition 18.106 (2) gives, with $I = \int f \int h > 0$,

$$\mathbf{s}^{\mathrm{c}}_\xi\big((3+2\delta)\mathsf{d}\big)\, I \le S_2^{\sigma_\xi}(f,h) \le \mathbf{s}^{\mathrm{c}}_\xi\big((3-2\delta)\mathsf{d}\big)\, I, \qquad \big((3+2\delta)\mathsf{d}\big)^{-6} I \le \mathcal{K}_{\text{free}}(f,h) \le \big((3-2\delta)\mathsf{d}\big)^{-6} I.$$

Hence $\mathbf{s}^{\mathrm{c}}_\xi((3+2\delta)\mathsf{d}) \le \mathsf{c}_2\mathsf{b}^{-2}((3-2\delta)\mathsf{d})^{-6}(1+\bar\varepsilon_{g,\vartheta_\delta}(\mathsf{d}))$ and $\mathbf{s}^{\mathrm{c}}_\xi((3-2\delta)\mathsf{d}) \ge \mathsf{c}_2\mathsf{b}^{-2}((3+2\delta)\mathsf{d})^{-6}(1-\bar\varepsilon_{g,\vartheta_\delta}(\mathsf{d}))$.

Step 3: (a). Let $0 < r \le r_\delta$. In a component σ_ξ the first inequality of Step 2 at $\mathsf{d} = r/(3+2\delta)$ and the second at $\mathsf{d} = r/(3-2\delta)$, both numbers being at most $\mathsf{d}_0(g,\vartheta_\delta)$, together with $\bar\varepsilon_{g,\vartheta_\delta}(r/(3+2\delta)) \le \varepsilon_\delta(r)$, give the two-sided bound for y^{c}_ξ, and $y^{\mathrm{c}}_\xi = y_\xi$ because $\mathbf{s}^{\mathrm{c}}_\xi = \mathbf{s}^{\mathrm{KL}}_\xi$ (Proposition 18.110 (a)). For the limit, Lemma 18.109 (c) gives $y_\sigma(r) = \int_{\mathsf{X}} y_\xi(r)\,\lambda(d\xi)$, the label being one number for the sequence and all the components; as neither member of the bound depends on ξ and $\lambda(\mathsf{X}) = 1$, $y_\sigma(r)$ lies between the same two members. With $\varepsilon = \varepsilon_\delta(r)$, $y - 1 \le a_\delta(1+\varepsilon) - 1$, and $1 - y \le 1 - a_\delta^{-1}(1-\varepsilon) \le a_\delta(1+\varepsilon) - 1$, because $a \mapsto a(1+\varepsilon) + a^{-1}(1-\varepsilon)$ takes the value 2 at $a = 1$ and has the derivative $(1+\varepsilon) - a^{-2}(1-\varepsilon) \ge 0$ for $a \ge 1$. As $r \to 0$, $\varepsilon_\delta(r) \to 0$, so that $a_\delta^{-1} \le \liminf y \le \limsup y \le a_\delta$; and $a_\delta \to 1$ as $\delta \to 0$; so $y(r) \to 1$. By Definition 18.106 (2), $\mathbf{s}^{\mathrm{c}} - \mathbf{s}^{\mathrm{KL}} = \kappa' - \mathfrak{c}'^2$, which is κ'_σ for the limit and 0 for a component (Lemma 18.109 (a)); so $r^6 \mathbf{s}^{\mathrm{c}}(r)\,\mathsf{b}^2/\mathsf{c}_2 = y(r) + r^6(\kappa' - \mathfrak{c}'^2)\,\mathsf{b}^2/\mathsf{c}_2 \to 1$.

Step 4: (b). Let $\eta > 0$. Choose δ with $a_\delta - 1 \le \eta/3$, and then $r' \in (0, r_\delta]$ with $64\,\varepsilon_\delta(r') \le \eta/3$; as $a_\delta \le 64$ and ε_δ is non-decreasing, (a) gives $|y(r) - 1| \le \frac23\eta$ for $0 < r \le r'$, for the limit and for every component. For a component $y^{\mathrm{c}} = y$. For the limit, $0 \le y^{\mathrm{c}}(r) - y(r) = r^6 \kappa'_\sigma \mathsf{b}^2/\mathsf{c}_2 \le r^6\, \bar c_g^2 L^2 (g^{-2} + \bar B)^2/\mathsf{c}_2$, by Lemma 18.109 (b) and since $\mathsf{b} \le L(g^{-2} + \bar B)$, the upper end of $I^{\mathrm{lab}}(g)$ (Definition 13.1 (2)). Let $r(\eta)$ be the largest number of $(0, r']$ with $r(\eta)^6\, \bar c_g^2 L^2 (g^{-2} + \bar B)^2 \le \eta\, \mathsf{c}_2/3$; it is formed from the frame, g and η alone and serves for all the functionals named in (b).

Step 5: (c). Over the convergent Gibbs sequences at g, the canonical decompositions of their limits, their components and their limits, the pairs $(\rho, \mathsf{A}_\mathsf{b})$ form a set $\mathfrak{F}_5$, and the pairs $(\mu^E, \mathsf{c}_2\mathsf{b}^{-2})$ a set $\mathfrak{F}_6$, of the kind of Lemma 18.107 (c) at $\alpha = 5$ and at $\alpha = 6$. Indeed, by Definition 18.106 (2), (3), $\mathcal{L}_\rho(r) = 4\pi r\, \mathbf{s}^{\mathrm{KL}}(r)$ and $\mathcal{L}_{\mu^E}(r) = \mathbf{s}^{\mathrm{KL}}(r)$, so that $r^5 \mathcal{L}_\rho(r)/\mathsf{A}_\mathsf{b} = r^6 \mathcal{L}_{\mu^E}(r)\,\mathsf{b}^2/\mathsf{c}_2 = y(r)$, which tends to 1 uniformly by (b). Lemma 18.107 (c) gives the two uniform laws, with $\Gamma(6) = 120$, $\Gamma(7) = 720$ and $\frac{4\pi\mathsf{c}_2}{120} = \frac{36}{1920\pi} = \frac{3}{160\pi}$. For the density of μ^E: $e^{-mr}/r = \int_m^\infty e^{-Er}\,dE$, and Tonelli's theorem gives $\mathbf{s}^{\mathrm{KL}}(r) = \int_0^\infty e^{-Er}\,\frac{\rho([0,E])}{4\pi}\,dE$; the uniqueness in Lemma 18.107 (a) identifies the two measures.

Step 6: (d). By (c), $\rho([0,\infty)) = \lim_{\mathsf{M}\to\infty} \rho([0,\mathsf{M}]) = \infty$. Let $C > 1$ and let $\epsilon_\rho(\mathsf{M})$ be the supremum in (c) for ρ; it tends to 0, so there is M_C, formed from the frame, g and C alone, with $\epsilon_\rho(\mathsf{M}') < (C^5-1)/(C^5+1)$ for all $\mathsf{M}' \ge \mathsf{M}_C$. For $\mathsf{M} \ge \mathsf{M}_C$

$$\mathsf{M}^{-5}\rho((\mathsf{M}, C\mathsf{M}]) = C^5(C\mathsf{M})^{-5}\rho([0, C\mathsf{M}]) - \mathsf{M}^{-5}\rho([0,\mathsf{M}]) \ge \frac{3}{160\pi}\,\mathsf{b}^{-2}\big[C^5 - 1 - (C^5+1)\max\{\epsilon_\rho(\mathsf{M}), \epsilon_\rho(C\mathsf{M})\}\big] > 0.$$

□

Proposition 18.112 (The two-point function of a component)**.** Under the statements granted at the head of this subsection, let $0 < g \le \gamma$ and $\xi \in \mathsf{X}$.

(a) There is exactly one positive Borel measure ρ_ξ on $[0,\infty)$ with $\int e^{-mr}\,d\rho_\xi(m) < \infty$ for all $r > 0$ such that $S_2^{\sigma_\xi}(f,h) = \iint f(x)h(y)\,G_\xi(|x-y|)\,dx\,dy$ for all $(f,h) \in \mathfrak{S}_2(\mathbb{R}^3)$, where $G_\xi(r) = (4\pi r)^{-1}\int e^{-mr}\,d\rho_\xi(m)$; and $G_\xi = \mathbf{s}^{\mathrm{c}}_\xi$. This measure has polynomial growth: $\rho_\xi([0,\mathsf{M}]) \le 1024\pi e\,(C^g_{\mathrm{rad}})^2 \max\{\mathsf{M}, \frac12\}^7$ for every $\mathsf{M} \ge 0$, with the common reconstruction constant C^g_{rad}.

(b) G_ξ is real-analytic, non-negative and non-increasing on $(0,\infty)$; $r \mapsto rG_\xi(r)$ is completely monotone and non-increasing with the limit $\rho_\xi(\{0\})/(4\pi)$ at infinity; and $G_\xi(r) \le \frac{r_0}{r}\,G_\xi(r_0)$ for $0 < r_0 \le r$.

(c) Let $0 < g \le \gamma_W$ and let b be the label. Then $r^6 G_\xi(r) \to \mathsf{c}_2\mathsf{b}^{-2}$ as $r \to 0$, and $r^6 G_\xi(r)\,\mathsf{b}^2/\mathsf{c}_2$ is held between a lower and an upper member: $a_\delta^{-1}(1-\varepsilon_\delta(r)) \le r^6 G_\xi(r)\,\mathsf{b}^2/\mathsf{c}_2 \le a_\delta(1+\varepsilon_\delta(r))$ for $0 < \delta \le \frac12$ and $0 < r \le r_\delta$, with members that are the same for all components of all canonical decompositions of the limits of all convergent Gibbs sequences at g. Further $\rho_\xi([0,\mathsf{M}]) \sim \frac{3}{160\pi}\,\mathsf{b}^{-2}\mathsf{M}^5$ as $\mathsf{M} \to \infty$, so that $\rho_\xi([0,\infty)) = \infty$; the Hilbert space $\mathcal{H}(\sigma_\xi, e_3)$ has infinite dimension; and its Hamiltonian H is unbounded.

■

Sketch of proof. Step 1: the measure. By Proposition 18.110 (a), ρ_ξ has the property, with $G_\xi = \mathbf{s}^{\mathrm{c}}_\xi$. Let ρ'' be a second measure with the property and G'' its function. Dominated convergence makes G'' continuous on $(0,\infty)$, and $\iint f(x)h(y)\,(G'' - \mathbf{s}^{\mathrm{c}}_\xi)(|x-y|)\,dx\,dy = 0$ on $\mathfrak{S}_2(\mathbb{R}^3)$; non-negative functions of class C^1 and of mass 1 whose supports shrink to two points at the distance r give $G''(r) = \mathbf{s}^{\mathrm{c}}_\xi(r)$. So $\mathcal{L}_{\rho''} = \mathcal{L}_{\rho_\xi}$, and $\rho'' = \rho_\xi$ by Lemma 18.107 (a). The same argument shows that a continuous radial kernel of σ_ξ on $\mathfrak{S}_2(\mathbb{R}^3)$ is unique.

Step 2: polynomial growth. By Thm. YM3_I:AP, the component is reconstruction data with exponent 4 and constant C^g_{rad}. Prop. YM3_I:108.3 bounds its two-point kernel at a separation re_3 by $(C^g_{\mathrm{rad}})^2 \min\{1, r/2\}^{-8}$, by taking the tube distance parameter $\eta = \min\{1, r/2\}$ in its point estimate. Rotation invariance gives the same bound at every point of separation r. This kernel is $\mathbf{s}_\xi$ by Definition 13.4(3). Since $0 \le G_\xi = \mathbf{s}_\xi - \mathfrak{c}_\xi^2 \le \mathbf{s}_\xi$, Lemma 18.107(a) gives for $\mathsf{M} \ge 1/2$

$$\rho_\xi([0,\mathsf{M}]) \le e\,\mathcal{L}_{\rho_\xi}(1/\mathsf{M}) = 4\pi e\,\mathsf{M}^{-1}G_\xi(1/\mathsf{M}) \le 4\pi e\,\mathsf{M}^{-1}(C^g_{\mathrm{rad}})^2(2\mathsf{M})^8 = 1024\pi e\,(C^g_{\mathrm{rad}})^2\mathsf{M}^7,$$

and $\rho_\xi([0,\mathsf{M}]) \le \rho_\xi([0,\frac12])$ for $0 \le \mathsf{M} < \frac12$.

Step 3: (b). $\mathbf{s}_\xi$ is real-analytic (Definition 13.4 (3)), and so is $G_\xi = \mathbf{s}_\xi - \mathfrak{c}_\xi^2$; the other assertions are Proposition 18.110 (b)–(d), a completely monotone function being non-negative and non-increasing.

Step 4: (c). The law, its enclosure between the two members and the growth are Proposition 18.111 (a), (c), (d) at $\sigma' = \sigma_\xi$, where $y^{\mathrm{c}}(r) = r^6 G_\xi(r)\,\mathsf{b}^2/\mathsf{c}_2$; the members a_δ, $\varepsilon_\delta(r)$ and the range r_δ are formed from the frame, g, δ and r (Definition 18.106 (4)). As $\rho_\xi([0,\mathsf{M}]) < \infty$ by (a), $\rho_\xi((\mathsf{M},\infty)) = \infty$ for every $\mathsf{M} \ge 0$, and Lemma 18.108 (c), at a real $h \in C^1_c(\mathbb{E}_+)$ with $h \ge 0$ and $h \ne 0$, gives the last two assertions. □

Proposition 18.113 (The connected functions of a limit and of its components)**.** Under the statements granted at the head of this subsection, let $0 < g \le \gamma$, and let σ' be the limit σ or a component σ_ξ; $(\mathbb{R}^3)^n_{\ne}$ is the open set of the n-tuples $x = (x_1,\dots,x_n)$ of pairwise distinct points of $\mathbb{R}^3$, and $x_J = (x_i)_{i\in J}$ for $J \subset \{1,\dots,n\}$.

(i) For every $n \ge 2$ there is exactly one continuous function k_n on $(\mathbb{R}^3)^n_{\ne}$ with $S_n^{\sigma'}(f_1,\dots,f_n) = \int k_n(x)\prod_{i=1}^n f_i(x_i)\,dx$ for all $(f_1,\dots,f_n) \in \mathfrak{S}_n(\mathbb{R}^3)$, and it is real-analytic; $k_2(x_1,x_2) = \mathbf{s}^{\mathrm{c}}(|x_1-x_2|)$.

(ii) For all $r > 0$, $\mathbf{s}^{\mathrm{c}}_\sigma(r) = \kappa'_\sigma + \int e^{-mr}(4\pi r)^{-1}\,d\rho_\sigma(m)$ with $\kappa'_\sigma = \int_{\mathsf{X}} \mathfrak{c}_\xi^2\,d\lambda(\xi)$, and $\mathbf{s}^{\mathrm{c}}_\xi(r) = \int e^{-mr}(4\pi r)^{-1}\,d\rho_\xi(m)$. In each of the two identities the pair formed by the constant term,

κ'_σ in the first and 0 in the second, and the positive Borel measure with finite Laplace transforms is unique.

(iii) Let $0 < g \le \gamma_W$ and let b be the label. Then $|x|^6 k_2(0,x) \to \mathsf{c}_2\mathsf{b}^{-2}$ as $x \to 0$.

(iv) In the situation of (iii), $\rho([0,\mathsf{M}]) \sim \frac{4\pi\mathsf{c}_2}{5!}\,\mathsf{b}^{-2}\mathsf{M}^5$ as $\mathsf{M} \to \infty$.

(v) In the situation of (iii), the Hamiltonian H of $\mathcal{H}(\sigma', e_3)$ is unbounded, and $\dim \mathcal{H}(\sigma', e_3) = \infty$.

(vi) In a component, $4\pi|x|\,k_2(0,x) \to \rho_\xi(\{0\})$ as $|x| \to \infty$, and $|v|\,S_2^{\sigma_\xi}(f, \tau_v h) \to \frac{1}{4\pi}\,\rho_\xi(\{0\}) \int f \int h$ as $|v| \to \infty$ for every $(f,h) \in \mathfrak{S}_2(\mathbb{R}^3)$. Hence $\rho_\xi(\{0\}) > 0$ if and only if there is a pair $(f,h) \in \mathfrak{S}_2(\mathbb{R}^3)$ with $\limsup_{|v|\to\infty} |v|\,|\sigma_\xi((f)\cdot\tau_v(h)) - \sigma_\xi((f))\,\sigma_\xi((h))| > 0$, that is, a pair at which the decay $|v|^{-1}$ of the cluster bound of Thm. YM3_I:AP is reached. ■

Sketch of proof. Step 1: (i). Thm. YM3_I:AP gives reconstruction data for the limit and each component. By Prop. YM3_I:108.3, for every $p \ge 1$ there is a real-analytic function s_p on $(\mathbb{R}^3)^p_{\neq}$ with $\sigma'(f_1,\dots,f_p) = \int \mathsf{s}_p(x) \prod_i f_i(x_i)\,dx$ on $\mathfrak{S}_p(\mathbb{R}^3)$. Write $X = (f_1,\dots,f_n) \in \mathfrak{S}_n(\mathbb{R}^3)$, and for a non-empty $J \subset \{1,\dots,n\}$ let X_J be the tuple of the f_i with $i \in J$, taken by increasing i. By the moment–cumulant formula, $S_n^{\sigma'}(X)$ is the sum over the partitions π of $\{1,\dots,n\}$ of $(-1)^{|\pi|-1}(|\pi|-1)!\prod_{J\in\pi}\sigma'(X_J)$; by Fubini's theorem each product is the integral of $\prod_{J\in\pi}\mathsf{s}_{|J|}(x_J)$ against $\prod_i f_i(x_i)$, and for $x \in (\mathbb{R}^3)^n_{\neq}$ every x_J consists of pairwise distinct points. So $k_n(x) = \sum_\pi (-1)^{|\pi|-1}(|\pi|-1)!\prod_{J\in\pi}\mathsf{s}_{|J|}(x_J)$ is real-analytic and represents $S_n^{\sigma'}$. A continuous function on $(\mathbb{R}^3)^n_{\neq}$ whose integrals against all these products vanish is 0: at a point x, take non-negative functions f_i of class C^1 and of mass 1 supported by pairwise disjoint balls about the points x_i, and let the balls shrink. This gives the uniqueness, and at $n = 2$ Definition 18.106 (2) gives k_2.

Step 2: (ii). By Lemma 18.109, $\kappa'_\sigma = \int \mathfrak{c}_\xi^2\,d\lambda$ and $\kappa'_\xi = \mathfrak{c}_\xi^2$; as $\mathfrak{c}' = 0$ for σ and $\mathfrak{c}' = \mathfrak{c}_\xi$ for σ_ξ, Proposition 13.25 (b) gives the two identities. If $\mathsf{s}^{\mathrm{c}}(r) = \varkappa + \int e^{-mr}(4\pi r)^{-1}\,d\rho''(m)$ for all $r > 0$, with a number $\varkappa$ and a positive Borel measure ρ'' with finite Laplace transforms, the integral is at most $\mathcal{L}_{\rho''}(1)/(4\pi r)$ for $r \ge 1$ and tends to 0; so $\varkappa = \lim_{r\to\infty}\mathsf{s}^{\mathrm{c}}(r)$, then $\mathcal{L}_{\rho''}(r) = 4\pi r(\mathsf{s}^{\mathrm{c}}(r) - \varkappa)$ is determined, and so is ρ'' (Lemma 18.107 (a)).

Step 3: (iii)–(v). By (i), $k_2(0,x) = \mathsf{s}^{\mathrm{c}}(|x|)$, so $|x|^6 k_2(0,x) = \mathsf{c}_2\mathsf{b}^{-2}y^{\mathrm{c}}(|x|)$, and (iii) is Proposition 18.111 (a); (iv) is Proposition 18.111 (c), as $5! = \Gamma(6)$. By Proposition 18.111 (d) and Lemma 18.107 (a), $\rho((\mathsf{M},\infty)) = \infty$ for every $\mathsf{M} \ge 0$; Lemma 18.108 (c), at a real $h \in C^1_c(\mathbb{E}_+)$ with $h \ge 0$ and $h \ne 0$, gives (v).

Step 4: (vi). In a component $k_2(0,x) = \mathsf{s}^{\mathrm{c}}_\xi(|x|)$, and Proposition 18.110 (d) gives the first limit. Let $(f,h) \in \mathfrak{S}_2(\mathbb{R}^3)$ have its supports in the ball of radius R about 0, and let $|v| > 2R$. Then $(f,\tau_v h) \in \mathfrak{S}_2(\mathbb{R}^3)$, and $S_2^{\sigma_\xi}(f,\tau_v h) = \iint f(x)h(y)\,\mathsf{s}^{\mathrm{c}}_\xi(|x-y-v|)\,dx\,dy$ by Definition 18.106 (2). On the supports $\big||x-y-v|-|v|\big| \le 2R$, so $|v|/|x-y-v| \to 1$ and, by Proposition 18.110 (d), $|x-y-v|\,\mathsf{s}^{\mathrm{c}}_\xi(|x-y-v|) \to \rho_\xi(\{0\})/(4\pi)$, both uniformly there as $|v| \to \infty$; this gives the second limit. If $\rho_\xi(\{0\}) > 0$, a pair with $f, h \ge 0$ and $\int f \int h > 0$ has $|v|\,S_2^{\sigma_\xi}(f,\tau_v h) \to \rho_\xi(\{0\}) \int f \int h/(4\pi) > 0$; if $\rho_\xi(\{0\}) = 0$, the limit is 0 at every pair. Finally, by the two-entry cumulant formula and $\sigma_\xi((\tau_v h)) = \mathfrak{c}_\xi \int h = \sigma_\xi((h))$ (Definition 13.4 (2)), $\sigma_\xi((f)\cdot\tau_v(h)) - \sigma_\xi((f))\,\sigma_\xi((h)) = S_2^{\sigma_\xi}(f,\tau_v h)$, the quantity that the cluster bound of Thm. YM3_I:AP controls at $X = (f)$, $Y = (h)$. □

When, beyond what is granted at the head of this subsection, a Setting is given whose first frame is the frame fixed there (Definition 13.6; there is one by Lemma 13.5), and Theorem F, Theorem S and the statements (M1)–(M12) are granted at both of its frames as in Theorem AL, the clauses (c) 1 and (c) 7 of that theorem, which by its clause (e) 4 apply at every reference coupling $g' \in (0,\gamma]$ to every convergent Gibbs sequence at g' and to every component of its limit, give $\mathfrak{c}_\xi = 0$ and $\rho_\xi(\{0\}) = 0$, the measure of its conclusion 3 being ρ_ξ once $\mathfrak{c}_\xi = 0$; the constant at infinity of σ is then 0 by Lemma 18.109 (b), and $|v|\,S_2^{\sigma_\xi}(f,\tau_v h) \to 0$ for every $(f,h) \in \mathfrak{S}_2(\mathbb{R}^3)$ by Proposition 18.113 (vi).

18.11. **Reflection positivity at the diagonal mirrors from a sheared torus; the pressure to two loops; loops of block fields under the box inequality.** Three further results hold in the setting of Section 17.2. First, with no hypothesis of the kind of BI: if along one defining sequence of tori of a continuum limit at a reference coupling the free energy E of the shear of the cube by half a period, the number of Theorem AZ(1)(f), has a finite lower limit, then the centred functional of the limit is reflection positive at every diagonal mirror of $\mathbb{R}^3$, and so, with the coordinate mirrors, at every mirror of the cubic lattice (Proposition 18.114); the lower limit is finite as soon as the doubling defect e of the half cube, or the cube number, stays bounded along the sequence, as $0 \le E \le \mathsf{e}$ and $E \le D_L$ hold exactly on one lattice. The cube is compared with the diamond, the torus of the same volume sheared back, by Schwarz's inequality across the shear; the diamond carries a chessboard estimate along three orthogonal normals that is dominated by the chessboard seminorms of the cubes, so that its cumulants obey bounds free of the cutoff and converge along a subsequence; and the operator that σ_S defines in the Hilbert space of the limit along the diamonds is positive, by the positivity of σ_S at a coordinate mirror, by bounded multiplications by columns, and because the half turn about the line in which the diagonal and the coordinate mirror meet acts trivially at infinity. Second, the pressure of one lattice to two loops, $P(\beta) = -3\log\beta + z_\infty + p_1/\beta + O((\log\beta)^2\beta^{-1.02})$ as $\beta \to \infty$ through the reals, with the constant z_∞ of Proposition 17.47(d) and $p_1 = 9G_0 - 36G_0^2 - 9J_{\mathrm{gh}} + 18J_3$, formed from the Green function G of the lattice Laplacian on $\mathbb{Z}^3$; p_1 is the limit per site of the vacuum diagrams with two loops of the Dirichlet boxes and of the periodic cubes (Proposition BF). The pressure is pinned between two periodic cubes of the side about $\beta^{0.34}$, where one chart about the flat field in Landau's gauge and three levels of large-field estimates give $\log Z$ to the order $1/\beta$, and the coefficient is computed on the Dirichlet boxes, the odd part of the cubes of twice their side, in the gauge of Feynman. Third, under the inequality BI of one box at one label, Wilson loops of the block fields of a fixed depth d obey an area law with the tension $0.66/\ell_0^2$, uniformly in the cutoff, on the tori, in the limit of the cutoffs and in the one periodic Gibbs state: the rectangle with four tapered links at all sizes, and the rectangle of block links itself with the constant 17 as long as its shorter side is at most a length ϱ_d, which grows without bound with the depth, besides a second term at all sizes; the two loops differ, uniformly in the side of the torus, by at most a number τ'_d that tends to 0 with the depth (Proposition 18.115). The flux ratio of the boxes obeys an area law under BI; loops that split at two planes are bounded through the flux of the transfer operator in the transverse direction; and the large fields of one cell of a block field are bounded by the discarding of the small-field chain, with no factor of the volume.

Setting. Use the constants and labels of §17.2. For a nonzero normal n write $\Theta_{n,c}x = x - 2(n\cdot x - c)n/|n|^2$. For the coordinate normals e_μ the lattice heights are $c \in (a/2)\mathbb{Z}$, and for $n = e_\mu \pm e_\nu$ they are $c \in a\mathbb{Z}$. We put $\mathsf{n}_\pm = e_1 \pm e_3$, $u_\diamond = \mathsf{n}_+/\sqrt{2}$, $\Sigma_\diamond = (u_\diamond, 0)$, $\Theta_\diamond = \Theta_{u_\diamond,0}$, $\Theta_2 = \Theta_{e_2,0}$, and $\mathsf{s}_y = \tau_{y\mathsf{n}_+/2}$. The last map raises the height $x_1 + x_3$ by y.

Write $\mathfrak{S}_n(O)$ for the n-tuples of real $C_c^1(O)$ tests with pairwise disjoint supports, and $\mathbb{C}\mathfrak{S}(O)$ for their finite complex linear combinations, including the empty tuple. Conjugate the coefficients and concatenate tuples when the combined supports are disjoint. Reflection positivity on an open half-space means $\sigma(\Theta\bar{F}\cdot F) \ge 0$ there. Put $\mathcal{D} = \mathbb{C}\mathfrak{S}(\{x_1 + x_3 > 0\})$. Use the cumulant and centred moment relations of Definition 18.205, and the norm $\|f\|_\sharp = \max(\sup|f|, 40M\,\mathrm{Lip}\,f)$. A tuple of type $(\mathsf{d}; R)$ has each support in a ball of radius R and distances at least d between distinct supports. A bound table bounds each n-linear form on such tuples by a constant $C_n(\mathsf{d}; R)$ times the product of their norms. For compactly supported Lipschitz tests and a law ν put $X_K^\nu = \prod_q[\mathcal{O}_K(f_q) - \nu(\mathcal{O}_K(f_q))]$. For a second law ν' set $\sigma_{\nu',\nu}(X) = \nu'(X_K^\nu)$. By expanding the centred product and using the moment–cumulant relations of ν',

$$\sigma_{\nu',\nu}(X) = \sum_{\pi\in\mathrm{Part}(n)} \prod_{I\in\pi,\ |I|=1} \delta_{\nu',\nu}(f_I) \prod_{I\in\pi,\ |I|\ge 2} S^T_{|I|}[\nu'](X_I), \qquad \delta_{\nu',\nu}(f) := \nu'(\mathcal{O}_K(f)) - \nu(\mathcal{O}_K(f)),$$

for $X = (f_1, \dots, f_n)$. A period lattice Γ is a finite-index subgroup of $a\mathbb{Z}^3$. Use the Wilson law $\mu_{\Gamma,\beta}$ on the quotient, periodically extended, and the unnormalized integral $\mathsf{I}_\Gamma(H) = Z_\Gamma[0]\mu_{\Gamma,\beta}(H)$. The cube is $\Gamma = \ell\mathbb{Z}^3$ and $p_\ell = \ell^{-3}\log Z_{K,\ell,\beta}$.

A board (i, o) of side $\mathsf{l} = a_i$, with $i < K$ and $o \in a_K\mathbb{Z}^3$, has cells of side l about $o + \mathsf{l}\mathbf{k}$, $\mathbf{k} \in \mathbb{Z}^3$. Use the bonds with both endpoints in a cell. The coordinate walls have heights $o_\mu + \mathsf{l}(\mathbb{Z} + 1/2)$. On a compatible cube of side ℓ' the chessboard seminorm $\|F\|_{\mathrm{ch},\ell'}$ is the $(\ell'/\mathsf{l})^3$-th root of the Wilson mean of the product of mirror copies in one period, conjugated for an odd number of reflections. These are the board and fold of Section YM3_I:86. Positivity, the product bound, and the comparison across volumes are Propositions YM3_I:86.3 and YM3_I:86.5. The triangle inequality follows by expanding the fold of a sum and using the product bound term by term. Each seminorm is at most the uniform norm, and $\|1\|_{\mathrm{ch}} = 1$. The eight-cell convention of §17.2 agrees with this one when $\ell' = 2\mathsf{l}$.

The diamond. For $K, m \in \mathbb{N}$, $\ell = 2L^m$ and $\beta \geq 0$ let

$$\Gamma^\diamond_\ell := \mathbb{Z}\,\ell\,\mathsf{n}_- \oplus \mathbb{Z}\,\ell e_2 \oplus \mathbb{Z}\,\tfrac{\ell}{2}\mathsf{n}_+ \subset a_K\mathbb{Z}^3, \qquad \mu^\diamond_{K,\ell,\beta} := \mu_{\Gamma^\diamond_\ell,\beta}, \qquad E(K,\ell,\beta) := \log Z_{\Gamma^\diamond_\ell}[0] - \log Z_{K,\ell,\beta}.$$

This is the lattice Γ of Theorem AZ(1)(f), and E is the free energy of the shear of that clause, here at every coupling: the cube $\ell\mathbb{Z}^3$ arises from $\Gamma^\diamond_\ell$ when its third generator is moved by $\frac{\ell}{2}\mathsf{n}_-$, half a period across the height. Use the fixed source radius ϱ and $C_{\mathrm{v}} = C_{\mathrm{S}} + C_g + C_{\mathrm{gap}}$ of [7, Lem. N.1]. Use $\mathsf{Q}_1(L), Q^\natural(n,R)$ and the functions $\Phi_1(R,D;\mathsf{l}), \mathsf{U}(R,\mathsf{d})$ of §5.2.1. Write $\mathsf{l}(n,R)$ for the least power of L at least $8n(R+1)$. Let $C^g_n(\mathsf{d};R)$ be the bound table for the cube cumulants of Proposition YM3_I:91.13.

Proposition 18.114 (A bounded free energy of the shear gives reflection positivity at the diagonal mirrors)**.** Let $0 < g \leq \gamma$, and let $S = (S_n)_{n\geq 2}$ be a continuum limit at g along growing tori in Section YM3_I:92 which has a defining sequence of tori $(K_j, \ell_j, \beta_j)_{j\in\mathbb{N}}$ with

$$\liminf_{j\to\infty} E(K_j, \ell_j, \beta_j) < \infty.$$

(a) For every $F \in \mathcal{D}$, $\sigma_S(\Theta_\diamond \bar{F} \cdot F) \geq 0$: the functional σ_S is reflection positive at the diagonal mirror $\Sigma_\diamond$.

(b) σ_S is reflection positive at every diagonal mirror $(2^{-1/2}(s\,e_\mu + s'e_\nu), c)$ of $\mathbb{R}^3$, $\mu \neq \nu$, $s, s' \in \{1, -1\}$, $c \in \mathbb{R}$; with Proposition YM3_I:92.4, it is reflection positive at every coordinate and at every diagonal mirror of $\mathbb{R}^3$.

(c) At all $K, m \in \mathbb{N}$, $\ell = 2L^m$ and $\beta \geq 0$: $0 \leq E(K,\ell,\beta) \leq \mathsf{e}(\ell/2a_K)$, and $E(K,\ell,\beta) \leq D_L(\ell/La_K)$ if $m \geq 2$. So the hypothesis holds whenever $\liminf_j \mathsf{e}(\ell_j/2a_{K_j}) < \infty$ or $\liminf_j D_L(\ell_j/La_{K_j}) < \infty$, each number taken at $\beta = \beta_j$.

■

Proof. At a fixed cutoff we write $a = a_K$. Steps 1–4 are exact statements on one lattice at every $\beta \geq 0$, and Steps 5 and 6, which work with the boards and chessboard seminorms above, are such statements at every $\beta > 0$; Steps 7–10 read the bounds at the first-passage data; Steps 11–18 work with the limit functionals.

Step 1: the diamond and its mirrors. The determinant of the three period generators has modulus ℓ^3, so the lattice index is $(\ell/a)^3$. A nonzero period has sup norm at least $\ell/2$: its first and third coordinates are integer multiples of $\ell/2$ and the second is a multiple of ℓ. Equality holds for $(\ell/2)\mathsf{n}_+$. The three generators are orthogonal. The period splits into a transverse sublattice and a pure normal period for $\mathsf{n}_+, \mathsf{n}_-, e_2$, with height periods $\ell, 2\ell, \ell$. These are the adapted-period conditions of YM3_I:(1820). Each corresponding lattice reflection flips just the normal generator in its linear part and preserves the quotient. It permutes the plaquette actions and product Haar factors, as do all lattice translations. The cube law is invariant under all signed coordinate permutations as well. With $\Gamma_\perp := \mathbb{Z}\ell\mathsf{n}_- \oplus \mathbb{Z}\ell e_2 \subset \mathsf{n}_+^\perp$ we have $\Gamma^\diamond_\ell = \Gamma_\perp \oplus \mathbb{Z}\frac{\ell}{2}\mathsf{n}_+$ and $\ell\mathbb{Z}^3 = \Gamma_\perp \oplus \mathbb{Z}\ell e_1$, as $\ell e_3 = \ell e_1 - \ell\mathsf{n}_-$; both $\frac{\ell}{2}\mathsf{n}_+$

and ℓe_1 raise the height by ℓ, and they differ by $\frac{\ell}{2}\mathsf{n}_-$. Moreover $\Gamma_\ell^\diamond = (\mathbb{Z}2\ell e_3 \oplus \mathbb{Z}\ell e_2) \oplus \mathbb{Z}\frac{\ell}{2}(e_1+e_3)$, as the vectors of $\Gamma_\ell^\diamond$ with first coordinate 0 are those of $\mathbb{Z}2\ell e_3 \oplus \mathbb{Z}\ell e_2$ and the first coordinates fill $\frac{\ell}{2}\mathbb{Z}$: with e_1 as the time, the diamond is the box of $\ell/2a$ layers over the cross-section of ℓ/a and $2\ell/a$ sites in the directions e_2 and e_3, closed up with the translation of a layer by $\frac{\ell}{2}e_3$.

Step 2: Schwarz's inequality across the shear. For all bounded Borel functions F, G of the bonds of the closed slab $\{0 \le x_1 + x_3 \le \frac{\ell}{2}\}$,

$$\left|\mathsf{I}_{\ell\mathbb{Z}^3}(\overline{\Theta_\diamond G}\, F)\right|^2 \le \mathsf{I}_{\Gamma_\ell^\diamond}(\overline{\Theta_\diamond G}\, G)\, \mathsf{I}_{\Gamma_\ell^\diamond}(\overline{\Theta_\diamond F}\, F),$$

both factors on the right being ≥ 0. At $F = G = 1$ this is Proposition 17.31(g), that is $E \ge 0$; at $G = F$, divided by $Z^2_{K,\ell,\beta}$, it gives $|\mu_{K,\ell,\beta}(\overline{\Theta_\diamond F} F)| \le e^{E(K,\ell,\beta)}\, \mu^\diamond_{K,\ell,\beta}(\overline{\Theta_\diamond F} F)$. The argument of Proposition 17.31(g) applies, with the two insertions carried along. The planes of the heights in $\frac{\ell}{2}\mathbb{Z}$ are diagonal lattice mirrors, as $\frac{\ell}{2} = L^{m+K}a \in a\mathbb{Z} = \mathrm{Adm}(\mathsf{n}_+)$; no bond crosses them because a bond changes the height by at most a. A plaquette meeting both open sides has two opposite corners on the plane and one corner at each of the heights $\pm a$ from it, by listing its four heights. Orient the two paths between the corners on the plane in the same direction and call their transports v, v'. The factor $e^{-\beta}\exp[(\beta/2)\,\mathrm{tr}(vv'^{-1})]$ has a positive kernel expansion: its m-th Taylor term is $e^{-\beta}(\beta/2)^m/m!$ times the trace of $v^{\otimes m}(v'^{\otimes m})^*$, the sum of products of corresponding matrix entries and their conjugates. The series is absolutely summable, since the sum of the absolute entry products at each m is at most 2^m by Hilbert–Schmidt Cauchy–Schwarz. Both lattices are $\Gamma_\perp \oplus \mathbb{Z}g$ with a g that raises the height by ℓ; cut at the heights $-\frac{\ell}{2}$, 0, $\frac{\ell}{2}$, the integral $\mathsf{I}_{\Gamma_\perp\oplus\mathbb{Z}g}(F_1F_2)$, F_1 a function of the lower and F_2 of the upper slab, is $\iint k_{F_2}(\tau_g\phi_0, \phi_1)\, k_{F_1}(\phi_1, \phi_0)$ over the data ϕ of the walls (their bonds modulo $\Gamma_\perp$ and the indices of the expansion at their cut plaquettes, under Haar measure and the weights of the expansion), with the kernels k_{F_i} of the two slabs, and τ_g carries the data of the height $-\frac{\ell}{2}$ to those of the height $\frac{\ell}{2}$ and keeps their measure. Schwarz's inequality in the wall data bounds $|\mathsf{I}_{\ell\mathbb{Z}^3}(F_1F_2)|^2$ by $\|k_{F_1}\|_2^2\|k_{F_2}\|_2^2$. The reflection $\Theta_{\mathsf{n}_+,0} = \Theta_\diamond$ exchanges the two slabs, exchanges the two corners of the cut plaquettes of the height 0, conjugates the kernels, and acts on the plane of the height $-\frac{\ell}{2}$ as the translation by $\frac{\ell}{2}\mathsf{n}_+$; so $\|k_{F_i}\|_2^2$ is the integral over the slab of F_i glued to its mirror image, that is over $\Gamma_\perp \oplus \mathbb{Z}\frac{\ell}{2}\mathsf{n}_+ = \Gamma_\ell^\diamond$, of F_i times its conjugated mirror image: the gluing in the proof of Proposition YM3_I:91.4, with nonnegativity from the squared norm. Take $F_1 = \overline{\Theta_\diamond G}$ and $F_2 = F$.

Step 3: the chessboard estimate along one normal, walls at all admissible heights. Let n be a normal, $c_0 \in \mathrm{Adm}(n)$, $h \in a\mathbb{N}$, $N \in \mathbb{N}$, Γ a period lattice adapted to n with the height period $2Nh$, and $\mu = \mu_{\Gamma,\beta}$. The heights $c_0 + jh$ lie in $\mathrm{Adm}(n)$; let $\Theta_j := \Theta_{n,c_0+jh}$ and $\mathbb{S}_j := \{c_0 + (j-1)h \le n\cdot x \le c_0 + jh\}$. For a function f of the bonds of $\mathbb{S}_1$ put $f^{[1]} := f$ and $f^{[j+1]} := \overline{\Theta_j f^{[j]}}$, a function of the bonds of $\mathbb{S}_{j+1}$; then $\overline{\Theta_i f^{[j]}} = f^{[2i+1-j]}$, $f^{[j+2]}$ is the translate of $f^{[j]}$ by $2h|n|^{-2}n \in a\mathbb{Z}^3$, and $f^{[j+2N]} = f^{[j]}$ on the Γ-periodic configurations. For a function F of the bonds of $\mathbb{S}_j$ let $\mathrm{Fold}\, F := \prod_{i=1}^{2N} f^{[i]}$, where $f^{[j]} = F$. Then $\mu(\mathrm{Fold}\, F) \ge 0$, and for functions F_j of the bonds of $\mathbb{S}_j$

$$\left|\mu\Big(\prod_{j=1}^{2N} F_j\Big)\right| \le \prod_{j=1}^{2N} \mu(\mathrm{Fold}\, F_j)^{1/2N}.$$

The index rule $\overline{\Theta_i f^{[j]}} = f^{[2i+1-j]}$ uses only the reflection maps and the lattice translation by $2hn/|n|^2$. In particular it is valid at odd diagonal spacings. For any division into two half-arrays at walls N slabs apart, Proposition YM3_I:91.4 and Cauchy–Schwarz bound the squared mean of the array by the product of the two means obtained by reflecting each half-array into the other half. Each reflected mean is nonnegative. For the constant array this also gives nonnegativity of the folded mean.

When all constant-array roots are positive, maximize the ratio of the modulus of the array mean to the product of its roots over arrays taking their entries in the finite set of the given model

functions. The denominator of the product of the two reflected ratios is the square of the original denominator. Maximality and Cauchy–Schwarz force both reflections of a maximizing array to maximize the ratio. Among maximizers choose one with a longest constant cyclic string. At its terminal wall the half-array retaining that string doubles its length if it is at most N and produces a constant array if it is longer than N. Thus a constant array maximizes the ratio, with value one. If a root vanishes, add a common real ϵ to the model functions. The folded means are nonnegative monic polynomials in ϵ of degree $2N$. Use values approaching zero outside their finitely many roots and pass to the limit. This proves the array estimate for all the admissible heights used here.

Step 4: three normals on the diamond. Let $h \in a\mathbb{N}$ with $M_h := \ell/h$ an even integer and $c_1, c_2, c_3 \in a\mathbb{Z}$. The walls are the lattice mirrors $\Sigma(\mathsf{n}_+, c_1 + h\mathbb{Z})$, $\Sigma(\mathsf{n}_-, c_2 + h\mathbb{Z})$, $\Sigma(e_2, c_3 + h\mathbb{Z})$; for each of the three normals the slabs of Step 3 are formed with these heights, with $2N = M_h$, $2M_h$, M_h respectively, and the cells are the intersections $\mathsf{C}_{\underline{j}}$ of three slabs, one of each normal; $\mathsf{C} := \mathsf{C}_{(1,1,1)}$, a box of the volume $\frac{1}{2}h^3$. The group W generated by the reflections in the walls acts simply transitively on the cells; its translations by $\Gamma_\ell^\diamond$ form a normal subgroup of the index $\mathsf{N} := 2M_h^3$. For a function G of the bonds of a cell put $\operatorname{FOLD} G := \prod_{[\mathsf{w}]\in \mathsf{W}/\Gamma_\ell^\diamond} (\mathsf{w}G)^{(\cdot)}$ on the $\Gamma_\ell^\diamond$-periodic configurations, the factor conjugated when w is a product of an odd number of reflections, and $q_\diamond(G) := \mu^\diamond_{K,\ell,\beta}(\operatorname{FOLD} G)^{1/\mathsf{N}}$. Then $\mu^\diamond(\operatorname{FOLD} G) \ge 0$; $|\mu^\diamond(\prod_{\mathsf{c}} G_{\mathsf{c}})| \le \prod_{\mathsf{c}} q_\diamond(G_{\mathsf{c}})$ for functions G_{c} of the bonds of cells c that are pairwise incongruent modulo $\Gamma_\ell^\diamond$; $q_\diamond$ is a seminorm on the functions of one cell, $q_\diamond(1) = 1$, and $q_\diamond(\mathsf{w}G) = q_\diamond(G)$ for $\mathsf{w} \in \mathsf{W}$; and for a function f of the bonds of C, with its copies $f^{[i]}$ along n_+ of Step 3, the column seminorm $\|f\|_{\mathrm{col},h} := \mu^\diamond(\prod_{i=1}^{M_h} f^{[i]})^{1/M_h}$ is at most $q_\diamond(f)$. Indeed, Step 3 along n_+, then along n_- for each slab of the first normal, then along e_2, gives the product bound, the reflections in walls of orthogonal normals commuting and those of one normal changing the height along that normal alone; the exponents multiply to $1/\mathsf{N}$, and the threefold fold is FOLD. Homogeneity holds as half of the factors are conjugated, the triangle inequality follows on expanding $\operatorname{FOLD}(G + G')$ and bounding each term by the product bound, and the column bound is Step 3 along n_- and then along e_2, with the factor 1 in all the other slabs.

Step 5: products over the cells of a board of $a\mathbb{Z}^3$, on the diamond. Let (i, o) be a board of $a\mathbb{Z}^3$ with the side $\mathsf{l} = a_i$ and $\ell' \in \mathfrak{L}$ with $2\mathsf{l} \le \ell' \le \ell/L$. For a set $\mathcal{K}^\diamond$ of indices that represents the classes of $\mathbb{Z}^3$ modulo $\mathsf{l}^{-1}\Gamma_\ell^\diamond$ and functions $H_{\mathbf{k}}$ of the inner bonds of the cells $\square_{\mathbf{k}}$,

$$\Big|\mathsf{I}_{\Gamma_\ell^\diamond}\Big(\prod_{\mathbf{k}\in\mathcal{K}^\diamond} H_{\mathbf{k}}\Big)\Big| \le Z_{K,\ell',\beta}^{(\ell/\ell')^3} \prod_{\mathbf{k}\in\mathcal{K}^\diamond} \|H_{\mathbf{k}}\|_{\mathrm{ch},\ell'}.$$

Here $\Gamma_\ell^\diamond \subset \mathsf{l}\mathbb{Z}^3$. A translation by this subgroup preserves the coordinate wall set and conjugates its reflection group to itself. It therefore just reindexes the mirror copies on the board. The folds and their means on the comparison cube are unchanged by reindexing and lattice translation, including if the parity convention conjugates the entire fold, since its mean is real. By Step 1 we may take $\mathcal{K}^\diamond = \{1 \le \mathbf{k}_1 \le q',\ 1 \le \mathbf{k}_2 \le \ell/\mathsf{l},\ 1 \le \mathbf{k}_3 \le 2\ell/\mathsf{l}\}$, where $q' := \ell/2\mathsf{l}$ equals L^{m+i} and is therefore odd, L being odd; we write $q' = 2r + 1$, and $\ell'/2\mathsf{l} \le q'/L \le r$. With e_1 as the time, $F_1 := \prod_{\mathbf{k}_1 \le r} H_{\mathbf{k}}$ and $F_2 := \prod_{\mathbf{k}_1 > r} H_{\mathbf{k}}$ are functions of the layers between the wall planes $c_0 = o_1 + \frac{\mathsf{l}}{2}$, $c_0 + r\mathsf{l}$ and $c_0 + (2r+1)\mathsf{l} = c_0 + \frac{\ell}{2}$; the trace formula of (M1), closed up through the unitary translation U_v of a layer by $v = \frac{\ell}{2}e_3$ as in the proof of Proposition 17.31(f), gives $\mathsf{I}_{\Gamma_\ell^\diamond}(F_1F_2) = \operatorname{Tr}(\mathsf{U}_v\mathfrak{Y}[\Phi_2]\mathfrak{Y}[\Phi_1])$. Schwarz's inequality in the Hilbert–Schmidt class and $\mathfrak{Y}[\Phi^\Theta] = \mathfrak{Y}[\Phi]^*$ bound its square by $\operatorname{Tr}(\mathfrak{Y}[\Phi_1]^*\mathfrak{Y}[\Phi_1])\operatorname{Tr}(\mathfrak{Y}[\Phi_2]^*\mathfrak{Y}[\Phi_2])$, the integrals over the coordinate lattices B_1, B_2 with $2r\mathsf{l}/a$ and $(2r+2)\mathsf{l}/a$ layers over the same cross-section of F_i times its conjugated mirror image in the wall $c_0 + r\mathsf{l}$. The mirror image of $H_{\mathbf{k}}$ is its mirror copy in the cell of the index $2r + 1 - \mathbf{k}_1$ in the direction 1, with the same seminorm; so each integrand is a product over all the cells of a period of a box with the even numbers $2r$ or $2r+2$, ℓ/l, $2\ell/\mathsf{l}$, all $\ge \ell'/\mathsf{l}$, of cells a side, and the chessboard estimate on a box (Proposition YM3_I:86.3) and the volume comparison

of Proposition YM3_I:86.5 down to the torus ℓ', bounds it by $Z^{\mathsf{N}_i/\mathsf{N}'}_{K,\ell',\beta}\prod\|H_{\mathbf{k}}\|^2_{\mathrm{ch},\ell'}$, the product over the indices of F_i, with $\mathsf{N}_1=2r\cdot 2(\ell/\mathsf{l})^2$, $\mathsf{N}_2=(2r+2)\cdot 2(\ell/\mathsf{l})^2$, $\mathsf{N}'=(\ell'/\mathsf{l})^3$; and $\frac12(\mathsf{N}_1+\mathsf{N}_2)=(\ell/\mathsf{l})^3$. With all $H_{\mathbf{k}}=1$, the board $(K-1,0)$ and $\ell'=\ell/L$, $m\ge 2$, this is $Z_{\Gamma^\diamond_\ell}[0]\le Z^{L^3}_{K,\ell/L,\beta}$, that is $E(K,\ell,\beta)\le D_L(\ell/La)$, at every $\beta>0$. At $\beta=0$ every weight is 1 and the bonds carry Haar probability measures, so all the partition functions equal 1, the numbers E, e and D_L vanish, and (c) is true there trivially. The other bound of (c), $E(K,\ell,\beta)\le\mathsf{e}(\ell/2a)$, is the upper bound in Step 1 of the proof of Theorem AZ(1)(f), which rests on Proposition 17.31(b), (f) alone and holds at every $\beta\ge 0$; and $E\ge 0$ is Step 2. This proves (c).

Step 6: the diamond is dominated by the cubes. A diagonal board $(h;c_1,c_2,c_3)$ of Step 4 is *compatible* with a board (i,o) of the side l if h is a power of L with $\mathsf{l}\le h\le\frac{\ell}{2}$ and $c_1\equiv o_1+o_3$, $c_2\equiv o_1-o_3$, $c_3\equiv o_2$ modulo l. Then: every $\mathsf{w}\in\mathsf{W}$ has $\mathsf{w}o-o\in\mathsf{l}\mathbb{Z}^3$, as $\Theta_{\mathsf{n}_+,c}o-o=(c-o_1-o_3)\mathsf{n}_+$, $\Theta_{\mathsf{n}_-,c}o-o=(c-o_1+o_3)\mathsf{n}_-$ and $\Theta_{e_2,c}o-o=2(c-o_2)e_2$, so that the offsets $\mathsf{w}o$ and o differ by a vector of $\mathsf{l}\mathbb{Z}^3$; the two offsets thus give the same walls and cells. Each generator of W permutes the coordinate directions up to sign and conjugates the coordinate-wall reflections to coordinate-wall reflections. It maps folds to folds, up to reindexing and possible overall conjugation, so preserves the seminorms by invariance of the cube law; a wall meets the interior of a cell $\square_{\mathbf{k}}$ only if it passes through its centre $o+\mathsf{l}\mathbf{k}$, and then its reflection maps $\square_{\mathbf{k}}$ onto itself; and the stabiliser $\mathsf{W}_{\mathbf{k}}$ of $\square_{\mathbf{k}}$ in W is generated by the reflections in the walls through its centre, $s_{\mathbf{k}}:=\#\mathsf{W}_{\mathbf{k}}\in\{1,2,4,8\}$. Let $\ell'\in\mathfrak{L}$, $2\mathsf{l}\le\ell'\le\ell/L$, let $\mathcal{K}_0$ be a finite set of indices of cells whose interiors meet that of C, let $F_{\mathbf{k}}$ be functions of the bonds of $\square_{\mathbf{k}}\cap\mathsf{C}$, and $H_{\mathbf{k}}:=\prod_{\mathsf{v}\in\mathsf{W}_{\mathbf{k}}}(\mathsf{v}F_{\mathbf{k}})^{(\cdot)}$, conjugated for odd v. Then

$$q_\diamond\Big(\prod_{\mathbf{k}\in\mathcal{K}_0}F_{\mathbf{k}}\Big)\le\exp\big[\tfrac12h^3(p_{\ell'}-p_\ell)\big]\prod_{\mathbf{k}\in\mathcal{K}_0}\|H_{\mathbf{k}}\|^{1/s_{\mathbf{k}}}_{\mathrm{ch},\ell'}.$$

Indeed, if $\gamma\mathsf{w}\square_{\mathbf{k}}=\mathsf{w}'\square_{\mathbf{k}'}$ with $\gamma\in\Gamma^\diamond_\ell$, $\mathsf{w},\mathsf{w}'\in\mathsf{W}$, $\mathbf{k},\mathbf{k}'\in\mathcal{K}_0$, then $\mathbf{k}=\mathbf{k}'$ and $\mathsf{w}'^{-1}\gamma\mathsf{w}\in\mathsf{W}_{\mathbf{k}}$, by the simple transitivity and the description of the stabilisers; so $\mathrm{FOLD}\prod_{\mathbf{k}}F_{\mathbf{k}}$ is a product of the functions $(\mathsf{w}H_{\mathbf{k}})^{(\cdot)}$ on cells of (i,o) pairwise incongruent modulo $\Gamma^\diamond_\ell$, $2M_h^3/s_{\mathbf{k}}$ of them for each $\mathbf{k}$, each of the seminorm $\|H_{\mathbf{k}}\|_{\mathrm{ch},\ell'}$; Step 5 with 1 in the other cells bounds $\mathsf{l}_{\Gamma^\diamond_\ell}(\mathrm{FOLD}\prod F_{\mathbf{k}})$ by $e^{\ell^3p_{\ell'}}\prod_{\mathbf{k}}\|H_{\mathbf{k}}\|^{2M_h^3/s_{\mathbf{k}}}_{\mathrm{ch},\ell'}$, Step 2 gives $Z_{\Gamma^\diamond_\ell}[0]\ge e^{\ell^3p_\ell}$, and $\ell^3/2M_h^3=\frac12h^3$.

Step 7. At a first-passage datum $(K,\beta)\in\mathfrak{d}(g)$ on any admitted side λ, Theorem YM3_I:AD and [7, Lem. N.1] give a vacuum energy E_λ with

$$E_\lambda-C_g\lambda^3\le\log Z_{K,\lambda,\beta}\le E_\lambda+C_{\mathrm{S}}\lambda^3,\qquad|E_{\lambda'}\lambda'^{-3}-E_\lambda\lambda^{-3}|\le C_{\mathrm{gap}}.$$

Thus $p_{\lambda'}-p_\lambda\le C_{\mathrm{v}}$. The cell-normalizer construction of §5.2.1 also applies to supports in balls of radius R with their centres at distance at least $R+D$ from the walls of a board of side l. If $\underline{f}$ has n such entries, use the polydisc $\mathbb{D}_\varrho(\underline{f})=\{z:\sum_q|z_q|\|f_q\|_\sharp<\varrho\}$ and write $\Pi_{\ell''}(z)$ for the product over occupied cells of the seminorms of $e^{\mathcal{O}_K(\sum z_qf_q)}$ in those cells, with each sum restricted to that cell. Equation eq. 5.xxviii gives a holomorphic $\mathcal{E}$ with $\mathcal{E}(0)=0$ and

$$|e^{-\mathcal{E}(z)}|\Pi_{\ell''}(z)\le\mathsf{Q}(\mathsf{l};R,D)^n,\qquad\mathsf{Q}(\mathsf{l};R,D)=\exp[C_{\mathrm{v}}\mathsf{l}^3+\Phi_1(R,D;\mathsf{l})]$$

on the stated polydisc and all admitted $\ell''\ge 2\mathsf{l}$. The bound is uniform in the cutoff, coupling datum, side, board offset and position.

Step 8: centred polynomials in one cell. Let $(K,\beta)\in\mathfrak{d}(g)$, (i,o) a board with the side l, $R,D,\mathsf{d}>0$, x_0 a point at the distance $\ge R+D$ from the walls and $\square$ the cell that holds it, $N\ge 1$, $X=(f_1,\dots,f_N)$ functions of Lip_c with supports in $\mathbb{B}(x_0,R)$ at pairwise distances $\ge\mathsf{d}$, and $\ell,\ell'\in\mathfrak{L}(g)$ with $\ell'\ge 2\mathsf{l}$ and $\ell\ge\max\{2\mathsf{l},16N(R+1),8R+8\}$. Then $X_K^{\mu_{K,\ell,\beta}}$ is a function of the inner bonds of $\square$, and

$$\big\|X_K^{\mu_{K,\ell,\beta}}\big\|_{\mathrm{ch},\ell'}\le\mathsf{P}_N\prod_{q=1}^N\|f_q\|_\sharp,\qquad\mathsf{P}_N:=\sum_{j=0}^N\binom{N}{j}\mathsf{k}_{N-j}\,\mathsf{g}_j,$$

where $\mathsf{g}_0 := 1$, $\mathsf{g}_j := \mathsf{Q}(\mathsf{l}; R, D)^N (N/\varrho)^j$ for $j \ge 1$, $\mathsf{t}_m := \sum_{\pi \in \mathrm{Part}_{\ge 2}(m)} \prod_{I \in \pi} C^g_{|I|}(\mathsf{d}; R)$, $\mathsf{k}_0 := 1$ and $\mathsf{k}_m := \mathsf{t}_m + \sum_{j=1}^m \binom{m}{j} \mathsf{k}_{m-j} \mathsf{g}_j$: a number that depends on none of K, β, ℓ, ℓ', the offset and the position. If some f_q is 0, then $\mathcal{O}_K(f_q) = 0$, the centred product $X_K^{\mu_{K,\ell,\beta}}$ is 0 and $\|f_q\|_\sharp = 0$, so that the two sides of the claim are 0; let now no f_q be 0. Let $\mathsf{X}_q := \mathcal{O}_K(f_q)$, real bounded continuous functions of the inner bonds of $\square$, $m_q := \mu_{K,\ell,\beta}(\mathsf{X}_q)$, $\mathcal{E}$ the function of Step 7 for X and $\mathsf{E}_z := \exp[\sum_q z_q \mathsf{X}_q - \mathcal{E}(z)]$; as one cell is occupied, homogeneity gives $\|\mathsf{E}_z\|_{\mathrm{ch},\ell''} \le \mathsf{Q}(\mathsf{l}; R, D)^N$ at $\ell'' = \ell$ and at $\ell'' = \ell'$. For $B \subset \{1, \dots, N\}$ let $\mathsf{G}_B := \partial_B \mathsf{E}_z|_{z=0}$, a polynomial in the X_q. Cauchy's formula on the polydisc of the radii $r_q < \varrho/(N\|f_q\|_\sharp)$, which lies in $\mathbb{D}_\varrho(X)$, writes G_B as a limit in the sup norm of Riemann sums of values of E_z; the seminorm being subadditive, homogeneous and below the sup norm, $\|\mathsf{G}_B\|_{\mathrm{ch},\ell''} \le \mathsf{g}_{|B|} \prod_{q \in B} \|f_q\|_\sharp$. From $e^{\sum z_q(\mathsf{X}_q - m_q)} = e^{\mathcal{E}(z) - \sum z_q m_q} \mathsf{E}_z$ and Leibniz's rule, $\prod_{q \in A}(\mathsf{X}_q - m_q) = \sum_{B \subset A} \kappa_{A \setminus B} \mathsf{G}_B$ with $\kappa_C := \partial_C (e^{\mathcal{E}(z) - \sum z_q m_q})(0)$. Taking the mean under $\mu_{K,\ell,\beta}$, the left side is $\sigma_{\mu_{K,\ell,\beta}}(X_A)$, a sum over $\mathrm{Part}_{\ge 2}(A)$ of products of torus cumulants; take $y \in a_K \mathbb{Z}^3$ with $|y - x_0|_\infty \le 1$: as $\mu_{K,\ell,\beta}$ is invariant under the translation by $-y$ (Step 1), each of these cumulants equals the cumulant of the functions translated by $-y$, which are supported in $[-R-1, R+1]^3$, a subset of $(-\frac{\ell}{4}, \frac{\ell}{4})^3$ as $\ell \ge 8R + 8$, and Proposition YM3_I:91.13 bounds it; so $|\sigma_{\mu_{K,\ell,\beta}}(X_A)| \le \mathsf{t}_{|A|} \prod_{q \in A} \|f_q\|_\sharp$, and induction on $|A|$ with $|\mu_{K,\ell,\beta}(\mathsf{G}_B)| \le \|\mathsf{G}_B\|_{\mathrm{ch},\ell}$ gives $|\kappa_A| \le \mathsf{k}_{|A|} \prod_{q \in A} \|f_q\|_\sharp$. The identity at $A = \{1, \dots, N\}$ and the bounds at $\ell'' = \ell'$ give the claim.

Step 9: a bound table on the diamonds. For $n \ge 2$ and $R > 0$ let $h(n, R)$ be the least power of L that is $\ge (n+1)\,\mathsf{l}(n, R)$, and put

$$Q^\diamond(n, R) := e^{\frac{n}{2} h(n,R)^3 C_{\mathrm{v}}} Q^\natural(n, R)^n, \qquad C^\diamond_n(\mathsf{d}; R) := \Big(\frac{n}{\varrho}\Big)^n \Big[\log 2 \,(2Q^\diamond(n, R) + 2)^n + \mathsf{U}(R, \mathsf{d})\Big],$$

$$Q^\diamond_1 := e^{\frac{1}{2} L^6 C_{\mathrm{v}}} \mathsf{Q}_1(L), \qquad C^\diamond_1(R) := (2R+3)^3 (1 + 40\sqrt{3}M)\, 2 \log 2\, (2Q^\diamond_1 + 2)/\varrho.$$

There are numbers $\ell_\diamond(n, R)$ such that for every $(K, \beta) \in \mathfrak{d}(g)$, every $\ell \in \mathfrak{L}$ with $\ell/L \in \mathfrak{L}(g)$ and $\ell \ge \ell_\diamond(n, R)$, and all functions $f_1, \dots, f_n$ of Lip_c of the type $(\mathsf{d}; R)$ with supports in $(-\frac{\ell}{8}, \frac{\ell}{8})^3$: $|S^T_n[\mu^\diamond_{K,\ell,\beta}](f_1, \dots, f_n)| \le C^\diamond_n(\mathsf{d}; R) \prod_q \|f_q\|_\sharp$ for $n \ge 2$, and $|\delta_{\mu^\diamond_{K,\ell,\beta}, \mu_{K,\ell,\beta}}(f_1)| \le C^\diamond_1(R) \|f_1\|_\sharp$. For $n \ge 2$, let $y_1, \dots, y_n$ be the centres of the balls and $\mathsf{l} = \mathsf{l}(n, R) \ge 8n(R+1)$. Fix a direction μ. The walls $x_\mu \in o_\mu + \mathsf{l}(\mathbb{Z} + \frac{1}{2})$ stay at the distance $\ge 2R+1$ from all the y_q unless o_μ falls, modulo l, within less than $2R+1$ of one of the n points $y_{q,\mu} - \frac{1}{2}$; on the circle $\mathbb{R}/\mathsf{l}\mathbb{Z}$ this excluded set is a union of n intervals of a total measure $\le n(4R+2) < \mathsf{l} - 4n$, so its complement consists of no more than n closed arcs whose measures add up to more than $4n$; one of these arcs is longer than 4, hence than a_K, and so meets $a_K\mathbb{Z}$. With o_μ taken there for each μ, every y_q lies at the distance $\ge 2R+1$ from the walls of the board (i, o) of the side l, and each support lies in the corresponding cell interior. Take besides a compatible diagonal board with $h = h(n, R)$ none of whose walls meets the interior of an occupied cell, which exists as $h/\mathsf{l} \ge n+1$ and each occupied cell excludes one class of c_r modulo h for each r; so each occupied cell lies in one diagonal cell, with $s_{\mathbf{k}} = 1$. For $\ell \ge 4h + 8\mathsf{l}$ no two diagonal cells that hold occupied cells are congruent modulo $\Gamma^\diamond_\ell$, as a diagonal cell has the sup-diameter h and $\mathrm{sys}(\Gamma^\diamond_\ell) = \frac{\ell}{2}$. With $w = \sum_q z_q f_q$, Step 4 over the at most n diagonal cells, Step 6 in each of them (after an element of W that carries it to C) and Step 7 at $\ell' = \ell/L \ge 2\mathsf{l}$ give $|\mu^\diamond_{K,\ell,\beta}(e^{\mathcal{O}_K(w)})| \le e^{\frac{n}{2} h^3 C_{\mathrm{v}}} \Pi_{\ell/L}(z)$; the normaliser of Proposition YM3_I:91.12(2) bounds $\Pi_{\ell/L}(z)$ by $|e^{\mathcal{E}(z)}| Q^\natural(n, R)^n$ on $\mathbb{D}_\varrho(\underline{f})$ and bounds $\partial_{z_1} \cdots \partial_{z_n} \mathcal{E}(0)$ by $(n/\varrho)^n \prod \|f_q\|_\sharp\, \mathsf{U}(R, \mathsf{d})$, as U does not increase in its second argument; and Proposition YM3_I:91.11 gives the bound, with $\ell_\diamond(n, R) := \max\{4h + 8\mathsf{l}, 2L\mathsf{l}\}$. For $n = 1$: write $f = \sum_{v \in \mathbb{Z}^3} f\chi(\cdot - v)$ with $\chi(x) = \prod_\mu \max\{0, 1 - |x_\mu|\}$, at most $(2R+3)^3$ terms, each of the norm $\le (1 + 40\sqrt{3}M)\|f\|_\sharp$; for each v take the board of the side L with the offset v, which has v as the centre of a cell at the distance $\frac{L}{2} \ge 3$ from its walls since $L \ge 13$, and the compatible diagonal board $h = L^2$, $c_r = \mathsf{n}_r \cdot v + L$ ($\mathsf{n}_1 = \mathsf{n}_+$, $\mathsf{n}_2 = \mathsf{n}_-$, $\mathsf{n}_3 = e_2$), none of whose walls passes through v; Proposition YM3_I:91.12(1) gives a normaliser with the bound $\mathsf{Q}_1(L)$ on all sides of

$\mathfrak{L}(g)$, Steps 4, 6, 7 give $|e^{-\mathcal{E}}\mu^\diamond(e^{\mathcal{O}_K(zf_v)})| \le Q_1^\diamond$ for $\ell \ge 2L^3$, the cube chessboard bound gives $|e^{-\mathcal{E}}\mu_{K,\ell,\beta}(e^{\mathcal{O}_K(zf_v)})| \le \mathsf{Q}_1(L)$, and the difference bound of Proposition YM3_I:91.11 at $n=1$ and the sum over v give the bound.

Step 10: columns. Let $F = \sum_i \zeta_i X_i \in \mathcal{D}$, $\rho(F)$ the larger of 1 and the largest $|x|$ on the supports of its entries, and l_F the least power of L with $\mathsf{l}_F \ge 2\rho(F)+2$; a power h of L is *admitted* for F if $h \ge L\mathsf{l}_F$. Then $F \in \mathbb{C}\mathfrak{S}(\{0 < x_1 + x_3 < h\})$. Let $(K_j, \ell_j, \beta_j)_j$ be a sequence of tori at g, $\mu_j := \mu_{K_j,\ell_j,\beta_j}$, $\mu_j^\diamond := \mu^\diamond_{K_j,\ell_j,\beta_j}$, and $F_j := \sum_i \zeta_i (X_i)^{\mu_j}_{K_j}$. There is a number $\mathsf{q}_h(F)$, which depends on F, h, g and the constants alone, such that for all large j, with the diagonal board $(h; 0, -\mathsf{l}_F, -\mathsf{l}_F)$ on $\Gamma^\diamond_{\ell_j}$, F_j is a function of the bonds of C and $\|F_j\|_{\mathrm{col},h} \le q_\diamond(F_j) \le \mathsf{q}_h(F)$. Indeed, this diagonal board is compatible with the board $(i,0)$ of the side l_F, and the one wall that meets the interior of the cell $[-\frac{\mathsf{l}_F}{2}, \frac{\mathsf{l}_F}{2}]^3$ is the plane $\{x_1 + x_3 = 0\}$, so that $\mathsf{W}_0 = \{1, \Theta_\diamond\}$; the plaquettes at which an entry does not vanish lie in that cell and on the upper side of the plane for all sufficiently small a_K, by compact separation from the plane, so F_j is a function of the bonds of $\square_0 \cap \mathsf{C}$. Step 4, Step 6 with $\mathcal{K}_0 = \{0\}$ and $\ell' = \ell_j/L$, and Step 7 give $q_\diamond(F_j) \le e^{\frac12 h^3 C_{\mathrm{v}}} \|H_j\|^{1/2}_{\mathrm{ch},\ell_j/L}$ with $H_j = F_j \overline{\Theta_\diamond F_j} = \sum_{i,k} \zeta_i \bar\zeta_k \, (X_i \cdot \Theta_\diamond X_k)^{\mu_j}_{K_j}$, by the invariance of μ_j under $\Theta_\diamond$; and Step 8 at $x_0 = 0$, $R = \rho(F)$, $D = 1$, d the least of 1 and of the separations of the tuples $X_i \cdot \Theta_\diamond X_k$, bounds each term in which $X_i \cdot \Theta_\diamond X_k$ has at least one entry; a term with $X_i = X_k = \varnothing$ is the constant 1, of seminorm 1. So $\mathsf{q}_h(F) := e^{\frac12 h^3 C_{\mathrm{v}}} [\sum_{i,k} |\zeta_i \zeta_k| \, \mathsf{P}_{N_{ik}} \|X_i\|_\sharp \|X_k\|_\sharp]^{1/2}$ serves, N_{ik} the length of $X_i \cdot \Theta_\diamond X_k$, $\mathsf{P}_0 := 1$, and $\|X\|_\sharp$ the product of the norms of the entries, 1 for the empty tuple. Moreover, in the setting of Step 3 at $(\mathsf{n}_+, 0, h)$ on $\Gamma^\diamond_\ell$, for a power p of L with $2N' := \ell/\mathsf{p}h$ an even integer, a function f of the bonds of $\mathbb{S}_1$, functions G, G' of the bonds of $\{0 \le x_1 + x_3 \le \mathsf{p}h\}$ and $k = \mathsf{p}k'$ with $2k' + 2 \le 2N'$,

$$\Big| \mu^\diamond \Big(\overline{\Theta_\diamond G'} \prod_{i=1}^{2k} f^{[i]} \, \tau_{kh\mathsf{n}_+} G \Big) \Big| \le \|G'\|_{\mathrm{col},\mathsf{p}h} \, \|G\|_{\mathrm{col},\mathsf{p}h} \, \|f\|^{2k}_{\mathrm{col},h},$$

the column seminorms taken with the walls at the heights $\mathsf{p}h\mathbb{Z}$ and $h\mathbb{Z}$: the block $\mathsf{b} := \prod_{i \le \mathsf{p}} f^{[i]}$ is a function of the first slab of the height $\mathsf{p}h$, its copies at the height $\mathsf{p}h$ are the products of p consecutive copies of f, so $\|\mathsf{b}\|_{\mathrm{col},\mathsf{p}h} = \|f\|^{\mathsf{p}}_{\mathrm{col},h}$, and Step 3 at the height $\mathsf{p}h$ with the factors $\mathsf{b}^{[i'']}$, $i'' \le 2k'$, $G^{[2k'+1]} = \tau_{kh\mathsf{n}_+} G$, $G'^{[2N']} = \overline{\Theta_\diamond G'}$, and 1 in the other slabs, gives the bound.

Step 11: limits along the diamonds. Let now $(K_j, \ell_j, \beta_j)_j$ be the defining sequence of the hypothesis. Pass to a subsequence along which $E_j := E(K_j, \ell_j, \beta_j) \to E_\infty := \liminf_j E(K_j, \ell_j, \beta_j) \in [0, \infty)$; it is again a defining sequence of tori of S. With $O_j := (-\frac{\ell_j}{8}, \frac{\ell_j}{8})^3$, the forms $\Phi_n^{(j)} := S_n^T[\mu_j^\diamond]$ on $\mathfrak{S}_n(O_j)$, $n \ge 2$, and $\Phi_1^{(j)} := \delta_{\mu_j^\diamond, \mu_j}$ make a symmetric sequence of forms with the table $\underline{C}^\diamond = (C_n^\diamond)_{n \ge 1}$ from 1 on, by Step 9, the indices being those from which $\ell_j \ge \ell_\diamond(n, R)$ and $\ell_j/L \in \mathfrak{L}(g)$; by Proposition YM3_I:90.1 a further subsequence converges to a family $S^\diamond$ with the same table $\underline{C}^\diamond$, and along it $\sigma'(X) := \lim_j \sigma_{\mu_j^\diamond, \mu_j}(X) = \sum_{\pi \in \mathrm{Part}(n)} \prod_{I \in \pi} S^\diamond_{|I|}(X_I)$ for every separated tuple X, by the formula of the setting. We fix this subsequence. Then: (P1) σ' and $\sigma := \sigma_S$ are symmetric functionals on separated tuples, real on tuples, invariant under all translations of $\mathbb{R}^3$, under $\Theta_\diamond$ and under Θ_2; for σ this is Proposition YM3_I:92.3, since $\Theta_\diamond, \Theta_2 \in W_3$. For σ' use the finite-lattice invariance under those reflections and lattice translations from Step 1. To pass a translation $v \in \mathbb{R}^3$ to the limit, approximate it by $v_j \in a_{K_j}\mathbb{Z}^3$. The translated tests differ by $o(1)$ in C^1, have supports in fixed compact sets, and remain separated. The table and multilinearity bound each resulting difference by $o(1)$. For $\eta \in C^1_c$ with $\int \eta = 1$, use both orders of the convolution $f * \eta = \eta * f$. The Riemann sums of translates converge in C^1 with supports in a fixed ball. Translation invariance and the first-order table then give $S_1^\diamond(f) = S_1^\diamond(\eta) \int f$. Its scalar coefficient is real. The inverse moment–cumulant formula identifies all the connected functions of σ' with $S_n^\diamond$. (P2) σ' is reflection positive at $\Sigma_\diamond$ and at $(e_2, 0)$, and σ at $(e_2, 0)$: for $F \in \mathcal{D}$ and large j, F_j is a function of the bonds of $\{0 \le x_1 + x_3 \le \frac{\ell_j}{2}\}$, $\overline{\Theta_\diamond F_j} F_j = (\Theta_\diamond \bar F \cdot F)^{\mu_j}_{K_j}$, and $\mu_j^\diamond(\overline{\Theta_\diamond F_j} F_j) \ge 0$ by Proposition YM3_I:91.4 at

the pair of the heights 0 and $\frac{\ell_j}{2}$; so $\sigma'(\Theta_\diamond \bar F\cdot F)\ge 0$, and the same at the site mirror $\Sigma(e_2,0)$ and the pair of $x_2=0$ and $x_2=\frac{\ell_j}{2}$; for σ it is Proposition YM3_I:92.4. (P3) $|\sigma(\Theta_\diamond\bar F\cdot F)|\le e^{E_\infty}\sigma'(\Theta_\diamond\bar F\cdot F)$ for $F\in\mathcal D$: Step 2 at $G=F=F_j$ gives $|\mu_j(\overline{\Theta_\diamond F_j}F_j)|\le e^{E_j}\mu_j^\diamond(\overline{\Theta_\diamond F_j}F_j)$; on the left, $\mu_j((\Theta_\diamond\bar F\cdot F)^{\mu_j}_{K_j})$ is the sum over $\mathrm{Part}_{\ge 2}$ of products of torus cumulants by the moment–cumulant formula, which tends to $\sigma_S(\Theta_\diamond\bar F\cdot F)$ along a defining sequence; the right side tends to $e^{E_\infty}\sigma'(\Theta_\diamond\bar F\cdot F)$. (P4) By (P1), (P2), Proposition YM3_I:94.1 applies to σ' at the unit vectors $u_\diamond$ and e_2: $\mathcal H:=\mathcal H(\sigma',u_\diamond)$, the completion of $\mathcal D$ modulo the null vectors for $\langle F,F'\rangle=\sigma'(\Theta_\diamond\bar F\cdot F')$, carries the semigroup $\mathcal T_t[F]=[\tau_{tu_\diamond}F]$ of self-adjoint operators, $0\le\mathcal T_t\le 1$, the unitary group $\mathcal U(v)[F]=[\tau_vF]$, $v\perp u_\diamond$, commuting with it and fixing $\Omega=[\varnothing]$, and $\mathcal T_t\to P_0$ strongly as $t\to\infty$, P_0 the projection onto $\ker H$; and $\mathcal H^{(2)}:=\mathcal H(\sigma',e_2)$ carries the like objects $\mathcal T_t^{(2)}$, $\mathcal U^{(2)}(v)$, $P_0^{(2)}$. Note $[\mathsf s_yF]=\mathcal T_{y/\sqrt2}[F]$ for $y\ge 0$, and the classes do not depend on the order of the entries, σ' being symmetric. (P5) For $X,G\in\mathcal D$, h admitted for X and a power $\mathsf p$ of L with $\mathsf ph$ admitted for G, and with the copies $X^{[1]}:=X$, $X^{[i+1]}:=\overline{\Theta_{(u_\diamond,ih/\sqrt2)}X^{[i]}}$ in the slabs of the height h: for all $k\in\mathsf p\mathbb N$,

$$\big|\sigma'(\Theta_\diamond\bar G\cdot X^{[1]}\cdots X^{[2k]}\cdot\mathsf s_{2kh}G)\big|\le \mathsf q_{\mathsf ph}(G)^2\,\mathsf q_h(X)^{2k}.$$

At large j the heights ih lie in $a_{K_j}\mathbb Z$, so the copies are lattice copies and $\mathsf s_{2kh}=\tau_{kh\mathsf n_+}$ is a lattice translation; the column bound of Step 10 and the bounds of Step 10 on the column seminorms give the inequality at j, and the left side converges.

Step 12: a bound on columns gives a bounded multiplication. Let $X\in\mathcal D$ have its entries supported in $\{0<x_1+x_3<h\}$, and put $X^\dagger:=\mathsf s_h\Theta_\diamond\bar X$, the conjugated mirror image of X in the plane of the height $\frac h2$, which lies in the same slab; then $X^{[2]}=\mathsf s_hX^\dagger$ and $X^{[i+2]}=\mathsf s_{2h}X^{[i]}$. For $\varsigma\in\{\sigma,\sigma'\}$ and $G,G'\in\mathcal D$, the invariance of ς under $\mathsf s_{-h}$, the relation $\Theta_\diamond\mathsf s_y=\mathsf s_{-y}\Theta_\diamond$ and the symmetry give

$$\varsigma(\Theta_\diamond\bar G'\cdot X\cdot\mathsf s_hG)=\varsigma(\Theta_\diamond\overline{(X^\dagger\cdot\mathsf s_hG')}\cdot G),$$

without any positivity. If besides h is admitted for X, then $G\mapsto X\cdot\mathsf s_hG$ and $G\mapsto X^\dagger\cdot\mathsf s_hG$ pass to the classes and extend to bounded operators $A_{X,h}$ and $A_{X^\dagger,h}=A_{X,h}^*$ of $\mathcal H$ of norms $\le\mathsf q_h(X)$. Indeed, with $\mathsf C_1G:=X^\dagger\cdot\mathsf s_hG$, $\mathsf C_2G:=X\cdot\mathsf s_hG$ and $\mathsf B:=\mathsf C_2\mathsf C_1$, the identity for σ' says $\langle G',\mathsf C_2G\rangle=\langle\mathsf C_1G',G\rangle$, so $\langle G',\mathsf BG\rangle=\langle\mathsf C_1G',\mathsf C_1G\rangle=\langle\mathsf BG',G\rangle$ and $\mathsf B^kG=X^{[1]}\cdots X^{[2k]}\cdot\mathsf s_{2kh}G$; the numbers $a_k:=\langle G,\mathsf B^kG\rangle$ satisfy $a_{2i}=\|\mathsf B^iG\|^2$, $a_{2i+1}=\|\mathsf C_1\mathsf B^iG\|^2$ and, by Schwarz's inequality, $a_k^2\le a_{k-1}a_{k+1}$; hence $a_1\le a_0^{1-1/k}a_k^{1/k}$, and (P5) along $k\in\mathsf p\mathbb N$ gives $\|\mathsf C_1G\|^2=a_1\le\mathsf q_h(X)^2\|G\|^2$; then $|\langle G',\mathsf C_2G\rangle|=|\langle\mathsf C_1G',G\rangle|\le\mathsf q_h(X)\|G'\|\|G\|$. Call a pair (B,y), $y>0$, $B\in\mathbb C\mathfrak S(\{0<x_1+x_3<y\})$, *bounded* if there is a bounded operator $A_{B,y}$ of $\mathcal H$ with $A_{B,y}[G]=[B\cdot\mathsf s_yG]$ for $G\in\mathcal D$; then $A_{B,y}\Omega=[B]$; $(B\cdot\mathsf s_yB',y+y')$ is bounded with the operator $A_{B,y}A_{B',y'}$; and for $v\perp u_\diamond$, (τ_vB,y) is bounded with the operator $\mathcal U(v)A_{B,y}\mathcal U(v)^*$.

Step 13: the operator $\mathsf R$. The form $\mathfrak b(G,F):=\sigma(\Theta_\diamond\bar G\cdot F)$ on $\mathcal D$ is Hermitian, by the reality, the invariance under $\Theta_\diamond$ and the symmetry of σ (P1), and $|\mathfrak b(F,F)|\le e^{E_\infty}\|F\|^2$ by (P3); polarisation of the Hermitian form gives $|\mathfrak b(G,F)|\le e^{E_\infty}\|G\|\|F\|$. So there is exactly one bounded self-adjoint operator $\mathsf R$ of $\mathcal H$ with $\sigma(\Theta_\diamond\bar G\cdot F)=\langle[G],\mathsf R[F]\rangle$, $\|\mathsf R\|\le e^{E_\infty}$, and in particular $\sigma(Z)=\langle\Omega,\mathsf R[Z]\rangle$ for $Z\in\mathcal D$. The invariance of σ under the translations, with $\tau_{-tu_\diamond}\Theta_\diamond=\Theta_\diamond\tau_{tu_\diamond}$ and $\tau_v\Theta_\diamond=\Theta_\diamond\tau_v$ for $v\perp u_\diamond$, shows that $\mathsf R$ commutes with every $\mathcal T_t$ and every $\mathcal U(v)$; and the identity of Step 12 for $\varsigma=\sigma$ shows $\langle[G'],\mathsf RA_{X,h}[G]\rangle=\langle A_{X^\dagger,h}[G'],\mathsf R[G]\rangle$, so that $\mathsf R$ commutes with $A_{X,h}$ and with $A_{X^\dagger,h}$ for every $X\in\mathcal D$ and every h admitted for X. It remains to show $\mathsf R\ge 0$.

Step 14: plateaux in the plane of $u_\diamond$ *and* e_2. Fix $t_1,s_1>0$; $\mathsf T:=\mathcal T_{t_1}$, $U:=\mathcal U(s_1e_2)$, $\mathsf E_U$ the projection onto $\ker(U-1)$, $P':=P_0\mathsf E_U$, and $x(k,m):=kt_1u_\diamond+ms_1e_2$. As P_0 is the strong limit of the $\mathcal T_t$, it commutes with U and $\mathsf R$; by von Neumann's ergodic theorem $\mathsf E_U$ commutes with P_0, the $\mathcal T_t$ and $\mathsf R$; so P' is a projection with $P'\mathcal T_t=P'=P'U$, $P'\Omega=\Omega$, $P'\mathsf R=\mathsf RP'$. *Claim:* for $A,B\in\mathbb C\mathfrak S(\mathbb R^3)$ the numbers $\sigma'(A\cdot\tau_{x(k,m)}B)$ converge as k and m tend to $\pm\infty$ together, with one and the same limit $c(A,B)$ in the four quadrants; $c(\Theta_\diamond\bar G,F)=\langle[G],P'[F]\rangle$ for $F,G\in\mathcal D$; $c(\tau_zA,\tau_{z'}B)=c(A,B)$

for $z, z' \in \mathbb{R}u_\diamond + s_1\mathbb{Z}e_2$; and $\mathcal{T}_t U^m \to P'$ weakly as $t \to \infty$ and $|m| \to \infty$ together. In the first picture, after a translation along $u_\diamond$, $\sigma'(A \cdot \tau_{x(k,m)}B) = \langle \chi, \mathsf{T}^{k-k_0}U^m\chi'\rangle$ for $k \geq k_0$ and all m, with classes $\chi, \chi' \in \mathcal{H}$, and it differs from $h_1(m) := \langle \chi, P_0U^m\chi'\rangle$ by at most $\epsilon_1(k-k_0) \to 0$, uniformly in m; in the second picture, in $\mathcal{H}^{(2)}$, it differs from a function $h_2(k)$ by at most $\epsilon_2(m-m_0) \to 0$, uniformly in k; the same for $k \to -\infty$ or $m \to -\infty$ with the roles of A and B exchanged, as $\sigma'(A \cdot \tau_x B) = \sigma'(B \cdot \tau_{-x}A)$. These approximations make $h_1(m)$ and $h_2(k)$ Cauchy sequences at $\pm\infty$ with equal limits in each quadrant, and the means $\frac{1}{N}\sum_{m\leq N} h_1(\pm m)$, which tend to $\langle \chi, P_0\mathsf{E}_U\chi'\rangle$ by von Neumann's theorem, together with the like means of h_2 and of the second functions, identify the four limits. At $A = \Theta_\diamond\bar{G}$, $B = F$ this gives $h_1(m) = \langle [G], P_0U^m[F]\rangle \to \langle [G], P'[F]\rangle$ as $|m| \to \infty$, hence the weak convergence. The invariance of c follows from $P'\mathcal{T}_t = P'$.

Step 15: the half turn acts trivially at infinity. Let $\rho := \Theta_\diamond\Theta_2$, the linear map with $\rho u_\diamond = -u_\diamond$, $\rho e_2 = -e_2$, $\rho\mathsf{n}_- = \mathsf{n}_-$; σ and σ' are invariant under it. For $Y \in \mathbb{C}\mathfrak{S}(\mathbb{R}^3)$ put $\pi(Y) := P'[\mathsf{s}_y Y]$ with y so large that $\mathsf{s}_y Y \in \mathcal{D}$; it does not depend on y, it is linear, $\pi(\tau_x Y) = \pi(Y)$ for $x \in \mathbb{R}u_\diamond + s_1\mathbb{Z}e_2$, the vectors $\pi(Y)$ are dense in $\mathcal{K} := P'\mathcal{H}$, and $\langle \pi(G), \pi(F)\rangle = c(\Theta_\diamond\bar{G}, F)$ by Step 14. *Claim:* $\pi(\rho Y) = \pi(Y)$. The invariance of σ' under ρ and $\rho\tau_x = \tau_{-x}\rho$ for x in that plane give $\langle \pi(\rho G), \pi(\rho F)\rangle = \langle \pi(G), \pi(F)\rangle$, the four limits being one; so $\mathsf{V}\pi(Y) := \pi(\rho Y)$ extends to a unitary operator of $\mathcal{K}$ with $\mathsf{V}^2 = 1$, $\mathsf{V} = \mathsf{V}^*$. Further $\langle \pi(Y), \mathsf{V}\pi(Y)\rangle = c(\Theta_\diamond\bar{Y}, \rho Y) = c(\Theta_2\bar{Y}, Y)$, by the invariance under $\Theta_\diamond$ and Θ_2. For large m, $V := \tau_{ms_1e_2}Y \in \mathbb{C}\mathfrak{S}(\{x_2 > 0\})$, and $\varphi_m(k) := \sigma'(\Theta_2\bar{V} \cdot \tau_{kt_1u_\diamond}V) = \sigma'(\Theta_2\bar{Y} \cdot \tau_{x(k,2m)}Y)$; as Θ_2 commutes with $\tau_{tu_\diamond}$, $\sum_{a,b\leq N}\varphi_m(b-a) = \sigma'(\Theta_2\bar{V}_N \cdot V_N) \geq 0$ with $V_N := \sum_{a\leq N}\tau_{at_1u_\diamond}V$ (P2); $\varphi_m(k)$ tends to $h_1(2m)$ and to $h_1^-(2m)$ as $k \to \pm\infty$, where h_1 is the function of the first picture of Step 14 for the pair $(A, B) = (\Theta_2\bar{Y}, Y)$ and $h_1^-(m) := \langle \chi^-, P_0U^{-m}\chi'^-\rangle$ is built, as h_1 is, from the classes χ^-, χ'^- that the first picture gives to the pair taken in the other order, $(Y, \Theta_2\bar{Y})$, as $\sigma'(A \cdot \tau_{x(k,m)}B) = \sigma'(B \cdot \tau_{x(-k,-m)}A)$; so the means give $\frac{1}{2}(h_1(2m) + h_1^-(2m)) \geq 0$, and as $m \to \infty$, both terms tending to $c(\Theta_2\bar{Y}, Y)$ by Step 14, as limits in the quadrants of $k, m \to +\infty$ and of $k \to -\infty$, $m \to +\infty$, $c(\Theta_2\bar{Y}, Y) \geq 0$. So $\mathsf{V} \geq 0$ on a dense subspace, hence $\mathsf{V} \geq 0$; a self-adjoint unitary $\mathsf{V} \geq 0$ is 1.

Step 16: at infinity a multiplication reads π alone. Let (B, y_B) be a bounded pair, $H \in \mathcal{D}$, $y > 0$ with $H^\rho := \mathsf{s}_y\rho H \in \mathcal{D}$ and h' admitted for H^ρ. Then $P'A_{B,y_B}\pi(H) = P'A_{H^\rho,h'}\pi(B)$. For $x = x(k,m)$, $k, m \to +\infty$: $[B \cdot \tau_x H] = A_{B,y_B}\mathcal{T}_{kt_1 - y_B/\sqrt{2}}U^m[H]$, which tends weakly to $A_{B,y_B}P'[H]$ by Step 14, so $P'[B \cdot \tau_x H] \to P'A_{B,y_B}\pi(H)$; on the other side, by Step 15 and the invariance of π under τ_x, $P'[B \cdot \tau_x H] = \pi(\rho B \cdot \tau_{-x}\rho H) = \pi(H^\rho \cdot \tau_x\mathsf{s}_y\rho B)$, and writing $\tau_x\mathsf{s}_y\rho B = \mathsf{s}_{h'}\tau_{t'u_\diamond}\tau_{ms_1e_2}B^\rho$ with $B^\rho := \mathsf{s}_{y'}\rho B \in \mathcal{D}$ and $t' \to \infty$, this is $P'A_{H^\rho,h'}\mathcal{T}_{t'}U^m[B^\rho] \to P'A_{H^\rho,h'}\pi(\rho B) = P'A_{H^\rho,h'}\pi(B)$. As the $\pi(H)$, $H \in \mathcal{D}$, are dense in $\mathcal{K}$, $P'A_{B,y_B}P'$ depends only on $\pi(B)$.

Step 17: $\mathsf{R} \geq 0$. Let $F \in \mathcal{D}$, h admitted for F, $\Phi := \Theta_\diamond\bar{F} \cdot F$; up to the order of the entries $\Theta_\diamond\bar{\Phi} = \Phi$, so $\Theta_2\bar{\Phi} = \rho\Phi$. Choose s_1 with $|x_2| < s_1$ on the supports of Φ. $\mathsf{A} := A^*_{F,h}A_{F,h} = A_{F^\dagger,h}A_{F,h} \geq 0$ is the operator of the bounded pair $(\mathsf{s}_h\Phi, 2h)$; with $F_2 := \Theta_2\bar{F} \in \mathcal{D}$, for which h is admitted, $\mathsf{A}^\rho := A^*_{F_2,h}A_{F_2,h} \geq 0$ is the operator of $(\mathsf{s}_h\rho\Phi, 2h)$. Put $\mathsf{M} := P'\mathsf{A}P' \geq 0$. (i) $P'\mathsf{A}^\rho P' = \mathsf{M}$, by Step 16, as $\pi(\mathsf{s}_h\rho\Phi) = \pi(\rho\Phi) = \pi(\Phi) = \pi(\mathsf{s}_h\Phi)$. (ii) R commutes with A, A^ρ, M (Steps 13, 14). (iii) For every real polynomial $p(\lambda) = \sum_{i\leq d} c_i\lambda^i$, $\langle p(\mathsf{M})\Omega, \mathsf{R}\,p(\mathsf{M})\Omega\rangle \geq 0$: let $\Phi_N := \frac{1}{N}\sum_{a\leq N}\tau_{as_1e_2}\mathsf{s}_h\Phi$, supported in $\{x_2 > 0\}$ at heights in $(0, 2h)$, $\mathsf{g} > 2h$, $W_0 := \varnothing$, $W_i := \mathsf{s}_\mathsf{g}\Phi_N \cdot \mathsf{s}_{2\mathsf{g}}\Phi_N \cdots \mathsf{s}_{i\mathsf{g}}\Phi_N$ for $i \geq 1$, $W := \sum_i c_i W_i \in \mathbb{C}\mathfrak{S}(\{x_2 > 0\})$ and $\varphi(k) := \sigma(\Theta_2\bar{W} \cdot \tau_{kt_1u_\diamond}W)$; by the positivity of σ at $(e_2, 0)$ (P2), $\sum_{a,b\leq N'}\varphi(b-a) \geq 0$ for all N', and $\varphi(-k) = \overline{\varphi(k)}$; so if $\varphi(k)$ converges as $k \to \infty$, the real part of the limit is ≥ 0. With $\mathsf{A}_N := \frac{1}{N}\sum_a U^a\mathsf{A}U^{-a}$, $\mathsf{A}^\rho_N := \frac{1}{N}\sum_a U^{-a}\mathsf{A}^\rho U^a$ and $\mathsf{T}_\circ := \mathcal{T}_{(\mathsf{g}-2h)/\sqrt{2}}$, Step 12 gives $(\mathsf{T}_\circ\mathsf{A}_N)^i[G] = [\mathsf{s}_{-2h}W_i \cdot \mathsf{s}_{i\mathsf{g}}G]$ and $(\mathsf{T}_\circ\mathsf{A}^\rho_N)^i[G] = [\mathsf{s}_{-2h}\Theta_2\bar{W}_i \cdot \mathsf{s}_{i\mathsf{g}}G]$, and so, with $t(k) := kt_1 - i\mathsf{g}/\sqrt{2} \geq 0$ and Step 13,

$$\sigma\big(\Theta_2\bar{W}_i \cdot \tau_{kt_1u_\diamond}W_{i'}\big) = \big\langle \Omega,\ \mathsf{R}\,(\mathsf{T}_\circ\mathsf{A}^\rho_N)^i\,\mathcal{T}_{t(k)}\,(\mathsf{T}_\circ\mathsf{A}_N)^{i'}\Omega\big\rangle.$$

As $k\to\infty$, $\mathcal{T}_{t(k)}\to P_0$ strongly, so $\varphi(k)$ converges; as $\mathsf{g}\to\infty$, $\mathsf{T}_\circ\to P_0$ strongly; as $N\to\infty$, for every vector y of $\mathcal{K}$, on which U acts as 1, $P_0\mathsf{A}_NP_0y\to\mathsf{E}_UP_0\mathsf{A}y=\mathsf{M}y$ and $P_0\mathsf{A}_N^\rho P_0y\to P'\mathsf{A}^\rho P'y=\mathsf{M}y$, by von Neumann's theorem and (i), and the operators being uniformly bounded, $(P_0\mathsf{A}_NP_0)^i\Omega\to\mathsf{M}^i\Omega$ and $(P_0\mathsf{A}_N^\rho P_0)^i\Omega\to\mathsf{M}^i\Omega$; all the operators are bounded, self-adjoint and commute with R, and $P_0\Omega=\Omega$; so $\langle p(\mathsf{M})\Omega,\mathsf{R}p(\mathsf{M})\Omega\rangle$ is a limit of numbers with real parts ≥0, and it is real. (iv) With real polynomials $p_r\to\sqrt{\lambda}$ uniformly on $[0,\|\mathsf{M}\|]$, (ii) and (iii) give $\langle\Omega,\mathsf{RM}\Omega\rangle=\lim_r\langle p_r(\mathsf{M})\Omega,\mathsf{R}p_r(\mathsf{M})\Omega\rangle\ge0$. Finally, by Step 12, (ii), $P'\Omega=\Omega$ and $P'\mathsf{R}=\mathsf{R}P'$,

$$\sigma_S(\Theta_\diamond\bar F\cdot F)=\langle[F],\mathsf{R}[F]\rangle=\langle A_{F,h}\Omega,\mathsf{R}A_{F,h}\Omega\rangle=\langle\Omega,\mathsf{RA}\Omega\rangle=\langle\Omega,\mathsf{RM}\Omega\rangle\ge0.$$

This is (a); as the classes $[F]$ are dense, also $0\le\mathsf{R}\le e^{E_\infty}$.

Step 18: every diagonal mirror. By (a), σ_S is reflection positive at the diagonal mirror $\Sigma_\diamond$; it is symmetric and invariant under all translations of $\mathbb{R}^3$ and under W_3 (P1); so translate the plane and apply a signed permutation of the coordinates to obtain (b). Proposition YM3_I:92.4 supplies the coordinate planes. □

18.11.1. *Two-loop pressure. Weak coupling: the group and the cube.* We identify SU(2) with the unit quaternions, $U=\operatorname{Sc}U+\mathrm{i}\operatorname{Vec}U\cdot\sigma$, σ the Pauli matrices, and put $a(U):=1-\frac12\operatorname{tr}U=\frac12|U-\mathbf{1}|^2$, so that $a_p=a(\partial U(p))$ and, as $|\operatorname{Vec}U|^2=a(2-a)$,

$$a(U)=\tfrac12|\operatorname{Vec}U|^2+\tfrac12a(U)^2.$$

The chart $q(u):=(1-|u|^2)^{1/2}+\mathrm{i}u\cdot\sigma$, $u\in\mathbb{R}^3$, $|u|<1$, covers $\{\operatorname{Sc}U>0\}$, where the Haar measure is $\sigma_{\mathrm{H}}(1-|u|^2)^{-1/2}d^3u$, $\sigma_{\mathrm{H}}=\frac{1}{2\pi^2}$; and $\mathsf{z}(\lambda):=\int e^{-\lambda a(U)}dU$ lies between $c\lambda^{-3/2}$ and $(2/\pi)^{1/2}\lambda^{-3/2}$ for $\lambda\ge1$. For an even $N\ge4$ let T_N be the periodic cube N^3, $Z_N:=Z(N^3)$, $P_N:=N^{-3}\log Z_N$ and $\delta_N:=\delta(N^3)$ (Section 17.2); $h_\mu(U)$ is the holonomy of the closed straight line through 0 in the direction μ, and $\mathsf{H}_r:=\{|h_\mu-\mathbf{1}|\le r,\ \mu=1,2,3\}$. On T_N let C^0,C^1,C^2 be the $\mathbb{R}^3$-valued functions on the sites, on the positively oriented bonds and on the plaquettes, with their ℓ^2 products, d and d^* the coboundary and its adjoint; $C^1=dC^0\oplus\mathsf{K}\oplus\mathsf{T}_0$ with the constant forms K, one vector $c_\mu\in\mathbb{R}^3$ for each direction, and $\mathsf{T}_0:=d^*C^2$; $\mathsf{T}:=\mathsf{K}\oplus\mathsf{T}_0=\ker d^*$. $Q:=d^*d$ on T_0 is $\ge4\sin^2\frac{\pi}{N}\ge16/N^2$; $G_N(x):=N^{-3}\sum_{k\ne0}e^{\mathrm{i}k\cdot x}/|\mathsf{k}|^2$, $|\mathsf{k}|^2:=\sum_\mu(2-2\cos k_\mu)$, $k\in\frac{2\pi}{N}(\mathbb{Z}/N)^3$; $H_N:=G_N*G_N$; $\mathsf{Cv}:=Q^{-1}$ on T_0 (and 0 on its complement), $\mathsf{Gr}:=(d^*d)^{-1}d^*$ with values in the functions of mean zero, and $\Pi:=dQ^{-1}d^*$, the orthogonal projection of C^2 onto dC^1. E_0, P_0 are the mean and the law of the centred Gaussian field on T_0 with the covariance $\beta^{-1}\mathsf{Cv}$, the density being proportional to $\exp[-\frac{\beta}{2}|du|_2^2]$; $L_\mu(u):=\sum_{x\in l_\mu}u_\mu(x)$ is the sum of a form along the axis l_μ; and

$$\mathsf{N}_0(N,\beta):=\sigma_{\mathrm{H}}^{2N^3+1}(2\pi/\beta)^{3(N^3-1)}\exp\bigl[-\tfrac32\Sigma_N\bigr],\qquad\Sigma_N:=\sum_{k\ne0}\log|\mathsf{k}|^2.$$

The chart and the two-loop number of the cube. For $\tilde u=c+u\in\mathsf{T}$ with $|\tilde u|_\infty<1$ let $q(\tilde u)$ be the configuration $b\mapsto q(\tilde u_b)$; $\mathsf{N}_p(\tilde u):=\operatorname{Vec}\partial q(\tilde u)(p)-(d\tilde u)_p$ is the nonlinear part of the plaquette, with its Taylor parts $\mathsf{N}^{(2)}$, $\mathsf{N}^{(3)}$ of the degrees 2 and 3; $\mathsf{B}(\tilde u):=Q^{-1}d^*\mathsf{N}(\tilde u)\in\mathsf{T}_0$; $\Phi_c(u):=u+\mathsf{B}(c+u)$; $\mathsf{X}:=D_u\mathsf{B}$ on T_0, with its parts $\mathsf{X}_1,\mathsf{X}_2$ of the degrees $1,2$ in $\tilde u$; $\mathsf{Y}_{\tilde u}:=\mathsf{Gr}(D_{\tilde u}-d)$ on the functions of mean zero, $(D_{\tilde u}\xi)_b:=c_b(d\xi)_b-\tilde u_b\times(\xi_x+\xi_y)$ at $b=(x,y)$, $c_b:=(1-|\tilde u_b|^2)^{1/2}$, with its linear part Y_1. With

$$F^{\mathrm{lead}}(\tilde u):=\tfrac{\beta}{2}|(1-\Pi)\mathsf{N}^{(2)}(\tilde u)|_2^2+\tfrac{\beta}{8}\sum_p|(d\tilde u)_p|^4+\operatorname{tr}\mathsf{X}_2-\tfrac12\operatorname{tr}\mathsf{X}_1^2+\tfrac12\operatorname{tr}\mathsf{Y}_1^2-\frac{|\tilde u|_2^2}{2N^3},$$

$m_1(N):=-\beta E_0F^{\mathrm{lead}}(u)$ is the *two-loop number* of the cube T_N: a number that depends on N alone, as the mean of a monomial of the degree $2j$ under E_0 is β^{-j} times a number of N, and $|m_1(N)|\le CN^3$ (Step 7). Gaussian integration by parts writes it as $m_1(N)/\beta=-E_0[\beta\mathsf{S}_4^{\mathrm{L}}+\Xi_2^{\mathrm{L}}]+\frac12E_0(\beta\mathsf{S}_3^{\mathrm{L}})^2$, with the

three forms of the Landau chart on the cube $\mathsf{S}_3^{\mathrm{L}} = \langle du, \mathsf{N}^{(2)}\rangle$, $\mathsf{S}_4^{\mathrm{L}} = \frac12|\mathsf{N}^{(2)}|_2^2 + \langle du, \mathsf{N}^{(3)}\rangle + \frac18\sum_p |du_p|^4$ and $\Xi_2^{\mathrm{L}} = \frac12 \operatorname{tr}\mathsf{Y}_1^2 - |u|_2^2/2N^3$: the vacuum diagrams with two loops of the cube in Landau's gauge.

The Dirichlet box and the lattice. $\Lambda_n = \{0,\dots,n\}^3$, its free bonds and forms, its partition function $Z_{n,\beta}$, the gauge parameter $\tau_{\mathrm{gf}} > 0$, the covariance $\mathsf{C}^{[n]}_{\tau_{\mathrm{gf}}}$, the kernels $\mathsf{G}, \mathsf{E}, \Pi, \mathsf{g}, \mathsf{D}$, the cubic and quartic vertices $\mathsf{S}_3 = \sum_p \mathsf{a}_p^{(3)}$ and V_2 (the quartic Wilson vertex, the Haar term, the ghost tadpole and the ghost loop) and the Gaussian family $\langle\cdot\rangle_0$ are those of Definitions 7.2, 7.3, 7.7 and 7.8; $d_1 := 3(n-1)^2(2n+1)$ is the number of the real coordinates of the forms in the axial gauge of Lemma 7.6, and

$$q_1^{[n]} := -\langle \mathsf{V}_2\rangle_0 + \tfrac12\langle \mathsf{S}_3; \mathsf{S}_3\rangle_0$$

at τ_{gf}. On $\mathbb{Z}^3$ let $G(y) := (2\pi)^{-3}\int_{[-\pi,\pi]^3} e^{ik\cdot y}\big(\sum_\mu(2-2\cos k_\mu)\big)^{-1}dk$ be the Green function of the lattice Laplacian, with the normalisation of the Fourier conventions of Definition 7.1(5), $G_0 := G(0)$, and

$$J_{\mathrm{gh}} := \sum_{y\in\mathbb{Z}^3}\big[G(y+e_1) - G(y-e_1)\big]^2 G(y),$$

$$J_3 := \sum_{y\in\mathbb{Z}^3}\big[G(y)^2 - G(y+e_2)G(y-e_2)\big]\big[2G(y) + G(y+e_1) + G(y-e_1)\big],$$

two absolutely convergent sums, their terms being $O(\langle y\rangle^{-5})$; we put $p_1 := 9G_0 - 36G_0^2 - 9J_{\mathrm{gh}} + 18J_3$, numerically $p_1 \approx 0.69788$. In this part C, c denote pure numbers, which may change from one occurrence to the next, and $\mathsf{y} := \log\beta$.

Detailed sketch BF (Two-loop pressure of the infinite lattice). Let $P(\beta)$ be the pressure of the lattice $\mathbb{Z}^3$ at the real coupling β, as in the setting of Section 17.2, and let p_1, $q_1^{[n]}$ and $m_1(N)$ be the numbers defined above.

(a) There are pure numbers C and β_* such that for every real $\beta \ge \beta_*$

$$\Big|P(\beta) + 3\log\beta - z_\infty - \frac{p_1}{\beta}\Big| \le C\,(\log\beta)^2\,\beta^{-1.02},$$

$z_\infty = \log\frac{2}{\pi} - \frac32 f_\Delta \approx -2.96167$ the number of Proposition 17.47(d); and $|P(\beta)+3\log\beta - z_\infty| \le C/\beta$ for $\beta \ge \beta_*$.

(b) For every $\tau_{\mathrm{gf}} > 0$, $\lim_{n\to\infty} n^{-3}q_1^{[n]} = p_1$; and $|N^{-3}m_1(N) - p_1| \le C\log N/N$ for every even $N \ge 4$.

■□

Proof sketch. The pressure is pinned between two periodic cubes of the side $N \approx \beta^{0.34}$; there N^3/β is a small positive power of β, so that factors β^C cost nothing against the term $m_1(N)/\beta$, while $N^2 \ll \beta$ allows one chart about the flat field. The window $\beta^{1/3} \ll N \ll \beta^{1/2}$ is not empty because the dimension is three.

Step 1: the Green function. There is a pure number C_{G} such that for all even N and $x \in T_N$, $|x|$ the distance on the torus and D, D' first differences, $|G_N(x)| \le C_{\mathrm{G}}/(1+|x|)$, $|DG_N(x)| \le C_{\mathrm{G}}/(1+|x|)^2$, $|DD'G_N(x)| \le C_{\mathrm{G}}/(1+|x|)^3$ and $|DD'H_N(x)| \le C_{\mathrm{G}}/(1+|x|)$. Indeed $G_N = \int_0^\infty (P_s - N^{-3})ds$ and $H_N = \int_0^\infty s(P_s - N^{-3})ds$, P_s the heat kernel of T_N, a product of three periodisations of the kernel $p_s(x) = \frac{1}{2\pi}\int e^{ikx - s(2-2\cos k)}dk$ on $\mathbb{Z}$; moving the contour to $k + i\eta$, $\eta = \operatorname{sgn}(x)\min\{1, |x|/2.2s\}$, gives $|D^j p_s(x)| \le C(1+s)^{-(1+j)/2}e^{-w(x,s)}$, $w = \min\{x^2/9s, |x|/4\}$, $j \le 2$; the periodisation keeps this for $|x| \le N/2$, $s \le N^2$, the nonzero modes decay like e^{-16s/N^2} beyond, and the integrals give the claims. Hence the kernels of Cv, $Q^{-1}d^*$, Gr and Π decay like $|x|^{-1}$, $|x|^{-2}$, $|x|^{-2}$ and $|x|^{-3}$; $|\mathsf{Gr}f|_\infty + |Q^{-1}d^*f|_\infty \le CN|f|_\infty$ and $|d\,\mathsf{Gr}f|_\infty \le C\log N|f|_\infty$; each component of $L_\mu(u)$ has under P_0 a variance $\le CN\log N/\beta$; and $g_0 := \sup_N G_N(0) < \infty$. The same bounds hold on $\mathbb{Z}^3$, and for $|x| \le N/2$ the differences of the kernels of T_N and of $\mathbb{Z}^3$ of the decay $|x|^{-e}$ are at most CN^{-e}.

Step 2: reflections. For a bounded Borel function F of the bonds of a periodic box Λ, $Z_\Lambda[F] := \int F \exp[-\beta \sum_p a_p]\, dU = Z(\Lambda)\langle F\rangle_\Lambda$, so that $Z_\Lambda[1] = Z(\Lambda)$ for the constant function 1, and $Z_\Lambda[E] := Z_\Lambda[1_E]$ for an event E; $Z_N[\cdot]$ is this bracket on T_N, and Z, $Z[\cdot]$ with no index refer to the box under consideration; inside the bracket the function multiplies the weight here, while in $Z_\Gamma[0]$ before Proposition 18.114 the bracket carries a source added to the exponent. (i) For every even $N \ge 4$ and $\beta \ge 0$, $8P_{2N} - 7P_N \le P \le P_{2N} \le P_N$ and $0 \le \delta_N \le 8 \log Z_N - \log Z_{2N}$: Theorem BC(1) at $q = 2$ and Proposition 17.31(c). (ii) Let $R \ge 2$ with N_1/R an even integer, let B be a *block of the side* R of T_{N_1}, that is, a translate of the closed cube $[0,R]^3$, which has $R+1$ sites along each edge, and let E be an event of the bonds of B; we move B to $[0,R]^3$ and let F_8 be the product of 1_E over the images of B under the eight reflections $x \mapsto (\pm x_1, \pm x_2, \pm x_3)$ of T_{2R}, which tile T_{2R}. Then $\langle 1_E\rangle_{N_1^3} \le (Z_{2R}[F_8]/Z_{2R})^{1/8} e^{\delta_{2R}/8}$. Lemma 18.2 gives $\langle 1_E\rangle_{N_1^3} \le \langle F_{\mathrm{all}}\rangle_{N_1^3}^{(R/N_1)^3}$, with F_{all} the product over all reflected blocks. With the time μ, for a bounded Borel function G of the bonds of the closed slab $\{0 \le x_\mu \le R\}$ let $\mathsf{A}_G(V, V')$, V and V' the configurations of its two end slices, be the integral over its other bonds of G times the weights $e^{-\beta a_p}$ of its plaquettes, taken with the power $\frac12$ at the plaquettes that lie in an end slice: a bounded kernel, which the reflection of the slab transposes. On a box whose side in the direction μ is $2kR$, the product of the functions $G, \Theta G, G, \Theta G, \dots$ on its $2k$ consecutive closed slabs, each the mirror image of the one before, has the integral $\mathrm{Tr}\big[(\mathsf{A}_G \mathsf{A}_G^{\mathrm{T}})^k\big] \le (\mathrm{Tr}(\mathsf{A}_G \mathsf{A}_G^{\mathrm{T}}))^k$, as $\mathsf{A}_G \mathsf{A}_G^{\mathrm{T}} \ge 0$, and $\mathrm{Tr}(\mathsf{A}_G \mathsf{A}_G^{\mathrm{T}})$ is the integral of the product of G and ΘG on the box with the side $2R$ in that direction; in the three directions this gives $Z_{N_1}[F_{\mathrm{all}}] \le Z_{2R}[F_8]^{(N_1/2R)^3}$. Finally $Z_{N_1}^{(R/N_1)^3} = e^{R^3 P_{N_1}} \ge e^{R^3 P} = (Z_{2R} e^{-\delta_{2R}})^{1/8}$ by (i). (iii) For $\beta \ge 1$, $\varepsilon > 0$, even $N_1 \ge 4$ and every plaquette p, $\langle 1[|\partial U(p) - \mathbf{1}| > \varepsilon]\rangle_{N_1^3} \le \exp[-\beta\varepsilon^2/4 + 14 + 3\mathsf{y}/N_1]$: The same slab dissemination bound at width one, in the three directions in turn, bounds the probability by the N_1^3-th root of the mean of the product of the indicators over the images of p, which are the $N_1^3/2$ plaquettes of the orientation of p in the layers at an even distance from that of p; on that event $\beta \sum a_p \ge \beta\varepsilon^2 N_1^3/4$ over these plaquettes; the plaquettes of the two other orientations integrate to at most the following quantity. Fix the bonds normal to the tested plaquette. For each of the two tangential directions, the bonds of that direction form N_1^2 chains along the normal axis, coupled consecutively by the retained plaquettes. Drop one interaction in each closed chain, which increases the integral. Integrate the open chain starting at an end. At each step Haar invariance gives exactly $\mathsf{z}(\beta)$, since the two normal bonds and the neighboring tangential bond are held fixed. The resulting bound is $\mathsf{z}(\beta)^{2N_1^2(N_1-1)} \le \beta^{-3N_1^2(N_1-1)}$; and $Z_{N_1} \ge e^{N_1^3 P}$ by (i), where $P \ge -3\mathsf{y} - 13.84$ for $\beta \ge \frac14$. For the last bound, a gauge transformation sets the $N^3 - 1$ bonds of a spanning tree of the cube T_N to $\mathbf{1}$ and leaves the remaining $2N^3 + 1$ bonds Haar distributed; where these lie within $s \le 1$ of $\mathbf{1}$, a set of the measure $\ge (s^3/2\pi)^{2N^3+1}$, as the Haar probability of $\{|U - \mathbf{1}| \le s\}$ is at least $\frac{2}{\pi}\int_0^s \sin^2 t\, dt \ge s^3/2\pi$, every plaquette has $|\partial U(p) - \mathbf{1}| \le 4s$ and $a_p \le 8s^2$; so $\log Z_N \ge (2N^3+1)\log(s^3/2\pi) - 24N^3\beta s^2$, and at $s = \frac12 \beta^{-1/2}$, as $N \to \infty$, $P \ge -3\mathsf{y} - 6\log 2 - 2\log 2\pi - 6 \ge -3\mathsf{y} - 13.84$.

Step 3: the law of a line of holonomies is of positive type. Let $\Lambda = (2R, N_2, N_3)$, $F \ge 0$ a bounded Borel function of the bonds of the slab of the first $R+1$ layers that is invariant under the gauge transformations of the slab, $F \otimes \Theta F$ the product of F and its mirror image on the second slab, h the holonomy of a closed line in the direction 1, and $w = \sum_j \hat w_j \chi_j$ a class function with $\hat w_j \ge 0$, $\sum \hat w_j d_j < \infty$. Then $Z_\Lambda[(F \otimes \Theta F)\, w(h)] \ge \hat w_0 Z_\Lambda[F \otimes \Theta F]$. In the gauge in which the bonds of the line are $\mathbf{1}$ but the last, which carries h, the integral is $\int w(h)\, \mathrm{Tr}(\mathsf{A}^\circ \mathsf{A}^{\circ\,\mathrm{T}} R(h)) dh$, A° the kernel A_F of Step 2 (ii), with the time 1, in which the bonds of the line are set to $\mathbf{1}$ and not integrated, and R the unitary representation of the gauge transformations at the one site of the line in a layer, which commutes with A°; by the Peter–Weyl theorem $\int w(h) R(h) dh = \sum_j (\hat w_j/d_j) P_j$ with orthogonal projections P_j commuting with A°, $\mathrm{Tr}(\mathsf{A}^\circ \mathsf{A}^{\circ\,\mathrm{T}} P_j) = \|P_j \mathsf{A}^\circ\|_2^2 \ge 0$, and the term $j = 0$ is $\hat w_0 Z_\Lambda[F \otimes \Theta F]$. For $w = e^{-\lambda a(\cdot)}$, an exponential series of a character with coefficients ≥ 0, $\hat w_0 = \mathsf{z}(\lambda)$. Apply the estimate in the three coordinate directions in turn. For the line gauge used in this trace,

successively transport the gauge along the line starting at the origin. At fixed original line bonds this is a Haar-preserving substitution on every other bond. The last line variable becomes h by Haar invariance. In the second slab a gauge at the last endpoint sets this last line bond to $\mathbf{1}$ and acts on the end-slice variable by $R(h)$, with the inverse convention giving the same integral because $w(h^{-1}) = w(h)$. Averaging the trace over h at $w = 1$ therefore gives the unpinned integral and inserts $P_0 = \int R(h)\, dh$. In the estimate for direction μ, each previously inserted pin lies entirely in the site wall $x_\mu = 0$ because the three loops go through the origin. Split the square root of that pin weight between the two reflected slabs. The product retains the required form $F_\mu \otimes \Theta_\mu F_\mu$. Thus for any nonnegative gauge-invariant Φ having this form in every direction, in particular $\Phi = 1$, insertion of the three pin weights costs at most the factor $\mathsf{z}(\lambda)^{-3}$. Since $\prod_\mu e^{-\lambda a(h_\mu)} \le 1_{\mathsf{H}_r} + e^{-\lambda r^2/2}$, this gives

$$Z[\Phi] \le \mathsf{z}(\lambda)^{-3}\{Z[\Phi 1_{\mathsf{H}_r}] + e^{-\lambda r^2/2} Z[\Phi]\}, \qquad Z\left(\mathsf{z}(\lambda)^3 - \langle 1_{A^c}\rangle - e^{-\lambda r^2/2}\right) \le Z[A \cap \mathsf{H}_r] \ \text{ for every event } A.$$

Step 4: gauges. All distances of group elements below are measured in the Euclidean norm of the unit quaternions. Products of unit quaternions satisfy $|u_1 \cdots u_j - v_1 \cdots v_j| \le \sum_i |u_i - v_i|$. In particular, commuting a lattice path across a plaquette changes its transport by at most the plaquette error. This is the estimate used in the following gauge constructions.

(i) A periodic gauge from a comb. Suppose the plaquettes on $(\mathbb{Z}/m)^3$ are within ε of the identity and the three coordinate holonomies through the origin are within r. On the lifted cube $[-m, m]^3$ use the gauge $g(x)$ given by the transport along the path from 0 to x which traverses the coordinates in order. For an edge (x, y) the two comb paths differ by sliding this edge past at most two coordinate segments, of total length at most $2m$. Thus $|g(x)T_{xy} - g(y)| \le 2m\varepsilon$. For lifts of the same site separated by one period in a direction, compare the comb paths by inserting the straight period loop at that site. Moving that loop to the origin uses at most Cm^2 plaquettes, and moving the inserted segment to its position in the comb uses at most Cm^2 more. It follows that the two values of g are within $r + Cm^2\varepsilon$. Lifts with positive weights below differ by at most one period per coordinate, so their mutual distances are at most $C(r + m^2\varepsilon)$.

For each lattice site x, average the values $g(x + mj)$ using weights $\prod_\mu (1 - |x_\mu + mj_\mu|/m)_+$. The weights sum to one, the average is periodic, and its norm is at least $1 - C(r + m^2\varepsilon)$. The sum of the absolute weight differences across an edge is $O(m^{-1})$. In the term containing these differences, subtract one fixed lift value at the second endpoint, since the differences sum to zero. The resulting error is $O((r + m^2\varepsilon)/m)$. The term with fixed weights is bounded by the comb estimate. Dividing the average by its norm therefore gives a periodic gauge in which all bonds are within $C(m\varepsilon + r/m)$ of the identity, provided $r + m^2\varepsilon$ is less than a sufficiently small pure constant.

(ii) Gluing local gauges. Let R be divisible by 4, N_1 be divisible by R, and $N_1 \ge 2R$. Write $h = R/2$. Suppose that on each block $B_j = jh + [0, 2h]^3$ there is a gauge g_j making all bonds within ρ_1 of the identity, and that the three coordinate holonomies on the N_1-torus are within r. The overlap transition $g_j(x)g_k(x)^{-1}$ changes by at most $2\rho_1$ across an edge of the overlap. Its oscillation on an overlap of neighboring blocks is therefore $O(R\rho_1)$. On the grid of block indices, define a nearest-neighbor bond by evaluating the transition at one point of the overlap and use its inverse on the reverse bond. Around a coarse plaquette all four blocks share a point. Comparing the four transitions with their values at that point shows that the coarse plaquette error is $O(R\rho_1)$. For a coarse coordinate loop, evaluate the transitions along the corresponding fine coordinate axis. Consecutive transition points can be joined in one block by a straight segment of length h. In the block gauge each segment transport is within $h\rho_1$ of the identity. Inserting the segments compares the coarse loop product to a conjugate of the original fine holonomy, with error $O(N_1\rho_1)$, including the errors from changing transition points.

The coarse torus has side N_1/h. Part (i) therefore gives constant changes of the block gauges making all transitions within $C(N_1\rho_1 + rR/N_1)$ of the identity, if $r + N_1^2\rho_1/R$ is sufficiently small. The same bound holds for any blocks which share a point. Indeed, one can change their indices one

coordinate step at a time through blocks that all contain the point, and the transition products telescope. Average the adjusted block gauges with the product tent functions of width h centered in the blocks. Their weights sum to one. For a fine lattice edge, every block with positive weight at an endpoint contains the edge, since the block boundaries have integer coordinates and the tents vanish there. The same normalized-average estimate as in (i), now with weight variation $O(R^{-1})$, gives a global gauge with bond error at most $C((N_1/R)\rho_1 + r/N_1)$.

(iii) The Landau chart. Put $\mathsf{D}_N(\rho) = \{\tilde{u} \in \mathsf{T} : |\tilde{u}|_\infty \le \rho\}$ and let GG consist of the gauges with $g_0 = \mathbf{1}$. Set $\Psi(g, \tilde{u}) = q(\tilde{u})^g$. If $W = q(w)$ has bond error at most ρ_a, its vector part after the gauge $e^{i\mu}$ is $w - d\mu + B(\mu, w)$. Direct multiplication of the three unit quaternions gives

$$|B(\mu, w)|_\infty \le C(\|\mu\|_\infty + \|w\|_\infty)(\|w\|_\infty + \|d\mu\|_\infty).$$

For the difference of two remainders the corresponding bound is

$$\begin{aligned}|B(\mu, w) - B(\nu, w)|_\infty \le{}& C(\|w\|_\infty + \|d\mu\|_\infty + \|d\nu\|_\infty)\|\mu - \nu\|_\infty \\ &+ C(\|w\|_\infty + \|\mu\|_\infty + \|\nu\|_\infty)\|d(\mu - \nu)\|_\infty.\end{aligned}$$

These follow by writing the gauge product as the conjugation of W at its initial site times $e^{i\mu_x} e^{-i\mu_y}$. The latter factor has vector part $-(d\mu)_{xy}$ plus a remainder of size $C\|\mu\|_\infty |(d\mu)_{xy}|$, with the same product estimate for differences. The equation $d^* \operatorname{Vec}(W^{e^{i\mu}}) = 0$ is $\mu = \mathsf{Gr}(w + B(\mu, w))$ on mean-zero site fields. The row bounds in Step 1 make this a contraction on a ball of radius $C\rho_a$ for the norm $\max\{\|\mu\|_\infty/N, \|d\mu\|_\infty/\log N\}$ if $N\rho_a \log N$ is sufficiently small. The resulting vector part has norm $O(\rho_a \log N)$. Its scalar parts are positive because the gauge and field are near the identity. A constant conjugation of the new field makes the inverse gauge based and preserves transversality.

For uniqueness, suppose $q(v) = q(u)^g$ with $u, v \in \mathsf{D}_N(\rho)$ and g based. The bond equation gives $|g_x - g_y| \le C\rho$ on every edge. Paths of length $O(N)$ give $\|g - \mathbf{1}\|_\infty \le CN\rho$. Multiply g on the left by a constant near the identity so that its logarithm μ has mean zero, conjugating $q(v)$ by that constant. This constant exists: the map sending the logarithm of the constant to the spatial mean of the new logarithm has derivative within $O(N\rho)$ of the identity on a ball of radius $CN\rho$. The product estimate for the remainder also gives

$$\|B(\mu, u)\|_2 \le C\rho\|\mu\|_2 + C(\|\mu\|_\infty + \rho)\|d\mu\|_2.$$

Pairing $v - u = -d\mu + B(\mu, u)$ with $d\mu$ and using $\|\mu\|_2 \le CN\|d\mu\|_2$ makes $d\mu = 0$ for small $N\rho$. The original based gauge is then the identity.

The differential of Ψ has tangent block equal to the identity on T and normal block given by the projection of $D_{\tilde{u}}$ onto dC^0. The derivative on a constant gauge parameter is an infinitesimal constant conjugation of $\tilde{u}$, hence lies in T. Thus the normal determinant can be computed on mean-zero parameters and multiplied by the determinant of the orthogonal projection from based parameters to mean-zero parameters. This projection has determinant $N^{-3/2}$ per color: it is the identity on the intersection of the two hyperplanes and has singular value $N^{-3/2}$ on the remaining direction. On the mean-zero space the determinant of d onto its range has magnitude $e^{\frac{3}{2}\Sigma_N}$, by the Fourier eigenvalues. The normal block is therefore $N^{-9/2} e^{\frac{3}{2}\Sigma_N} \det(1 + \mathsf{Y}_{\tilde{u}})$. The product of the bond Haar densities contributes $\sigma_{\mathrm{H}}^{3N^3} \prod_b (1 - |\tilde{u}_b|^2)^{-1/2}$. Writing the gauge measure as normalized Haar divides out $\sigma_{\mathrm{H}}^{N^3-1}$. Consequently, for sufficiently small $N\rho$,

$$\Psi^*\Big(\prod_b dU_b\Big) = \sigma_{\mathrm{H}}^{2N^3+1} N^{-9/2} e^{\frac{3}{2}\Sigma_N} \det(1 + \mathsf{Y}_{\tilde{u}}) \prod_b (1 - |\tilde{u}_b|^2)^{-1/2}\, d\tilde{u} \prod_{x \ne 0} dg_x, \qquad d\tilde{u} = N^{27/2} dc\, du,$$

with $\|\mathsf{Y}_{\tilde{u}}\| \le N\rho$, $\operatorname{tr} \mathsf{Y}_{\tilde{u}} = (1 - N^{-3}) \sum_b (c_b - 1)$ and $\|\mathsf{Y}_{\tilde{u}}\|_{\mathrm{HS}}^2 \le C|\tilde{u}|_2^2$: the Jacobian is triangular in the splitting into T and dC^0, and its block on the gauge directions is $\det(d^*d)^{1/2} \det(1 + \mathsf{Y}_{\tilde{u}})$ up to the Gram factor $N^{-9/2}$ of the condition $g_0 = \mathbf{1}$; ϵ_* is a small pure number. Indeed, $\|\mathsf{Gr}\| \le N/4$, and $\|D_{\tilde{u}} - d\| \le \sqrt{12}(\rho + 1 - \sqrt{1 - \rho^2}) \le 4\rho$ for $\rho \le 1/8$, by summing the squared endpoint terms over the six bonds at each site. This gives the operator norm of $\mathsf{Y}_{\tilde{u}}$. Each column of $\mathsf{Gr}(D_{\tilde{u}} - d)$ is

a finite sum of first-difference Green columns with coefficients $O(|\tilde{u}_b|)$ from bonds at the site. The columns of Gr have uniformly bounded ℓ^2 norm by Step 1. Squaring and summing therefore gives $\|\mathsf{Y}_{\tilde{u}}\|_{\mathrm{HS}}^2 \le C|\tilde{u}|_2^2$. The cross-product blocks have trace zero in color. In the remaining scalar term, cyclicity gives the trace of $(c_b - 1)d\mathsf{Gr}$ over bonds and colors. The diagonal of $d\mathsf{Gr}$ is $(1 - N^{-3})/3$ per color by cubic symmetry and the rank $N^3 - 1$ of the gradient projection per color. This proves the stated trace formula.

Step 5: the action in the chart. For $\tilde{u} = c + u \in \mathsf{T}$, $|\tilde{u}|_\infty \le \rho \le \frac{1}{8}$: by the identity for $a(U)$ and as $\Pi\mathsf{N} = d\mathsf{B}$,

$$\sum_p a_p(q(\tilde{u})) = \tfrac{1}{2}|d\Phi_c(u)|_2^2 + \tfrac{1}{2}|(1-\Pi)\mathsf{N}(\tilde{u})|_2^2 + \tfrac{1}{2}\sum_p a_p(q(\tilde{u}))^2;$$

$|\mathsf{N}_p| \le 14m_p^2$ and $a_p \le 9m_p^2$, m_p the largest $|\tilde{u}_b|$ at p; $\|D\mathsf{N}\| \le 29\rho$; $\|\mathsf{X}\| \le \frac{29}{4}N\rho$, $\|\mathsf{X}\|_{\mathrm{HS}}^2 + |\operatorname{tr}\mathsf{X}| \le C|\tilde{u}|_2^2$, $\operatorname{tr}\mathsf{X}_1 = 0$ by the colour trace, $\mathsf{B}(c) = 0$ and $|\mathsf{B}|_\infty \le CN|\tilde{u}|_\infty^2$; and if $N\rho \le \epsilon_*$, then Φ_c is one-to-one on $\mathsf{D}_c(\rho) := \{u \in \mathsf{T}_0 : |c+u|_\infty \le \rho\}$ with $|u - v|_2 \le 2|\Phi_c(u) - \Phi_c(v)|_2$, and for $|c| \le \rho/4$ its image contains $\mathsf{Gd} := \{u' \in \mathsf{T}_0 : |u'|_\infty \le \rho/2\}$.

Here are the derivative and image estimates used in this step. On a plaquette write its four oriented factors as $1 + E_i$, where $|E_i| \le 1.01m_p$. The vector part of the linear sum of the E_i is precisely $d\tilde{u}$, so N_p is the vector part of the terms with at least two factors. Expanding the four factors gives $|\mathsf{N}_p| \le 14m_p^2$, while product telescoping and $a = \frac{1}{2}|\partial q - \mathbf{1}|^2$ give $a_p \le 9m_p^2$. In the derivative with respect to one bond, subtract the derivative of its vector part alone. Moving the three other unitary factors to the identity costs at most 3.03ρ times the derivative norm, which is at most 1.01 for $\rho \le 1/8$. Thus each derivative block has norm at most 4.1ρ. Each plaquette has four bonds and each bond belongs to four plaquettes, so the operator norm is at most 16.4ρ by the row and column sum bounds. This implies the stated bound for $D\mathsf{N}$ and, since $\|Q^{-1}d^*\| \le N/4$, the one for X.

Write $\mathsf{R} = Q^{-1}d^*$ on plaquette cochains. Each column of R has bounded squared ℓ^2 norm by the first-difference bound in Step 1. A column of $\mathsf{R}D\mathsf{N}$ is a sum of at most four such columns, with matrix coefficients bounded by Cm_p at their plaquettes. Summing the squared column norms proves $\|\mathsf{X}\|_{\mathrm{HS}}^2 \le C|\tilde{u}|_2^2$. The trace on T_0 equals the trace of the same product on all bond cochains because the range of R lies in T_0. The color-independent kernel of R multiplies each local color derivative of $\mathsf{N}^{(2)}$, which is a cross-product matrix and has trace zero. The derivative of the remainder on a plaquette is $O(m_p^2)$ by the Taylor expansion of the four factors. Taking the diagonal and summing gives $|\operatorname{tr}\mathsf{X}| \le C|\tilde{u}|_2^2$. For a constant form c, $\mathsf{N}(c)$ is a constant plaquette cochain, so $d^*\mathsf{N}(c) = 0$. The ℓ^∞ row bound on R in Step 1 gives $|\mathsf{B}|_\infty \le CN\rho^2$. On the convex domain $\mathsf{D}_c(\rho)$ the Lipschitz bound $\|D\mathsf{B}\| \le 1/2$ in ℓ^2 gives the stated injectivity and inverse bound. If $|c| \le \rho/4$ and $|u'|_\infty \le \rho/2$, the map $u \mapsto u' - \mathsf{B}(c+u)$ maps $\mathsf{D}_c(\rho)$ into itself because $|\mathsf{B}|_\infty \le \rho/4$ when ϵ_* is small. It is the same ℓ^2 contraction, so its fixed point gives the image assertion.

Step 6: the Gaussian number. Let $p_s^{(3)}$ be the infinite-lattice heat kernel. Subtract the heat integral for $N^3 f_\Delta$ from the one for Σ_N, using the periodic heat kernel and omitting its zero mode. The difference is

$$\int_0^\infty \left[1 - e^{-s} - N^3 \sum_{j \in \mathbb{Z}^3 \setminus \{0\}} p_s^{(3)}(Nj)\right] \frac{ds}{s}.$$

For $0 < s \le 1$ the image sum is bounded by the probability that a rate-six Poisson variable of mean $6s$ is at least N. The integral of this bound times N^3 is at most $N^2 e^6 6^N/N!$, uniformly bounded in N. For $1 \le s \le N^2$, the heat-kernel bound of Step 1 and the product of the three one-dimensional kernels bound the image sum times N^3 by $CN^3 s^{-3/2}(e^{-cN^2/s} + e^{-cN})$. For this sum, one may group the images by $|j|_\infty$ and use $\min\{N^2|j|_\infty^2/s, N|j|_\infty\} \ge |j|_\infty \min\{N^2/s, N\}$. The integral of this image bound against ds/s is uniformly bounded, and the $1 - e^{-s}$ term contributes at most $2\log N$. For $s \ge N^2$, write the integrand before division by s as $-e^{-s} - \sum_{k \ne 0} e^{-s|\mathsf{k}|^2} + N^3 p_s^{(3)}(0)$. The Fourier

sum is bounded by Ce^{-cs/N^2} using $|\mathsf{k}|^2 \ge c|m|^2/N^2$ for $k = 2\pi m/N$ in the centered frequency cube. The last term is at most $CN^3 s^{-3/2}$. These bounds are integrable there against ds/s with a uniform integral. Hence $|\Sigma_N - N^3 f_\Delta| \le C(1+\log N)$, and $|\log \mathsf{N}_0(N,\beta) - N^3(-3\mathsf{y} + z_\infty)| \le C(\mathsf{y} + (\log N)^2)$ and $|8\log \mathsf{N}_0(N,\beta) - \log \mathsf{N}_0(2N,\beta)| \le C(\mathsf{y} + (\log N)^2)$, as $3\log 2\pi - 2\log 2\pi^2 = \log \frac{2}{\pi}$.

Step 7: the chart, from below and from above. Assume (S): $N \ge 16$ even, $\beta \ge e$, $0 < r \le \rho$, $N\rho \le \epsilon_*$, $N^2 \log N \le \epsilon_* \beta$, and put $\mathsf{W}_N(\rho) := \Psi(\mathsf{GG} \times \mathsf{D}_N(\rho)) \cap \mathsf{H}_r$. With $u' = \Phi_c(u)$, Steps 4, 5 and the area formula give, for Borel $D' \subset \mathsf{D}_N(\rho)$,

$$\int_{\mathsf{GG}\times D'} \Psi^*(e^{-\beta \sum a_p} dU) = N^9 \mathsf{N}_0(N,\beta) \int dc\, E_0\big[1\{c + \Phi_c^{-1} u' \in D'\}\, e^{-F_c(\Phi_c^{-1}u')}\big],$$

$$F_c(u) := \tfrac{\beta}{2} |(1-\Pi)\mathsf{N}(\tilde u)|_2^2 + \tfrac{\beta}{2} \sum_p a_p^2 + \log\det(1+\mathsf{X}) - \log\det(1+\mathsf{Y}_{\tilde u}) + \tfrac12 \sum_b \log(1 - |\tilde u_b|^2).$$

(i) *Crude bounds.* The quadratic remainders of the log determinants and the Haar term give $e^{-F_c(u)} \le e^{C|c+u|_2^2}$; the two terms multiplied by β in F_c have nonnegative sign. For clarity, the determinant bound uses $|\log\det(1+B) - \operatorname{tr} B| \le C\|B\|_{\mathrm{HS}}^2$ when $\|B\| \le 1/2$. The linear parts of both traces vanish, and the remaining parts are $O(|c+u|_2^2)$. For $u' = \Phi_c(u)$ the smallness of $N\rho$ also gives $|c+u|_2^2 \le C(|u'|_2^2 + N^3|c|^2)$, since $\|Q^{-1} d^*\| \le CN$ and $|\mathsf{N}(\tilde u)|_2 \le C\rho|\tilde u|_2$. The axis holonomy differs in vector part from $Nc_\mu + L_\mu(u)$ by at most $CN^2\rho^2$ by multiplying the N factors and bounding the terms beyond first order. Also $|L_\mu(u) - L_\mu(u')| \le CN^2\rho^2$. On H_r this gives $N^3|c|^2 \le C(N\sum_\mu |L_\mu(u')|^2 + N^5\rho^4 + Nr^2)$. Here and below $|c| = \max_\mu |c_\mu|$.

For a centered Gaussian vector of covariance C_0, the formula $\mathbb{E}\exp[t|Z|^2] = \det(1-2tC_0)^{-1/2}$ bounds this expectation by $\exp(Ct \operatorname{tr} C_0)$ when $2t\|C_0\| \le 1/2$. Apply it to u' and to the nine axis components, using Cauchy–Schwarz to combine the bounds. The covariance of u' has norm $O(N^2/\beta)$ and trace $O(N^3/\beta)$, and that of the axis vector has norm $O(N\log N/\beta)$. The smallness of $N^2\log N/\beta$ makes these estimates valid even for twice the constants in the exponent above. The c integration has bounded volume because $|c| \le \rho \le 1/8$, and $Nr^2 \le N\rho^2 \le 1$. This gives

$$Z_N[\mathsf{W}_N(\rho)] \le N^9 \mathsf{N}_0 \exp[C(1 + N^3/\beta + N^5\rho^4)].$$

For the shell $\mathsf{W}_N(\rho) \setminus \mathsf{W}_N(\rho/2)$, injectivity and $|u-u'|_\infty \le CN\rho^2$ imply that either $|u'|_\infty \ge c\rho$ or $|c| \ge c'\rho$. In the latter case the holonomy estimate forces $\max_\mu |L_\mu(u')| \ge c'' N\rho$ after decreasing the smallness constant and using $r \le \rho$, $N \ge 16$. The first event has Gaussian probability at most $CN^3 e^{-c\beta\rho^2}$ by the uniform diagonal covariance bound. The second has probability at most $Ce^{-c\beta N\rho^2/\log N}$ by the axis covariance bound. One more application of Cauchy–Schwarz gives the shell bound $N^{13}\mathsf{N}_0 \exp[C(1+N^3/\beta+N^5\rho^4) - \beta\rho^2/C]$, with constants adjusted.

(ii) *The mean behind the change of variables.* On $\mathsf{D}_c(\rho)$ the Taylor bound is $|F_c - F^{\mathrm{lead}}(c+\cdot)| \le C(\beta N^3\rho^5 + N^4\rho^3)$. Indeed, in each action term the first discarded power has degree at least five. In a log determinant with matrix B, the terms beyond the quadratic in B cost at most $C\|B\|\|B\|_{\mathrm{HS}}^2 = O(N^4\rho^3)$. The remaining trace remainders are sums of local coefficients against the diagonal of a bounded kernel and cost $O(N^3\rho^3)$.

Both functions are Lipschitz in $|\cdot|_2$ with constant $C(\beta\rho^3+\rho)N^{3/2}$. For the squared action terms this follows by bounding the nonlinear term in ℓ^2 by $C\rho^2 N^{3/2}$ and its derivative in operator norm by $C\rho$. For a determinant, write the differential as $\operatorname{tr}(DB) + \operatorname{tr}(((1+B)^{-1} - 1)DB)$. The first trace has zero constant term and is bounded by $C\rho N^{3/2}|\delta u|_2$ from its local coefficients. For the second use $\|B\|_{\mathrm{HS}} \le C\rho N^{3/2}$ and $\|DB[\delta u]\|_{\mathrm{HS}} \le C|\delta u|_2$. These Hilbert–Schmidt estimates follow by expanding the local multiplication and difference operators in B and using the square-summable first-difference Green kernels in Step 1. The Haar factor follows by differentiating its product logarithm.

For $|c| \le c_0 \le \rho/4$ the change from u to u' costs $C(\beta\rho^3+\rho)N^{3/2} \cdot N^{3/2} N\rho^2$ by the Lipschitz estimate. In $E_0[F^{\mathrm{lead}}(c+u')]$ the terms odd in u' vanish. The quadratic terms involving c are bounded by $CN^3 c_0^2$ by the trace and Hilbert–Schmidt estimates. In a quartic term the contribution containing two copies of c costs $C\beta N^3 c_0^2 \beta^{-1}$ by the local diagonal covariance bound

and the contraction property of $1-\Pi$. The term containing four copies costs $C\beta N^3 c_0^4$. Thus $|E_0[F^{\mathrm{lead}}(c+u')] - E_0[F^{\mathrm{lead}}(u')]| \le C(N^3c_0^2 + \beta N^3 c_0^4)$. If $N \le \beta$ and $\rho^2 \ge K_*^\flat \mathsf{y}^3/\beta$, the Gaussian union bound gives $P_0(\mathsf{Gd}^c) \le e^{-\mathsf{y}^3}$. The polynomial moments on that complement are $O(1)$ by Cauchy–Schwarz, since the moments on the whole Gaussian space are bounded by fixed powers of N and β. Together these estimates give the asserted mean bound $C(\beta N^4\rho^5 + N^4\rho^3 + N^3 c_0^2 + \beta N^3 c_0^4 + 1)$.
(iii) *Two loops in the chart.* With $\mathsf{EE} := \beta N^4\rho^5 + N^4\rho^3 + \beta N^5\rho^6 + N^5\rho^2/\beta + N^{5/2}/\beta + 1$, under (S), $N \le \beta$ and $\rho^2 \ge K_*^\flat \mathsf{y}^3/\beta$:

$$\log Z_N \ge \log \mathsf{N}_0 + \frac{m_1(N)}{\beta} - C(\mathsf{y} + \mathsf{EE}),$$

by restricting to $|c_\mu| \le \beta^{-10}$ and to Gd, where Ψ is one-to-one, and Jensen's inequality; and if besides $N^{5/4}\rho^2\beta^{1/2} \le \epsilon_*$, $r \le N^{3/4}\beta^{-1/2}/8$ and $N^{1/2}/\log N \ge K_*^\flat(1 + N^3/\beta + N^5\rho^4)$,

$$\log Z_N[\mathsf{W}_N(\rho)] \le \log \mathsf{N}_0 + \frac{m_1(N)}{\beta} + C(\log N + \mathsf{EE}),$$

as follows. For $|c| \le 2N^{-1/4}\beta^{-1/2}$ this bound on c is at most $\rho/4$ under the stated radius assumptions, after increasing $K_*^\flat$. The inverse map is 2-Lipschitz. Extend $F_c \circ \Phi_c^{-1}$ from the image to T_0 with the same Lipschitz constant, by the infimum formula for Lipschitz extensions. The extension agrees on Gd, and its mean outside Gd costs $O(1)$ by the Gaussian tail and its linear growth. Gaussian concentration with covariance norm at most $N^2/(16\beta)$ bounds the logarithm of the exponential moment by minus its mean plus $C(\beta N^5\rho^6 + N^5\rho^2/\beta)$. The mean estimate in (ii) adds at most $CN^{5/2}/\beta$ from the constants c. The integral of these estimates over c costs a bounded volume.

If $|c| > 2N^{-1/4}\beta^{-1/2}$, the holonomy estimate of (i) forces $\max_\mu |L_\mu(u')| \ge N^{3/4}\beta^{-1/2}$: the two errors $CN^2\rho^2$ and r are smaller than the margin by the extra radius hypotheses. The Gaussian tail of the axis vector is bounded by $C\exp[-cN^{1/2}/\log N]$. Combining it with the exponential weight bound in (i) by Cauchy–Schwarz shows that this part is at most $N^9\mathsf{N}_0\exp[-C_1N^3/\beta]$ for any fixed C_1 if $K_*^\flat$ is sufficiently large. For the comparison, $|m_1(N)| \le CN^3$ follows directly from the local Gaussian fourth moments of $\mathsf{N}^{(2)}$ and du, and the Hilbert–Schmidt and trace bounds for the quadratic terms of F^{lead}. The prefactor N^9 then costs only $O(\log N)$ in the upper bound.

For the Gaussian identity used to identify $m_1(N)$, write $\mathsf{B}_j = Q^{-1}d^*\mathsf{N}^{(j)}$ for $j = 2, 3$ at $c = 0$. For the Gaussian measure on T_0, integration by parts gives

$$E_0[\beta\langle u, QV(u)\rangle] = E_0[\operatorname{div} V(u)]$$

for each polynomial vector field V. Since $\operatorname{div}\mathsf{B}_2 = \operatorname{tr}\mathsf{X}_1 = 0$ and $W = \beta\mathsf{S}_3^{\mathrm{L}} = \beta\langle u, Q\mathsf{B}_2\rangle$, taking $V = W\mathsf{B}_2$ gives

$$E_0 W^2 = E_0\Big[\beta|\Pi\mathsf{N}^{(2)}|_2^2 + \beta\langle u, Q(D\mathsf{B}_2)\mathsf{B}_2\rangle\Big] = E_0\Big[\beta|\Pi\mathsf{N}^{(2)}|_2^2 + \operatorname{tr}\mathsf{X}_1^2\Big].$$

In the second equality use integration by parts again and $\operatorname{div}((D\mathsf{B}_2)\mathsf{B}_2) = \operatorname{tr}(D\mathsf{B}_2)^2 + D(\operatorname{div}\mathsf{B}_2)[\mathsf{B}_2]$. Taking $V = \mathsf{B}_3$ gives $E_0[\beta\langle du, \mathsf{N}^{(3)}\rangle] = E_0[\operatorname{tr}\mathsf{X}_2]$. These equalities give the expression in terms of $\mathsf{S}_3^{\mathrm{L}}, \mathsf{S}_4^{\mathrm{L}}, \Xi_2^{\mathrm{L}}$.

Step 8: three levels. Let $R_\flat := 4\lceil\beta^{0.22}\rceil$, $n_\flat := 2R_\flat$, $k_\flat := \lceil\beta^{0.12}\rceil$, $N := 2k_\flat R_\flat$, so that $8\beta^{0.34} \le N \le 32\beta^{0.34}$, and let $N' \in \{N, 2N\}$; $\varepsilon_0^2 := K_0^\flat\mathsf{y}^3/\beta$, $\rho_1^2 := K_1^\flat\mathsf{y}^3/\beta$, $\rho_2^2 := K_2^\flat N'^3/\beta^2$, $\lambda := \beta^4$, $r := \beta^{-1.9}$, with large pure numbers $K_0^\flat, K_1^\flat, K_2^\flat$. There is a pure β_* such that for $\beta \ge \beta_*$:

(a) $\delta_{n_\flat} \le C\mathsf{y}^2$. By Step 2 (iii) all plaquettes of $T_{n_\flat}$ lie within ε_0 of $\mathbf{1}$ outside an event of the probability $e^{-9.5\mathsf{y}^3}$; there Step 4 (i), (iii) put the field in $\mathsf{W}_{n_\flat}(C\beta^{-0.28}\mathsf{y}^{5/2})$, if it lies in H_r; Step 3 with $\mathsf{z}(\lambda)^3 \ge c\beta^{-18}$ and Step 7 (i) give $\log Z_{n_\flat} \le \log\mathsf{N}_0(n_\flat) + C\mathsf{y}$, Step 7 (iii) at ρ_1 gives $\log Z_{n'} \ge \log\mathsf{N}_0(n') - C\mathsf{y}$ at $n' = n_\flat, 2n_\flat$, and Step 2 (i) with Step 6 bounds $\delta_{n_\flat} \le 8\log Z_{n_\flat} - \log Z_{2n_\flat}$.

(b) For every block B of side $R_\flat$ on $T_{N'}$, let E_B be the event that some gauge on B puts its bonds within ρ_1 of $\mathbf{1}$. Let F_8 be the product of the eight reflected indicators of E_B^c on $T_{n_\flat}$. It has the factorization into reflected halves in each coordinate used in Step 3. With $Z = Z_{n_\flat}$, that step gives

$$(\mathsf{z}(\lambda)^3 - e^{-\lambda r^2/2}) Z[F_8] \le Z[F_8\, 1_{\mathsf{H}_r}].$$

The factor on the left is at least $c\beta^{-18}$ for large β. The part on the right where a plaquette exceeds ε_0 is at most $Ze^{-9.5\mathsf{y}^3}$ by (a). On the rest the field lies in the chart of radius $C\beta^{-0.28}\mathsf{y}^{5/2}$ by (a). If its chart radius is at most $\rho_1/1.01$, its gauge restricts to a gauge of bond error at most ρ_1 on B, so $F_8 = 0$. The intervening dyadic shells number $O(\mathsf{y})$ and have radii at least $\rho_1/1.01$. Uniformly on them, $n_\flat^3/\beta = o(1)$ and $n_\flat^5\rho^4 = o(1)$. The shell bound of Step 7(i), divided by the lower bound $Z \ge \mathsf{N}_0 e^{-C\mathsf{y}}$ from (a), is at most $\exp(-10\mathsf{y}^3)$ after increasing $K_1^\flat$. Thus $Z[F_8]/Z$ is at most $\exp(-9\mathsf{y}^3)$ for large β. The eighth root in Step 2(ii) and $\delta_{n_\flat} \le C\mathsf{y}^2$ give $\langle 1_{\mathsf{E}_B^c}\rangle \le e^{-\mathsf{y}^3}$.

(c) $Z_{N'} \le \beta^{19} Z_{N'}[\mathsf{W}_{N'}(\rho_2)]$. Let A be the intersection of the events E_B for the blocks on the grid of spacing $R_\flat/2$ used in Step 4(ii). There are $O(\beta^{0.36})$ such blocks, so $\langle 1_{A^c}\rangle \le \beta e^{-\mathsf{y}^3}$ by (b). The gluing condition holds since $N'^2\rho_1/R_\flat = O(\beta^{-0.04}\mathsf{y}^{3/2})$. On $A \cap \mathsf{H}_r$, the gauge from Step 4(ii) has bond error $O(\beta^{-0.38}\mathsf{y}^{3/2})$, and Step 4(iii) puts the field in $\mathsf{W}_{N'}(\rho_{\max})$ with $\rho_{\max} = C\beta^{-0.38}\mathsf{y}^{5/2}$. By Step 3,

$$Z_{N'}[\mathsf{W}_{N'}(\rho_{\max})] \ge (\mathsf{z}(\lambda)^3 - \beta e^{-\mathsf{y}^3} - e^{-\beta^{0.2}/2}) Z_{N'} \ge c\beta^{-18} Z_{N'}.$$

To compare with the smaller chart, cover the radii between ρ_2 and $\rho_{\max}$ by $O(\mathsf{y})$ dyadic shells. At outer radius ρ in this range, Step 7(i) divided by the lower bound of Step 7(iii) at ρ_2 bounds the relative mass of a shell by

$$N'^{13} \exp\left[C(\mathsf{y} + \mathsf{EE}(\rho_2) + N'^3/\beta) + CN'^5\rho^4 - c\beta\rho^2\right].$$

Here we used $|m_1(N')| \le CN'^3$ from Step 7(iii). Since $N'^5\rho_{\max}^2/\beta = O(\beta^{-0.06}\mathsf{y}^5)$, the quartic term is at most $c\beta\rho^2/2$ for large β. Also $\mathsf{EE}(\rho_2) \le 2$ for large β by the powers listed in (d). The choice of $K_2^\flat$ then makes the sum of the shell bounds at most β^{-30} because $\beta\rho_2^2 = K_2^\flat N'^3/\beta$ and $N'^3/\beta \gg \mathsf{y}^2$. Subtracting this shell mass gives (c).

(d) $|\log Z_{N'} - N'^3(-3\mathsf{y} + z_\infty) - m_1(N')/\beta| \le C\mathsf{y}^2$: from below by Step 7 (iii) at ρ_2, from above by (c) and Step 7 (iii), and by Step 6; at ρ_2 every member of EE except 1 is a negative power of β, the largest $\beta N'^4\rho_2^5 \approx \beta^{-0.09}$, so that $\mathsf{EE} \le 2$, and the hypotheses of Step 7 hold, as $N'\rho_2 \approx \beta^{-0.15}$, $N'^{1/2} \approx \beta^{0.17}$ and $N'^3/\beta \approx \beta^{0.02}$.

Step 9: the Dirichlet box. For every $n \ge 2$ and $\tau_{\mathrm{gf}} > 0$ there are $q_0^{[n]}$ and $C(n)$ with $|\log Z_{n,\beta} + \frac{d_1}{2}\log\beta - q_0^{[n]} - q_1^{[n]}/\beta| \le C(n)\beta^{-2}$ for $\beta \ge 1$; so $q_1^{[n]}$ does not depend on τ_{gf}. The reduction in the proof of Proposition 7.12, taken at the insertion 1 (the axial gauge on the tree of Lemma 7.6(b), the exponential chart of Definition 7.4 and Lemma 7.5, the discarding of the large fields, and the change of variables eq. 7.viii to the covariant gauge with the Gaussian weight of d^*A), writes $Z_{n,\beta}$, up to $O(e^{-c\beta})$ and an explicit factor, as an integral $\int_{\mathcal{W}} e^{-\beta\Phi_\tau - \Theta}$ with $\Phi_\tau = S(e^{\mathrm{i}A}) + \frac{1}{2\tau}\|d^*A\|^2$, whose Hessian at 0 is the positive form S_2 of Definition 7.7 (Lemma 7.6(c)), and Θ the Haar and ghost terms. Laplace's method to the second order (the Gaussian scaling $A = \beta^{-1/2}z$, the Taylor expansion of the exponent, and the moment–cumulant relation for the coefficient) gives the expansion, with the coefficient $-\langle W_2\rangle_0 + \frac{1}{2}\langle W_1; W_1\rangle_0$, $W_1 = \mathsf{S}_3$ and $W_2 = \mathsf{V}_2$; the left side does not involve τ_{gf}, so neither does the coefficient. In the Landau chart of the box, with the gauges of the box (a forest of lines that each end on the boundary) in the place of the periodic ones and no constant modes, Step 4 (iii), Step 5, the change of variables displayed at the head of Step 7, without c and without the factor N^9, and the first two bounds of Step 7 (ii) hold with the same proofs at fixed n, with numbers $C(n)$ in the place of C; so on the chart of the radius ρ, $|F - F^{\mathrm{lead}}| \le C(n)(\beta\rho^5 + \rho^3)$, both are Lipschitz

with the constant $C(n)(\beta\rho^3+\rho)$, and $|F|\le C(n)(\beta\rho^4+\rho^2)$ by the bounds of Steps 4 (iii) and 5. Take $\rho=\mathsf{y}\beta^{-1/2}$. The fields outside the chart of the radius ρ have an action $\ge\rho^2/C(n)$, so that their part of $Z_{n,\beta}$ is at most $e^{-\mathsf{y}^2/C(n)}$, smaller than $\mathsf{N}_0^{\mathrm{D}}(n,\beta)$, a number of the order $\beta^{-d_1/2}$, by a factor that decays faster than every power of β; in the chart the shift of u to u' costs the Lipschitz constant times $|\mathsf{B}|_2\le C(n)\rho^2$, the Gaussian tails of single bonds make the probability of Gd^c and the mean of $|F^{\mathrm{lead}}|$ on Gd^c smaller than every power of β, and the expansion $e^{-F}=1-F+O(F^2)$ applies, with $F^2=O(\mathsf{y}^8\beta^{-2})$; as $\beta\rho^5=\mathsf{y}^5\beta^{-3/2}$, this gives $\log Z_{n,\beta}=\log\mathsf{N}_0^{\mathrm{D}}(n,\beta)+m_1^{\mathrm{D}}(n)/\beta+O(\beta^{-3/2}\mathsf{y}^5)$, where $m_1^{\mathrm{D}}(n):=-\beta E_0^{\mathrm{D}}F^{\mathrm{lead}}$ is taken in the box: E_0^{D} is the Gaussian mean of the covariance $\beta^{-1}\mathsf{Cv}$ of the box, every kernel is that of the box, the constants c are absent, and the final term of F^{lead} takes the form $\sum_b|u_b|^2[\frac{3}{2}(d\,\mathsf{Gr})_{bb}-\frac{1}{2}]$, the quadratic part of $-\operatorname{tr}\mathsf{Y}_u+\frac{1}{2}\sum_b\log(1-|u_b|^2)$, which for the periodic cube, where $(d\,\mathsf{Gr})_{bb}=(1-N^{-3})/3$, reduces to $-|\tilde u|_2^2/2N^3$. Further $\log\mathsf{N}_0^{\mathrm{D}}=-\frac{d_1}{2}\log\beta+\mathrm{a}$ constant. The two expansions have one coefficient of β^{-1}: $m_1^{\mathrm{D}}(n)=q_1^{[n]}$.

Step 10: comparison of the box and the torus. Reflect the cochains of T_{2n} in the three coordinate walls through the origin. Odd extension in all three reflections identifies the Dirichlet cochains of Λ_n with the corresponding subspace of the torus cochains. The coboundary and its adjoint commute with the reflected cochain maps, including their orientation signs. Each box kernel is therefore the signed sum of the eight reflected torus kernels. If r is the distance between the two arguments in the box and D is the distance from the first argument to the boundary, each nonidentity image with decay exponent e has size at most $C(1+\max(r,D))^{-e}$. This follows coordinatewise: the distance from x to the image of y in a reflected coordinate is $\min(x+y,2n-x-y)$ for $0\le x,y\le n$. This is at least both $|x-y|$ and the distance of x to the two endpoints. Offsets from bond and plaquette orientations change these bounds by at most a constant.

To estimate the coefficient, use the expression before Step 1 with the local quartic term, the quadratic determinant terms and the two cubic vertices. The local quartic terms have errors $O((1+D)^{-1})$ under image replacement. Each nonlocal summand is a product of three kernels with decay powers $(3,1,1)$ or $(2,2,1)$. The first two patterns come from the two cubic vertices: the two curl legs are either paired together or paired with plain legs at the opposite vertices. The determinant loop has two first-difference Green kernels and a plain covariance, which gives $(2,2,1)$. For each changed line the sum over the second cell is bounded by

$$C\sum_{r\ge0}(1+r)^2(1+\max(r,D))^{-e}(1+r)^{-(5-e)}\le\frac{C'}{1+D}.$$

For $r\le D$ sum the power $(1+r)^{e-3}$ and for $r>D$ sum $(1+r)^{-3}$. The omitted second cells outside the box give the same bound from their distance at least D. Since the number of first cells at any given integer boundary depth is $O(n^2)$, the total error is $O(n^2\log n)$. Consequently $|m_1^{\mathrm{D}}(n)-m_1(2n)/8|\le Cn^2\log n$ and Step 9 gives $|(2n)^{-3}m_1(2n)-n^{-3}q_1^{[n]}|\le C\log n/n$.

Step 11: the value. Let $\tau_{\mathrm{gf}}>0$. By Lemma 7.9 each term of $q_1^{[n]}$ is a finite sum, with coefficients that do not depend on the place, of products of the kernels $\mathsf{C},\mathsf{E},\Pi,\mathsf{D},\mathsf{g}$ of the box; the pairings of $\langle\mathsf{S}_3;\mathsf{S}_3\rangle_0$ with a line from a cubic vertex to itself vanish by the colour sum, so each of the others has three lines between two plaquettes. In the standard writing of Definition 7.8(3) every monomial of $\mathsf{a}_p^{(3)}$ carries exactly one curl leg, its two other legs being plain, so these three lines are a line between the two curl legs and two lines between plain legs, or two lines from a curl leg to a plain leg and one line between plain legs, and the majorants eq. 7.xxxi give them the decay exponents $3,1,1$ or $2,2,1$, a decay $\langle y\rangle^{-5}$ in all. These majorants hold for the kernels of $\mathbb{Z}^3$ (Step 1 of the proof of Lemma 7.27); by the images of the proof of Proposition 7.39 and Lemma 7.38(a), (b), the kernels of the boxes are signed sums of eight periodised kernels, which obey the same majorants with a constant that does not depend on n and have the kernels of $\mathbb{Z}^3$ as their pointwise limits; at the places at the distance $\ge R$ from the boundary the image terms change the density of a site by CR^{-1}, the truncation of

the second cell to $|y|_\infty < R$ costs CR^{-2}, and the remaining finite sums converge to those of $\mathbb{Z}^3$. So $n^{-3}q_1^{[n]} \to -v_2 + \frac{1}{2}s_{33}$, the density of $\mathbb{Z}^3$ at the site 0:

$$v_2 := \sum_{x_p=0} \langle \mathsf{a}_p^{(4)} \rangle_0 + \sum_{b_-=0} (1 + 2\mathsf{g}(b))\mathsf{C}(b,b) - 12 \sum_{b_-=0} \sum_{b'} \mathsf{D}(b;b')\mathsf{D}(b';b)\mathsf{C}(b,b'), \qquad s_{33} := \sum_{x_p=0} \sum_{p'} \langle \mathsf{a}_p^{(3)}; \mathsf{a}_{p'}^{(3)} \rangle_0,$$

which does not depend on τ_{gf}, as $q_1^{[n]}$ does not. At $\tau_{\mathrm{gf}} = 1$, $\mathsf{C}((x,\mu),(y,\nu)) = \delta_{\mu\nu}G(x-y)$, $\mathsf{g}(b) = \frac{1}{3}$ and $G(e_\nu) = G_0 - \frac{1}{6}$. (i) Write the signed vectors around a plaquette as $w_1, \dots, w_4$, with the two pairs of opposite edges $(1,3)$ and $(2,4)$. Put $g = G_0 - 1/6$. The variance of each color component is G_0, the covariance across opposite edges is $-g$, and the two directions are independent. In the fourth Taylor coefficient of the scalar part of the plaquette product, the contributions from a single fourth-order exponential and from two second-order exponentials have means $5G_0^2/2$ and $27G_0^2/2 + 3g^2$, respectively. The terms with two vector factors have mean $-28G_0 g$: for each opposite pair the terms with a cubic vector factor give $-5G_0 g$, and the terms with a second-order scalar factor on another edge give $-9G_0 g$. For the term with four vector factors, the Pauli trace identity gives the three products of dot products, with signs $+,-,+$. Their expectations are $3g^2, 9g^2, 3g^2$, giving $-3g^2$ after the signs. Reversing sign to obtain the action, $\langle \mathsf{a}_p^{(4)} \rangle_0 = -16G_0^2 + 28G_0 g = 12G_0^2 - \frac{14}{3}G_0$. There are three plaquettes per site.

(ii) The Haar term and the ghost tadpole give $(1 + \frac{2}{3})G_0$ for each of the three bonds at a site, $5G_0$ in all. (iii) The ghost loop: for bonds of one direction, $\mathsf{D}(b;b') = \frac{1}{2}[G(y - e_\mu) - G(y + e_\mu)] = -\mathsf{D}(b';b)$, and bonds of two directions do not interact at $\tau_{\mathrm{gf}} = 1$; so $-12 \sum \mathsf{DDC} = 3 \sum_\mu \sum_y [G(y + e_\mu) - G(y - e_\mu)]^2 G(y) = 9J_{\mathrm{gh}}$. So $v_2 = 36G_0^2 - 9G_0 + 9J_{\mathrm{gh}}$. (iv) The cubic vertex: $\mathsf{a}_p^{(3)} = T^{\mu\nu}(x) + T^{\nu\mu}(x)$ for $p = p_{\mu\nu}(x)$, with $T^{\mu\nu}(x) := -(A_\mu(x) \times A_\mu(x + e_\nu)) \cdot (A_\nu(x) + A_\nu(x + e_\mu))$; at $\tau_{\mathrm{gf}} = 1$ lines join equal directions, so only the pairs $T^{\mu\nu}, T^{\mu\nu}$ interact; the line of the two legs of the direction μ to each other vanishes by the antisymmetry, and the two pairings of these legs with those at y give $6G(y)^2$ and $-6G(y + e_\nu)G(y - e_\nu)$ times the line $2G(y) + G(y + e_\mu) + G(y - e_\mu)$ of the third legs; the six ordered pairs of directions give $s_{33} = 36J_3$. Hence $-v_2 + \frac{1}{2}s_{33} = 9G_0 - 36G_0^2 - 9J_{\mathrm{gh}} + 18J_3 = p_1$. This is the first claim of (b).

Step 12: the rate and the conclusion. For an even $N_1 \geq 4$ let $\mu_T(N_1)$ be the density per site of $-m_1(N_1)$ on T_{N_1}, and μ_∞ the same expression with the kernels of $\mathbb{Z}^3$ and the sums over $\mathbb{Z}^3$; by the last bounds of Step 1, replacing a kernel of the decay e costs $C\langle y \rangle^{-(5-e)} N_1^{-e}$ for $|y| \leq N_1/2$ and the second cells beyond $N_1/2$ cost CN_1^{-2}, so $|\mu_T(N_1) - \mu_\infty| \leq C \log N_1 / N_1$; by Steps 10 and 11, $-\mu_T(2n) = (2n)^{-3} m_1(2n) \to p_1$, so $\mu_\infty = -p_1$, and $|N_1^{-3} m_1(N_1) - p_1| \leq C \log N_1 / N_1$: the second claim of (b). Finally let $\pi(\beta) := -3 \log \beta + z_\infty + p_1/\beta$ and $\mathrm{Er}_{N'} := P_{N'} - \pi(\beta)$. By Step 2 (i), $8\mathrm{Er}_{2N} - 7\mathrm{Er}_N \leq P - \pi \leq \mathrm{Er}_{2N}$, so $|P - \pi| \leq 15 \max\{|\mathrm{Er}_N|, |\mathrm{Er}_{2N}|\}$; by Step 8 (d), $|\mathrm{Er}_{N'}| \leq |N'^{-3} m_1(N') - p_1|/\beta + C\mathsf{y}^2 N'^{-3}$, and $N'^{-3} \leq \beta^{-1.02}/512$; with (b) this is (a). The same with $|m_1(N')| \leq CN'^3$ in the place of (b) gives $|P + 3 \log \beta - z_\infty| \leq C/\beta$. □

Block fields and tapered links. $\mathcal{M}$ is the double-block average of Proposition YM3_I:4.5; on the torus ℓ at the cutoff K, $V_j := \mathcal{M}^{K-j} U$ is the block field of the depth j, a configuration of $\Lambda_{j,\ell} := a_j \mathbb{Z}^3 / \ell \mathbb{Z}^3$, $0 \leq j \leq K$, $V_K = U$. Its value at a bond c reads only the bare bonds with both ends in the double block $Q(c)$, the union of the two blocks of L^{K-j} sites a side about c_- and c_+ (Proposition YM3_I:4.5); the map is Borel on every branch, gauge covariant and equivariant under lattice isometries by Lemma 18.211; so the same formulas, read on $a_K \mathbb{Z}^3$ or on a periodic box whose sides are multiples of L^{K-j}, define block fields $\widetilde{\mathcal{M}}^{K-j} U$ there. For a closed path C of $\Lambda_{d,\ell}$, $W_C(V)$ is $\frac{1}{2}$ tr of the ordered product of V along C. Fix a depth $d \geq 0$ and put $w := a_d$. For a positively oriented bond c of $\Lambda_{d,\ell}$ of the direction e and $0 \leq i \leq K - d$ let $y_i^\mp := c_\mp \pm \frac{1}{2}(a_d - a_{d+i})e$; the straight path $[y_{i-1}^-, y_i^-]$ consists of $\frac{1}{2}(L-1)$ bonds of $\Lambda_{d+i,\ell}$, and $y_{K-d}^+ = y_{K-d}^- + a_K e$. The *tapered*

link is

$$\widetilde V(c) := \prod_{i=1}^{K-d} V_{d+i}([y^-_{i-1}, y^-_i]) \cdot U(\langle y^-_{K-d}, y^+_{K-d}\rangle) \cdot \prod_{i=K-d}^{1} V_{d+i}([y^+_i, y^+_{i-1}]) :$$

links L times thinner at each stage, one bare bond across the middle plane of c, and back. Let C be the boundary of a rectangle of bonds of $\Lambda_{d,\ell}$ in a coordinate plane, with the two sides of the length T along a direction e_{μ_0} (the *legs*) and the two sides of the length R along e_ν, $R, T \in a_d\mathbb{N}$. $W_C^{\rm tap}$ is $W_C(V_d)$ with V_d replaced by $\widetilde V$ at the first and at the last link of each leg; for $d \le D \le K$, $W_C^{(D)}$ is $W_C(V_d)$ with these four links tapered down to the depth D only, the piece across the middle plane being the link $V_D(c''_D)$, $c''_D := \langle y^-_{D-d}, y^+_{D-d}\rangle$; so $W_C^{(d)} = W_C(V_d)$ and $W_C^{(K)} = W_C^{\rm tap}$.

The numbers of the block fields. Use the canonical constants of §17.2 and the calibrated choice (Th1), (Th2) of §2.3.1. Write $\varepsilon_{\rm th}(x) = A_0 x^{-1/2}(\log x)^{\mathfrak{p}_0}$ as in YM3_I:(634), with the cut constant c_ρ and threshold $\mathfrak{t}_\natural$ of that calibration. Use the history constants $c', C_{\rm maj}, C^\Sigma_{\rm maj}, c_{\rm low}$ from Section YM3_I:115, and set $C_{\rm low}(x) = c_{\rm low} + \frac{9}{2}\log x$. Use $C_{\rm tt}, C'_{\rm tt}, E_0$ in Proposition YM3_I:74.5. As in Proposition YM3_I:74.1, $M = L^{m'}$, $R(x) = \min\{L^j : j \ge 0,\ L^j \ge (\log x)^r\}$, and the room constant $C_{\rm s}$ satisfies $2LC_{\rm s} \ge C_L$. Put

$$\mathsf{m}(x) = 1 + m' + \max\{\log_L R(x + \bar B), \lceil \log_L C_{\rm s}\rceil\}.$$

If $m \ge \mathsf{m}(x)$, then $L^m \ge LMR(x)$ and $2L^m \ge C_L M$, as required in Proposition YM3_I:74.5. For a label $\mathsf{b} \ge \gamma^{-2}$ and integers $D > D' \ge 0$ let $\eta_D := \log(L^D\mathsf{b})$, $\omega_D := 2c_\rho\,\varepsilon_{\rm th}(L^{D+1}\mathsf{b})$, $\mu(D') := \mathsf{m}(L^{D'}\mathsf{b})$, $\mathsf{n}(D') := 2L^{\mu(D')}$, $\Delta(D') := \mathsf{C}_{\rm maj} + 2 + C_{\rm low}(L^{D'}\mathsf{b}) + 2C_{\rm tt}C'_{\rm tt}E_0$,

$$\mathsf{R}(D', D) := 2M^{-3}\big(\mathsf{n}(D')L^{D-D'}\big)^3 e^{-c'A_0^2\eta_D^{2\mathfrak{p}_0}} e^{(\mathsf{C}^\Sigma_{\rm maj}+2+C_{\rm low}(L^{D'}\mathsf{b}))\,\mathsf{n}(D')^3}, \qquad \varepsilon''(D', D) := \mathsf{R}(D', D)^{1/\mathsf{n}(D')^3} e^{\Delta(D')},$$

$\tau^{\rm ch}_d := \sum_{D\ge d}(13L^2\omega_D + 2\varepsilon''(d-1, D))$ for $d \ge 1$; $D_\flat$ the least integer ≥ 1 such that $L^D\mathsf{b} \ge \mathfrak{t}_\natural$, $\omega_D \le 1/200L^2$ and $D - 1 + m' + \log_L R(\mathsf{b}) \ge \mu(D-1)$ for all $D \ge D_\flat$; $\varepsilon'_D := 13L^2\omega_D + 2\varepsilon''(D-1, D)$ for $D \ge D_\flat$ and $\varepsilon'_D := 2$ for $D < D_\flat$; $\tau'_d := 4\sum_{D\ge d}\varepsilon'_D$. With the tension $\sigma_{\rm bl} := 0.66/\ell_0^2$: $\varrho_d := w + \log(1/4\tau^{\rm ch}_d)/(\sigma_{\rm bl}Lw)$ and $\kappa_d := \log(1/2\tau^{\rm ch}_d)/(Lw)$. None of these numbers depends on K, m or ℓ.

Proposition 18.115 (Wilson loops of block fields under the box inequality)**.** Let $\mathsf{b} \ge \gamma^{-2}$, $\ell_0 = 2L^{m_0}$ with $m_0 \in \mathbb{N}$, and assume BI$[\mathsf{b}, \ell_0, K_0; 0.069]$ (Definition 17.28) with $\ell_0/2a_K \ge 4$ for $K \ge K_0$. Let $\langle\cdot\rangle_K$ be the mean on the torus ℓ at $\beta = L^K\mathsf{b}$, ν_K the periodic Gibbs state of Theorem AZ(1)(b), $d \ge 0$, $w = a_d$, $\sigma_{\rm bl} = 0.66/\ell_0^2$, and C a rectangle as above.

(a) *Tapered loops on the tori.* For every $\ell = \ell_0 L^j$, $j \ge 1$, every $K \ge \max\{K_0, d+1\}$ and $2w \le R, T \le \ell/2$: $|\langle W_C^{\rm tap}\rangle_K| \le 1.3\, e^{-\sigma_{\rm bl}(R-w)(T-w)}$. The same bound holds when the four links are replaced by arbitrary products $X_- \cdot S \cdot X_+$ of the bare bond $S = U(\langle y^-_{K-d}, y^+_{K-d}\rangle)$ of the straight path $[c]$ that crosses the middle plane of c and of unitary Borel transporters X_- from c_- to y^-_{K-d} and X_+ from y^+_{K-d} to c_+ that read only bare bonds of the block about c_-, respectively c_+; here, for bare sites x, y, a *transporter* from x to y is a Borel map X on the bare configurations, with values in the 2×2 matrices, such that $X(U^u) = u(x)X(U)u(y)^{-1}$ for all gauge transformations u, where $U^u(b) := u(b_-)U(b)u(b_+)^{-1}$; the ordered product of U along a path from x to y is one, and $V_d(c)$ and each product $X_- \cdot S \cdot X_+$ are transporters from c_- to c_+.

(b) *Tapered loops in the Gibbs state.* For $K \ge \max\{K_0, d+1\}$ and all $R, T \in a_d\mathbb{N}$ with $R, T \ge 2w$: $|\nu_K(W_C^{\rm tap})| \le e^{-\sigma_{\rm bl}(R-w)(T-w)}$, the block fields being formed with $\widetilde{\mathcal{M}}$.

(c) *The telescope, without the side.* For every $\ell = 2L^m$ with $MR(\mathsf{b}) \le L^m$, every $K > d$ and $2w \le R, T < \ell$: $|\langle W_C(V_d)\rangle_K - \langle W_C^{\rm tap}\rangle_K| \le \tau'_d$; the limits $\mu_d(W_C) := \lim_K \langle W_C(V_d)\rangle_K$ and $\mathsf{w}_C := \lim_K \langle W_C^{\rm tap}\rangle_K$ exist, $|\mu_d(W_C) - \mathsf{w}_C| \le \tau'_d$, and τ'_d, $\tau^{\rm ch}_d$ tend to 0 as $d \to \infty$. These assertions do not use BI. Under BI and at $\ell = \ell_0 L^j$, $j \ge 1$, with $MR(\mathsf{b}) \le \ell/2$ and

$2w \le R,T \le \ell/2$: $|\mathsf{w}_C| \le 1.3\, e^{-\sigma_{\rm bl}(R-w)(T-w)}$ and $|\mu_d(W_C)| \le 1.3\, e^{-\sigma_{\rm bl}(R-w)(T-w)} + \tau'_d$, with the error τ'_d the same on all these tori.

(d) *Block loops: a range and a second term.* Let $d \ge 1$ with $L^d\mathsf{b} \ge \mathsf{t}_\natural$ and $\omega_D \le 1/200L^2$ for all $D \ge d$, $K \ge \max\{K_0, d+1\}$, $\ell = 2L^m \ge 13\ell_0$ with $m+d-2 \ge \mu(d-1)$, and $2w \le R,T \le \ell/2$. If $\min\{R,T\} \le \varrho_d$, then $|\langle W_C(V_d)\rangle_K| \le 17\, e^{-\sigma_{\rm bl}(R-w)(T-w)}$. If $2\tau_d^{\rm ch} \le 1$, then for all such R,T, $|\langle W_C(V_d)\rangle_K| \le 5(2+\max\{R,T\}/Lw)^2\big[e^{-\sigma_{\rm bl}(R-w)(T-w)} + e^{-\kappa_d(\max\{R,T\}-3Lw)}\big]$. The same two bounds hold for $\mu_d(W_C)$ if besides $MR(\mathsf{b}) \le L^m$, and for $\nu_K\big(W_C(\widetilde{\mathcal{M}}^{K-d}U)\big)$ for all $R,T \ge 2w$. As $\tau_d^{\rm ch} \to 0$ and $w = a_d \to 0$, for a rectangle of fixed physical sides the first bound holds at every large depth.

■

Proof. Lengths are in lattice units of a_K where nothing else is said; $N := \ell_0/2a_K$, so that BI says $\mathsf{e}(N) \le 0.069$ at $\beta = L^K\mathsf{b}$, $K \ge K_0$; $N_k := 2^k N$ and $\chi_k := \delta((2N_k)^3)$. For a box $\Lambda = (n_0, n_1, n_2)$ with the time 0 over the slice (n_1, n_2), D is the transfer operator of the setting of Section 17.2 over that slice and $\lambda_0 = \|\mathsf{D}\|$, while T keeps its meaning of the statement, the length of the legs; $S_\mu(x;\Sigma)$ is the number r_x of Proposition 17.31 for the time μ over the cross-section Σ, and $S_0(x) := S_0(x;(n_1,n_2))$; J_1 is the involution of Proposition 17.31(d) that reverses the sign of the bonds of a layer that cross one plane $x_1 = $ const between sites; and Φ^Θ is the conjugated mirror image of a slab function, as in (M1) of Section 17.2; for a function Φ with values in matrices, Φ^Θ is the adjoint matrix of its mirror image, $(\Phi^\Theta)_{ab} := (\Phi_{ba})^\Theta$. For a time direction over a cross-section Σ of a box, with the action A_Σ of a layer, the crossing operator K and the transfer operator $\mathsf{D} = \mathsf{D}_\Sigma$ of the setting of Section 17.2, and for a bounded Borel function Φ on $\mathcal{Y}_\vartheta$, $\vartheta \ge 2$, or one with values in matrices, taken entry by entry, put $\hat\Phi := e^{\beta A_\Sigma/2}\,\mathfrak{S}[\Phi]\,e^{\beta A_\Sigma/2}$, with the operator $\mathfrak{S}[\Phi]$ of (M1): its kernel is that of $\mathfrak{S}[\Phi]$ with the weight $e^{-\beta A_\Sigma}$ of each of the two end layers taken with the power $\frac12$. Then $\mathfrak{Y}[\Phi] = \mathsf{K}^{1/2}e^{-\beta A_\Sigma/2}\,\hat\Phi\,e^{-\beta A_\Sigma/2}\mathsf{K}^{1/2}$ and $e^{-\beta A_\Sigma/2}\mathsf{K}\,e^{-\beta A_\Sigma/2} = \mathsf{D}$, so the identities of (M1) and the cyclicity of the trace give $\hat{\mathsf{1}}_\vartheta = \mathsf{D}^{\vartheta-1}$ and the trace formula in the form $Z(\Lambda)\langle\prod_s(\Phi^s)_{\tau_{s-1}}\rangle_\Lambda = \mathrm{Tr}(\hat\Phi^r\mathsf{D}\,\hat\Phi^{r-1}\mathsf{D}\cdots\hat\Phi^1\mathsf{D})$ for consecutive slabs of $\vartheta_s \ge 2$ layers that fill the time, one factor D standing for the step from each slab to the next; the weights being positive, the kernels obey $|\hat\Phi(V',V)| \le \sup|\Phi|\,\mathsf{D}^{\vartheta-1}(V',V)$; and as the mirror reverses the order of the layers and keeps the weight, the kernel of $\widehat{\Phi^\Theta}$ at (V',V) is the complex conjugate of that of $\hat\Phi$ at (V,V'), and for matrix values its adjoint matrix, that is $\widehat{\Phi^\Theta} = \hat\Phi^*$, the adjoint being taken in the second case on the L^2 space of the vector-valued functions.

Step 1: flux on one lattice. Let $Z^\tau(\Lambda) := Z^{(10;0)}(n_0,(n_1,n_2))$ be the partition function with the sign of $\mathrm{tr}\,\partial U$ reversed on one column of plaquettes of the plane $(0,1)$, $Z_e := \frac12(Z - Z^\tau)$, $\mathfrak{f} := Z_e/Z$, $\hat{\mathfrak{f}} := \mathfrak{f}e^{\delta(\Lambda)} = Z_e e^{-P|\Lambda|}$, and $q := \|\mathsf{D}P_o\|/\lambda_0$ with $P_o := \frac12(1-\mathsf{J}_1)$. By Proposition 17.31(d), J_1 is a unitary involution commuting with D, $Z^\tau = \mathrm{Tr}(\mathsf{J}_1\mathsf{D}^{n_0}) > 0$, $Z_e = \mathrm{Tr}(P_o\mathsf{D}^{n_0}) \ge 0$, the top lies in the even sector, and $0 \le \mathfrak{f} < \frac12$. Then: (i) $\mathfrak{f} \le \hat{\mathfrak{f}} \le e^{\delta(\Lambda)} - 1$, as $Z_e \le \lambda_0^{n_0}S_0(n_0)$ and $\delta(\Lambda) = n_0\varepsilon(n_1,n_2) + \log(1+S_0(n_0))$ with $\varepsilon \ge 0$ (Proposition 17.31(c)), so that $\hat{\mathfrak{f}} \le S_0(n_0)e^{n_0\varepsilon}$; (ii) $\hat{\mathfrak{f}}(n'_0,n'_1,n_2) \le \hat{\mathfrak{f}}(n_0,n_1,n_2)^{n'_0n'_1/n_0n_1}$ for $n'_i \ge n_i$, as $x \mapsto (\mathrm{Tr}\,B^x)^{1/x}$ does not increase for $B = \mathsf{D}P_o \ge 0$, as in Proposition 17.31(b), in the direction 0 and, with the flips of the other plane of Proposition 17.31(d), in the direction 1, $e^{-P|\Lambda|}$ being an exact power; (iii) $q^{n_0} \le \hat{\mathfrak{f}}$, as $(\lambda_0 q)^{n_0} \le Z_e$ and $\lambda_0^{n_0} \ge e^{Pn_0|\Sigma|}$; (iv) for integers $4 \le m \le n'$, at a fixed slice (n_0,n_1), with the time 2 and $S_2(x) := S_2(x;(n_0,n_1))$, $\mathfrak{f}(n_0,n_1,n') \le (n'/m)(\mathfrak{f}(n_0,n_1,2m) + \frac12 S_2(m)) + \frac12 S_2(n')$: with the time 2 the reversed column lies in every layer, $Z^\tau = \mathrm{Tr}(\mathsf{T}^{(1)})^{n_2}$ with the operator $\mathsf{T}^{(1)} \ge 0$ of Proposition 17.31(d), whose top is at least $(Z^\tau(2m)/Z^\tau(m))^{1/m}$, and $Z^\tau(m) \le Z(m)$; so $1 - 2\mathfrak{f}(n') \ge \big[(1-2\mathfrak{f}(2m))/(1+S_2(m))\big]^{n'/m}/(1+S_2(n'))$, and Bernoulli's inequality gives the claim.

Step 2: the numbers under BI. One doubling of the scale, as in Proposition 17.32, with the three sides doubled in turn and each defect read through Proposition 17.31(b), gives $\mathsf{e}(2n) \le$

$\Psi(\mathsf{e}(n))$ for $\mathsf{e}(n) \le 0.069$, where $\Psi(\epsilon) = 2\log(1+s_3^2)$, $s_1 = \varphi(e^{\epsilon}-1)$, $s_2 = \varphi(e^{4\log(1+s_1)}-1)$, $s_3 = \varphi(e^{4\log(1+s_2)}-1)$, φ the function of Remark 17.29, the three doublings having the defects at most $2\log(1+s_i^2)$, $i=1,2,3$; the identity $\delta(\Lambda) = \frac12(\delta(\Lambda')+2F(\Lambda)-F(\Lambda'))$ for a box Λ' with one side of Λ doubled, along the three doublings from $(2N_k)^3$ to $(4N_k)^3$, gives $\chi_k \le c_k + \chi_{k+1}/8$ with $c_k := \log(1+s_1^2)+\frac12\log(1+s_2^2)+\frac14\log(1+s_3^2)$ at $\epsilon = \mathsf{e}(N_k)$, and $8^{-J}\chi_{k+J} \to 0$; this gives the upper bounds $\mathsf{e}(N_k) \le 0.069$, 0.060454, 0.043318, 0.019604, 0.0034431 for $k = 0,\dots,4$, $\mathsf{e}(N_{k+1}) \le 8.5\,\mathsf{e}(N_k)^2$ and $8.5\,\mathsf{e}(N_k) \le \exp(-0.2207\cdot 2^k)$ for $k \ge 4$; $\chi_0,\dots,\chi_4 \le 0.012838$, 0.0090476, 0.0040840, 0.00073315, 0.000021695, $\chi_k \le 1.83\,\mathsf{e}(N_k)^2$ for $k \ge 4$ and $\chi_k \le 0.004084$ for $k \ge 2$; $S_\mu(N;(2N,2N)) \le 0.035764$, $\delta(N,2N,2N) \le 0.04092$, $N\varepsilon(2N,2N) \le \chi_0/2 \le 0.00642$; and $S_\mu(t;(2N_k,2N_k)) \le (e^{\chi_k}-1)^{t/2N_k}$ for real $t \ge 2N_k$.

Step 3: the area law of the flux. (a) If $n_2 = 2N$, $n_0 \ge N$, $n_1 \ge 2N$, then $\mathfrak{f} \le \hat{\mathfrak{f}} \le \exp(-1.66\,n_0n_1/N^2)$: at $(N,2N,2N)$, by the bound of Step 1 (i) through S_0, $\hat{\mathfrak{f}} \le 0.035764\,e^{0.00642} \le e^{-3.3243}$, and Step 1 (ii). (b) If $k \ge 1$, $24\cdot 4^{k-1}N \le n_2 \le 96\cdot 4^{k-1}N$ and $n_0, n_1 \ge 2^{k+1}N$, then $\mathfrak{f} \le \hat{\mathfrak{f}} \le \exp(-0.165\,n_0n_1/N^2)$. Let $b_k := 2^{k+1}N = 2N_k$, $h_k := 24\cdot 4^kN$, and let $\bar u_k$ bound $\hat{\mathfrak{f}}(b_k,b_k,n_2)$ for $n_2 \in [h_{k-1},h_k]$ ($k \ge 1$), $\bar u_0$ at $n_2 = h_0$. Step 1 (i) and $\delta(2N,2N,24N) \le 12\chi_0$ give $\bar u_0 := e^{12\chi_0}-1 \le 0.16656$; Step 1 (ii) gives $\mathfrak{f}(b_{k+1},b_{k+1},h_k) \le \hat{\mathfrak{f}}(b_k,b_k,h_k)^4 \le \bar u_k^4$; Step 1 (iv) at $m = h_k/2$ and $n' \in [h_k,h_{k+1}]$, with the thermal bounds $S_2(m) \le \xi_{k+1}^{3\cdot 2^k}$, $S_2(n') \le \xi_{k+1}^{6\cdot 2^k}$ of Step 2 over the slice (b_{k+1},b_{k+1}), $\xi_{k+1} := e^{\chi_{k+1}}-1$, gives $\mathfrak{f}(b_{k+1},b_{k+1},n') \le 8\bar u_k^4 + 4.5\,\xi_{k+1}^{3\cdot 2^k}$, and the factor $e^{\delta(b_{k+1},b_{k+1},n')} \le \exp(24\cdot 2^k\chi_{k+1})$ turns this into the bound $\bar u_{k+1} := (8\bar u_k^4 + 4.5\,\xi_{k+1}^{3\cdot 2^k})\exp(24\cdot 2^k\chi_{k+1})$ on $\hat{\mathfrak{f}}$ over the whole window; the resulting numbers $\bar u_1 \le e^{-4.872}$, $\bar u_2 \le e^{-17.21}$, $\bar u_3 \le e^{-66.70}$ and, inductively, $\bar u_k \le \exp(-0.66\cdot 4^k - 0.7)$ for $k \ge 3$ satisfy $-\log \bar u_k \ge 0.165\,b_k^2/N^2$, and Step 1 (ii) carries the bound to all $n_0, n_1 \ge b_k$. (c) In these two cases $q \le \exp(-1.66\,n_1/N^2)$, respectively $q \le \exp(-0.165\,n_1/N^2)$, over the slice (n_1,n_2), by Step 1 (iii). Every $n_2 \ge 24N$ lies in one of the windows of (b).

Step 4: two tools of the transfer operator. (i) *Two odd slab functions.* Let Φ, Φ' be bounded Borel functions of slabs of $\vartheta \ge 2$ layers that change their sign when the reversal J_1 is applied to all their layers, placed g and g' layers apart, $2 \le g \le g'$, $2\vartheta + g + g' = n_0$. Then $|\langle \Phi\Phi'\rangle_\Lambda| \le 2\sup|\Phi|\sup|\Phi'|\,q^{g+1}(1+S_0(n_0-g-1))$, and $\langle \Phi\,\Phi^\Theta\rangle_\Lambda \ge 0$ when Φ^Θ stands on the slab g layers after that of Φ: the operators $\hat\Phi$, $\hat\Phi'$ anticommute with J_1, so they exchange the even and the odd sector; in the trace formula $Z\langle\Phi\Phi'\rangle_\Lambda = \mathrm{Tr}(\mathsf{D}^{g'+1}\hat\Phi'\mathsf{D}^{g+1}\hat\Phi)$ each of the two parts carries on the odd sector at least the power D^{g+1}, as $g \le g'$, and Schwarz's inequality in the Hilbert–Schmidt class with $\widehat{\Phi^\Theta} = \hat\Phi^*$ bounds the rest by $\mathrm{Tr}\,\mathsf{D}^{n_0-g-1}$. (ii) *The temporal gauge at single steps.* In the integral of a bounded gauge-invariant Borel function, the time-like bonds of steps no two of which are equal or neighbours may be set to $\mathbf{1}$; at such a step the factor D of the trace formula is replaced by $\mathsf{D}_{\mathbf{1}} \ge 0$, the operator D with the crossing bonds set to $\mathbf{1}$, whose kernel is of positive type by the exponential series of $\frac12\,\mathrm{tr}(VV'^{-1})$, and $\mathsf{D} = P_G\mathsf{D}_{\mathbf{1}} = \mathsf{D}_{\mathbf{1}}P_G$ with the projection P_G onto the gauge-invariant functions of a layer.

Step 5: loops that split at two planes. Let $\Lambda = (n_0,n_1,n_2)$; in the direction 0 let the consecutive slabs S_B, S_I, S_T have ϑ_c, ϑ_I, ϑ_c layers and a rest $a \ge 2$ layers, the last layers of S_B and S_I being t_1 and t_2; in the direction 1 let Str_L, Str_R be two slabs of ϑ layers, $g \le g'$ layers apart; and let $\mathbf{B},\mathbf{T},\mathbf{R},\mathbf{L}$ be Borel transporters with values in the 2×2 matrices of norm ≤ 1, $\mathbf{B}$ of the inner bonds of S_B from (t_1,ξ_L) to (t_1,ξ_R), $\mathbf{R}$ of the inner bonds of $S_I \cap \mathrm{Str}_R$ from (t_1+1,ξ_R) to (t_2,ξ_R), $\mathbf{T}$ of S_T from (t_2+1,ξ_R) to (t_2+1,ξ_L), $\mathbf{L}$ of $S_I \cap \mathrm{Str}_L$ from (t_2,ξ_L) to (t_1+1,ξ_L), and $f := \frac12\,\mathrm{tr}[\mathbf{B}S^{t_1}_{\xi_R}\mathbf{R}S^{t_2}_{\xi_R}\mathbf{T}(S^{t_2}_{\xi_L})^{-1}\mathbf{L}(S^{t_1}_{\xi_L})^{-1}]$, S^t_ξ the time-like bond at (t,ξ). If $q(n_0',n_2) \le e^{-\varsigma n_0'}$ for all large n_0', over the slices (n_0',n_2) of the direction 1, then for every integer $\mathsf{k} \ge 4$

$$|\langle f\rangle_\Lambda| \le \big(1+S_0(n_0-\vartheta_I;(n_1,n_2))\big)\exp\big((\vartheta_I/\mathsf{k})\,\delta(\mathsf{k},n_1-g-1,n_2)\big)\,e^{-\varsigma\vartheta_I(g+1)}.$$

Indeed, with the steps t_1, t_2 set to $\mathbf{1}$ (Step 4 (ii)), $Z[f] = \frac{1}{2}\operatorname{Tr}(\mathcal{Q}X')$ on $L^2 \otimes \mathbb{C}^4$ with $\mathcal{Q} := \mathsf{D}_{\mathbf{1}}^{1/2} \hat{\Phi}\, \mathsf{D}_{\mathbf{1}}^{1/2}$, $\hat{\Phi}$ the operator of the head of the proof for the matrix-valued function $\Phi = \mathbf{R}^{\mathrm{T}} \otimes \mathbf{L}$ of S_I, and X' built in the same way from the caps and from D^{a+1}; so $|Z[f]| \le \frac{1}{2}\|\mathcal{Q}\|\,\|X'\|_1$, Schwarz's inequality with kernels of positive type bounds $\|X'\|_1$ by $2\operatorname{Tr}\mathsf{D}^{n_0-\vartheta_I} = 2\lambda_0^{n_0-\vartheta_I}(1+S_0(n_0-\vartheta_I))$, and $Z \ge \lambda_0^{n_0}$. For $\|\mathcal{Q}\|$: on the box $(2k\vartheta_I, n_1, n_2)$ let Φ_R be the trace of the product, upward through the $2k$ slabs, of alternating copies of $\mathbf{R}$, $\mathbf{R}^\Theta$, each followed by the time-like bond $S^t_{\xi_R}$ of the step from its last layer t to the next slab, and Φ_L the trace of the like product, downward, of the copies of $\mathbf{L}$, $\mathbf{L}^\Theta$, each followed by the inverse $(S^t_{\xi_L})^{-1}$ of the bond of the step below it; here $\mathbf{R}^\Theta$ and $\mathbf{L}^\Theta$ are the adjoint matrices of the mirror images, as at the head of the proof, so that $\Phi^\Theta = (\mathbf{R}^\Theta)^{\mathrm{T}} \otimes \mathbf{L}^\Theta$, and as $(u(x)Xu(y)^{-1})^* = u(y)X^*u(x)^{-1}$, $\mathbf{R}^\Theta$ is a transporter from the bottom to the top of its slab and $\mathbf{L}^\Theta$ one from the top to the bottom, like $\mathbf{R}$ and $\mathbf{L}$. So $\Phi_R\Phi_L$ is gauge invariant, and with the steps between the copies set to $\mathbf{1}$ (Step 4 (ii)) it has the integral $\operatorname{Tr}(\mathcal{Q}^*\mathcal{Q})^k \ge \|\mathcal{Q}\|^{2k}$, as $\widehat{\Phi^\Theta} = \hat{\Phi}^*$ and $\operatorname{tr}_{\mathbb{C}^4}\prod_i(A_i \otimes B_i) = \operatorname{tr}\prod_i A_i \operatorname{tr}\prod_i B_i$; Φ_R and Φ_L change their sign under the reversal of the time-like bonds of one step, so as functions of the slabs Str_R, Str_L of the direction 1 they fall under Step 4 (i) in the direction 1, which bounds their mean by $8q(2k\vartheta_I, n_2)^{g+1} e^{\delta(2k\vartheta_I, n_1-g-1, n_2)}$, while $Z(2k\vartheta_I, n_1, n_2) = \lambda_0^{2k\vartheta_I}(1 + S_0(2k\vartheta_I))$; with $\delta(2k\vartheta_I, \cdot) \le (2k\vartheta_I/\mathsf{k})\delta(\mathsf{k}, \cdot)$ (Proposition 17.31(c)), the root of the order $2k$ and $k \to \infty$ give $\|\mathcal{Q}\| \le \lambda_0^{\vartheta_I} e^{-\varsigma\vartheta_I(g+1)} \exp((\vartheta_I/\mathsf{k})\delta(\mathsf{k}, n_1-g-1, n_2))$, and the claim follows.

Step 6: tube, sign fields, tapered links, telescope. (i) $W_C \circ \mathcal{M}^{K-d}$ is a real gauge-invariant Borel function, $|\cdot| \le 1$, of the bare bonds of the tube of C, the bonds with both ends in one double block $Q(c)$, $c \in C$; its bonds lie at the sup distance $\le \frac{1}{2}(w - a_K)$ from the sites of C. For a direction μ and an integer i, the *block layer* i of μ is the slab of the L^{K-d} bare layers with $|x_\mu - ia_d| \le \frac{1}{2}(w - a_K)$, which contains the blocks centred at those sites of $\Lambda_{d,\ell}$ that have $x_\mu = ia_d$; the block layers i and $i+1$ abut, and together all block layers fill the direction. So the double blocks of the bonds of C whose ends have $x_\mu \in \{j_- a_d, \dots, j_+ a_d\}$ lie in the $(j_+ - j_- + 1)L^{K-d}$ layers of the block layers $j_-, \dots, j_+$; the tube of a side of C that lies in a plane $x_\mu = ja_d$ lies in the block layer j of μ, a slab of exactly L^{K-d} layers; and a link of the direction μ from the height $j-1$ to the height j reads the block layers $j-1$ and j, which its middle plane parts. (ii) If a field $\gamma = \pm 1$ on the bare bonds has the product 1 over the four bonds of every plaquette with its corners in $Q(c)$, then $\mathcal{M}^{K-d}(\gamma U)(c) = \gamma([c])\mathcal{M}^{K-d}(U)(c)$: on $Q(c)$, γ is a gauge transformation by $\pm\mathbf{1}$ (Proposition YM3_I:4.5); so a flip across a plane between sites multiplies $W_C(V_d)$ by (-1) to the number of the bonds of C that cross it. (iii) $\widetilde{V}(c) = A^-\, U(\langle y^-_{K-d}, y^+_{K-d}\rangle)\, A^+$ with Borel transporters A^- from c_- to y^-_{K-d} and A^+ from y^+_{K-d} to c_+, in the sense of (a), that read only the block about c_-, respectively c_+, as the double blocks of the links of the paths $[y^\mp_{i-1}, y^\mp_i]$ lie in it; so W_C^{tap} is gauge invariant, $|W_C^{\mathrm{tap}}| \le 1$, reads the tube alone and obeys (ii). (iv) $W_C^{(D)}$ is a bounded gauge-invariant Borel function of V_D alone, and pointwise $|W_C^{(D)} - W_C^{(D+1)}| \le \sum_{\text{four links}} |V_D(c''_D) - V_{D+1}([c''_D])|$, as $V_{D+1}([c''_D])$ is the next stage of the taper and $\frac{1}{2}|\operatorname{tr}(A(X-Y)B)| \le |X-Y|$ for unitary A, B.

Step 7: (a). Let $n := \ell/a_K = 2NL^j \ge 26N$, since L is an odd integer at least 13; $T' = T/a_K$, $R' = R/a_K$, $\vartheta = L^{K-d}$, and the legs lie along the direction 0, the sides of the length R along the direction 1. Take for S_B, S_I, S_T the block layers of the lower side, the layers between, and the block layers of the upper side, so that $\vartheta_I = T' - \vartheta$, and for Str_L, Str_R the block layers of the two legs, $g = R' - \vartheta \le g'$; the four replaced links each carry one bare bond across the planes of t_1 or t_2, the parts on either side joining the caps or the legs. So W_C^{tap}, and every loop with the four links replaced by products $X_- \cdot S \cdot X_+$ as in (a), is an f of Step 5, with caps of norm 1. By Step 3 (c), case (b), with the directions 0 and 1 exchanged (Proposition 17.31(a)) and $n_2 = n \ge 24N$, $\varsigma = 0.165/N^2$. Let k be the largest index with $2N_k \le n/2$, so that $k \ge 2$ and $n < 8N_k$. As S_0 does not increase and $\delta/|\underline{n}|$ does not increase when a side grows, $1 + S_0(n - \vartheta_I; (n,n)) \le e^{\delta(n/2,n,n)} \le e^{32\chi_k} \le 1.1397$, and

the factor $\exp((\vartheta_I/\mathsf{k})\delta(\mathsf{k},n-g-1,n))$ with $\mathsf{k}=2N_k$ is $\le e^{32\chi_k}\le 1.1397$, by Step 2; $1.1397^2\le 1.3$; and $0.165\,\vartheta_I(g+1)/N^2\ge 0.165\,(T-w)(R-w)/(Na_K)^2=\sigma_{\rm bl}(R-w)(T-w)$, as $Na_K=\ell_0/2$.

Step 8: the large fields of a cell, without the volume. (i) *One averaging step.* If $\varpi_c(V)$, the largest $|\partial V(p)-\mathbf{1}|$ over the plaquettes of the double block of c, is $<\omega_M=1/200L^2$, then $|\mathcal{M}(V)(c)-V[c]|\le 12.2\,L^2\varpi_c(V)$, and always ≤ 2: use the small-curvature branch in Proposition YM3_I:4.5, where $\mathcal{M}(V)(c)=e^X V[c]$ with $X=L^{-3}\sum_x \log W_x$. In the proof of Lemma YM3_I:4.4, retain the curvature $\varpi_c(V)$ in the two rearrangement bounds. Writing $u=L^2\varpi_c(V)$, the two contour families each have diameter at most $e^{9u/8}-1$, and their transported loops differ from the straight loop by at most $e^{25u/8}-1$. Each contour mean differs from any member of its family by at most four times the diameter, by Proposition YM3_I:4.3. Use the product of the resulting three unitaries in the formula for W_x and telescope from the identity. This gives $|W_x-\mathbf{1}|\le 8(e^{9u/8}-1)+(e^{25u/8}-1)\le 12.175u$ for $0\le u<1/200$, since each quotient $(e^{au}-1)/u$ is increasing there. The principal SU(2) angle is $2\arcsin(|W_x-\mathbf{1}|/2)$ and hence at most $12.177u$ on this interval. Thus $|e^X-\mathbf{1}|\le|X|\le 12.177u$, which gives the stated bound.

(ii) *Discarding on one torus.* In the calibrated setting of §2.3.1, the small-field weight through level t is supported where the level $t-1$ field belongs to Cut_{t-1}, by its defining product in Section YM3_I:115. By YM3_I:(2159) this implies $\varpi(\mathcal{M}^{t-1}U)<2c_\rho\varepsilon_{\rm th}(x_{t-1})$. Proposition YM3_I:115.2 gives mass at least $(1-R_t)Z$ to this weight and domination by the unsourced Wilson integral on nonnegative gauge-invariant functions. Thus the Wilson probability of the complementary curvature event is at most R_t in YM3_I:(2187). (iii) *The cell bound.* For $K>D'\ge 0$ let a (D')-box be a periodic box of the spacing a_K with the sides $\lambda\mathsf{n}_\mu$, $\lambda=L^{K-D'}$, $\mathsf{n}_\mu\ge\mathsf{n}(D')$ even, at $\beta=L^K\mathsf{b}$; a cell is a cube of the side $a_{D'}$ of a board with its offset in $a_{D'+1}\mathbb{Z}^3$; and for $D'<D<K$ the event $E_D(\square)$ is that a plaquette of the block field of the depth $D+1$ with its corners in $\square$ has $|\partial V_{D+1}(p)-\mathbf{1}|\ge\omega_D$. Then for pairwise different cells of one board and $D'<D_s<K$ with $L^{D_s}\mathsf{b}\ge\mathsf{t}_\natural$,

$$\Big\langle\prod_s 1_{E_{D_s}(\square_s)}\Big\rangle\le\prod_s\varepsilon''(D',D_s),\qquad \|1_{E_D(\square)}\|_{\rm ch}\le\varepsilon''(D',D).$$

The chessboard estimate of the box (Proposition YM3_I:86.3) gives the product of the seminorms; the subadditivity in the volume (Proposition YM3_I:86.5) passes from the (D')-box Γ, with $\mathsf{N}:=\prod_\mu\mathsf{n}_\mu$ cells in all, to the cube $\Gamma^\flat$ with $\mathsf{n}(D')$ cells along each side, $\mathsf{N}^\flat:=\mathsf{n}(D')^3$ cells in all, at the price $\exp[F(\Gamma^\flat)/\mathsf{N}^\flat-F(\Gamma)/\mathsf{N}]$, $F=\log Z$, which is at most $e^{\Delta(D')}$ as follows. Enclose the side counts of both boxes by a cubic count $2L^j$, and compare the unnormalized partition functions by Proposition YM3_I:86.5 with insertion 1. The pressure per cell of this larger cube is a lower bound on that of Γ. Relabel the two cubes by D' to cutoff $K-D'$ and label $L^{D'}\mathsf{b}$, leaving the bond action and Haar measures unchanged. The room conditions just verified apply to both cubes. Use the upper and lower vacuum bounds of Proposition YM3_I:74.4 and the per-volume vacuum comparison of Proposition YM3_I:74.5 to bound the pressure gap by $\Delta(D')$; on that cube the copies of an indicator are indicators, so the seminorm is at most the probability of $E_D(\square)$ to the power $\mathsf{n}(D')^{-3}$; and the cube is the torus $2L^{\mu(D')}$ at the cutoff $K-D'$ and the label $L^{D'}\mathsf{b}$, where (ii) at $t=K-D$ bounds this probability by $\mathsf{R}(D',D)$. Moreover, as $R(x)\le L(\log x)^r$ and $\mathsf{n}(D')\le 2L^2M\max\{\eta_{D'+1}^r,C_{\rm s}\}$, $\log\varepsilon''(D',D)\le -c_\natural\eta_D^{2\mathfrak{p}_0}/\max\{\eta_{D'+1}^r,C_{\rm s}\}^3+\eta_D+9\eta_{D'}+C_\natural$ with $c_\natural:=c'A_0^2/8L^6M^3$ and a number $C_\natural$ of the constants; by the floor $2\mathfrak{p}_0>3r+2$ of the list of constants, $\varepsilon''(D',D)\le\exp(-c_\natural\eta_D^2+10\eta_D+C_\natural)$ for all $D>D'$ when $\eta_{D'+1}^r\ge C_{\rm s}$. So $\sum_D\varepsilon''(D-1,D)<\infty$, $\sum_{D>D'}\varepsilon''(D',D)<\infty$ for every D', and $\sum_{D\ge d}\varepsilon''(d-1,D)\to 0$ as $d\to\infty$; as $\omega_D=2c_\rho A_0(L^{D+1}\mathsf{b})^{-1/2}\eta_{D+1}^{\mathfrak{p}_0}$, also $\tau_d^{\rm ch}\to 0$ and $\tau_d'\to 0$ as $d\to\infty$. (iv) *One link.* For $D\ge D_\flat$, every torus $\ell=2L^m$ with $MR(\mathsf{b})\le L^m$, every $K>D$ and every bond c of $\Lambda_{D,\ell}$: $\langle|V_D(c)-V_{D+1}([c])|\rangle_K\le\varepsilon_D'$, by (i) off $E_D(\square)$ for the cell $\square$ about c_- of the side a_{D-1} of the board with the offset c_-, which holds $Q(c)$ as $L\ge 3$, by $|V_D(c)-V_{D+1}([c])|\le 2$ on $E_D(\square)$, and by (iii) at $D'=D-1$: the torus is a $(D-1)$-box, as $m+D-1\ge m'+\log_L R(\mathsf{b})+D-1\ge\mu(D-1)$.

Step 9: (c). By Step 6 (iv) and Step 8 (iv), $|\langle W_C^{(D)}\rangle_K - \langle W_C^{(D+1)}\rangle_K| \le 4\varepsilon'_D$ for $d \le D < K$, and the sum over D is $\le \tau'_d$, a number free of K, m, ℓ and C. As $W_C^{(D)}$ is a bounded gauge-invariant Borel function of V_D, $\lim_K \langle W_C^{(D)}\rangle_K$ exists by the convergence of the laws of the block fields (Corollary 2.8; (M4)(iii) of Section 17.2), and these limits form a Cauchy sequence in D, whose limit is w_C, with $|\mu_d(W_C) - \mathsf{w}_C| \le \tau'_d$. With (a) the last bound of (c) follows.

Step 10: (b). By Theorem AZ(1)(b), (c) and Proposition 17.38(c), the torus means of bounded Borel functions of finitely many bonds converge to ν_K as $\ell \to \infty$; on the tori $\ell > 2(R+T+2w)$, $W_C^{\mathrm{tap}} \circ \widetilde{\mathcal{M}}$ is $W_C^{\mathrm{tap}} \circ \mathcal{M}$. In Step 7 on the torus $\ell = \ell_0 L^j$, with $\mathsf{k} = 2N_k$, the two factors in front are at most $\exp \delta(n/2, n, n) \le e^{32\chi_k}$ and $\exp((\vartheta_I/\mathsf{k})\delta(\mathsf{k}, n-g-1, n)) \le \exp((\vartheta_I/2N_k)16\chi_k)$; at fixed R, T both tend to 1 as $j \to \infty$, since $k \to \infty$, $\chi_k \to 0$ and $\vartheta_I/N_k \to 0$, while $e^{-0.165\,\vartheta_I(g+1)/N^2} \le e^{-\sigma_{\mathrm{bl}}(R-w)(T-w)}$ does not move; so $|\nu_K(W_C^{\mathrm{tap}})| \le e^{-\sigma_{\mathrm{bl}}(R-w)(T-w)}$ for all $R, T \ge 2w$.

Step 11: (d). Let $J := T/w$ and $\vartheta = L^{K-d}$; the legs lie along the direction 0, their links c_j^{R}, c_j^{L} join the heights $j-1$ and j in units of w, $1 \le j \le J$, the link at the height j reads the block layers $j-1$ and j, and its middle plane parts them. (i) *One defect.* On a $(d-1)$-box let $x_c := |V_d(c) - \widetilde{V}(c)|$ for a link c of a leg; it is a gauge-invariant Borel function with $x_c \le 2$, as $V_d(c)$ and $\widetilde{V}(c)$ are transporters of one kind. By Step 6 (iv) along the taper of the one link and Step 8 (i), with $\omega_D \le 1/200L^2$ for $D \ge d$, $x_c \le \sum_{D=d}^{K-1}(13L^2\omega_D + 2 \cdot 1_{E_D(\square)})$ for the cell $\square$ of the side a_{d-1} that holds $Q(c)$. The seminorm is homogeneous and subadditive with $\|1\|_{\mathrm{ch}} = 1$ (Proposition YM3_I: 86.4), and it does not decrease on functions ≥ 0 of a cell, whose fold is the product of their copies; so Step 8 (iii) at $D' = d-1$ gives $\|x_c\|_{\mathrm{ch}} \le \tau_d^{\mathrm{ch}}$. (ii) *The expansion.* $W_C(V_d)$ is linear in each link. At a height j write the pair $(V_d(c_j^{\mathrm{R}}), V_d(c_j^{\mathrm{L}}))$ as the tapered pair $(\widetilde{V}(c_j^{\mathrm{R}}), \widetilde{V}(c_j^{\mathrm{L}}))$, plus a defect of the right leg, $(V_d(c_j^{\mathrm{R}}) - \widetilde{V}(c_j^{\mathrm{R}}), V_d(c_j^{\mathrm{L}}))$, plus a defect of the left leg, $(\widetilde{V}(c_j^{\mathrm{R}}), V_d(c_j^{\mathrm{L}}) - \widetilde{V}(c_j^{\mathrm{L}}))$. Expand from below at the heights $t_s := 1 + sL$, in the two defect terms again at the next height; in a term with the tapered pair at t_s expand from above at the heights $u_{s'} := J - s'L$; and stop at $s + s' = s_B := \lfloor (J-2)/L \rfloor$, which keeps $u_{s'} > t_s$. Then $W_C(V_d)$ is the sum of the main terms $f[\iota, s; \iota', s']$, $s + s' \le s_B$, $\iota \in \{\mathrm{R}, \mathrm{L}\}^s$, $\iota' \in \{\mathrm{R}, \mathrm{L}\}^{s'}$, with a defect of the leg ι_i at the height t_i for $i < s$, one of the leg ι'_i at the height u_i for $i < s'$, and tapered pairs at t_s and at $u_{s'}$, and of $(s_B+2)2^{s_B+1}$ remainders, each with exactly s_B+1 defects. (iii) *Main terms.* A main term is an f of Step 5 in which S_B consists of the block layers $0, \dots, t_s - 1$ and S_T of the block layers $u_{s'}, \dots, J$, of $\vartheta_B = (sL+1)\vartheta$ and $\vartheta_T = (s'L+1)\vartheta$ layers, S_I of the block layers between, $\vartheta_I = (J-1-(s+s')L)\vartheta$, $g = R' - \vartheta$, the rest $a = n - (J+1)\vartheta$, and the halves $A^{\mp}$ of the tapered links at t_s and $u_{s'}$ joining the caps or the legs as in Step 7; the legs $\mathbf{R}$, $\mathbf{L}$ are unitary, and $|\mathbf{B}| \le \beta_B$, $|\mathbf{T}| \le \beta_T$, the products of the defects x_c of the caps. In Step 5 the caps may be paid in the mean, with caps of different thicknesses: Schwarz's inequality with kernels of positive type bounds the trace norm of the operator of the caps through $\mathrm{Tr}(\hat\beta_B^* \mathsf{D}_{\mathbf{1}} \hat\beta_B \mathsf{D}^{a_B+1})$, which is $Z(\Lambda_B)\langle \beta_B^\Theta \beta_B\rangle_{\Lambda_B}$ by the trace formula of the head of the proof with the step between the two slabs set to $\mathbf{1}$ (Step 4 (ii)), and through the like number of the top, using $\mathsf{D}^{a+1} \le \lambda_0^{a-a_B}\mathsf{D}^{a_B+1}$; this gives

$$|\langle f\rangle_\Lambda| \le \big[(1 + S_0(2\vartheta_B + a_B))(1 + S_0(2\vartheta_T + a_T))\big]^{1/2} \big[\langle \beta_B^\Theta \beta_B\rangle_{\Lambda_B} \langle \beta_T^\Theta \beta_T\rangle_{\Lambda_T}\big]^{1/2} e^{(\vartheta_I/\mathsf{k})\delta(\mathsf{k}, n-g-1, n)} e^{-\varsigma\vartheta_I(g+1)}$$

on the shortened boxes $\Lambda_B = (2\vartheta_B + a_B, n, n)$ and $\Lambda_T = (2\vartheta_T + a_T, n, n)$, on which β_B stands on a slab of ϑ_B layers and β_B^Θ on the next one, for integers $2 \le a_B, a_T \le a$. Take for a_B the largest integer $\le a$ with $x_B := 2\vartheta_B + a_B \in 2L\vartheta\mathbb{Z}$; then $a_B \ge 2$, and as $T \le \ell/2$ and $n = 2L^{m+d-1} \cdot L\vartheta \ge 8L\vartheta$, $x_B > n/2 - 2L\vartheta \ge n/4$; so Λ_B has the sides $L\vartheta(\mathsf{n}_0, \mathsf{n}, \mathsf{n})$ with $\mathsf{n} = 2L^{m+d-1}$ and an even $\mathsf{n}_0 \ge \mathsf{n}/4 \ge 2L^{m+d-2} \ge \mathsf{n}(d-1)$: a $(d-1)$-box; the like for Λ_T. Number the block layers of Λ_B so that β_B stands on $0, \dots, t_s - 1$ and β_B^Θ on $t_s, \dots, 2t_s - 1$: the defect at t_i reads the block layers iL, $iL+1$, and its mirror image the block layers $(2s-i)L$, $(2s-i)L+1$. A board of the side Lw with its offset in $a_d\mathbb{Z}^3$ whose walls across the direction 0 part the block layers $\equiv 1$ and $\equiv 2$ modulo L cuts no block, puts each of the $2s$ double blocks into one cell and these cells into $2s$ different layers of cells; so the

chessboard estimate and (i) give $\langle \beta_B^{\Theta} \beta_B \rangle_{\Lambda_B} \le (\tau_d^{\mathrm{ch}})^{2s}$, and $\langle \beta_T^{\Theta} \beta_T \rangle_{\Lambda_T} \le (\tau_d^{\mathrm{ch}})^{2s'}$. Now $\varsigma = 0.165/N^2$, as $n \ge 26N$ by $\ell \ge 13\ell_0$; let $k' \ge 1$ be the largest index with $2N_{k'} \le n/4$, so that $n < 16N_{k'}$ and $N_{k'} \ge 8$: then $\log(1 + S_0(x_B)) \le \delta(\lceil n/4 \rceil, n, n) \le \frac{(n/4+1)n^2}{8N_{k'}^3} \chi_{k'} \le 132 \chi_{k'} \le 1.195$, the like for the top, the factor $e^{(\vartheta_I/\mathsf{k})\delta(\mathsf{k}, n-g-1, n)} \le e^{32\chi_k} \le e^{0.131}$ as in Step 7, and with $C_\sharp := e^{1.195+0.131} \le 3.77$ and $\varsigma \vartheta_I (g+1) \ge \sigma_{\mathrm{bl}}(R-w)(T-w-(s+s')Lw)$:

$$|\langle f[\iota, s; \iota', s'] \rangle| \le C_\sharp (\tau_d^{\mathrm{ch}})^{s+s'} e^{\sigma_{\mathrm{bl}}(R-w)Lw(s+s')} e^{-\sigma_{\mathrm{bl}}(R-w)(T-w)}.$$

(iv) *Remainders.* A remainder is at most the product of its $s_B + 1$ defects. The torus is a $(d-1)$-box, as $m + d - 1 \ge \mu(d-1)$; a board of the side Lw with its offset in $a_d \mathbb{Z}^3$ whose walls across the direction 0 part neither the block layers $\equiv 0, 1$ nor the block layers $\equiv J-1, J$ modulo L, which exists as $L \ge 3$, puts every double block of a defect into one cell, two defects from below, or two from above, into different cells, L block layers apart, and a defect from below at a height $t_i \le t_s - L$ and one from above at a height $u \ge t_s + 1$ into different layers of cells; so $|\langle \mathsf{r} \rangle| \le (\tau_d^{\mathrm{ch}})^{s_B+1}$. (v) *The sums.* Let $\upsilon := 2\tau_d^{\mathrm{ch}} e^{\sigma_{\mathrm{bl}}(R-w)Lw}$. The main terms sum to at most $C_\sharp e^{-\sigma_{\mathrm{bl}}(R-w)(T-w)} \sum_{s+s' \le s_B} \upsilon^{s+s'}$ and the remainders to at most $(s_B+2)(2\tau_d^{\mathrm{ch}})^{s_B+1}$, where $(s_B+1)Lw \ge T - w$ and $s_B Lw \le T - 2w$. If $\upsilon \le \frac{1}{2}$, the first sum is ≤ 4, and $(2\tau_d^{\mathrm{ch}})^{s_B+1} = \upsilon^{s_B+1} e^{-\sigma_{\mathrm{bl}}(R-w)Lw(s_B+1)} \le 2^{-(s_B+1)} e^{-\sigma_{\mathrm{bl}}(R-w)(T-w)}$ with $(s_B+2)2^{-(s_B+1)} \le 1$: the total is at most $(4C_\sharp + 1) e^{-\sigma_{\mathrm{bl}}(R-w)(T-w)} \le 17\, e^{-\sigma_{\mathrm{bl}}(R-w)(T-w)}$. The condition $\upsilon \le \frac{1}{2}$ is $R \le \varrho_d$; the lattice, the tori and the hypotheses are symmetric in the two sides, so $\min\{R, T\} \le \varrho_d$ suffices. If only $2\tau_d^{\mathrm{ch}} \le 1$: $\sum_{s+s' \le s_B} \upsilon^{s+s'} \le (s_B+1)^2 \max\{1, \upsilon^{s_B}\}$ and $\upsilon^{s_B} e^{-\sigma_{\mathrm{bl}}(R-w)(T-w)} \le (2\tau_d^{\mathrm{ch}})^{s_B}$, so the total is at most $(C_\sharp + 1)(s_B+2)^2 [e^{-\sigma_{\mathrm{bl}}(R-w)(T-w)} + (2\tau_d^{\mathrm{ch}})^{s_B}]$, with $C_\sharp + 1 \le 5$, $s_B + 2 \le 2 + T/Lw$, and $(2\tau_d^{\mathrm{ch}})^{s_B} = e^{-\kappa_d Lw s_B} \le e^{-\kappa_d(T-2w-Lw)} \le e^{-\kappa_d(T-3Lw)}$; with the legs along the longer side this is the second bound. The limit $K \to \infty$ follows by the convergence of the laws of the block fields, as in Step 9, and the bounds in ν_K by the convergence of Step 10, $W_C \circ \widetilde{\mathcal{M}}^{K-d}$ being a bounded Borel function of finitely many bonds that equals $W_C \circ \mathcal{M}^{K-d}$ on large tori, on which the hypotheses on ℓ hold. □

18.12. **Free laws of the action density at every order: the law on atoms in every state, and the tangent field of every limit and of every component, given by the free template.** This subsection treats the action density $\mathcal{O}$, obtained by summing the three plaquette orientations, or by using the scalar entry of the curvature tensor, at short distance and at every number n of entries. Building on Theorems F and S and on the results of the main text, we establish the following. Let $0 < g \le \gamma_W^{\mathrm{sd}}$ be a reference coupling, $n \ge 2$, $\Lambda \ge 1$ and $0 < \vartheta < 1$, and let $0 < \mathsf{d} \le \mathsf{d}_0$, where $\mathsf{d}_0 > 0$ is a number formed with n, Λ and g, into which ϑ does not enter. Let (K, β) be a first-passage datum at g with label b whose cutoff lies above the depth of the scale d, that is, $K \ge s_g(\mathsf{d}) + 1$, and let $\mathfrak{s}$ be any state at g at (K, β). For real Lipschitz functions $f_1, \dots, f_n$, none identically 0, each carried by a ball of radius d, any two of them with supports at distance at least d, all of them carried by one ball of radius $\Lambda\mathsf{d}$, and with $\mathrm{Lip}\, f_i \le \|f_i\|/(\vartheta \mathsf{d})$, the n-th joint cumulant of $\mathcal{O}$ under $\mathfrak{s}$ at $(f_1, \dots, f_n)$ differs from $3b^{-n} \mathcal{K}_{\mathrm{free}}^{(n)}(f_1, \dots, f_n)$, the sum of the rings of the dipole kernel $\mathbb{K}_3$ of three free photon fields, by at most $[\Phi_n(\mathsf{d}) + 3C_n^{\mathrm{rg}} a_K/(\vartheta\mathsf{d})]\, b^{-n} \prod_i \|f_i\|$; here $\Phi_n(\mathsf{d}) = \mathsf{C}_\sharp(n)(\log \frac{1}{\mathsf{d}})^{\mathsf{c}_\sharp(n)} \mathsf{d}^{13/256}$, the numbers $\mathsf{C}_\sharp(n)$ and $\mathsf{c}_\sharp(n)$ involve neither g nor Λ, and C_n^{rg} is defined below. If the entries are not required to be carried by balls of radius d, a bound of this form still holds when d is at most a number of the same kind, with the bracket $(6N_\Lambda)^n [\Phi_n(\frac{1}{2}\mathsf{d}) + 255\, C_n^{\mathrm{rg}} a_K/(\vartheta\mathsf{d})]$, $N_\Lambda = (32\Lambda + 3)^3$, and under $K \ge s_g(\frac{1}{2}\mathsf{d}) + 1$, in every state and on every torus of a side $\ell \in \mathfrak{L}(g)$ with $8\Lambda\mathsf{d} < \ell$; and it holds at every pair (K, β) with $\beta > X_g$ and $b = a_K \beta$, for the periodic Gibbs states and for the torus measures whose sides, multiplied by $L^{K-K'}$, lie in $\mathfrak{L}(g)$, with $\Phi_n(\frac{1}{2} L^{K-K'} \mathsf{d})$ in the bracket, the smallness condition imposed on $L^{K-K'}\mathsf{d}$ in the place of d, and the condition $K' \ge s_g(\frac{1}{2} L^{K-K'} \mathsf{d}) + 1$, where (K', β) is the first-passage datum at g with the same β. In the limit σ of every convergent sequence of periodic Gibbs states at any reference coupling $0 < g_0 \le \gamma$, in every component of its

canonical decomposition and in every limit in its frame, the label $b = \lim_j a_{K_j}\beta_j$ exists; for σ' any of these, every $n \geq 2$ and every tuple X of C^1 functions with compact, pairwise disjoint supports, with no bound on the ratio of its diameter to its least separation and none on the Lipschitz constants of its entries, $b^n S_n^{\sigma'}(X_r) \to 3\mathcal{K}_{\mathrm{free}}^{(n)}(X)$ as the real dilation factor r tends to 0, at the explicit rate $\mathsf{C}(\log\frac{1}{r})^{\mathsf{c}} r^{13/256}$, of the order $z^{\mathsf{c}} L^{-13z/256}$ along $r = L^{-z}$; and, as $r \to 0$, the functionals $X \mapsto \sigma'(X_r)$, for σ' the limit or one of its components, converge on separated tuples to the centred functional of the free template $S^{\mathrm{fr}}[3, b]$. So at every point y the tangent field of the action density, by which we mean the functional $X \mapsto \lim_{r\to 0} \sigma'((f_i(y + (\cdot - y)/r))_i)$, is this centred functional; its connected functions are the limits, at a fixed label, of the joint cumulants of the density $\frac{1}{2}\sum_c (\theta^c)^2$ formed with the curvatures θ^c of three free photon fields on lattice tori (Proposition 18.128(b)).

The law on atoms is obtained on one small torus. A dilation by L^{z}, with z fixed by d from both sides, carries a first-passage datum at g to a first-passage datum at a lowered coupling g', the length d to $\mathsf{d}' = L^{\mathsf{z}}\mathsf{d} \leq \mathsf{d}^{15/16}$, and every state at g to a state over the sides at g' from the least one, ℓ', on, whose size is a power of $\log\frac{1}{\mathsf{d}}$ (Lemma 18.119). On $T_{\ell'}$ the dilated entries are placed in one cell of a board with eight cells and copied into the seven other cells by the mirror maps. The renormalisation group of the main text, entered with these $8n$ sources, gives their jets at the top level as the Gaussian rings of the curvature slices up to $(\log\frac{1}{\mathsf{d}})^{\mathsf{c}}\mathsf{d}^{15/32}$ (Proposition 18.122); the rings give the free value (Lemma 18.123); the jets give the cumulants of the small torus (Lemma 18.121); and the chessboard estimate together with the pressure gap of Theorem S carries these cumulants to every state, at the price of an eighth root and of a factor $\mathsf{d}^{-1/128}$ (Lemma 18.120); indeed $\frac{1}{8}(\frac{15}{32} - \frac{1}{16}) = \frac{13}{256}$. A decomposition of the entries into atoms, the exact covariance of the lattice theory under the dilations by powers of L, and the passage to the limits give the rest.

Setting.

Definition 18.116 (Notation of this subsection)**.** (1) Use the canonical real and sourced construction of Theorems YM3_I:D, YM3_I:AJ and YM3_I:AD at the same fixed auxiliary data. Write $X_g = L(g^{-2} + B_\sharp)$, $\bar{B} = LB_\sharp/(L-1)$, and use the first-passage data $(K, \beta) \in \mathfrak{d}(g)$, running couplings $x_0 = \beta, \dots, x_K$, labels $b = a_K\beta$ and sides $\mathfrak{L}(g)$ of Proposition YM3_I:74.1. Here $R(x)$ is the least power of L at least $(\log x)^{\mathfrak{r}}$, with the room exponent $\mathfrak{r}$ of that construction. The ceilings $\gamma_W^{\mathrm{sd}} \leq \gamma_W^{\mathrm{ref}}$ are the small-side and reference thresholds in Section YM3_I:126. For a set $\mathfrak{l}$ of sides, a state over $\mathfrak{l}$ means a periodic Gibbs state in $\mathcal{G}_{K,\beta}$ or the periodic lift $\tilde{\mu}_{K,\ell,\beta}$ of the Wilson law for some $\ell \in \mathfrak{l}$. A state at g means a state over $\mathfrak{L}(g)$. Periodic Gibbs states are invariant under all lattice isometries by Proposition YM3_I:103.4. Set $g_\star = \gamma_W^{\mathrm{sd}}$, $\mathsf{c}_\star = L(g_\star^{-2} + \bar{B})$ and

$$Y_s^g = (s+1)\log L + \log(g^{-2} + \bar{B}), \quad C_W(s) = C_{W,0} A_0^2 (Y_s^g)^{2\mathfrak{p}_0}, \quad C_{W,0} = \max\{1, 4L^2 M/A_0^2\}.$$

The witness depth $s_g(\mathsf{d})$ is the least nonnegative integer s with $L^s\mathsf{d} \geq C_W(s)$. It exists by exponential growth of L^s, is nonincreasing in d, and tends to infinity as $\mathsf{d} \downarrow 0$. These are the room numbers of Section YM3_I:126.

(2) For a compactly supported real weight f put $\mathcal{O}_K(f) = \mathcal{O}_K^T(f\mathbf{1}) = a_K^{-1}\sum_p f(x(p))\, a_p$. For a plaquette array w use $\mathcal{O}(w) = a_K^{-1}\sum_p w(p)\, a_p$. Write $S_n^T[\nu]$ for their joint cumulants under ν and $X_K^\nu = \prod_i[\mathcal{O}_K(f_i) - \nu(\mathcal{O}_K(f_i))]$ for a tuple $X = (f_i)_i$. For the lifted torus law, collecting the plaquettes in each period class gives the torus cumulant with each f_i replaced by $f_i^{\langle\ell\rangle}(x) = \sum_{m\in\mathbb{Z}^3} f_i(x + \ell m)$. Indeed the plaquette action is constant on each period class. Write $\|f\| = \sup|f|$.

(3) For $u \neq 0$ let $\mathbb{K}_3(u) = (4\pi|u|^3)^{-1}(3\widehat{u}\widehat{u}^{\mathsf{T}} - \mathbf{1})$. Write $\mathrm{Cyc}(n)$ for the cyclic orders of $\{1, \dots, n\}$, represented by the permutations with first entry 1, and read $i+1$ modulo n. Put

$$k_n(x) = \frac{1}{2}\sum_{\varsigma\in\mathrm{Cyc}(n)} \mathrm{tr}\prod_{i=1}^n \mathbb{K}_3(x_{\varsigma(i)} - x_{\varsigma(i+1)}), \qquad \mathcal{K}_{\mathrm{free}}^{(n)}(f_1, \dots, f_n) = \int \prod_i f_i(x_i)\, k_n(x)\, dx$$

for bounded Borel functions with compact, positively separated supports. On a torus these integrals use compact lifts in a common ball of radius less than $\ell/4$. The functional of fixed dual directions $\iota \in \{1,2,3\}^n$ is the same integral with the trace product replaced by the product of entries $[\mathbb{K}_3]_{\iota_{\varsigma(i)},\iota_{\varsigma(i+1)}}$. Summing over the directions restores the trace. For the sum $\mathcal{O}$ over all three plaquette orientations the free template is $S_n^{\mathrm{fr}}[3,b] = 3b^{-n}\mathcal{K}_{\mathrm{free}}^{(n)}$. Proposition 18.152 derives this normalization, including its kernel at $n=2$.

On the torus at spacing a_K, let $C_K^{\mathrm{free}}(p,q)$ be the matrix of the orthogonal projection onto the exact two-forms, in the positive plaquette basis. Its Fourier formula and its comparison with $\mathbb{K}_3$ are in §YM3_I:121.1. Define the lattice ring

$$\mathcal{K}_K^{(n)}(f_1,\dots,f_n) = \frac{1}{2}\sum_{\varsigma\in\mathrm{Cyc}(n)}\sum_{p_1,\dots,p_n}\prod_i f_i(x(p_i))\prod_i C_K^{\mathrm{free}}(p_{\varsigma(i)},p_{\varsigma(i+1)}).$$

Let C_{lat} be a constant in the absolute error bound of equation YM3_I:(2245) and set $C_n^{\mathrm{rg}} = 22\,n!\,50^n(1+C_{\mathrm{lat}})^n$.

(4) Let $n\ge 2$, $\mathsf{d}>0$, $\vartheta\in(0,1)$ and $\Lambda\ge 1$. $P_n(\mathsf{d};\vartheta;\Lambda)$ consists of the tuples $X=(f_1,\dots,f_n)$ of real Lipschitz functions on $\mathbb{R}^3$, no one of which vanishes identically, subject to: (P1) all the supports lie in one closed ball $\bar{\mathbb{B}}(x_0,\Lambda\mathsf{d})$; (P2) two different supports are at distance at least d; (P3) $\mathrm{Lip}\,f_i \le \|f_i\|/(\vartheta\mathsf{d})$ for every i. The atoms form the subset $\mathfrak{A}_n(\mathsf{d};\vartheta;\Lambda)$ of the tuples that satisfy moreover (P4): every support lies in a closed ball $\bar{\mathbb{B}}(x_i,\mathsf{d})$ of radius d. For a torus T_ℓ with $8\Lambda\mathsf{d}<\ell$, $P_n^{T_\ell}(\mathsf{d};\vartheta;\Lambda)$ is formed in the same way from functions on T_ℓ and the distance of T_ℓ. We put $N_\Lambda := (32\Lambda+3)^3$, $\mathsf{d}_1 := \frac{1}{2}\mathsf{d}$, $\vartheta_1 := 2\vartheta/(1+84\vartheta)$ and $\Lambda_1 := 2\Lambda+1$.

(5) For $r>0$ set $f_r(x)=f(x/r)$ and $X_r=(f_{i,r})_i$. For integral z set $f^{[z]}=f_{L^z}$, and let $\nu^{(z)}$ be the image of ν by the lattice relabeling $x\mapsto L^z x$.

(6) Use the separated tuples and the Gibbs sequences of Definition 18.205. A limit in the frame of a convergent sequence $(K_j,\beta_j,\nu_j)_j$ means a functional σ' with $\sigma'(X)=\lim_j \rho_j(X_{K_j}^{\nu_j})$ at all separated tuples X, where each ρ_j is periodic Gibbs at the same (K_j,β_j). The centering in $X_{K_j}^{\nu_j}$ uses the means of ν_j. The canonical decomposition is the one in Theorems YM3_I:AL and YM3_I:AP.

(7) Let B_m count the partitions of an m-element set and put $\mathsf{a}_m=\sum_{\pi\in\mathrm{Part}(m)}|\pi|!$ and $\mathsf{a}'_m=\sum_{\pi\in\mathrm{Part}(m)}(|\pi|-1)!$. For $u_a>0$ write $u^\gamma=\prod_{a\in\gamma}u_a$. For a normalized linear map ω on a commutative algebra and $M_A=\omega(\prod_{a\in A}F_a)$, the cumulant is

$$\kappa_\gamma = \sum_{\pi\in\mathrm{Part}(\gamma)}(-1)^{|\pi|-1}(|\pi|-1)!\prod_{A\in\pi}M_A.$$

In the algebra $z_a^2=0$, this is the coefficient of z^γ in $\log(1+\sum_{A\neq\emptyset}z^A M_A)$. Exponentiating gives the inverse relation $M_\gamma=\sum_\pi\prod_{A\in\pi}\kappa_A$ and uniqueness. Adding constants c_a to the F_a multiplies the moment polynomial by $\exp(\sum_a z_a c_a)$, so only the singletons change. If $|M_A|\le\prod_{a\in A}o_a$ the cumulant has modulus at most $\mathsf{a}'_{|\gamma|}\prod_{a\in\gamma}o_a$. These identities also hold for a map into bounded measurable functions modulo null sets, since each polynomial is finite.

■

The free kernel and the atoms.

Lemma 18.117 (The free kernel; decomposition into atoms)**.** Let $n\ge 2$, $\mathsf{d}>0$, $\vartheta\in(0,1)$ and $\Lambda\ge 1$.

(a) If $x_1,\dots,x_n\in\mathbb{R}^3$ satisfy $|x_i-x_j|\ge\mathsf{d}$ for $i\neq j$, then $|k_n(x)|\le\frac{3}{2}(n-1)!\,(2\pi\mathsf{d}^3)^{-n}$. For $X\in P_n(\mathsf{d};\vartheta;\Lambda)$, $|\mathcal{K}_{\mathrm{free}}^{(n)}(X)|\le\frac{3}{2}(n-1)!\,(\frac{2}{3}\Lambda^3)^n\prod_i\|f_i\|$, and for $X\in\mathfrak{A}_n(\mathsf{d};\vartheta;\Lambda)$, $|\mathcal{K}_{\mathrm{free}}^{(n)}(X)|\le$

$\frac{3}{2}(n-1)!\,(\frac{2}{3})^n\prod_i\|f_i\|$. $\mathcal{K}^{(n)}_{\mathrm{free}}$ is linear in each entry, and it does not change under a common translation of the entries nor under $f_i\mapsto f_{i,r}$, $r>0$.

(b) For every real $r>0$ the map $f_i\mapsto f_{i,r}$ takes $P_n(\mathsf{d};\vartheta;\Lambda)$ into $P_n(r\mathsf{d};\vartheta;\Lambda)$ and $\mathfrak{A}_n(\mathsf{d};\vartheta;\Lambda)$ into $\mathfrak{A}_n(r\mathsf{d};\vartheta;\Lambda)$; a common translation of the entries keeps both classes; and both classes become larger when Λ increases or ϑ decreases.

(c) Every $X=(f_1,\dots,f_n)\in P_n(\mathsf{d};\vartheta;\Lambda)$ admits decompositions $f_i=\sum_{\mu\in\mathcal{M}_i}\epsilon_{i,\mu}a_{i,\mu}$ into at most $2N_\Lambda$ non-negative Lipschitz pieces $a_{i,\mu}$ with signs $\epsilon_{i,\mu}\in\{1,-1\}$, such that $\|f_i\|\le\|a_{i,\mu}\|\le 3\|f_i\|$, each piece is carried by the $\frac{\sqrt3}{8}\mathsf{d}$-neighbourhood of $\operatorname{supp}f_i$, and each choice of one piece for every entry gives a tuple $(a_{1,\mu_1},\dots,a_{n,\mu_n})$ in $\mathfrak{A}_n(\mathsf{d}_1;\vartheta_1;\Lambda_1)$. Hence, if T is defined on the n-tuples of bounded Borel functions whose compact supports are mutually at positive distance and is linear in each entry, a bound $|\mathsf{T}(Y)|\le\tau\prod_i\|a_i\|$ for all $Y=(a_1,\dots,a_n)\in\mathfrak{A}_n(\mathsf{d}_1;\vartheta_1;\Lambda_1)$ implies $|\mathsf{T}(X)|\le(6N_\Lambda)^n\tau\prod_i\|f_i\|$ for all $X\in P_n(\mathsf{d};\vartheta;\Lambda)$. ■

Sketch. (a) The matrix $\mathbb{K}_3(u)=(4\pi|u|^3)^{-1}(3\hat u\hat u^{\mathrm T}-1)$ has the eigenvalues $2(4\pi|u|^3)^{-1}$ and $-(4\pi|u|^3)^{-1}$ (twice), so its operator norm is $(2\pi|u|^3)^{-1}$; the trace of a product of 3×3 matrices is at most 3 times the product of their operator norms, and $\mathrm{Cyc}(n)$ has $(n-1)!$ members; this gives the bound on k_n. Integrating it against $\prod_i|f_i(x_i)|$ over supports of volume at most $\frac{4\pi}{3}(\Lambda\mathsf{d})^3$, respectively $\frac{4\pi}{3}\mathsf{d}^3$, gives the two bounds, as $\frac{4\pi}{3}/(2\pi)=\frac23$. Linearity follows from the integral. A common translation preserves the differences. Under a common dilation by r the r^{-3n} from the kernel cancels the Jacobian r^{3n}. (b) Under $f\mapsto f_r$ supports and their distances are multiplied by r, Lipschitz constants by r^{-1}, and suprema are kept. (c) Let $h:=\mathsf{d}/16$ and let $\chi_m(x)=\prod_\mu\max\{0,1-|x_\mu/h-m_\mu|\}$, $m\in\mathbb{Z}^3$, be the tents of mesh h: they form a partition of unity, χ_m is carried by $hm+[-h,h]^3\subset\bar{\mathbb{B}}(hm,\sqrt3h)$, and $\operatorname{Lip}\chi_m\le\sqrt3/h$: the three partial slopes each have modulus at most $1/h$. With $A_i:=\|f_i\|>0$ and M_i the set of the m whose cube meets $\operatorname{supp}f_i$, put $g_{i,m}:=(f_i+2A_i)\chi_m$ and $e_{i,m}:=2A_i\chi_m$; then $f_i=\sum_{m\in M_i}(g_{i,m}-e_{i,m})$, and the $a_{i,\mu}$ are the $g_{i,m}$, with the sign $+$, and the $e_{i,m}$, with the sign $-$. A member of M_i has $|hm-x_0|_\infty\le\Lambda\mathsf{d}+h$, so each coordinate of m ranges over at most $32\Lambda+3$ integers, and $\#M_i\le N_\Lambda$. Since $A_i\le f_i+2A_i\le3A_i$, $A_i\le\|g_{i,m}\|\le3A_i$ and $\|e_{i,m}\|=2A_i$; both functions are carried by $\bar{\mathbb{B}}(hm,\sqrt3h)\subset\bar{\mathbb{B}}(hm,\mathsf{d}_1)$, which is (P4) at d_1. Their Lipschitz constants are at most $A_i(\frac{1}{\vartheta\mathsf{d}}+\frac{48\sqrt3}{\mathsf{d}})\le\|g_{i,m}\|\frac{1/\vartheta+84}{\mathsf{d}}$, respectively $2A_i\frac{16\sqrt3}{\mathsf{d}}\le\|e_{i,m}\|\frac{1/\vartheta+84}{\mathsf{d}}$, and $\frac{1/\vartheta+84}{\mathsf{d}}=\frac{1}{\vartheta_1\mathsf{d}_1}$: this is (P3). A point of the support of a piece lies within $2\sqrt3h=\frac{\sqrt3}{8}\mathsf{d}$ of the support of its entry, so points of pieces of two different entries are at a distance at least $(1-\frac{\sqrt3}{4})\mathsf{d}>\mathsf{d}_1$, which is (P2), and every such point lies within $\Lambda\mathsf{d}+\frac{\sqrt3}{8}\mathsf{d}<(2\Lambda+\frac12)\mathsf{d}_1\le\Lambda_1\mathsf{d}_1$ of x_0, which is (P1). Expanding $\mathsf{T}(X)$ entry by entry, which is legitimate because every intermediate tuple has supports at positive distances, gives at most $(2N_\Lambda)^n$ terms, each at most $\tau\,3^n\prod_iA_i$. □

Lemma 18.118 (Lattice rings at atoms)**.** Let (ℓ,K) be a lattice, $n\ge2$, $\vartheta\in(0,1)$, $\Lambda\ge1$, and $\mathsf{d}>0$ with $4a_K\le\mathsf{d}$ and $4\Lambda\mathsf{d}<\ell$. For every $(\hat f_1,\dots,\hat f_n)\in\mathfrak{A}_n(\mathsf{d};\vartheta;\Lambda)$, with $f_i:=\hat f_i^{\langle\ell\rangle}$,

$$\Big|\mathcal{K}^{(n)}_K(f_1,\dots,f_n)-\mathcal{K}^{(n)}_{\mathrm{free}}(\hat f_1,\dots,\hat f_n)\Big|\le C^{\mathrm{rg}}_n\Big[\frac{a_K}{\vartheta\mathsf{d}}+\Big(\frac{\mathsf{d}}{\ell}\Big)^3\Big]\prod_i\|\hat f_i\|.$$

■

Proof. Set $a=a_K$, $d=\mathsf{d}$ and $A=\prod_i\|\hat f_i\|$. There is a unique compact lift of each participating barycentre in the common ball. Since $2\Lambda d<\ell/2$, every difference of two such lifts is a least lift. Two barycentres contributing to a ring lie in different supports, so their separation is at least d. By equation YM3_I:(2245), dividing each signed projection entry by a^3 gives the corresponding dipole entry with error at most

$$C_{\mathrm{lat}}d^{-3}[(a/d)^2+(d/\ell)^3].$$

The two orientation signs attached to a plaquette cancel in a cycle. The dipole entries are bounded by d^{-3} and the divided lattice entries by $(1+C_{\mathrm{lat}})d^{-3}$. Replacing the n factors one at a time costs at most $n(1+C_{\mathrm{lat}})^n d^{-3n}[(a/d)^2+(d/\ell)^3]$ for each cycle and each choice of barycentres. At a fixed orientation, the a-cubes centred at the contributing barycentres are disjoint and contained in a ball of radius $d+\sqrt{3}a/2$, of volume less than $8d^3$. Including the a^{3n} from the entries, the resulting error after summing over the 3^n choices of orientation and $(n-1)!$ cycles is at most $\frac{1}{2}n!\,24^n(1+C_{\mathrm{lat}})^n[(a/d)^2+(d/\ell)^3]A$.

For the Riemann sums, fix the orientations and one cycle. Let y_i be a grid barycentre and x_i a point of its cube. If either the integrand at x or the summand at y is nonzero, all n cubes meet the respective supports. Along the straight segment between x and y every separation between different entries is at least $d-\sqrt{3}a>0.56d$. The dipole entries there have modulus at most d^{-3} and directional derivative at most $8d^{-4}$ per unit displacement, by differentiating $\mathbb{K}_3$ and using $\|\partial_e\mathbb{K}_3(u)\|\le 9/(4\pi|u|^4)$ for $|e|=1$. Thus replacing one dipole factor by its value at the grid point costs at most $14ad^{-4}$. Each function value changes by at most $\|\hat f_i\|a/(\vartheta d)$, by the Lipschitz bound and $|x_i-y_i|\le\sqrt{3}a/2$. The difference of the two full integrands is at most $15n\,a(\vartheta d)^{-1}d^{-3n}A$ by telescoping. The union of cubes meeting the support of entry i lies in a ball of radius $d+\sqrt{3}a$, of volume less than $13d^3$. Integrating, and summing the orientations and cycles with the factor $1/2$, gives an error at most $\frac{15}{2}n!\,39^n a(\vartheta d)^{-1}A$. The integral sum over orientations is the trace defining the continuum ring. Since $(a/d)^2\le a/(\vartheta d)$, the two error bounds are below the stated one. □

One small torus at a lowered coupling.

Lemma 18.119 (One small torus at a lowered coupling)**.** Let $0<g\le\gamma_W^{\mathrm{sd}}$, let $C_{\mathrm{S}}\ge 1$ be the upper stability constant of Theorem YM3_I:AD enlarged if necessary, $\mathsf{C}_{\mathrm{Q}}:=32L^9M^3C_{\mathrm{S}}$ and $\mathsf{C}_{\mathrm{r}}:=16\cdot 2^{3\mathfrak{r}+1}\mathsf{C}_{\mathrm{Q}}$. For $0<\mathsf{d}<1$ with $16\mathsf{C}_{\mathrm{Q}}(Y_1^g)^{3\mathfrak{r}+1}\le\log\frac{1}{\mathsf{d}}$ put $\mathsf{z}(\mathsf{d}):=\max\{z\ge 1: 16\mathsf{C}_{\mathrm{Q}}(Y_z^g)^{3\mathfrak{r}+1}\le\log\frac{1}{\mathsf{d}}\}$; it is formed with the constants, g and d, and tends to ∞ as $\mathsf{d}\to 0$. For $(K,\beta)\in\mathfrak{d}(g)$ with run $(x_0,\dots,x_K)$ and label b, and for such d with $K-s_g(\mathsf{d})\ge 1$, the dilated data are: $\mathsf{z}:=\mathsf{z}(\mathsf{d})$; $k:=K-\mathsf{z}$; the coupling g' with $g'^{-2}=L^{-1}x_k-B_\sharp$; the least side $\ell'=2L^m$ at g'; $\mathsf{d}':=L^{\mathsf{z}}\mathsf{d}$; $b':=L^{\mathsf{z}}b$; $y_j:=\log x_j$; the depth $s':=s_{g'}(\mathsf{d}')$; the working level $\mathsf{k}:=\max\{k-s',2\}$; $N:=k-\mathsf{k}$; $Y:=Y_{s'}^{g'}$; $\hat{\mathsf{d}}_i:=\mathsf{d}'/a_{k-i}$ and $\hat{\mathsf{d}}:=\hat{\mathsf{d}}_{\mathsf{k}}=L^N\mathsf{d}'$; $\mathfrak{q}:=\max\{x_{\mathsf{k}}^{-1/2},x_kL^{-N}\}$; the set of sides $\mathfrak{l}':=\{\ell\in\mathfrak{L}(g'):\ell\ge\ell'\}$; and $\mathsf{Q}':=\exp[\frac{1}{8}\ell'^3(2C_{\mathrm{S}}+C_{g'})]$, where $C_{g'}=C_{\mathrm{st}}+\frac{9}{2}\log X_{g'}$ is the lower stability constant of [7, Section 2]. There is a number $\mathsf{d}_{\mathrm{sm}}(g)\in(0,1)$, formed with the constants and g, such that for every $(K,\beta)\in\mathfrak{d}(g)$ and every $0<\mathsf{d}\le\mathsf{d}_{\mathrm{sm}}(g)$ with $K-s_g(\mathsf{d})\ge 1$ the following holds.

(a) $\mathsf{z}\ge 1$, $L^{k-2}\ge 6M$ and $g'<g$; (k,β) is a first-passage datum at g', with the run $(x_0,\dots,x_k)$ and the label b'; for every state $\mathfrak{s}$ at g at (K,β) the image law $\mathfrak{s}^{(\mathsf{z})}$ is a state over $\mathfrak{l}'$ at (k,β), and $S_n^T[\mathfrak{s}](f_1,\dots,f_n)=L^{\mathsf{z}n}S_n^T[\mathfrak{s}^{(\mathsf{z})}](f_1^{[\mathsf{z}]},\dots,f_n^{[\mathsf{z}]})$ for all $n\ge 1$ and all bounded real functions f_i with compact supports; and $Y_{\mathsf{z}}^g-2\log L\le y_k\le Y_{\mathsf{z}}^g$.

(b) $x_k\le\mathsf{d}^{-1/16}$, $\mathsf{d}'\le\mathsf{d}^{15/16}$ and $\frac{3}{4}x_k\le b'\le\frac{5}{4}x_k$; $2My_k^{\mathfrak{r}}\le\ell'<2L^3My_k^{\mathfrak{r}}$ and $\ell'\ge 2LM$, and ℓ' is small over $(x_0,\dots,x_k)$ in the sense of Lemma YM3_I:125.3; for every $\ell\in\mathfrak{l}'$ the pressures at (k,β) satisfy $e^{(\ell'/2)^3(p_{\ell'}-p_\ell)}\le\mathsf{Q}'$; and $\mathsf{Q}'^8\le e^{\mathsf{C}_{\mathrm{Q}}y_k^{3\mathfrak{r}+1}}\le\mathsf{d}^{-1/16}$.

(c) $\log\frac{1}{\mathsf{d}}<\mathsf{C}_{\mathrm{r}}\,y_k^{3\mathfrak{r}+1}$.

(d) $2\le\mathsf{k}\le k-1$ and $N\ge 1$; $4MY^{2\mathfrak{p}_0}\le\hat{\mathsf{d}}<LC_{W,0}A_0^2Y^{2\mathfrak{p}_0}$; $a_k/\mathsf{d}'\le\frac{1}{4}$; $x_{\mathsf{k}}>L^Ng'^{-2}$; $Y-\log(2L^3)<y_{\mathsf{k}}\le Y$; and $\frac{15}{16}\log\frac{1}{\mathsf{d}}\le\log\frac{1}{\mathsf{d}'}\le Y\le 2\log\frac{1}{\mathsf{d}}$.

(e) $\mathfrak{q}\le\mathsf{d}^{15/32}$.

■

Proof. Write $s=s_g(\mathsf{d})$ and $\Xi=\log(1/\mathsf{d})$. By the reference threshold of Section YM3_I:126, $g^{-2}\ge 4\bar B$. The first-passage estimates in Proposition YM3_I:74.1 give $g^{-2}<x_K\le X_g$ and

$|x_j - L^{-(j-i)}x_i| \le \bar{B}$. In particular,

$$L^{\mathsf{z}}(g^{-2} - \bar{B}) < x_k \le L^{\mathsf{z}}(X_g + \bar{B}) = e^{Y_{\mathsf{z}}^g}, \qquad Y_{\mathsf{z}}^g - 2\log L \le y_k \le Y_{\mathsf{z}}^g.$$

The lower logarithmic bound follows from $g^{-2} - \bar{B} \ge L^{-1}(g^{-2} + \bar{B})$. Because $C_{\mathrm{S}} \ge 1$, $\mathsf{z}\log L \le Y_{\mathsf{z}}^g \le \Xi/16$. The witness room condition gives $s\log L \ge \Xi$. Thus $\mathsf{z} \le s/16$ and $k \ge 15s/16$, so $L^{k-2} \ge 6M$ for small d.

For (a), Corollary YM3_I:74.3 gives $g' < g$, $X_{g'} = x_k$, the first-passage datum with the shortened run, and $L^{\mathsf{z}}\ell \in \mathfrak{L}(g')$ whenever $\ell \in \mathfrak{L}(g)$. Relabeling the sites by $x \mapsto L^{\mathsf{z}}x$ preserves the bond Haar factors, plaquette products and coupling. It therefore takes the torus law to the law on the dilated torus. On the infinite lattice it takes the Gibbs kernels for finite bond sets to the corresponding kernels and preserves periodicity. Since $a_k = L^{\mathsf{z}}a_K$, the smeared action at the original spacing is L^{z} times the smeared action with the dilated weight. Multilinearity gives the asserted cumulant scaling.

For (b), $x_k, L^{\mathsf{z}} \le e^{Y_{\mathsf{z}}^g} \le \mathsf{d}^{-1/16}$ and $|b' - x_k| \le \bar{B}$. Lemma YM3_I:126.3 puts the least side at g' in the small-side family, with $MR(x_k) \le L^m \le L^2 MR(x_k)$ and $L^m \ge LM$. This gives the stated side bounds. At zero source, Theorem YM3_I:AD writes $p_\ell = \ell^{-3}E_\ell + \ell^{-3}\log \widetilde{Z}_\ell(0)$, where the vacuum densities differ by at most C_{S} and $-C_{g'} \le \ell^{-3}\log \widetilde{Z}_\ell(0) \le C_{\mathrm{S}}$. It follows that $p_{\ell'} - p_\ell \le 2C_{\mathrm{S}} + C_{g'}$. Using $C_{g'} \le C_{\mathrm{S}}(1 + \log g'^{-2}) \le C_{\mathrm{S}}(1 + y_k)$ and $y_k \ge 1$ gives

$$\log(\mathsf{Q}'^8) \le \ell'^3 C_{\mathrm{S}}(3 + y_k) \le \mathsf{C}_{\mathrm{Q}} y_k^{3\mathfrak{r}+1} \le \Xi/16.$$

For (c), the next integer fails the test defining z. Since $Y_{\mathsf{z}}^g + \log L \le 2y_k$ for $y_k \ge 3\log L$, the failure is exactly the required strict upper bound on Ξ.

For (d), the envelope at g' at depth $\tilde{s}$ is $L^{\tilde{s}}(x_k + \bar{B}) \le e^{Y^g_{\tilde{s}+\mathsf{z}+1}}$. At $\tilde{s} = s - \mathsf{z} + 1$ the available room $L^{\tilde{s}}\mathsf{d}' = L \cdot L^s \mathsf{d}$ is therefore at least the required one. Indeed, $C_W(s+2)/C_W(s) = (1 + 2\log L/Y_s^g)^{2\mathfrak{p}_0} \le L$ for $Y_s^g \ge 4\mathfrak{p}_0$. Thus $s' \le s - \mathsf{z} + 1 \le k$. Apply Lemma YM3_I:126.1 at the shortened run, with $d = \mathsf{d}'$. Its room and coupling bounds YM3_I:(2323)–(2324) give the assertions about $\mathsf{k}, N, \hat{\mathsf{d}}, a_k/\mathsf{d}'$ and y_{k}. The witness inequality gives $\log(1/\mathsf{d}') \le Y$. Minimality of s' gives

$$s'\log L < \log(1/\mathsf{d}') + 2\mathfrak{p}_0 \log Y + \log(LC_{W,0}A_0^2).$$

Since $Y = s'\log L + \log(x_k + \bar{B})$ and $y_k \le \Xi/16$, this implies $Y \le (17/16)\Xi + 2\mathfrak{p}_0 \log Y + C$ with a fixed constant C. As $Y \to \infty$ with Ξ, this gives $Y \le 2\Xi$ for small d. Part (b) supplies the lower bound $15\Xi/16$ for $\log(1/\mathsf{d}')$.

Finally, $x_{\mathsf{k}} > L^N = \hat{\mathsf{d}}/\mathsf{d}' \ge 1/\mathsf{d}' \ge \mathsf{d}^{-15/16}$. Also $x_k L^{-N} \le \mathsf{d}^{-1/16}\mathsf{d}^{15/16}$. Taking the maximum gives (e). All smallness conditions are uniform in the cutoff and the datum because they use the fixed constants, g, and quantities bounded above or below by functions of Ξ. In particular $y_k \to \infty$ uniformly as $\mathsf{d} \downarrow 0$ by the lower bound in (a). □

Transfer by mirrors.

Lemma 18.120 (Transfer by mirrors)**.** Fix $K \in \mathbb{N}$ and $\beta > 0$, a board of $\mathbb{L}_K$ with centers $o + a_i\mathbf{k}$, $\mathbf{k} \in \mathbb{Z}^3$, and cell side $a_i = \ell'/2$, an odd multiple of a_K, with $o \in a_K\mathbb{Z}^3$, an unbounded set $\mathfrak{l}$ of sides $\ell \ge \ell'$, and a number $\mathsf{Q}_0 \ge 1$ that bounds $e^{(\ell'/2)^3(p_{\ell'} - p_\ell)}$ for all $\ell \in \mathfrak{l}$, with pressures $p_\ell = \ell^{-3}\log Z_{K,\ell,\beta}$; let $\mathfrak{s}$ be a state over $\mathfrak{l}$ at (K,β), and $\mathcal{K} := \{0,1\}^3$. Let $n \ge 2$; let $f_1, \dots, f_n$ be bounded real functions on $\mathbb{R}^3$, each equal to 0 off the open cube interior to $\square_0$, with the mirror images $f_{i,\mathbf{k}'} := f_i \circ \hat{\mathsf{r}}^{-1}_{\mathbf{k}' \leftarrow 0}$; let $c_i \in \mathbb{R}$; and for $\emptyset \ne \gamma \subset I := \{1,\dots,n\} \times \mathcal{K}$ write κ_γ for the joint cumulant, under $\tilde{\mu} := \tilde{\mu}_{K,\ell',\beta}$, of $\mathcal{O}_K(f_{i,\mathbf{k}'}) - c_i$, $(i,\mathbf{k}') \in \gamma$. Suppose that, with numbers $u_i > 0$, $u_{(i,\mathbf{k}')} := u_i$, $C_1 \ge 1$ and $0 \le \eta_\times \le 1$, (i) $|\kappa_\gamma| \le C_1 u^\gamma$ when γ lies in one cell $\{1,\dots,n\} \times \{\mathbf{k}'\}$, and (ii) $|\kappa_\gamma| \le \eta_\times u^\gamma$ when γ meets two cells. If $\eta := 2\mathsf{Q}_0 B_{8n}^{1/8} C_1^n \eta_\times^{1/8} \le 1$, then

$$|S_n^T[\mathfrak{s}](f_1,\dots,f_n) - S_n^T[\tilde{\mu}](f_1,\dots,f_n)| \le \mathsf{a}_n(B_nC_1^n + 1)^{n-1}\,\eta \prod_i u_i.$$

■

Sketch. 1. One state against the small torus. For a function F of the cell $\square_0$, $|\mathfrak{s}(F)| \le \mathsf{Q}_0 \|F\|_{\mathrm{ch},\ell'}$. If $\mathfrak{s} = \tilde{\mu}_{K,\ell,\beta}$ with $\ell \in \mathfrak{l}$, this is $|\mathfrak{s}(F)| \le \|F\|_{\mathrm{ch},\ell}$ followed by the comparison of the two sides, $\|F\|_{\mathrm{ch},\ell} \le \|F\|_{\mathrm{ch},\ell'} e^{(\ell'/2)^3(p_{\ell'}-p_\ell)}$ (Proposition YM3_I:86.3 and Corollary YM3_I:86.6). If $\mathfrak{s} \in \mathcal{G}_{K,\beta}$, the domination of Proposition YM3_I:91.9 along a sequence of sides of $\mathfrak{l}$ that tends to ∞ gives $|\mathfrak{s}(F)| \le \liminf \|F\|_{\mathrm{ch},\ell}$, and the same comparison applies. *2. The seminorm of the small torus.* At the side $\ell' = 2a_i$ the period box is $\mathcal{K}$, and $\|F\|^8_{\mathrm{ch},\ell'} = \tilde{\mu}(\prod_{\mathbf{k}' \in \mathcal{K}} F^{[\mathbf{k}']})$ by the definition of the chessboard seminorm in Proposition YM3_I:86.3. *3. Moments.* For $\emptyset \ne J \subset \{1,\dots,n\}$ put $X_i := \mathcal{O}_K(f_i) - c_i$, a function of the inner bonds of $\square_0$: a plaquette centered in the open cell stays inside it, since the walls are midplanes and the barycenter is a half-lattice site in each plaquette direction, $m_J := \tilde{\mu}(\prod_{i\in J} X_i)$ and $G_J := \prod_{i\in J} X_i - m_J$. The mirror maps are isometries of $\mathbb{L}_K$, $\mathsf{r}\mathcal{O}_K(f) = \mathcal{O}_K(f \circ \mathsf{r}^{-1})$, and the copies of a real function are its images; so the copy of G_J in $\square_{\mathbf{k}'}$ is $P_{\mathbf{k}'} - m_J$ with $P_{\mathbf{k}'} := \prod_{i\in J}(\mathcal{O}_K(f_{i,\mathbf{k}'}) - c_i)$. Expand $\tilde{\mu}(\prod_{\mathbf{k}'}(P_{\mathbf{k}'} - m_J)) = \sum_{S\subset\mathcal{K}} (-m_J)^{8-|S|} \tilde{\mu}(\prod_{\mathbf{k}'\in S} P_{\mathbf{k}'})$ and write each moment as the sum over the partitions of $J \times S$ of the products of the κ_γ. The partitions without a block that meets two cells give $\prod_{\mathbf{k}'\in S} \tilde{\mu}(P_{\mathbf{k}'})$, and these terms add up to $\prod_{\mathbf{k}'\in\mathcal{K}}(\tilde{\mu}(P_{\mathbf{k}'}) - m_J) = 0$, the factor of $\mathbf{k}' = 0$ being 0. Every other term has a block that meets two cells; by (i), (ii), $|m_J| \le B_{|J|} C_1^{|J|} u^J$ and $B_{q_1}^{q_3} B_{q_1 q_2} \le B_{q_1(q_2+q_3)}$ for integers $q_1, q_2, q_3 \ge 1$ (distinct choices of partitions of the parts give distinct partitions of their union), they add up to at most $2^8 B_{8n} C_1^{8n} \eta_\times (u^J)^8$. So $\|G_J\|_{\mathrm{ch},\ell'} \le 2 B_{8n}^{1/8} C_1^n \eta_\times^{1/8} u^J$, and by step 1, $|\mathfrak{s}(\prod_{i\in J} X_i) - m_J| \le \eta u^J$. *4. Cumulants.* $S_n^T[\cdot](f_1,\dots,f_n)$ is the joint cumulant of the X_i, the constants dropping out at the order $n \ge 2$; in the cumulant formula in Definition 18.116(7), for a partition π, $|\prod_{J\in\pi}(m_J + \epsilon_J) - \prod_{J\in\pi} m_J| \le |\pi|\, \eta\, (B_n C_1^n + 1)^{|\pi|-1} \prod_i u_i$ when $|\epsilon_J| \le \eta u^J \le u^J$, and $\sum_\pi (|\pi|-1)!\,|\pi| = \mathsf{a}_n$. □

Jets and the cumulants of a torus.

Lemma 18.121 (Jets and cumulants of the history measures)**.** On a finite Wilson torus, use the canonical real progression and assume that the history split is available through level T_*, as in YM3_I:(2270). Let $m_t[F]$ be the unnormalized measure of the all-small-field history through level t with insertion F, and set $\mathsf{m}_t = m_t[1]$ and $\Phi^{(t)}[F] = dm_t[F]/d\mathsf{m}_t$. Let w_t be the normalized mass of histories that first leave the small-field branch at level t. For a finite set of real sources w_a, $a \in I$, put $F_a = \mathcal{O}(w_a)$ and let $J_S^{(t)}$ be their conditional cumulant with respect to $\Phi^{(t)}$ for $\emptyset \ne S \subset I$. In particular $J^{(0)}_{\{a\}} = F_a$ and $J_S^{(0)} = 0$ for $|S| \ge 2$. Write

$$\mathsf{s}_{t,S} = \operatorname*{ess\,sup}_{\mathsf{m}_t} |J_S^{(t)}|, \qquad \mathsf{o}_{t,S} = \inf_{c\in\mathbb{C}} \operatorname*{ess\,sup}_{\mathsf{m}_t} |J_S^{(t)} - c|.$$

When the source progression of Proposition YM3_I:122.1 is admitted through level t, let $D_t^\lambda(U)$ be the sourced exponent less the unsourced exponent, namely

$$D_t^\lambda(U) = \mathcal{O}\Big(\sum_a \lambda_a w_a\Big)(U) + \sum_{i\le t} \sum_{X,z} [E_\lambda^{(i)} - E_0^{(i)}](X,U,z).$$

Write $\mathcal{J}_S^{(t)}(U) = \partial_S D_t^\lambda(U)|_{\lambda=0}$. Then $J_S^{(t)}(W) = \mathcal{J}_S^{(t)}(U_t(W))$ almost everywhere on the passing set $\mathcal{V}_t^\chi$ of Proposition YM3_I:123.1, where $U_t(W)$ is the minimal background over the output W. On this set we take $\mathcal{J}_S^{(t)}(U_t(W))$ as the Borel representative whenever the source progression is admitted.

(a) The $J_S^{(t)}$ are bounded Borel functions, real m_t-almost everywhere, and

$$\Phi^{(t)}\Big[\prod_{a\in S} F_a\Big] = \sum_{\pi\in \mathrm{Part}(S)} \prod_{\gamma\in\pi} J_\gamma^{(t)}.$$

(b) For $1 \le j \le T_*$ and $|S| \ge 2$,

$$\mathsf{s}_{j,S} \le \mathsf{s}_{j-1,S} + \sum_{\pi \in \mathrm{Part}(S),\, |\pi| \ge 2} \mathsf{a}'_{|\pi|} \prod_{\gamma \in \pi} \mathsf{o}_{j-1,\gamma}.$$

For every constant c, the essential supremum of $|J^{(j)}_{\{a\}} - c|$ is nonincreasing in j.

(c) Let $1 \le T \le T_*$ and partition I into cells. Take $c_a \in \mathbb{R}$, set $X_a = F_a - c_a$, and write $\tilde{J}_{\{a\}} = J^{(T)}_{\{a\}} - c_a$ and $\tilde{J}_\gamma = J^{(T)}_\gamma$ for $|\gamma| \ge 2$. Let $u_a > 0$, $C_2 \ge 1$, and let $\bar{J}_\gamma$ be real and zero on sets γ meeting more than one cell. Suppose $\epsilon = \epsilon_{\mathrm{sc}} + \epsilon_{\mathrm{lk}} + \epsilon_{\mathrm{rare}} \le 1$, and, almost everywhere under m_T:

(i) $|\tilde{J}_\gamma - \bar{J}_\gamma| \le \epsilon_{\mathrm{sc}} u^\gamma$ and $|\bar{J}_\gamma| \le C_2 u^\gamma$ in a single cell.

(ii) $|\tilde{J}_\gamma| \le \epsilon_{\mathrm{lk}} u^\gamma$ if γ meets more than one cell.

(iii) For every nonempty $\gamma \subset I$,

$$\sum_{t=1}^{T} \mathsf{w}_t \left(1 + (u^\gamma)^{-1} \operatorname*{ess\,sup}_{\mathsf{m}_{t-1}} \left| \Phi^{(t-1)}\Big[\prod_{a \in \gamma} X_a \Big] \right| \right) \le \epsilon_{\mathrm{rare}}.$$

Then the Wilson cumulants κ_γ of the X_a satisfy $|\kappa_\gamma - \bar{J}_\gamma| \le \mathsf{C}_{|\gamma|} \epsilon u^\gamma$, where $\mathsf{C}_m = \mathsf{a}_m [6 m B_m (C_2 + 1)^m]^m$.

■

Proof. The history measure is positive, so $|m_t[F]| \le \|F\|_\infty \mathsf{m}_t$. This gives bounded Borel versions of the quotients, and real versions for real insertions. Use the algebra with variables z_a and relations $z_a^2 = 0$. If $z^S = \prod_{a \in S} z_a$, the conditional moment polynomial is $M_t = 1 + \sum_{S \ne \emptyset} z^S \Phi^{(t)}[\prod_{a \in S} F_a]$. The coefficient of z^S in $\log M_t$ is $J^{(t)}_S$ by the cumulant formula. Expanding the exponential recovers the moments and proves (a).

For the identification with the local exponent, the source weights in Proposition YM3_I:122.1 enter as a single linear array $\sum_a \lambda_a w_a$. The polydisc condition there is a bound on the sum of the norms of its source entries, so any finite array is allowed on a sufficiently small polydisc. In the proof of Proposition YM3_I:123.1 the exact sum rule is applied to that one array and then divided by the positive unsourced density. Thus the density of $m_t[\exp(\sum_a \lambda_a F_a)]$ relative to m_t is $\exp D^\lambda_t(U_t(W))$. The identity holds as an analytic germ. To differentiate, test against any bounded Borel function of W and expand the bounded insertions in the original finite-volume integral. On the other side the finite-lattice exponent is uniformly bounded on a smaller polydisc by the local Lipschitz estimates of Proposition YM3_I:122.1. Coefficient extraction shows that $\exp D^\lambda_t(U_t(W))$ and M_t agree modulo λ_a^2, almost everywhere. Taking the logarithm gives the stated identification.

For (b), let g_j be the nonnegative all-small-field step factor. Define $Q_j[G] = d\mathcal{M}_*(G g_j \mathsf{m}_{j-1})/d\mathsf{m}_j$. The pushforward identity YM3_I:(2269) gives $\mathsf{m}_j = \mathcal{M}_*(g_j \mathsf{m}_{j-1})$ and $\Phi^{(j)}[F] = Q_j[\Phi^{(j-1)}[F]]$. Thus $Q_j[1] = 1$ and Q_j is positive, with the essential supremum bound from level $j-1$ to level j. In the same finite algebra,

$$\log M_j = \log Q_j \left[\exp \left(\sum_{\gamma \ne \emptyset} z^\gamma J^{(j-1)}_\gamma \right) \right].$$

The coefficient of z^S in this logarithm is the sum, over partitions π of S, of the Q_j-cumulants with entries $J^{(j-1)}_\gamma$, $\gamma \in \pi$. Indeed products with overlapping subsets vanish, and for each partition the surviving terms are exactly its cumulant expansion. The one-block term is $Q_j[J^{(j-1)}_S]$. For the other terms subtract constants from the entries, apply the supremum bound to their products, and take the infimum over the constants. The cumulant formula gives the factor $\mathsf{a}'_{|\pi|}$. The singleton case gives $J^{(j)}_{\{a\}} - c = Q_j[J^{(j-1)}_{\{a\}} - c]$ directly.

For (c), let $\bar{M}_\gamma$ be the moment polynomial formed from $\bar{J}$. By (a), the analogous polynomial formed from $\tilde{J}$ is the conditional moment of the centered insertions at T. Telescoping each product of at most $m = |\gamma|$ factors gives

$$\Big|\Phi^{(T)}\Big[\prod_{a\in\gamma} X_a\Big] - \bar{M}_\gamma\Big| \le mB_m(C_2+1)^{m-1}(\epsilon_{\mathrm{sc}}+\epsilon_{\mathrm{lk}})u^\gamma, \qquad |\bar{M}_\gamma| \le B_m C_2^m u^\gamma.$$

Use the first-large-field split YM3_I:(2270). The all-small-field term has mass $1-\sum_{t=1}^{T}\mathsf{w}_t$. For a history first leaving at t, the nonnegative step factor has mass w_t after normalization, and multiplies $\Phi^{(t-1)}[\prod_{a\in\gamma}X_a]$. Thus (iii) controls the sum of the discarded contributions and the mass deficit of the all-small-field term. The full moment differs from $\bar{M}_\gamma$ by at most $3mB_m(C_2+1)^m\epsilon u^\gamma$. For a fixed γ of size m, divide the moments on each subset A by u^A. Both families of normalized moments are bounded by $R = 6mB_m(C_2+1)^m$, and their difference is at most $R\epsilon$. In a product indexed by a partition π, telescope again to bound the difference by $|\pi|R^{|\pi|}\epsilon$. The cumulant coefficients have moduli $(|\pi|-1)!$ and $\sum_\pi |\pi|! = \mathsf{a}_m$. Since the cumulants of the reference moments are $\bar{J}$, this proves (c). □

The jets of the mirrored sources on the small torus.

Proposition 18.122 (The jets of the mirrored sources)**.** Let $0 < g \le \gamma_W^{\mathrm{sd}}$ and $n \ge 2$. There are numbers $\mathsf{C}_{\mathrm{jt}}, \mathsf{c}_{\mathrm{jt}} \ge 0$, formed with the constants and n, and a number $\mathsf{d}_n^\circ(g) \in (0, \mathsf{d}_{\mathrm{sm}}(g)]$, formed with the constants, n and g, such that the following holds; $C_{\mathrm{tp}} \ge 1$ and $\delta_{\mathrm{tp}} > 0$ are the kernel constants of Proposition YM3_I:120.6, taking common constants for its three bounds, and $\mathsf{c}_{\mathrm{g}} := \max\{1, 1900\max\{1, C_{\mathrm{tp}}\}\delta_{\mathrm{tp}}^{-3}\}$. Let $(K,\beta) \in \mathfrak{d}(g)$ and $0 < \mathsf{d} \le \mathsf{d}_n^\circ(g)$ with $K - s_g(\mathsf{d}) \ge 1$, with the dilated data of Lemma 18.119, $\ell' = 2L^m$. Let $o \in a_k\mathbb{Z}^3$, let $(-m, o)$ be the board of $\mathbb{L}_k$ of side $\ell'/2$ with the cells $\square_{\mathbf{k}'} = o + \frac{\ell'}{2}\mathbf{k}' + [-\frac{\ell'}{4}, \frac{\ell'}{4}]^3$ and the mirror maps $\hat{\mathsf{r}}_{\mathbf{k}'\leftarrow 0}$, $\mathbf{k}' \in \{0,1\}^3$; let $I := \{1,\dots,n\}\times\{0,1\}^3$, whose eight cells are the sets $\{1,\dots,n\}\times\{\mathbf{k}'\}$; and let $F_1,\dots,F_n$ be real Lipschitz functions on $\mathbb{R}^3$ with:

(M1) $|x-o|_\infty \le \ell'/8$ for every i and every $x \in \operatorname{supp} F_i$;
(M2) for every i some closed ball of radius d' contains $\operatorname{supp} F_i$, and every weight w_a below is non-zero;
(M3) $|x-y|_\infty \ge \mathsf{d}'/\sqrt{3}$ whenever $x \in \operatorname{supp} F_i$, $y \in \operatorname{supp} F_j$ and $i \ne j$.

Put $f_{(i,\mathbf{k}')} := (F_i \circ \hat{\mathsf{r}}^{-1}_{\mathbf{k}'\leftarrow 0})^{\langle \ell'\rangle}$, $w_a := f_a \circ x$ on the bare plaquettes of $T_{\ell'}$, and $u_{(i,\mathbf{k}')} := b'^{-1}\|F_i\|$. The jets $J_S^{(t)}$ are those of Lemma 18.121 on (ℓ', k) through level k. Let $\upsilon_j := 1/(a_{k-j+1}x_{j-1})$, let $\mathcal{C}_{(j)}$ be the curvature slices of YM3_I:(2226) on (ℓ', k), $G_i := \sum_{\mathsf{k}<j\le i}\upsilon_j\mathcal{C}_{(j)}$, W_a the multiplication by w_a, and, for $\emptyset \ne S \subset I$ and $\mathsf{k} \le i \le k$,

$$n_S^{(i)} := \tfrac{3}{2}\sum_{\varsigma\in\mathrm{Cyc}(S)}\operatorname{Tr}\prod_{t=1}^{|S|}(G_iW_{\varsigma(t)}) \quad (|S|\ge 2), \qquad n_{\{a\}}^{(i)} := \tfrac{3}{2}\operatorname{Tr}(G_iW_a) + \mathcal{J}_{\{a\}}^{(\mathsf{k})}(\mathbf{1}),$$

where, for $|S| \ge 2$, $\mathrm{Cyc}(S)$ consists of the bijections ς from $\mathbb{Z}/|S|\mathbb{Z}$ onto S that send 1 to a member of S chosen once and for all; these cyclic orders of S number $(|S|-1)!$; the product is ordered, $G_iW_{\varsigma(1)}G_iW_{\varsigma(2)}\cdots G_iW_{\varsigma(|S|)}$, and as the trace is cyclic the sum does not depend on the chosen member. Let $\epsilon_{\mathrm{jt}} := \mathsf{C}_{\mathrm{jt}}(\log\frac{1}{\mathsf{d}})^{\mathsf{c}_{\mathrm{jt}}}\mathsf{d}^{15/32}$. There are numbers $0 \le \rho_{\mathrm{fo}} \le \epsilon_{\mathrm{rare}}$ that depend on the constants, n, the run $(x_0,\dots,x_k)$, ℓ' and d' only, and in particular not on o or on the F_i, such that:

(a) $|J_S^{(k)}(W) - n_S^{(k)}| \le \epsilon_{\mathrm{jt}}u^S$ for every $W \in \mathcal{V}_k^\chi$ and every $S \subset I$ with $1 \le |S| \le 8n$;
(b) $|n_S^{(k)}| \le \frac{3}{2}(n-1)!\,\mathsf{c}_{\mathrm{g}}^n u^S$ if S lies in one cell and $2 \le |S| \le n$, and $|n_S^{(k)}| \le 254\,(8n)!\,\mathsf{c}_{\mathrm{g}}^{8n}\mathsf{d}'^6u^S$ if S meets two cells and $|S| \le 8n$;

(c) the mean $c_a := \langle \mathcal{O}(w_a)\rangle_{k,\ell',\beta}$ is real, it is the same for the eight members $(i,\mathbf{k}')$ of a row, and $|n^{(k)}_{\{a\}} - c_a| \le (\epsilon_{\rm jt} + 2\rho_{\rm fo})u_a$;

(d) $\rho_{\rm fo} \le \epsilon_{\rm rare} \le \frac14$, $\mathsf{Q}'^8\epsilon_{\rm rare} \le 2\mathsf{d}^{15/16}$, and with $X_a := \mathcal{O}(w_a) - c_a$, for every $\emptyset \ne \gamma \subset I$,

$$\sum_{t=1}^{k} \mathsf{w}_t\Big(1 + (u^\gamma)^{-1}\operatorname*{ess\,sup}_{\mathsf{m}_{t-1}}\Big|\Phi^{(t-1)}\Big[\prod_{a\in\gamma} X_a\Big]\Big|\Big) \le \epsilon_{\rm rare},$$

with the notation of Lemma 18.121;

(e) $b'\upsilon_j \le \frac32$ for $\mathsf{k} < j \le k$.

■

Sketch. Put $\Xi = \log(1/\mathsf{d})$, $\eta_i = L^{-i}$, $g_i = x_i^{-1/2}$ and $\mathsf{ang}_p^{[i]}(A) = \eta_i(\mathrm{d}A)(p)$. Use the shift system of Section YM3_I:124 and the curvature kernels of Proposition YM3_I:120.6. A number formed with the constants, n and the dilated data is called tame if it is at most $\mathsf{C}Y^{\mathsf{c}}$ with C,c formed with the constants and n; as $Y \le 2\Xi$ and $\mathsf{q} \le \mathsf{d}^{15/32}$ (Lemma 18.119(d), (e)), a tame number times q is at most $\mathsf{C}(2\Xi)^{\mathsf{c}}\mathsf{d}^{15/32}$. Every condition laid on d below has the form $\Xi \ge \Xi_0$, with Ξ_0 formed with the constants, n and g: the conditions bear on $y_k \ge (\mathsf{z}(\mathsf{d}) - 1)\log L$, on $Y \in [\frac{15}{16}\Xi, 2\Xi]$, on $\mathsf{q} \le \mathsf{d}^{15/32}$ and on $\mathsf{d}' \le \mathsf{d}^{15/16}$, and a tame number times a positive power of d is at most 1 for large Ξ. To these we add, already here, the four inequalities that Lemma 18.123 and Proposition 18.124 use: $\delta_{\rm tp}L(L-1)\hat{\mathsf{d}} \ge \sqrt{3}(3\log L + \log 2)$, the hypothesis of the fluctuation-kernel bound of Proposition YM3_I:120.6 at the depth N; $162L^3C_{\rm tp}\hat{\mathsf{d}}^3e^{-\delta_{\rm tp}L\hat{\mathsf{d}}/\sqrt{3}} \le \mathsf{d}'$; $\mathsf{c}'_{\rm val}\mathsf{d}' \le 1$; and $\mathsf{C}'\Xi^{\mathsf{c}_{\rm jt}/8}\mathsf{d}^{13/256} \le 1$, with the numbers $\mathsf{c}'_{\rm val}$ of Lemma 18.123 and C' of Proposition 18.124, which are formed with the constants and n. They too have the form $\Xi \ge \Xi_0$: the first because $\hat{\mathsf{d}} \ge 4MY^{2\mathfrak{p}_0}$ grows with Ξ; the second because, besides, $2\mathfrak{p}_0 \ge 2$ puts the exponential below every power of d for large Ξ, while $\hat{\mathsf{d}}^3$ is tame and $\mathsf{d}' \ge \mathsf{d}$; the third because $\mathsf{d}' \le \mathsf{d}^{15/16}$; the fourth by its form. $\mathsf{d}^\circ_n(g)$ is the least of all the resulting thresholds and of $\mathsf{d}_{\rm sm}(g)$.

Step 1: geometry and settings. The maps between cells are compositions of reflections at their walls. The walls are lattice midplanes because $\ell'/(2a_k)$ is odd. Thus the maps preserve the lattice, Euclidean and sup distances, and send the first cell center to $o + (\ell'/2)\mathbf{k}'$. By (M1) each support lifts to its ball inside its cell and is at least $\ell'/8$ from its walls. The periodization preserves the sup norm. Distinct supports in one cell are at sup distance at least $\mathsf{d}'/\sqrt{3}$, and those in different cells at least $\ell'/4$ in the torus metric. Counting points on the three translated grids of plaquette centers gives $n_a := \#\operatorname{supp} w_a \le 81(\mathsf{d}'/a_k)^3$. A plaquette corner is at sup distance at most $a_k/2$ from its center. Hence the distance between distinct sets of corners, in units of the working-level spacing, is at least $\hat{\mathsf{d}}/\sqrt{3} - 1 \ge 3M$ by Lemma 18.119(d).

The shortened run is first passage at $g' \le \gamma_W^{\rm ref}$, $k \ge 3$ and $MR(x_k) \le L^m$. Thus Lemma YM3_I:126.2 gives the canonical progression, density and regularity conditions through level k. Proposition YM3_I:122.1 then admits the linear array of all the sources for parameters near zero at these finitely many levels. The source parameter radii may depend on the cutoff here. The derivative estimates below use the array norm to give bounds uniform in the cutoff. We take d small enough that also $g'^{-2} \ge x_{\rm J}$ of Lemma 4.6, which is possible since $x_k \to \infty$ and $X_{g'} = x_k$. Write $\delta_i = A_1x_i^{-1/2}y_i^{\mathfrak{p}_0}$ and $\varepsilon_i = A_0x_i^{-1/2}y_i^{\mathfrak{p}_0}$. They are nondecreasing in i in this run, since $y_i \ge 2\mathfrak{p}_0$ and the x_i decrease. The flow estimate in Proposition YM3_I:74.1 gives $\frac34L^{j-i}x_j \le x_i \le \frac54L^{j-i}x_j$ for $i \le j$ and $|a_{k-j}x_j - b'| \le \bar{B}a_{k-j}$. Since $x_j \ge 4\bar{B}$, $a_{k-j}x_j \ge (2/3)b'$. This last bound gives (e).

Step 2: the exact step for all the sources. Use the chart and lowering map of Proposition YM3_I:124.2. For a height i let ϱ satisfy eq. 2.viii, let $A \in \mathsf{C}\mathsf{c}_{i+1}(\varrho)$, and set $\widetilde{U} = e^{i\eta_{i+1}A}$, $v = v_A^{[i+1]}$, $\varpi = \nu_{i,v}$, and $\widetilde{U}^{\rm lw}(B) = e^{i\eta_iA^{\rm lw}(v,g_iB)}$. The chart conditions ensure that the array actions used below are defined at the upper and the lowered backgrounds. In the weighted progression use the single bare array $f_{\lambda,i}$ formed with the weight $\sum_a \lambda_a w_a$, as in Proposition YM3_I:122.1. For any finite

source family, the norm condition for that array holds on a polydisc about zero. The counterterms of $f_{\lambda,i}$ are the same as those of $f_{0,i}$. Its difference $g_\lambda = f_{\lambda,i} - f_{0,i}$ has bare-array action $D_i^\lambda(U) - D_i^\lambda(\mathbf{1})$ by the weight normalization YM3_I:(2256). Consequently the sum rule YM3_I:(2289) gives

$$(\mathbb{V}'[g_\lambda])^{\mathrm{tot}}(P[v];B) = D_i^\lambda(\widetilde{U}^{\mathrm{lw}}(B)) - D_i^\lambda(\widetilde{U}).$$

The whole-torus step integral for $f_{\lambda,i}$ is $\exp \mathsf{Sum}[\mathsf{St}_i(f_{\lambda,i})](P[v])$ by Theorem YM3_I:V, as in eq. 2.xii. Dividing by the integral at zero gives the ϖ-mean of $\exp(\mathbb{V}'[g_\lambda])^{\mathrm{tot}}$, since the step potentials are linear in the added array. By the update of the source families in Proposition YM3_I:122.1, the same quotient is $\exp[D_{i+1}^\lambda(\widetilde{U}) - D_i^\lambda(\widetilde{U})]$. Thus

$$e^{D_{i+1}^\lambda(\widetilde{U})} = \int e^{D_i^\lambda(\widetilde{U}^{\mathrm{lw}}(B))}\, d\varpi(B).$$

The holomorphic local families are uniformly bounded on the fluctuation box on a smaller source polydisc by the bounds of Proposition YM3_I:122.1, so Cauchy's formula permits coefficient extraction under the integral. Take the logarithm in the algebra $\lambda_a^2 = 0$ used in Lemma 18.121. The coefficient of $\prod_{a\in S}\lambda_a$ is

$$\mathcal{J}_S^{(i+1)}(\widetilde{U}) = \sum_{\pi\in\mathrm{Part}(S)} \kappa_\varpi\big(\mathcal{J}_\gamma^{(i)}(\widetilde{U}^{\mathrm{lw}}(\cdot)) : \gamma\in\pi\big).$$

Step 3: the Gaussian template. For a real symmetric $\mathcal{G}\ge 0$ and a real diagonal W with $\|\mathcal{G}^{1/2}W\mathcal{G}^{1/2}\| < 1$ put $\mathcal{D}[\mathcal{G}](F) := -\frac{3}{2}\operatorname{Tr}\log(1-\mathcal{G}W) + \frac{1}{2}(F, W(1-\mathcal{G}W)^{-1}F)$ for $\mathfrak{g}$-valued functions F of the bare plaquettes. Completing the square, $\int \exp\mathcal{D}[\mathcal{G}](F+\phi)\, d\gamma_\Gamma(\phi) = \exp\mathcal{D}[\mathcal{G}+\Gamma](F)$ for the centred Gaussian measure γ_Γ with the covariance $\Gamma\otimes 1_3$; indeed, $e^{\mathcal{D}[\mathcal{G}](F)}$ is the expectation of $e^{\frac{1}{2}(F+\zeta, W(F+\zeta))}$ over an independent Gaussian ζ with covariance $\mathcal{G}\otimes 1_3$. This formula follows by completing the square on the range of $\mathcal{G}$, so it holds for singular covariances as well. Integrating first in ζ and then in ϕ replaces that covariance by $(\mathcal{G}+\Gamma)\otimes 1_3$. These Gaussian integrals converge for source parameters near zero, which is the domain needed to extract the mixed derivatives. At $W = a_k^{-1}\sum_a \lambda_a W_a$, $\mathcal{G} = a_k G_i$ and $\Gamma = a_k \upsilon_{i+1}\mathcal{C}_{(i+1)}$, the mixed derivative $\partial_S \mathcal{D}[a_k G_i](F)|_0$ is $n_S^{(i)} + \mathsf{Q}_S^{(i)}(F)$, without the constant at $|S| = 1$, where $\mathsf{Q}_S^{(i)}(F) := \frac{1}{2}\sum_{p,p'} k_S^{(i)}(p,p')\langle F_p, F_{p'}\rangle$ and $k_S^{(i)} := a_k^{-1}\sum W_{a_1}G_i W_{a_2}\cdots G_i W_{a_q}$, the sum over the orders $(a_1,\dots,a_q)$ of S (expand $-\operatorname{Tr}\log(1-x)$; the orders of S fall into the cyclic classes). Hence, with $P_\gamma(\phi) := \mathsf{Q}_\gamma^{(i)}(F+\phi) - \mathsf{Q}_\gamma^{(i)}(F)$ and the Gaussian joint cumulants κ^{G} for the covariance $a_k\upsilon_{i+1}\mathcal{C}_{(i+1)}\otimes 1_3$,

$$n_S^{(i)} + \mathsf{Q}_S^{(i)}(F) + \sum_{\pi\in\mathrm{Part}(S)} \kappa^{\mathrm{G}}(P_\gamma : \gamma\in\pi) = n_S^{(i+1)} + \mathsf{Q}_S^{(i+1)}(F).$$

Step 4: the recursion down the chain classes. Let the radii be $\varrho_i := L^{-1}\varrho_{i+1} + \frac{11}{10}\mathsf{c}_{\mathfrak{h}}\delta_i$ below a top radius ϱ_k, with the constant $\mathsf{c}_{\mathfrak{h}}\ge 1$ of the shift system in Section YM3_I:124, and consider for $\mathsf{k}\le i\le k$ the bounds

$$(\mathrm{I}_i)\qquad |\mathcal{J}_S^{(i)}(e^{i\eta_i A}) - n_S^{(i)} - \mathsf{Q}_S^{(i)}(\mathsf{ang}^{[i]}(A))| \le e_{S,i}\qquad (A\in \mathsf{Cc}_i(\varrho_i),\ 1\le|S|\le 8n).$$

Let $\mathsf{k}\le i<k$, and suppose that $\varrho_{i+1}\le\frac{1}{2}\varrho_{\mathrm{ch}}$, $\delta_i\le\frac{1}{2}\varrho_{\mathrm{fl}}$ and $6L^{-2}\varrho_{i+1} + 8C_{\mathrm{db}}\delta_i < \varepsilon_{\mathcal{W}}\alpha_0$, which are the conditions of Step 2 at $\varrho = \varrho_{i+1}$ with room to spare, and that the number $\bar{e}_i$ formed below is at most 1. Then (I_i) implies (I_{i+1}), with the numbers $e_{S,i+1}$ that the display below forms from the $e_{\gamma,i}$, $\gamma\subset S$. Both suppositions hold at every such i for small d: by the recursion, ϱ_{i+1} is at most ϱ_k plus a number of the constants times $\delta(x_k)$, since $\delta(\cdot)$ does not increase and $x_i\ge x_k$; $\bar{e}_i\le \mathsf{c}_{\mathrm{e}}[\delta(x_k)+\varrho_k]$; and $\delta(x_k)$ and ϱ_k (Step 7) tend to 0 with d. The lowered form lies in $\mathsf{Cc}_i(\varrho_i)$ (Proposition YM3_I:124.2). The plaquette angles of the lowered form are those of the upper form plus the linear image $g_i\mathsf{T}_i^{\mathfrak{h}}B$ of the fluctuation field, with $\mathsf{T}_i^{\mathfrak{h}} = \pm\mathsf{T}_i^{\mathrm{cv}}\otimes 1$ of row sums at most $C_{\mathrm{tp}}^{\mathrm{row}}\eta_i^2$ ($C_{\mathrm{tp}}^{\mathrm{row}} > 0$ the row-sum constant in YM3_I:(2239), formed with the constants), up to a remainder

of the second order (Lemmas YM3_I:124.3 and YM3_I:124.4); so each $\mathcal{J}_\gamma^{(i)}$ at the lowered form is $n_\gamma^{(i)}$ plus a polynomial of degree two in the fluctuation field plus an error of the size $e_{\gamma,i}$ and of the third order in the fields. On the support of ϖ, where $|g_iB| < \delta_i$, the angles of the upper form plus the linear image are at most $2\eta_i^2 x_i^{-1/2}\mathsf{t}_i$ in modulus, $\mathsf{t}_i := x_i^{1/2}(L^{-2}\varrho_{i+1} + \mathsf{c}_\mathfrak{h}\delta_i)$, and Lemma YM3_I:124.4 bounds the remainder as well; so, with $\mathsf{m}_{\gamma,i} := x_i^{-1}a_k^{-1}\eta_i^4\mathsf{N}_\gamma^{(i)}$, $\mathsf{N}_\gamma^{(i)}$ being the sum defined at the end of this step, the polynomial is at most $\mathsf{p}_{\gamma,i} := 2\mathsf{t}_i^2\mathsf{m}_{\gamma,i}$ in modulus, the ℓ^1 norm of its coefficients of degrees one and two is at most $\mathsf{l}_{\gamma,i} := 4\max\{1, C_{\mathrm{tp}}^{\mathrm{row}}\}^2(1+\mathsf{t}_i)\mathsf{m}_{\gamma,i}$, and the error is at most $e'_{\gamma,i} := e_{\gamma,i} + \mathsf{c}_1 x_i^{-1/2}\mathsf{t}_i^3\mathsf{m}_{\gamma,i}$, with a number c_1 of the constants. For Step 8 put $p_i := \max_{1\le|\gamma|\le 8n}\mathsf{p}_{\gamma,i}/u^\gamma$, $l_i := \max_{1\le|\gamma|\le 8n}\mathsf{l}_{\gamma,i}/u^\gamma$ and $s_i := \max_{1\le|\gamma|\le 8n}(e'_{\gamma,i} - e_{\gamma,i})/u^\gamma$. For the conditional measure $\varpi = \nu_{i,v}$ in the admitted chart, Lemma 4.14(a) gives the component cumulant comparison at every order $q \le 16n$. To see the dependence on the order, place each tested component in its entry block and put all q insertions into a single quadratic-sort origin on the polydisc $|z_a| < w_\star/(q\mathsf{n}_\mathrm{f})$. The difference of connected terms between the perturbed step and the uncut Gaussian is bounded on that disc by $(K_\Pi\mathsf{n}_i^{\mathbb{V}} + K_P^\Pi\mathsf{p}_{\star,i})e^{-\lambda_{\mathrm{out}}d_{i+1}(X)}$ by YM3_I:(724). The mixed derivative vanishes unless X contains all entry blocks. Anchoring at one of these blocks and applying Cauchy's inequality bounds the sum of derivatives by

$$C_{\mathrm{E},0}(K_\Pi\mathsf{n}_i^{\mathbb{V}} + K_P^\Pi\mathsf{p}_{\star,i})(q\mathsf{n}_\mathrm{f}/w_\star)^q.$$

Here $\mathsf{n}_i^{\mathbb{V}} = O(\delta_i)$ and $\mathsf{p}_{\star,i} = O(\delta_i)$ by YM3_I:(2294): the latter decays exponentially in $y_i^{2\mathfrak{p}_0}$, whereas $\delta_i = A_1 y_i^{\mathfrak{p}_0}e^{-y_i/2}$ and $\mathfrak{p}_0 \ge 1$. Thus the error is $O_n(\delta_i)$ uniformly in the entry blocks and the admitted background. The Gaussian covariance obeys $|\mathbf{C}_v - \mathbf{C}_0| \le 2\mathsf{c}_\mathbf{C}\varrho_{i+1}/r_\alpha$, with the constants of Proposition YM3_I:124.5, and $\mathbf{C}_0 = (\mathsf{A}_i^{\mathrm{cv}})^{-1}\otimes 1$. The curvature covariance identity in YM3_I:(2297) gives $\eta_i\mathcal{C}_{(i+1)}$ after applying $\mathsf{T}_i^{\mathrm{cv}}$, with the identity on colors. The radius recursion bounds the combined error by $\bar e_i \le \mathsf{c}_\mathrm{e}[\delta_i + L^{-(k-i-1)}\varrho_k]$, with c_e depending only on the construction and n. For polynomials of degree two in a vector whose cumulants of odd orders and of orders at least 4 are at most $\bar e$ and whose covariance is within $\bar e$ of a covariance with entries at most $\mathsf{c}_\mathbf{C}$, the joint cumulants of ρ such polynomials differ from the Gaussian ones by at most $2\rho B_{2\rho}(\mathsf{c}_\mathbf{C}+1)^{2\rho-1}\bar e$ times the ℓ^1 norms of their coefficients (expand over the partitions of the factors into blocks; under the Gaussian measure only pairs survive); and Step 3 identifies the Gaussian value. The constants drop out of the cumulants of order at least 2. Expanding each cumulant of Step 2 multilinearly in the polynomials and the errors of its entries, bounding every term that holds an error by $\mathsf{a}'_{|\pi|}$ times the product of the bounds of its entries (Definition 18.116(7)), and comparing the term without an error with its Gaussian value as above, one obtains (I_{i+1}) with

$$e_{S,i+1} := \sum_{\pi\in\mathrm{Part}(S)}\Big\{\mathsf{a}'_{|\pi|}\Big[\prod_{\gamma\in\pi}(\mathsf{p}_{\gamma,i}+e'_{\gamma,i}) - \prod_{\gamma\in\pi}\mathsf{p}_{\gamma,i}\Big] + 2|\pi|B_{2|\pi|}(\mathsf{c}_\mathbf{C}+1)^{2|\pi|-1}\bar e_i\prod_{\gamma\in\pi}\mathsf{l}_{\gamma,i}\Big\}.$$

At the top $|\mathsf{ang}_p^{[k]}(A)| \le 2\eta_k^2\varrho_k$, so that $|\mathcal{J}_S^{(k)}(e^{i\eta_k A}) - n_S^{(k)}| \le \mathsf{o}_S := e_{S,k} + 2a_k^{-1}\eta_k^4\mathsf{N}_S^{(k)}\varrho_k^2$ on $\mathsf{Cc}_k(\varrho_k)$, where $\mathsf{N}_S^{(i)}$ is the sum over the orders of S and over the plaquettes of the products $|w_{a_1}||G_i|\cdots|G_i||w_{a_q}|$.

Step 5: sizes. By Proposition YM3_I:120.6, $|\mathcal{C}_{(j)}(p,p')| \le C_{\mathrm{tp}}(a_k/a_{k-j+1})^3 e^{-\delta_{\mathrm{tp}}\mathsf{R}/a_{k-j+1}}$ at the sup distance R of the barycentres. With $\mathsf{R} \ge \mathsf{d}'/\sqrt{3}$, $\upsilon_j|w_a|_\infty \le \frac{3}{2}u_a$ (Step 1), $n_a(a_k/a_{k-j+1})^3 \le 81\hat{\mathsf{d}}_{j-1}^3$, and $\sum_{l\in\mathbb{Z}}(t_0L^l)^3e^{-ct_0L^l} \le 3c^{-3}$ for $c, t_0 > 0$ (the greatest term is at most $\frac{27}{e^3}c^{-3}$ and the others at most $(\log L)^{-1}\int_0^\infty x^2e^{-cx}\,dx = \frac{2}{c^3\log L}$ together, and $L \ge 13$), every link that joins two different sources has $n_{a'}|w_{a'}|_\infty \sup|G_i(p,p')| \le \mathsf{c}_\mathrm{g}u_{a'}$, and $\le 13\mathsf{c}_\mathrm{g}(\mathsf{d}'/\ell')^3u_{a'}$ if the cells differ ($\mathsf{R} \ge \ell'/4$). In an order, and in a cyclic order, two neighbouring members are never the same source. Summing over the plaquettes one link at a time, each order $(a_1,\dots,a_q)$ of S, $q = |S|$, contributes to $\mathsf{N}_S^{(i)}$ at most $n_{a_1}|w_{a_1}|_\infty\,\mathsf{c}_\mathrm{g}^{q-1}\prod_{t\ge 2}u_{a_t}$; as $|w_a|_\infty \le \|f_a\| = b'u_a$ and $n_a \le 81(\mathsf{d}'/a_k)^3$ for every a (Step 1), this is at

most $81(\mathsf{d}'/a_k)^3\, b'\, \mathsf{c}_{\mathrm{g}}^{q-1} u^S$, and therefore $\mathsf{N}_S^{(i)} \le q!\, \mathsf{c}_{\mathrm{g}}^{q-1}\, 81(\mathsf{d}'/a_k)^3\, b'\, u^S$. Also $|n_S^{(i)}| \le \frac{3}{2}(q-1)!\, \mathsf{c}_{\mathrm{g}}^q u^S$ for $q \ge 2$; a cyclic order that passes through two cells crosses between cells at least twice, and $\frac{3}{2}\cdot 13^2 < 254$ gives the bound $254\,(q-1)!\, \mathsf{c}_{\mathrm{g}}^q (\mathsf{d}'/\ell')^6 u^S$. With $\ell' \ge 1$ this is (b).

Step 6: the start at the working level. We first bound the mixed families on every level $t \le \mathsf{k}$. Use the bare-array iteration and its norm in Prop. YM3_I:122.1, equations YM3_I:(2251) and YM3_I:(2253). Write θ_j for the step Lipschitz constant in the first equation, $N_{\star,j}$ for its array ceiling, and put

$$m_{j,a} = 12M^3\alpha_0^2 L^{k-j}|w_a|_\infty, \qquad v_{j,a} = \theta_j m_{j,a}.$$

Here θ_j is a fixed multiple of $\delta(x_j)$ and $\theta_j N_{\star,j}$ is fixed. By the running-coupling comparison and the first-derivative recurrence in equation YM3_I:(2258), $N_j(\partial_a \mathfrak{f}_{\lambda,j}|_0) \le 2m_{j,a}$ at $1 \le j < k$, and the first derivative family at level i has norm at most $Cv_{i-1,a}$ at output rate κ^+. Indeed the numerical condition for (2258) holds once $\theta(x_k)$ is small enough, since it is an upper bound for all the θ_j. The ordinary input is in the half-ball $N_j \le N_{\star,j}/2$ by the same weighted ceiling used in Prop. YM3_I:122.2. All these conditions hold for small d, since $x_k \to \infty$.

For $S \subset I$ of size $s \ge 2$, let $D_i(S)$ be the largest of the pairwise distances between the sets of plaquette corners, in units of the spacing at level i. Every member of $E_S^{(i)} = \partial_S E_\lambda^{(i)}|_0$ vanishes unless its domain meets all the carriers. Thus its domain size is at least $[D_i(S)/M - 2]_+$. The locality and diameter assertions are Lem. 4.6(a), (d). Here $D_i(S) = L^{t-i} D_t(S)$ for $i \le t$ and $D_t(S) \ge 3M$ for $t \le \mathsf{k}$ by Step 1.

We claim that for $1 \le i \le \mathsf{k}$ there is a constant A_s depending only on the construction constants and s such that

$$\|E_S^{(i)}\|_{i,\kappa^+} \le A_s \prod_{a\in S} v_{i-1,a}. \tag{E}$$

The first-step estimate in Lem. 4.6(e), (f) implies (E) at $i = 1$, since $v_{0,a}$ is a constant times $x_0^{-1/2} y_0^{\mathfrak{p}_0} L^k |w_a|_\infty$ and $y_0 \ge 1$.

To pass from j to $j+1$, first suppose (E) for S up to level j and for all smaller subsets. For $s \ge 2$ the derivative $\mathfrak{f}_{S,j}$ of the input array has no explicit weight member. Its norm at input rate κ is at most

$$\sum_{i=1}^{j} \omega_{j+1-i} e^{-4\beta_{\mathrm{s}}\kappa[D_i(S)/M-2]_+} A_s \prod_{a\in S} v_{i-1,a} \le H_s A_s \prod_{a\in S} v_{j,a}. \tag{L}$$

For this inequality use $v_{i-1,a}/v_{j,a} \le CL^{(j-i+1)/2}(j-i+2)^{\mathfrak{p}_0}$, which follows from the comparison of the x_i and their logarithms in Step 1. The resulting sum over the lag $h = j - i$ is finite uniformly in j, since $D_i(S)/M \ge 3L^h$ and the weights $\omega_{h+1} = (h+2)L^{-h}$. Call its bound H_s.

For a derivative of the step in q input directions $G_1, \dots, G_q$, the bound on the half-ball is

$$\big\|D^q \mathsf{St}_j[G_1,\dots,G_q]\big\|_{j+1,\kappa^+} \le C_q \theta_j N_{\star,j}^{1-q} \prod_b N_j(G_b). \tag{C}$$

For $q = 1$ this is the Lipschitz estimate. For $q \ge 2$ apply Cauchy's formula to the first derivative in direction G_1, in the other directions with radii $N_{\star,j}/[2(q-1)N_j(G_b)]$, omitting zero directions. The polydisc lies in the admitted array ball. This gives $C_q = [2(q-1)]^{q-1}$. Equivalently the prefactor in (C) is a constant times θ_j^q.

By the chain rule of Lem. 4.6(a) the output derivative is the sum over partitions of S. The partition with one block contributes at most $\theta_j H_s A_s \prod_{a\in S} v_{j,a}$ by (L). For a partition with at least two blocks use (L) for the nonsingleton blocks, which have smaller size, and $2m_{j,a} = 2v_{j,a}/\theta_j$ for a singleton. There are at most q singleton blocks, so the factor θ_j^q in (C) absorbs their denominators, as $\theta_j \le 1$. The resulting sum is at most $A_s^* \prod_{a\in S} v_{j,a}$, with A_s^* formed from the constants and the A_b for $b < s$. Choose A_s at least twice A_s^* and at least the first-step constant. Impose $\theta(x_k) \max_{2\le s\le 8n} H_s \le 1/2$. Then (E) follows by induction on the size and on the level. There are finitely many orders and the added condition holds for all sufficiently small d.

At any configuration whose lower-level pairs lie in the cores, sum (E) over the domains and marked points up to level $t \le \mathsf{k}$. In a contributing family fix a carrier $a \in S$ and anchor the domain in a cube containing one of its plaquette corners. At level i there are at most $C(1+\hat{\mathsf{d}}_t)^3 L^{3(t-i)}$ choices of anchor. A domain of size $d_i(X)$ has at most $8M^3(1+d_i(X))$ marked points. The domain count in Lem. YM3_I:88.1 bounds the number of size-$d_i(X)$ domains through the anchor by $2048\,9216^{d_i(X)}$. Choose $c>0$ small enough that $\kappa^+ - c > \log 9216$. The norm decay therefore bounds the anchored sum, including the marked points, by a fixed constant times $e^{-c[D_i(S)/M-2]_+}$. Using the scale comparison of v in (L), the lag sum is bounded by a convergent series with terms at most $C_s L^{(3+s/2)h}(h+2)^{s\mathfrak{p}_0} e^{-3c(L^h-1)}$, $h=t-i$. For $s\ge 2$ the explicit source in D_t^λ is linear and contributes no mixed derivative. We have proved

$$|\mathcal{J}_S^{(t)}(U)| \le C_s(1+\hat{\mathsf{d}}_t)^3 e^{-c[D_t(S)/M-2]_+} \prod_{a\in S} v_{t,a} \qquad (1\le t\le \mathsf{k}). \tag{J}$$

This holds on the real passing backgrounds of Prop. YM3_I:123.1 as well as on the chart at the working level. In particular, after dropping the exponential, it is at most $(C_n x_t^5)^s u^S$: $\hat{\mathsf{d}}_t \le x_t$ and $v_{t,a} \le C\sqrt{x_t} y_t^{\mathfrak{p}_0} u_a \le C' x_t^{3/4} u_a$ by the coupling comparison. At $t=\mathsf{k}$ we have $D_t(S)/M \ge \hat{\mathsf{d}}/(\sqrt{3}M) - 1/M$, $\hat{\mathsf{d}} \ge 4MY^{2\mathfrak{p}_0}$, and $y_{\mathsf{k}} \le Y$. Hence the exponential in (J) absorbs $x_{\mathsf{k}}^{s/2}$ and leaves a tame number times $e^{-Y} \le \mathsf{q}$. Since $G_{\mathsf{k}}=0$, both the ring and quadratic terms of order at least two vanish at this level. This proves the corresponding initial estimates of (I_{k}).

For a singleton, the recursion for ϱ_i gives $\varrho_{\mathsf{k}} \le \mathsf{y}\mathsf{q}$, where $\mathsf{y} = 1 + 2\mathsf{c}_{\mathfrak{h}} A_1 Y^{\mathfrak{p}_0}$. Put $\varrho' = 2\varrho_{\mathsf{k}}$. For small d, the chart is regular at radius $3\varrho'$ and its lower pairs lie in the cores by Lem. 2.3. Apply Lem. YM3_I:124.4 at this chart with zero fluctuation. The difference between its plaquette action and half the squared linear angle is at most $C\eta_{\mathsf{k}}^4 \varrho'^3$ per plaquette. After smearing, this costs at most $C\hat{\mathsf{d}}^{\,3} x_{\mathsf{k}} \varrho'^3 u_a$. For the first-order source families apply the regular background estimate YM3_I:(2264) with $T=\mathsf{k}$ and $\varepsilon = 3\varrho'$. Its bound on their variation from the identity is at most

$$C(1+\hat{\mathsf{d}})^3[\varrho'^2 + e^{-d_*}]\delta(x_{\mathsf{k}}) x_{\mathsf{k}} u_a, \qquad d_* = \min\left\{\frac{c_{\mathrm{A}}\alpha_0}{3M\varrho'}, \frac{L^{m+N}-4}{2M}\right\} - 1.$$

Both entries in the minimum exceed $Y+1$ for small d, since $\varrho' \le 2\mathsf{y}\mathsf{q}$, $L^m \ge LM$ and $L^N \ge 1/\mathsf{d}'$. Thus $e^{-d_*} \le x_{\mathsf{k}}^{-1}$. Also $x_{\mathsf{k}}\mathsf{q}^2 \le C$: the $x_{\mathsf{k}}^{-1/2}$ term gives 1, and the other term is bounded by $Cx_k^3 L^{-N}$ using $x_{\mathsf{k}} \le (5/4)L^N x_k$. Here $x_k \le \mathsf{d}^{-1/16}$ and $L^{-N} \le \mathsf{d}' \le \mathsf{d}^{15/16}$. Consequently each bound is at most a tame number times $\mathsf{q}u_a$, using $\delta(x_{\mathsf{k}}) = A_1 x_{\mathsf{k}}^{-1/2} y_{\mathsf{k}}^{\mathfrak{p}_0}$. The constant of the singleton at the working level is $\mathcal{J}_{\{a\}}^{(\mathsf{k})}(\mathbf{1})$, and its quadratic part is precisely half the smeared squared linear angle. This proves (I_{k}) with $e_{S,\mathsf{k}} \le \mathsf{E}\mathsf{q}u^S$, where E is tame.

Step 7: the top. Write $N_0 = \ell'$ for the number of sites along each axis of the level-k torus. By the passing-test argument in Prop. YM3_I:68.1, every $W \in \mathcal{V}_k^\chi$ has $\varpi(W) \le 2\varepsilon_k$, where $\varepsilon_k = \varepsilon(x_k)$. For small d this is below $\varepsilon_{\mathcal{W}}\alpha_0$.

The periodic gauge. Put $\epsilon = \varpi(W)$, and let H_μ be the holonomy of the full positive axis through 0 in direction μ. Work with representatives $x \in \{0,\dots,N_0-1\}^3$. Take $g(x)$ to be the transport from 0 to x along the path which traverses its coordinate segments in order. Swapping two consecutive steps in different directions changes the transport by at most ϵ in operator norm: the two products differ by multiplication by a plaquette holonomy, and the other factors are unitary. This holds also for a swap across a periodic seam.

If a positive bond $b = (x, x+e_\mu)$ does not cross a seam, moving its last step in the path to x followed by b to the place of direction μ changes at most $2N_0$ adjacent pairs. Hence $|W^g(b) - \mathbf{1}| \le 2N_0\epsilon$. For a seam bond first move the N_0-1 steps in direction μ in the path to x to the beginning. This makes at most $2N_0^2$ swaps. Then move the seam step past the remaining transverse segment, at a cost of at most $2N_0$ swaps. The resulting path is the full positive axis followed by the path to the

endpoint of the seam bond, by periodicity. Thus $|W^g(b) - H_\mu| \le CN_0^2\epsilon$. Similarly the two paths with N_0 steps in direction μ followed by N_0 in direction ν, and the reverse order, require N_0^2 swaps. Their transports are $H_\mu H_\nu$ and $H_\nu H_\mu$, so $|H_\mu H_\nu - H_\nu H_\mu| \le N_0^2\epsilon$.

Write $H_\mu = a_\mu \mathbf{1} + i\mathbf{v}_\mu \cdot \sigma$ in quaternion coordinates and $D = N_0^2\epsilon$. The operator norm of the commutator difference is $2|\mathbf{v}_\mu \times \mathbf{v}_\nu|$. If $\max_\mu |\mathbf{v}_\mu| \le \sqrt{D}$, replace each H_μ by its nearest central sign. The change has norm at most $\sqrt{2}\sqrt{D}$ since $2(1 - |a_\mu|) \le 2|\mathbf{v}_\mu|^2$. Otherwise choose the direction of a largest $\mathbf{v}_\mu$ as a common axis. The component of any $\mathbf{v}_\nu$ perpendicular to it has modulus at most $D/(2|\mathbf{v}_\mu|) \le \sqrt{D}/2$. Discard these perpendicular components and renormalize the remaining quaternions to unit norm. For $D < 1/4$ the renormalization changes the result by at most the modulus of the discarded component. In either case there are commuting approximants $\widetilde{H}_\mu = e^{iB_\mu}$ with commuting Hermitian logarithms B_μ of norms at most π, and $|H_\mu - \widetilde{H}_\mu| \le C\sqrt{D}$.

In this fundamental box make the additional gauge change $s(x) = \exp[-i\sum_\mu x_\mu B_\mu/N_0]$. For the bond field with interiors equal to $\mathbf{1}$ and seams equal to $\widetilde{H}_\mu$, this gauge produces e^{iB_μ/N_0} on every bond of direction μ. On an interior bond this is the quotient at consecutive representatives, and on the seam the extra factor $\widetilde{H}_\mu$ gives the same quotient. The errors in the preceding comparisons are unchanged under multiplication on the left and right by these unitary gauge factors. The intrinsic angle distance on SU(2) is at most $\pi/2$ times the operator norm of the difference, since the chord for angle $r \in [0, \pi]$ is $2\sin(r/2)$. Its triangle inequality now gives a real bond logarithm B of W^{sg} with

$$\sup|B| \le \mathsf{b}_k := \frac{\pi}{\ell'} + C\big(\ell'^2\varepsilon_k + \ell'\sqrt{\varepsilon_k}\big).$$

Here the coarse gauge is defined on the torus by the chosen representatives. Both $D < 1/4$ and the smallness of b_k hold uniformly in W for small d, since $\ell' \asymp y_k^{\mathfrak{r}}$ and $\varepsilon_k = A_0 y_k^{\mathfrak{p}_0} e^{-y_k/2}$.

The critical response. Use the constant whole-torus tower of depth k, in level-k units. Its lower layers are empty, its reduced datum consists of all top bonds, and its constraint map is exactly $\mathcal{M}^k$. The region-separation inequalities are automatic for whole-torus regions. The fixed powers used for the partition divide the side in the respective level units once ℓ' is large. The uniform global response hypotheses are those of the constant-tower case following equation YM3_I:(2132); its side condition, $2L^{m+1} \ge C_L M$, holds for small d since $\ell' \to \infty$. In particular the top lattice has the fixed number of sites required in Thm. YM3_I:E. Take the reference datum $\mathbf{1}$ and the reference critical configuration $\mathbf{1}$, which has zero action and is the axial representative of the regular orbit over this datum. Apply the theorem to the perturbation e^{iB}, with $\varepsilon_1 = \varepsilon_k$. The curvature hypothesis for the reference is automatic, and ε_k and b_k tend to zero and thus fit the two fixed radii.

The theorem and Lem. YM3_I:51.6 give a real potential $A = \mathcal{H}(B)$ on the bare bonds and an axial representative $\Phi_{\mathbf{1}}(B) = (e^{i\eta_k A})^{u_B}$ of the regular critical orbit over e^{iB}. The response is defined holomorphically on the admitted datum ball. In equation YM3_I:(838) the local pillar scales are 1 for this constant tower. Integrating its derivative bound along sB, $0 \le s \le 1$, gives

$$\max\{|A(b)|, |\nabla^{\eta_k} A(b)|, |D^{\mathsf{T}} DA(b)|\} \le B_5 \sum_{c>0} e^{-\delta_{\mathrm{tw}} d(y, y_c)} |B(c)|.$$

Here y is a pillar top at an endpoint of b and y_c is an endpoint of the top bond c. This is also the integrated first-difference estimate YM3_I:(997). The sum of exponential weights is uniformly bounded on the level-k torus, as in the constant-tower application in the proof of Lem. YM3_I:113.6. Indeed the top lattice has unit spacing and the number of bond endpoints in successive distance shells is bounded by a fixed polynomial in the shell index. The derivatives here are with the identity as reference.

For the current use the current estimate of Thm. YM3_I:E with $\mathsf{L}(b) = 1$. The current is $D_U^{\mathsf{T}} F_U$ at bare spacing η_k, the normalization of equation YM3_I:(69). Its norm is unchanged by removing the gauge u_B, by covariance of the plaquette and divergence. We obtain

$$\max\{\sup|A|, \sup|\nabla^{\eta_k} A|, \sup|J^{(k)}(e^{i\eta_k A})|\} \le \mathsf{c}_{\mathrm{top}}(\mathsf{b}_k + \varepsilon_k) =: \varrho_k,$$

with a constant formed from the fixed construction constants.

The passing-field background $U_k(W)$ of Prop. YM3_I:123.1 is in the whole-torus regular critical orbit given by Thm. YM3_I:E, as in the proof of Prop. YM3_I:68.1. Extend sg from the top sites to the bare sites. The constraint and the Wilson action are gauge covariant, so this gauge carries the regular critical orbit over W to the one over $W^{sg} = e^{iB}$. The regular-orbit uniqueness in Thm. YM3_I:E now identifies $e^{i\eta_k A}$ as a gauge transform of $U_k(W)$. Together with the current bound and the cutoff on $\varpi(W)$, this is exactly membership of A in $\mathsf{Cc}_k(\varrho_k)$.

Finally, the lower-level pairs of the passing background are admitted by Prop. YM3_I:123.1, and the same is true after a real gauge change. Use the admitted plain triples of the real backgrounds. The local norm inequalities in Def. YM3_I:49.1 are gauge invariant. For a plain triple, the complex and real data on each smaller tower coincide, so the relative logarithm is zero. The averaged real data transform by endpoint gauges, and their regular critical orbits transform by covariance of the constraint and uniqueness. The continued background at zero perturbation is the real background. Admissible positive continuation radii exist at both data by the same real-background hypotheses, whose bounds are gauge invariant. This preserves the core conditions. In particular the relative exponent of the two gauge-related backgrounds is the same: the local terms are gauge-invariant functions of the admitted pairs by Def. YM3_I:49.4 and the explicit plaquette source is gauge invariant. Differentiating gives $J_S^{(k)}(W) = \mathcal{J}_S^{(k)}(e^{i\eta_k A})$ for every S. The bound on b_k and $y_k \to \infty$ give $\varrho_k \to 0$, so the top radius and all the smallness conditions in Step 4 hold for small d.

Step 8: summing the error recursion. Write $h = i-\mathsf{k}$. The radius recursion and $\delta_{i+j} \le \sqrt{5/4}L^{j/2}\delta_i$ give

$$\varrho_{i+1} \le L^{-(k-i-1)}\varrho_k + C\delta_i.$$

Also $x_i \le (5/4)L^{k-i}x_k$ and $\sqrt{x_k}L^{-N/2} \le \sqrt{\mathsf{q}}$. Hence $\mathsf{t}_i \le C(1+Y^{\mathfrak{p}_0})L^{h/2}$. By Step 5 and $b'/a_{k-i} \le (3/2)x_i$,

$$\mathsf{m}_{\gamma,i} \le C\,(\mathsf{d}'/a_{k-i})^3 u^\gamma = C\hat{\mathsf{d}}^{\,3}L^{-3h}u^\gamma,$$

where C can depend on the maximal order $8n$. Together with $x_i^{-1/2} \le CL^{h/2}x_{\mathsf{k}}^{-1/2}$ these give

$$p_i \le \mathsf{p}L^{-2h}, \quad l_i \le \mathsf{l}L^{-5h/2}, \quad s_i \le \mathsf{u}L^{-h},$$

where p,l are tame and u is at most a tame multiple of q. In the covariance error, $\delta_i \le CL^{h/2}\delta_{\mathsf{k}}$, so

$$\bar{e}_i \le CL^h(\delta_{\mathsf{k}} + L^{1-N}\varrho_k).$$

Put

$$e_0 = \max_{1\le|S|\le 8n} e_{S,\mathsf{k}}/u^S + \mathsf{u} + \delta_{\mathsf{k}} + L^{1-N}\varrho_k.$$

Step 6 and $L^{-N} \le \mathsf{q}$ bound e_0 by a tame multiple of q. In particular $Ne_0 \le 1$ for small d, since $N \le Y/\log L$.

We prove by induction on q that $e_{S,i}/u^S \le \Gamma_q e_0$ for $|S| \le q$ and every $\mathsf{k} \le i \le k$, with tame Γ_q. In the recurrence of Step 4 the partition with one block contributes $e_{S,i}/u^S$, plus an increment bounded by $s_i + C\bar{e}_i l_i$. The latter two terms have total at most a tame multiple of e_0 by their geometric bounds. This proves the assertion for $q = 1$. For a partition with at least two blocks, every block is smaller than q. Its Gaussian comparison term is bounded by $C\bar{e}_i l_i^{|\pi|}$ and is summable by the same geometric bounds. For the other term expand the difference of products. Every term contains an error factor $e'_{\gamma,i}/u^\gamma \le (\Gamma_{q-1}+1)e_0$. If a polynomial factor also occurs, its factor L^{-2h} makes the sum of the term over i at most a tame multiple of e_0. If all factors are errors, there are at least two, and their total is at most a tame multiple of $Ne_0^2 \le e_0$. The number of partitions and terms depends only on q. Adding the initial error gives a tame Γ_q and proves the assertion through $q = 8n$.

At the top, Step 5 bounds the omitted quadratic term by $Cb'\mathsf{d}'^3\varrho_k^2 u^S$. Since $b' \le (5/4)x_k \le (5/4)\mathsf{d}^{-1/16}$, $\mathsf{d}' \le \mathsf{d}^{15/16}$ and $\varrho_k \le 1$, this is at most $C\mathsf{d}^{44/16}u^S$. Also $\mathsf{q} \ge x_{\mathsf{k}}^{-1/2} \ge e^{-Y/2} \ge \mathsf{d}$. The

top error is therefore bounded by a tame multiple of $\mathsf{q}\,u^S$. Step 7 carries this estimate to the passing backgrounds. Finally $Y \le 2\log(1/\mathsf{d})$ and $\mathsf{q} \le \mathsf{d}^{15/32}$ give (a).

Step 9: the first order and the means; (c). At $1 \le t \le k$, Prop. YM3_I:123.1 writes $J^{(t)}_{\{a\}} = \mathsf{c}^{(t)}_a + X_{t,a} + I_{t,a}$, where $\mathsf{c}^{(t)}_a$ is the sum of the first-derivative families at the identity, $X_{t,a} = \mathcal{O}(w_a)(U_t)$, and $I_{t,a}$ is the change of those families from the identity to the regular background U_t. Equations YM3_I:(2264) and YM3_I:(2268) give on the passing set

$$|X_{t,a}| + |I_{t,a}| \le P_t u_a, \qquad P_t = C(1+\hat{\mathsf{d}}_t)^3(y_t^{2\mathfrak{p}_0} + \sqrt{x_t}\,y_t^{\mathfrak{p}_0}). \tag{P}$$

For the first term, multiply the plaquette count of Step 1 by $2B_3^2\varepsilon(x_t)^2L^{-4t}a_k^{-1}|w_a|_\infty$. It is at most $C\hat{\mathsf{d}}_t^3\varepsilon(x_t)^2x_tu_a$ since $L^{k-t}b' \le 3x_t/2$. For the second term the number of anchor cubes is at most $C(1+\hat{\mathsf{d}}_t)^3$. In (2264), take $\varepsilon = 2B_3\varepsilon(x_t)$. The bracket is bounded by a fixed constant: $d_*(t;t,\varepsilon) \ge 3$ because $L^{m+k-t} \ge LM \ge 8M+4$ and $\varepsilon(x_t) \le \varepsilon(x_k) \to 0$. Now $\delta(x_{t-1}) \le \delta(x_t)$ and the same bound on $L^{k-t}b'$ gives (P). At $t=0$ take $\mathsf{c}^{(0)}_a = 0$ and $P_0 = C\hat{\mathsf{d}}_0^3x_0$ from $a_p \le 2$. In particular $P_t \le C'x_t^4$ for $t \le \mathsf{k}$, using $y_t^{\mathfrak{p}_0} \le Cx_t^{1/4}$ and $\hat{\mathsf{d}}_t \le x_t$. For $\mathsf{k} \le t \le k$, (P) gives $P_t \le C(1+\hat{\mathsf{d}})^3(Y^{2\mathfrak{p}_0} + \sqrt{x_{\mathsf{k}}}Y^{\mathfrak{p}_0}) \le x_{\mathsf{k}}$ for small d, since $y_{\mathsf{k}} > Y - \log(2L^3)$.

The history bound Lem. YM3_I:125.3 on the small torus gives $W_k := \sum_{t\le k}\mathsf{w}_t < 1$ for small d by the side and coupling bounds in Lem. 18.119(b). In particular m_k has positive mass. The one-entry tower identity of Lem. 18.121(b) shows $|J^{(k)}_{\{a\}} - \mathsf{c}^{(t)}_a| \le P_tu_a$ m_k-almost everywhere. Combine it with (a) on the passing set to get $|\mathsf{c}^{(t)}_a - n^{(k)}_{\{a\}}| \le (P_t + \epsilon_{\mathrm{jt}})u_a$. The Wilson measure is invariant under the mirror maps: they permute the Haar factors and the plaquette traces. They carry the sources in each row to one another, so c_a is real and is constant along that row. Apply the first-creation identity eq. 4.xxxi to $\mathcal{O}(w_a) - n^{(k)}_{\{a\}}$. The top quotient is bounded by $\epsilon_{\mathrm{jt}}u_a$ and the quotient at $t-1$ is bounded by $(2P_{t-1} + \epsilon_{\mathrm{jt}})u_a$. The masses in that identity sum to one, so (c) holds with $\rho_{\mathrm{fo}} := \sum_{t=1}^k \mathsf{w}_tP_{t-1}$.

Step 10: the weighted rare histories; (d). Put $m_* = 8n$ and $\mathsf{v} = 1 + \sum_{\pi\in\mathrm{Part}(m_*)}\mathsf{a}'_{|\pi|}$. Choose $C_n \ge 1$ such that $2P_t + 1 \le C_nx_t^5$ for $t \le \mathsf{k}$ and the bound (J), with its exponential removed, is at most $(C_nx_t^5)^{|S|}u^S$ in the same range. Define

$$B^*_t = \begin{cases} C_nx_t^5, & 0 \le t \le \mathsf{k}, \\ 3\mathsf{v}Nx_{\mathsf{k}}, & \mathsf{k} < t < k, \end{cases} \qquad \epsilon_{\mathrm{rare}} = \sum_{t=1}^k \mathsf{w}_t\big[1 + B_{m_*}(B^*_{t-1})^{m_*}\big]. \tag{R}$$

By (P), P_{t-1} is at most the bracket of its term, so $\rho_{\mathrm{fo}} \le \epsilon_{\mathrm{rare}}$.

We first bound (R) using only the numerical history bound. For $t \le \mathsf{k}+1$, $y_t \ge Y - \log(2L^3) - \log(5L/4) \ge Y/2$ for small d. The running comparison gives $x_{t-1} \le (5/4)Lx_t$ and $L^{k-t} \le x_t$. By Lem. YM3_I:125.3 the part of (R) through $\mathsf{k}+1$ is thus at most

$$C'_n\ell'^3 \sum_{t\le \mathsf{k}+1} \exp[(3+5m_*)y_t - cy_t^{2\mathfrak{p}_0}], \qquad c = \tfrac{1}{2}c'A_0^2 > 0.$$

For large Y each summand is at most $e^{-y_t}e^{-c(Y/2)^{2\mathfrak{p}_0}/2}$. The sum of e^{-y_t} over this range is bounded by a geometric sum, since $x_t \ge (3/4)L^{\mathsf{k}+1-t}x_{\mathsf{k}+1}$. Also $\ell'^3 \le Cy_k^{3\mathfrak{r}} \le CY^{3\mathfrak{r}}$. Since $Y \ge (15/16)\log(1/\mathsf{d})$ and $2\mathfrak{p}_0 > 1$, this part is at most d. Multiplying by $\mathsf{Q}'^8 \le \mathsf{d}^{-1/16}$ makes it at most $\mathsf{d}^{15/16}$.

For $t \ge \mathsf{k}+2$, the common bracket is at most $\exp(C''_nY)$ since $N \le Y/\log L$ and $y_{\mathsf{k}} \le Y$. Use $\sum_t \mathsf{w}_t \le 2M^{-3}\ell'^3e^{-cy_k^{2\mathfrak{p}_0}}$ from the same history bound at k. By Lem. 18.119(b), (c), (d), $Y \le 2\log(1/\mathsf{d}) < 2\mathsf{C}_{\mathrm{r}}y_k^{3\mathfrak{r}+1}$ and $\mathsf{Q}'^8 \le e^{\mathsf{C}_{\mathrm{Q}}y_k^{3\mathfrak{r}+1}}$. As $2\mathfrak{p}_0 > 3\mathfrak{r}+1$ in the construction, the negative exponent absorbs all these factors and $\log(1/\mathsf{d})$ for sufficiently large y_k. This part, multiplied by Q'^8, is therefore at most d. Altogether $\mathsf{Q}'^8\epsilon_{\mathrm{rare}} \le 2\mathsf{d}^{15/16}$ and $\epsilon_{\mathrm{rare}} \le 1/4$ after shrinking d.

It remains to verify that (R) bounds the actual inserted moments. Let $\tilde J^{(t)}_{\{a\}} = J^{(t)}_{\{a\}} - c_a$ and $\tilde J^{(t)}_S = J^{(t)}_S$ if $|S| \ge 2$. Step 9 and $\rho_{\mathrm{fo}} \le \epsilon_{\mathrm{rare}} \le 1/4$ give $\|\tilde J^{(t)}_{\{a\}}\|_{L^\infty(\mathsf m_t)} \le (2P_t + 2\epsilon_{\mathrm{jt}} + 2\rho_{\mathrm{fo}})u_a$. Take $\epsilon_{\mathrm{jt}} \le 1/4$. For $t \le \mathsf k$ this is bounded by $B_t^* u_a$, and (J) and the zero initial mixed jets give the corresponding bounds $(B_t^*)^{|S|}u^S$ at order $|S| \ge 2$. For $\mathsf k \le t < k$ the singleton bound is Bu_a with $B = 3x_{\mathsf k}$. At $t = \mathsf k$ the stronger bound (J) gives $\|\tilde J^{(\mathsf k)}_S\|_\infty \le u^S$ for $|S| \ge 2$ on the passing set, as it has a tame prefactor times $\mathsf q$. This uses (J) on actual passing backgrounds, independently of the chain chart.

For each size $s = |S| \ge 2$, divide the recurrence of Lem. 18.121(b) by u^S. Its partition with one block transports the preceding jet by a positive conditional quotient of norm one. Assuming the bound $(\mathsf v N)^{b-1}B^b$ at every smaller size b, each partition with $q \ge 2$ blocks contributes at most $\mathsf a'_q(\mathsf v N)^{s-q}B^s$ by the moment–cumulant bound. Their sum is at most $(\mathsf v - 1)(\mathsf v N)^{s-2}B^s$. The constant shifts of singletons have no effect in these cumulants. With at most N steps and initial bound 1, the total is at most $(\mathsf v N)^{s-1}B^s$. Induction on s proves the bound through m_*. In particular it is at most $(B_t^*)^{|S|}$ for $t > \mathsf k$.

By Lem. 18.121(a), $\Phi^{(t)}[\prod_{a\in\gamma} X_a]$ is the sum over partitions of γ of products of these centred jets. Its essential supremum is at most $B_{m_*}(B_t^*)^{m_*}u^\gamma$ for $t < k$, since $B_t^* \ge 1$ and $|\gamma| \le m_*$. Substitution in (d) gives precisely the bound (R). □

Lemma 18.123 (The value of the rings)**.** In the setting of Proposition 18.122, let besides $\vartheta \in (0,1)$, $\Lambda \ge 1$, $(F_1,\dots,F_n) \in \mathfrak A_n(\mathsf d';\vartheta;\Lambda)$ and $4\Lambda\mathsf d' < \ell'$. With $\mathsf c'_{\mathrm{val}} := 365\,C_{\mathrm{tp}}\delta_{\mathrm{tp}}^{-2} + 1 + 81\,C_{\mathrm{tp}}$ and $\mathsf c_{\mathrm{val}} := \frac32\, n!\,\mathsf c'_{\mathrm{val}}(\mathsf c_{\mathrm g}+1)^{n-1} + 3C_n^{\mathrm{rg}}$, numbers formed with the constants and n,

$$\Big|n^{(k)}_{\{1,\dots,n\}\times\{0\}} - 3b'^{-n}\mathcal K^{(n)}_{\mathrm{free}}(F_1,\dots,F_n)\Big| \le \Big[\mathsf c_{\mathrm{val}}\mathsf d' + \frac{3C_n^{\mathrm{rg}}a_k}{\vartheta\mathsf d'}\Big]\prod_i b'^{-1}\|F_i\|.$$

■

Sketch. By YM3_I:(2226), $C_k^{\mathrm{free}} = \sum_{1\le j\le k}\mathcal C_{(j)} + C_{k,0}^{\mathrm{bg}}$ and $\sum_{j\le\mathsf k}\mathcal C_{(j)} = C_{k,N}^{\mathrm{fl}}$; so $\Delta := G_k - b'^{-1}C_k^{\mathrm{free}} = \sum_{\mathsf k<j\le k}(\upsilon_j - b'^{-1})\mathcal C_{(j)} - b'^{-1}C_{k,N}^{\mathrm{fl}} - b'^{-1}C_{k,0}^{\mathrm{bg}}$. At plaquettes p,p' of two different sources of the cell 0, the sup distance $\mathsf R$ of the barycentres is at least $\mathsf d'/\sqrt3$. The run gives $|\upsilon_j - b'^{-1}| \le \bar B a_{k-j+1}\upsilon_j/b'$ with $a_{k-j+1} = \mathsf d'/\hat{\mathsf d}_{j-1}$ by the flow estimate of Proposition YM3_I:74.1; with Proposition YM3_I:120.6 and $\sum_l (t_0L^l)^2e^{-ct_0L^l} \le 3c^{-2}$ (as in Step 5 there), the first part, multiplied by $n_a|w_a|_\infty$, is at most $1094\,C_{\mathrm{tp}}\delta_{\mathrm{tp}}^{-2}\bar B\mathsf d'b'^{-1}u_a$. the fluctuation-kernel bound of Proposition YM3_I:120.6 at the depth N, whose condition is met, as $\mathsf R \ge \mathsf d'/\sqrt3$ and $\mathsf d^\circ_n(g)$ was taken small enough for it, bounds the second part by $162L^3C_{\mathrm{tp}}\hat{\mathsf d}^3e^{-\delta_{\mathrm{tp}}L\hat{\mathsf d}/\sqrt3}u_a$, which is at most $\mathsf d'u_a$ for the same reason; the background-kernel bound of Proposition YM3_I:120.6 bounds the third by $81C_{\mathrm{tp}}\mathsf d'^3u_a$. With $\bar B \le \frac13 b'$: $n_a|w_a|_\infty \sup|\Delta| \le \mathsf c'_{\mathrm{val}}\mathsf d'u_a \le u_a$, where $\mathsf c'_{\mathrm{val}}\mathsf d' \le 1$ is one of the inequalities that fix $\mathsf d^\circ_n(g)$. Telescoping every cyclic product link by link, each link with its weight and its count being at most $\mathsf c_{\mathrm g}u$, $(\mathsf c_{\mathrm g}+1)u$ or $\mathsf c'_{\mathrm{val}}\mathsf d'u$ (Step 5 of the proof of Proposition 18.122), the ring number differs from $\frac32\sum_\varsigma \mathrm{Tr}\prod(b'^{-1}C_k^{\mathrm{free}}W_a) = 3b'^{-n}\mathcal K_k^{(n)}(f_{(1,0)},\dots,f_{(n,0)})$ by the definition of $\mathcal K_k^{(n)}$ and cyclicity of trace by at most $\frac32(n-1)!\,n\,\mathsf c'_{\mathrm{val}}\mathsf d'(\mathsf c_{\mathrm g}+1)^{n-1}\prod_a u_a$. As $f_{(i,0)} = F_i^{\langle\ell'\rangle}$, $4a_k \le \mathsf d'$ and $4\Lambda\mathsf d' < \ell'$, Lemma 18.118 on (ℓ',k) gives the free rings with the error $3C_n^{\mathrm{rg}}[a_k/(\vartheta\mathsf d') + (\mathsf d'/\ell')^3]\prod_i b'^{-1}\|F_i\|$, and $(\mathsf d'/\ell')^3 \le \mathsf d'$. □

The law on atoms.

Proposition 18.124 (The law on atoms, at every order and in every state)**.** For every $n \ge 2$ let $C_2 := 1 + \frac32(n-1)!\,\mathsf c_{\mathrm g}^n$, $\mathsf C_m := \mathsf a_m(6mB_m(C_2+1)^m)^m$, $C_1 := C_2 + \mathsf C_n$, $\mathsf C'_{\mathrm{jt}} := 2\mathsf C_{\mathrm{jt}} + 254\,(8n)!\,\mathsf c_{\mathrm g}^{8n} + 2$,

$\mathsf{C}' := 2B_{8n}^{1/8} C_1^n (\mathsf{C}_{8n}\mathsf{C}'_{\mathrm{jt}})^{1/8}$, and

$$\mathsf{C}_\sharp(n) := \mathsf{a}_n(B_nC_1^n+1)^{n-1}\mathsf{C}' + \mathsf{C}_n\mathsf{C}'_{\mathrm{jt}} + \mathsf{c}_{\mathrm{val}}, \qquad \mathsf{c}_\sharp(n) := \mathsf{c}_{\mathrm{jt}}, \qquad \Phi_n(t) := \mathsf{C}_\sharp(n)(\log\tfrac{1}{t})^{\mathsf{c}_\sharp(n)} t^{13/256} \quad (0<t<1),$$

numbers formed with the constants and n (Proposition 18.122, Lemma 18.123). Let $0 < g \le \gamma_W^{\mathrm{sd}}$, $\Lambda \ge 1$ and $\vartheta \in (0,1)$ be arbitrary; let $(K,\beta) \in \mathfrak{d}(g)$ have the label b; let $\mathfrak{s}$ be any state at g at (K,β); let d satisfy

$$0 < \mathsf{d} \le \mathsf{d}_n^{\mathrm{at}}(g,\Lambda) := \min\Big\{\mathsf{d}_n^\circ(g), \Big(\frac{LM}{4(\Lambda+1)}\Big)^{16/15}\Big\} \qquad \text{and} \qquad K - s_g(\mathsf{d}) \ge 1;$$

and let $(f_1,\dots,f_n) \in \mathfrak{A}_n(\mathsf{d};\vartheta;\Lambda)$. Then

$$\big|S_n^T[\mathfrak{s}](f_1,\dots,f_n) - 3b^{-n}\mathcal{K}_{\mathrm{free}}^{(n)}(f_1,\dots,f_n)\big| \le \Big[\Phi_n(\mathsf{d}) + \frac{3C_n^{\mathrm{rg}}a_K}{\vartheta\mathsf{d}}\Big] b^{-n}\prod_i \|f_i\|.$$

Of these data, only the threshold depends on Λ, only the lattice term of the bracket on ϑ, and only $\mathsf{d}_n^\circ(g)$ on g; the bracket involves K only by way of a_K and involves neither β nor a side nor the state, and outside the bracket the datum (K,β) enters the right side only through the factor b^{-n}. ∎

Sketch. Let x_0, x_i be the points of (P1), (P4), and take the dilated data of Lemma 18.119. Put $F_i := f_i^{[\mathsf{z}]}$ and choose $o \in a_k\mathbb{Z}^3$ with $|o - L^{\mathsf{z}}x_0|_\infty \le a_k$. By Lemma 18.117(a), (b), $(F_i) \in \mathfrak{A}_n(\mathsf{d}';\vartheta;\Lambda)$, $\|F_i\| = \|f_i\|$ and $\mathcal{K}_{\mathrm{free}}^{(n)}(F) = \mathcal{K}_{\mathrm{free}}^{(n)}(f)$. A point of $\operatorname{supp} F_i$ lies within the sup distance $\Lambda\mathsf{d}' + a_k \le (\Lambda+1)\mathsf{d}^{15/16} \le \frac14 LM \le \frac18\ell'$ of o, by the threshold and $\ell' \ge 2LM$ (Lemma 18.119(b)): this is (M1); also $4\Lambda\mathsf{d}' < \ell'$; (P4) gives the first half of (M2), and (P2) with $|v|_\infty \ge |v|/\sqrt{3}$ gives (M3). *Step 0: an entry that vanishes at every barycentre.* The mirror maps carry barycentres to barycentres, so $w_{(i,\mathbf{k}')} = 0$ if and only if F_i vanishes at every barycentre of $\mathbb{L}_k$. In that case $\mathcal{O}_k(F_i) = 0$, the cumulant of order $n \ge 2$ vanishes, and so does $S_n^T[\mathfrak{s}](f)$ by Lemma 18.119(a); a barycentre lies within $\frac{\sqrt3}{2}a_k$ of a point where $|F_i| = \|F_i\|$, so (P3) gives $a_K/(\vartheta\mathsf{d}) = a_k/(\vartheta\mathsf{d}') \ge \frac{2}{\sqrt3}$, and the right side is at least $3C_n^{\mathrm{rg}}b^{-n}\prod_i\|f_i\|$, while $3b^{-n}|\mathcal{K}_{\mathrm{free}}^{(n)}(f)| \le \frac92(n-1)!(\frac23)^n b^{-n}\prod_i\|f_i\|$ (Lemma 18.117(a)) is smaller. From here on (M2) holds, and Proposition 18.122 and Lemma 18.123 apply. *Step 1: the cumulants of the small torus.* Apply Lemma 18.121(c) on (ℓ',k) at $T = k$, with the eight cells, the means c_a of Proposition 18.122(c), $u_a = b'^{-1}\|F_i\|$, C_2, $\bar J_\gamma := \operatorname{Re} n_\gamma^{(k)}$ for γ in one cell with $|\gamma| \ge 2$, $\bar J_{\{a\}} := \operatorname{Re} n_{\{a\}}^{(k)} - c_a$, $\epsilon_{\mathrm{sc}} := \epsilon_{\mathrm{jt}}$, $\epsilon_{\mathrm{lk}} := \epsilon_{\mathrm{jt}} + 254\,(8n)!\,\mathsf{c}_{\mathrm{g}}^{8n}\mathsf{d}'^6$ and the ϵ_{rare} of Proposition 18.122(d). Its hypotheses (i)–(iii) are (a)–(d) there, the jets being real almost everywhere (Lemma 18.121(a)), so that the real parts are at least as near, and $|\bar J_{\{a\}}| \le (\epsilon_{\mathrm{jt}} + 2\rho_{\mathrm{fo}})u_a \le u_a$. So the joint cumulants κ_γ of the X_a under $\mu_{k,\ell',\beta}$ obey $|\kappa_\gamma - \bar J_\gamma| \le \mathsf{C}_{|\gamma|}\epsilon u^\gamma$ with $\epsilon := \epsilon_{\mathrm{sc}} + \epsilon_{\mathrm{lk}} + \epsilon_{\mathrm{rare}}$. *Step 2: the numbers.* With $\mathsf{d}' \le \mathsf{d}^{15/16}$ and $\mathsf{Q}'^8 \le \mathsf{d}^{-1/16}$ (Lemma 18.119(b)): $\mathsf{Q}'^8\epsilon \le \mathsf{d}^{-1/16}(2\epsilon_{\mathrm{jt}} + 254\,(8n)!\,\mathsf{c}_{\mathrm{g}}^{8n}\mathsf{d}^{45/8}) + 2\mathsf{d}^{15/16} \le \mathsf{C}'_{\mathrm{jt}}(\log\frac{1}{\mathsf{d}})^{\mathsf{c}_{\mathrm{jt}}}\mathsf{d}^{13/32}$, as $\frac{15}{32} - \frac{1}{16} = \frac{13}{32}$. With $\eta_\times := \mathsf{C}_{8n}\epsilon$ and $\eta' := 2\mathsf{Q}'B_{8n}^{1/8}C_1^n\eta_\times^{1/8} = 2B_{8n}^{1/8}C_1^n(\mathsf{C}_{8n}\mathsf{Q}'^8\epsilon)^{1/8}$: $\eta' \le \mathsf{C}'(\log\frac{1}{\mathsf{d}})^{\mathsf{c}_{\mathrm{jt}}/8}\mathsf{d}^{13/256} \le 1$, the last inequality being one of those that fix $\mathsf{d}_n^\circ(g) \ge \mathsf{d}_n^{\mathrm{at}}(g,\Lambda)$ (sketch of Proposition 18.122); and $\epsilon \le \eta_\times \le 1$. *Step 3: every state.* Apply Lemma 18.120 at (k,β) to the board $(-m,o)$, the set $\mathfrak{l}'$ and the number Q' of Lemma 18.119(b), the state $\mathfrak{s}^{(\mathsf{z})}$ over $\mathfrak{l}'$ (Lemma 18.119(a)), the functions F_i and the constants $c_i := c_{(i,0)}$: its cumulants are the κ_γ of step 1, by periodization and the equality of the means along the rows; its (i) holds with C_1, since $|\kappa_\gamma| \le |\bar J_\gamma| + \mathsf{C}_{|\gamma|}\epsilon u^\gamma$ and $|\gamma| \le n$ in one cell; its (ii) holds with $\eta_\times$; and $\eta = \eta' \le 1$. So $|S_n^T[\mathfrak{s}^{(\mathsf{z})}](F) - S_n^T[\tilde\mu_{k,\ell',\beta}](F)| \le \mathsf{a}_n(B_nC_1^n+1)^{n-1}\eta'\prod_i u_i$. *Step 4: the value.* $S_n^T[\tilde\mu_{k,\ell',\beta}](F) = \kappa_{\{1,\dots,n\}\times\{0\}}$ by periodization; by step 1 it is within $\mathsf{C}_n\epsilon\prod_i u_i$ of $\operatorname{Re} n_{\{1,\dots,n\}\times\{0\}}^{(k)}$, which by Lemma 18.123 is within $[\mathsf{c}_{\mathrm{val}}\mathsf{d}' + 3C_n^{\mathrm{rg}}a_k/(\vartheta\mathsf{d}')]\prod_i u_i$ of the real number

$3b'^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}(F)$. Adding,

$$|S^T_n[\mathfrak{s}^{(\mathsf{z})}](F) - 3b'^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}(f)| \le \Big[\mathsf{a}_n(B_nC_1^n+1)^{n-1}\eta' + \mathsf{C}_n\epsilon + \mathsf{c}_{\mathrm{val}}\mathsf{d}' + \frac{3C_n^{\mathrm{rg}}a_K}{\vartheta\mathsf{d}}\Big]\prod_i b'^{-1}\|f_i\|,$$

and the first three members are together at most $\Phi_n(\mathsf{d})$, because $\epsilon \le \mathsf{Q}'^8\epsilon$, $\mathsf{d}' \le \mathsf{d}^{15/16}$ and $\log\frac{1}{\mathsf{d}} \ge 1$. Multiplying by $L^{\mathsf{z}n}$, with $S^T_n[\mathfrak{s}](f) = L^{\mathsf{z}n}S^T_n[\mathfrak{s}^{(\mathsf{z})}](F)$ and $L^{\mathsf{z}}b'^{-1} = b^{-1}$ (Lemma 18.119(a)), gives the claim. □

Separated tuples of a bounded aspect; every pair; the limits.

Proposition 18.125 (Separated tuples of a bounded aspect, in every state and on every torus)**.** Let $0 < g \le \gamma_W^{\mathrm{sd}}$, $n \ge 2$, $\vartheta \in (0,1)$ and $\Lambda \ge 1$, and put $\mathsf{d}^P_n(g,\Lambda) := \min\{2\mathsf{d}^{\mathrm{at}}_n(g,\Lambda_1), L^{-2\mathfrak{p}_0}\}$. If $(K,\beta) \in \mathfrak{d}(g)$ has the label b, $\mathfrak{s}$ is a state at g at (K,β), $0 < \mathsf{d} \le \mathsf{d}^P_n(g,\Lambda)$ and $K - s_g(\frac{1}{2}\mathsf{d}) \ge 1$ (which holds when $K - s_g(\mathsf{d}) \ge 2$), then for each $X = (f_1,\dots,f_n) \in P_n(\mathsf{d};\vartheta;\Lambda)$

$$\Big|S^T_n[\mathfrak{s}](X) - 3b^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}(X)\Big| \le (6N_\Lambda)^n\Big[\Phi_n(\tfrac{1}{2}\mathsf{d}) + 255\,C_n^{\mathrm{rg}}\frac{a_K}{\vartheta\mathsf{d}}\Big]b^{-n}\prod_i\|f_i\|.$$

For a torus T_ℓ with $\ell \in \mathfrak{L}(g)$ and $8\Lambda\mathsf{d} < \ell$, the inequality holds for $S^T_{n;K,\ell,\beta}(X)$ at each $X \in P^{T_\ell}_n(\mathsf{d};\vartheta;\Lambda)$, regardless of where on the torus the supports are placed, with $\mathcal{K}^{(n)}_{\mathrm{free}}$ taken at a lift. The threshold and the first member of the bracket are free of ϑ. ■

Sketch. The depth at half the length. For $0 < \mathsf{d} \le L^{-2\mathfrak{p}_0}$, $s_g(\frac{1}{2}\mathsf{d}) \le s_g(\mathsf{d}) + 1$: at $s := s_g(\mathsf{d})$, $L^s\mathsf{d} \ge C_W(s) \ge 1$ and $\mathsf{d} \le L^{-2\mathfrak{p}_0}$ give $L^s \ge L^{2\mathfrak{p}_0}$, that is $s \ge 2\mathfrak{p}_0$, so, as $Y^g_s \ge (s+1)\log L$ and $L \ge 13$, $C_W(s+1)/C_W(s) = (1+\log L/Y^g_s)^{2\mathfrak{p}_0} \le e^{2\mathfrak{p}_0/(s+1)} < \frac{L}{2}$, and $L^{s+1}\frac{\mathsf{d}}{2} \ge \frac{L}{2}C_W(s) \ge C_W(s+1)$. *The bound.* The map $\mathsf{T} := S^T_n[\mathfrak{s}] - 3b^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}$ is linear in each entry on the bounded functions with compact supports at positive mutual distances by the cumulant and integral formulas. As $\mathsf{d}_1 = \frac{1}{2}\mathsf{d} \le \mathsf{d}^{\mathrm{at}}_n(g,\Lambda_1)$ and $K - s_g(\mathsf{d}_1) \ge 1$, Proposition 18.124 at $(\mathsf{d}_1;\vartheta_1;\Lambda_1)$ bounds T on $\mathfrak{A}_n(\mathsf{d}_1;\vartheta_1;\Lambda_1)$ by $\tau := [\Phi_n(\mathsf{d}_1) + 3C_n^{\mathrm{rg}}a_K/(\vartheta_1\mathsf{d}_1)]b^{-n}$, and $\vartheta_1\mathsf{d}_1 = \vartheta\mathsf{d}/(1+84\vartheta) \ge \vartheta\mathsf{d}/85$; Lemma 18.117(c) carries the bound to $P_n(\mathsf{d};\vartheta;\Lambda)$. *Tori.* Let x_0 be the point of (P1) and $\tilde{x}_0$ a lift of it. As $\Lambda\mathsf{d} < \ell/8$, the covering map is isometric on $\bar{\mathbb{B}}(\tilde{x}_0,\Lambda\mathsf{d})$, and the lifts $\hat{f}_i$ of the entries at this ball keep suprema, Lipschitz constants and the distances of the supports, and have $\hat{f}_i^{\langle\ell\rangle} = f_i$ by extending by zero off the lifted ball; so $\hat{X} \in P_n(\mathsf{d};\vartheta;\Lambda)$, $S^T_{n;K,\ell,\beta}(X) = S^T_n[\tilde{\mu}_{K,\ell,\beta}](\hat{X})$ by periodization, and $\tilde{\mu}_{K,\ell,\beta}$ is a state at g. □

Proposition 18.126 (Every pair (K,β); one modulus in d/b)**.** Let $0 < g \le \gamma_W^{\mathrm{sd}}$, $n \ge 2$, $\vartheta \in (0,1)$, $\Lambda \ge 1$, $K \in \mathbb{N}$, $\beta > X_g$ and $b := a_K\beta$; let K' be the integer for which $(K',\beta) \in \mathfrak{d}(g)$, and $z := K - K' \in \mathbb{Z}$. Then $g^{-2} < L^z b \le L(g^{-2}+\bar{B})$. Let $\mathsf{d} > 0$ with $L^z\mathsf{d} \le \mathsf{d}^P_n(g,\Lambda)$ and $K' - s_g(\frac{1}{2}L^z\mathsf{d}) \ge 1$. Then for each law ν that is a member of $\mathcal{G}_{K,\beta}$ or a torus measure $\tilde{\mu}_{K,\ell,\beta}$ with $L^z\ell \in \mathfrak{L}(g)$, and for each $X = (f_1,\dots,f_n) \in P_n(\mathsf{d};\vartheta;\Lambda)$,

$$\Big|S^T_n[\nu](X) - 3b^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}(X)\Big| \le (6N_\Lambda)^n\Big[\Phi_n(\tfrac{1}{2}L^z\mathsf{d}) + 255\,C_n^{\mathrm{rg}}\frac{a_K}{\vartheta\mathsf{d}}\Big]b^{-n}\prod_i\|f_i\|.$$

At $g = g_\star$ put $\mathsf{t}_n(\Lambda) := \min\{\mathsf{d}^P_n(g_\star,\Lambda), 2e^{-256\,\mathsf{c}_\sharp(n)/13}\}$, a number that does not depend on ϑ; if $\mathsf{c}_\star\mathsf{d}/b \le \mathsf{t}_n(\Lambda)$ and $K' - s_{g_\star}(\frac{1}{2}L^z\mathsf{d}) \ge 1$, the same bound holds with $\Phi_n(\mathsf{c}_\star\mathsf{d}/(2b))$ in the place of $\Phi_n(\frac{1}{2}L^z\mathsf{d})$. ■

Sketch. Proposition YM3_I:74.1 gives the unique first-passage cutoff K' at this β and bounds the label $a_{K'}\beta = L^z b$ in $(g^{-2}, L(g^{-2}+\bar{B})]$. The lattice relabeling by L^z preserves the Gibbs kernels and Wilson torus density as in Lemma 18.119(a), so $\nu^{(z)}$ is a state at g at (K',β). $X^{[z]} \in P_n(L^z\mathsf{d};\vartheta;\Lambda)$, $\mathcal{K}^{(n)}_{\mathrm{free}}(X^{[z]}) = \mathcal{K}^{(n)}_{\mathrm{free}}(X)$ and $\|f^{[z]}\| = \|f\|$ (Lemma 18.117(a), (b)). Proposition 18.125 at (K',β), $\nu^{(z)}$, $L^z\mathsf{d}$ and $X^{[z]}$, together with $S^T_n[\nu](X) = L^{zn}S^T_n[\nu^{(z)}](X^{[z]})$ by the scaling of the smeared actions,

$L^{zn}(L^z b)^{-n} = b^{-n}$ and $a_{K'}/(L^z\mathsf{d}) = a_K/\mathsf{d}$, gives the bound. At $g_\star$: $L^z\mathsf{d} = (L^z b)\mathsf{d}/b \le \mathsf{c}_\star\mathsf{d}/b \le \mathsf{t}_n(\Lambda) \le \mathsf{d}_n^P(g_\star,\Lambda)$; for $\mathsf{C},\mathsf{c} \ge 0$ and $\alpha > 0$ the function $t \mapsto \mathsf{C}(\log\frac{1}{t})^{\mathsf{c}}t^\alpha$ is continuous on $(0,1)$, has the limit 0 at 0, and is non-decreasing on $(0, e^{-\mathsf{c}/\alpha}]$, where its logarithmic derivative $t^{-1}[\alpha - \mathsf{c}/\log\frac{1}{t}]$ is ≥ 0; as $\frac{1}{2}L^z\mathsf{d} \le \frac{1}{2}\mathsf{c}_\star\mathsf{d}/b \le e^{-256\mathsf{c}_\sharp(n)/13}$, $\Phi_n(\frac{1}{2}L^z\mathsf{d}) \le \Phi_n(\mathsf{c}_\star\mathsf{d}/(2b))$. □

Proposition 18.127 (The limits: every limit, every component, every limit in the frame; the label)**.** Let $n \ge 2$, $\vartheta \in (0,1)$ and $\Lambda \ge 1$.

(i) (Tori.) Let $0 < g \le \gamma_W^{\mathrm{sd}}$, $\ell \in \mathfrak{L}(g)$, $(K_j,\beta_j) \in \mathfrak{d}(g)$ with $K_j \to \infty$ and $a_{K_j}\beta_j \to b$, $0 < \mathsf{d} \le \mathsf{d}_n^P(g,\Lambda)$ with $8\Lambda\mathsf{d} < \ell$, and $X = (f_1,\dots,f_n) \in P_n^{T_\ell}(\mathsf{d};\vartheta;\Lambda)$. Any accumulation point S of the sequence $(S^T_{n;K_j,\ell,\beta_j}(X))_j$ obeys $|S - 3b^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}(X)| \le (6N_\Lambda)^n\Phi_n(\frac{1}{2}\mathsf{d})\,b^{-n}\prod_i\|f_i\|$.

(ii) ($\mathbb{R}^3$.) Let $0 < g_0 \le \gamma$. Let σ be the limit of a convergent Gibbs sequence $(K_j,\beta_j,\nu_j)_j$ at g_0, and let σ' denote σ itself, any component of any canonical decomposition of σ, or any limit in the frame of that sequence. The labels $a_{K_j}\beta_j$ converge to a number $b \in [g_0^{-2}, L(g_0^{-2}+\bar B)]$, and for $\mathsf{d} > 0$ with $\mathsf{c}_\star\mathsf{d}/b < \mathsf{t}_n(\Lambda)$ and $X = (f_1,\dots,f_n) \in P_n(\mathsf{d};\vartheta;\Lambda)\cap\mathfrak{S}_n(\mathbb{R}^3)$,

$$\Big|S_n^{\sigma'}(X) - 3b^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}(X)\Big| \le (6N_\Lambda)^n\,\Phi_n\Big(\frac{\mathsf{c}_\star\mathsf{d}}{2b}\Big)\,b^{-n}\prod_i\|f_i\|.$$

Since ϑ appears neither in the condition on d nor on the right side, the inequality is valid for each $X \in \mathfrak{S}_n(\mathbb{R}^3)$ without identically vanishing entries that satisfies (P1) and (P2) at (d,Λ), with no condition on the Lipschitz constants of its entries.

■

Sketch. (i) $s_g(\frac{1}{2}\mathsf{d})$ does not depend on the cutoff, so $K_j - s_g(\frac{1}{2}\mathsf{d}) \ge 1$ for large j; Proposition 18.125 on T_ℓ at (K_j,β_j), with $a_{K_j}\beta_j \to b \ge g^{-2} > 0$ and $a_{K_j} \to 0$. (ii) *1.* By Proposition YM3_I:74.1, $b_j := a_{K_j}\beta_j \in [b_-,b_+] := [g_0^{-2}, L(g_0^{-2}+\bar B)]$; as $K_j \to \infty$, $\beta_j = L^{K_j}b_j \to \infty$, and $\beta_j > X_{g_\star}$ for large j. *2.* σ uses the approximants ν_j themselves. Every component has approximants $\rho_j = \nu_j(\,\cdot\mid E_j)$ at the same data by Theorem YM3_I:AL, equation YM3_I:(1988). The events E_j are translation invariant, so these approximants belong to $\mathcal{G}_{K_j,\beta_j}$ by Proposition YM3_I:106.3. *3.* For a limit in the frame with approximants ρ_j, $S_n^{\sigma'}(X) = \lim_j S_n^T[\rho_j](X)$ for $n \ge 2$ and $X \in \mathfrak{S}_n(\mathbb{R}^3)$: the connected functions of order at least 2 of $X \mapsto \rho_j(X^{\nu_j}_{K_j})$ are the cumulants $S_n^T[\rho_j]$ because subtracting the means of ν_j does not affect cumulants of order at least two. The cumulant formula is a fixed polynomial in the values at subtuples. *4.* Let b be a limit point of (b_j) along an infinite set $\mathcal{J}$ of indices, let $\mathsf{c}_\star\mathsf{d}/b < \mathsf{t}_n(\Lambda)$ and $X \in P_n(\mathsf{d};\vartheta;\Lambda)\cap\mathfrak{S}_n(\mathbb{R}^3)$. For large $j \in \mathcal{J}$, $\mathsf{c}_\star\mathsf{d}/b_j \le \mathsf{t}_n(\Lambda)$. With K_j' the integer for which $(K_j',\beta_j) \in \mathfrak{d}(g_\star)$ and $z_j := K_j - K_j'$, $g_\star^{-2} < L^{z_j}b_j \le \mathsf{c}_\star$ (Proposition 18.126); so $L^{z_j} \le \mathsf{c}_\star/b_-$ and $K_j' \to \infty$, while $L^{z_j}\mathsf{d} \ge g_\star^{-2}\mathsf{d}/b_+$, so that $s_{g_\star}(\frac{1}{2}L^{z_j}\mathsf{d}) \le s_{g_\star}(g_\star^{-2}\mathsf{d}/(2b_+))$ by monotonicity of the witness depth and $K_j' - s_{g_\star}(\frac{1}{2}L^{z_j}\mathsf{d}) \ge 1$ for large j. Proposition 18.126 at $g_\star$ and $\nu = \rho_j$ gives

$$\Big|S_n^T[\rho_j](X) - 3b_j^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}(X)\Big| \le (6N_\Lambda)^n\Big[\Phi_n\Big(\frac{\mathsf{c}_\star\mathsf{d}}{2b_j}\Big) + 255\,C_n^{\mathrm{rg}}\frac{a_{K_j}}{\vartheta\mathsf{d}}\Big]b_j^{-n}\prod_i\|f_i\|;$$

letting $j \to \infty$ in $\mathcal{J}$, with step 3, $a_{K_j} \to 0$ and the continuity of Φ_n, gives the bound with this b. *5. One label.* Let $\psi_1(x) := (1-|x|^2)_+^2$ and $\psi_2 := \psi_1(\cdot - 3e_1)$: two C^1 functions with $\|\psi_i\| = 1$ and $\operatorname{Lip}\psi_i = \frac{8}{3\sqrt{3}} < 2$, supported in the unit balls centred at 0 and at $3e_1$, which are one unit apart and are contained in $\bar{\mathbb{B}}(\frac{3}{2}e_1,\frac{5}{2})$. So $\Psi_r := (\psi_{1,r},\psi_{2,r}) \in P_2(r;\frac{1}{2};\frac{5}{2})\cap\mathfrak{S}_2(\mathbb{R}^3)$ for every $r > 0$, and $\kappa := \mathcal{K}^{(2)}_{\mathrm{free}}(\Psi_r) = \frac{3}{16\pi^2}\iint\psi_1(x)\psi_2(y)|x-y|^{-6}\,dx\,dy > 0$ does not depend on r by homogeneity and $\operatorname{tr}[(3\hat u\hat u^{\mathsf T} - \mathbf{1})^2] = 6$. If b and $\tilde b$ are two limit points, step 4 at $n=2$ and $X = \Psi_r$, for small r and for both, gives $3\kappa|b^{-2} - \tilde b^{-2}| \le (6N_{5/2})^2[\Phi_2(\frac{\mathsf{c}_\star r}{2b})b^{-2} + \Phi_2(\frac{\mathsf{c}_\star r}{2\tilde b})\tilde b^{-2}]$, which tends to 0 with r; so $b = \tilde b$,

and the bounded sequence (b_j) converges. The last sentence: an entry of $X \in \mathfrak{S}_n(\mathbb{R}^3)$ that is not identically 0 has $0 < \operatorname{Lip} f_i < \infty$, so (P3) holds at $\vartheta := \min\{\frac{1}{2}, \min_i \|f_i\|/(\mathsf{d} \operatorname{Lip} f_i)\}$. □

The tangent field.

Proposition 18.128 (The tangent field of the action density is the centred functional of the free template)**.** Let $0 < g_0 \le \gamma$, let σ be the limit of a convergent Gibbs sequence $(K_j, \beta_j, \nu_j)_j$ at g_0, let σ' be σ itself, any component of any canonical decomposition of σ, or any limit in the frame of that sequence, and let $b = \lim_j a_{K_j}\beta_j$ be the label of Proposition 18.127(ii).

(a) Let $n \ge 2$ and let $X = (f_1, \dots, f_n) \in \mathfrak{S}_n(\mathbb{R}^3)$ have no identically vanishing entry. Let $\mathsf{d}_X > 0$ be the least distance between two of its supports, let $\mathcal{R} > 0$ be such that some closed ball of radius $\mathcal{R}$ contains every support, and put $\Lambda := \max\{1, \mathcal{R}/\mathsf{d}_X\}$. Then for each real $r > 0$ with $\mathsf{c}_\star r \mathsf{d}_X / b < \mathsf{t}_n(\Lambda)$

$$\left| S_n^{\sigma'}(X_r) - 3b^{-n}\mathcal{K}_{\mathrm{free}}^{(n)}(X) \right| \le (6N_\Lambda)^n \, \Phi_n\Big(\frac{\mathsf{c}_\star \mathsf{d}_X}{2b}\, r\Big)\, b^{-n} \prod_i \|f_i\|,$$

and the right side tends to 0 as $r \to 0$; so $b^n S_n^{\sigma'}(X_r) \to 3\mathcal{K}_{\mathrm{free}}^{(n)}(X)$. At $r = L^{-z}$, $z \in \mathbb{N}$, the right side is $(6N_\Lambda)^n \mathsf{C}_\sharp(n) (\frac{\mathsf{c}_\star \mathsf{d}_X}{2b})^{13/256} (\log \frac{2b}{\mathsf{c}_\star \mathsf{d}_X} + z \log L)^{\mathsf{c}_\sharp(n)} L^{-13z/256}\, b^{-n} \prod_i \|f_i\|$, of the order $z^{\mathsf{c}_\sharp(n)} L^{-13z/256}$; in terms of the dilates defined by $S_n^{[z]}(Y) = L^{-zn} S_n(Y^{[-z]})$, $(L^z b)^n S_n^{\sigma'[z]}(X) = b^n S_n^{\sigma'}(X^{[-z]}) \to 3\mathcal{K}_{\mathrm{free}}^{(n)}(X)$ as $z \to \infty$, where $\sigma'[z]$ is the dilate of σ' by L^z, the limit along the dilated sequence, whose label is $L^z b$ by lattice relabeling.

(b) Let σ' be σ or a component. For every $n \ge 1$ and every $X \in \mathfrak{S}_n(\mathbb{R}^3)$,

$$\lim_{r \to 0} \sigma'(X_r) = \sum_{\pi \in \mathrm{Part}_{\ge 2}(n)} \prod_{J \in \pi} 3b^{-|J|} \mathcal{K}_{\mathrm{free}}^{(|J|)}(X_J) = \sigma_{S^{\mathrm{fr}}[3,b]}(X),$$

the centred functional of the free template with the data $(3, b)$. The same limit is obtained for the dilations about any point y, that is, for the tuples $(f_i(y + (\cdot - y)/r))_i$. The tangent field at a point $y \in \mathbb{R}^3$, in σ', of the action density is by definition the functional $X \mapsto \lim_{r \to 0} \sigma'((f_i(y + (\cdot - y)/r))_i)$ on $\mathfrak{S}(\mathbb{R}^3)$. At every point, for the limit and for each of its components, the tangent field is thus $\sigma_{S^{\mathrm{fr}}[3,b]}$. Its connected functions $3b^{-n}\mathcal{K}_{\mathrm{free}}^{(n)}$, $n \ge 2$, are, at every tuple of $P_n(\mathsf{d}; \vartheta; \Lambda)$ for every $\mathsf{d} > 0$, $\vartheta \in (0, 1)$ and $\Lambda \ge 1$, the limits as $a_K \to 0$ and $\ell \to \infty$, at the fixed label b, of the joint cumulants at the periodised entries of the variables $\mathcal{O}^{\mathrm{G}}$ of the Gaussian lattice model with the data $(\ell, K, 3, b)$: $\mathcal{O}^{\mathrm{G}}(f) = a_K^{-1} \sum_p f(x(p)) \frac{1}{2} \sum_{c \le 3} \theta^c(p)^2$ smears with f the plaquette action $\frac{1}{2} \sum_{c \le 3} \theta^c(p)^2$ of three independent free photon fields, $\theta^1, \theta^2, \theta^3$ being their curvatures.

■

Sketch. (a) $\mathsf{d}_X > 0$, as the supports are finitely many compact and pairwise disjoint sets. (P1) holds at (d_X, Λ), since $\mathcal{R} \le \Lambda \mathsf{d}_X$; every entry is of class C^1 with compact support and not identically 0, so $0 < \operatorname{Lip} f_i < \infty$, and (P3) holds at $\vartheta := \min\{\frac{1}{2}, \min_i \|f_i\|/(\mathsf{d}_X \operatorname{Lip} f_i)\}$; so $X \in P_n(\mathsf{d}_X; \vartheta; \Lambda) \cap \mathfrak{S}_n(\mathbb{R}^3)$, and $X_r \in P_n(r\mathsf{d}_X; \vartheta; \Lambda) \cap \mathfrak{S}_n(\mathbb{R}^3)$ with $\mathcal{K}_{\mathrm{free}}^{(n)}(X_r) = \mathcal{K}_{\mathrm{free}}^{(n)}(X)$ and $\|f_{i,r}\| = \|f_i\|$ (Lemma 18.117(a), (b)). Proposition 18.127(ii) at $\mathsf{d} = r\mathsf{d}_X$ is the bound, and $\Phi_n(t) \to 0$ as $t \to 0$. The value at $r = L^{-z}$ is the formula of Φ_n; $X_{L^{-z}} = X^{[-z]}$, and the definition $S_n^{[z]}(Y) = L^{-zn} S_n(Y^{[-z]})$ gives the last form. (b) By moment–cumulant inversion, $\sigma'(X_r) = \sum_{\pi \in \mathrm{Part}(n)} \prod_{J \in \pi} S_{|J|}^{\sigma'}((X_J)_r)$. A block with $|J| \ge 2$ tends to $3b^{-|J|}\mathcal{K}_{\mathrm{free}}^{(|J|)}(X_J)$ by (a), both sides being 0 when an entry is 0 by multilinearity. A block $\{i\}$ gives $S_1^{\sigma'}(f_{i,r})$: it is 0 for σ by the centering of the sequence, and for a component it is $\mathfrak{c}_\xi \int f_{i,r} = \mathfrak{c}_\xi r^3 \int f_i \to 0$ by Theorem YM3_I:AP. So the partitions with a block of one element drop out in the limit, and the sum over $\mathrm{Part}_{\ge 2}(n)$ is $\sigma_{S^{\mathrm{fr}}[3,b]}(X)$. Dilations

about y: the tuple dilated about y is the translate by y of the tuple $(f_i(\cdot+y))_i$ dilated about 0; σ and its components are invariant under the translations by Theorem YM3_I:AP, and so is $\mathcal{K}^{(n)}_{\mathrm{free}}$ by translation of the integration variables. So the tangent field at every point is the functional of the display. For the Gaussian lattice model, take the three curvature fields to be independent centered Gaussians with covariance $a_K b^{-1} C_K^{\mathrm{free}}$ in each color. If W_i multiplies by the periodized weight at the plaquettes, the log moment generating function of the smeared quadratic actions is $-\frac{3}{2}\operatorname{Tr}\log(1-b^{-1}C_K^{\mathrm{free}}\sum_i z_i W_i)$ near zero, by the finite-dimensional Gaussian integral on the range of the covariance. In the term of degree n, each cyclic order occurs n times, which cancels the denominator n in the logarithm. The mixed derivative is exactly $3b^{-n}\mathcal{K}^{(n)}_K(f_1^{\langle\ell\rangle},\dots,f_n^{\langle\ell\rangle})$. For $X=(f_1,\dots,f_n)\in P_n(\mathsf{d};\vartheta;\Lambda)$, once $4a_K\le \mathsf{d}_1$ and $4\Lambda_1\mathsf{d}_1<\ell$, Lemma 18.118 at the atoms of $\mathfrak{A}_n(\mathsf{d}_1;\vartheta_1;\Lambda_1)$, carried to X by Lemma 18.117(c) with the map $Y\mapsto \mathcal{K}^{(n)}_K(Y^{\langle\ell\rangle})-\mathcal{K}^{(n)}_{\mathrm{free}}(Y)$, which is linear in each entry, gives $|\mathcal{K}^{(n)}_K(X^{\langle\ell\rangle})-\mathcal{K}^{(n)}_{\mathrm{free}}(X)|\le (6N_\Lambda)^n C_n^{\mathrm{rg}}[\frac{85a_K}{\vartheta\mathsf{d}}+(\frac{\mathsf{d}}{2\ell})^3]\prod_i\|f_i\|$, as $\vartheta_1\mathsf{d}_1\ge\vartheta\mathsf{d}/85$; the right side tends to 0. □

18.13. **Under the Wilson measure the squared plaquette density decouples from the action density, and the shifted density has the torus limits.** We show that under the Wilson measure the density of the squared plaquette action, $\mathcal{O}^{(2)}_K(f)=(2a_K)^{-1}\sum_p f(x(p))\,a_p^2$, drops out of the joint cumulants when the ultraviolet cutoff is removed, at every label $b>0$ and on the torus of every side $\ell=2L^m$. For $n\ge 2$ real Lipschitz functions whose supports have no common point, each joint cumulant whose entries are $\mathcal{O}_K(f_i)$ or $\mathcal{O}^{(2)}_K(f_i)$, with an entry of the second kind among them, is bounded by a constant times $K^{\mathfrak{p}^\natural_n}L^{-K/10}\prod_i\|f_i\|_\sharp$ for all cutoffs beyond a threshold, where $\mathfrak{p}^\natural_n:=\max\{2\mathfrak{p}_0(n+1)+\frac12,(2\mathfrak{p}_0+2)n\}$ with the calibrated exponent $\mathfrak{p}_0$; consequently the joint cumulants of the shifted density $\mathcal{O}'_K(f)=\mathcal{O}_K(f)-\mathcal{O}^{(2)}_K(f)$ approach, at the same rate, the torus limits $S_n^{(\ell,b)}$ of the action density (Proposition 18.129). Three facts carry the argument. An insertion of a_p^2 is a second derivative in a source that acts at the single plaquette p; the renormalisation step with a source admits sources w whose numbers $\tau_p:=L^K w(p)$, by which the bare coupling $\beta=L^K b$ at the single plaquette p is moved to $\beta-\tau_p$ ($\rho_0^w=\rho_0\exp[\sum_p\tau_p a_p]$), may vary from a plaquette to a nearby one by up to the order $\beta^{1/2}$, and on this larger class the flows of effective-action terms of the main text keep their properties (Lemma 18.131); so one insertion is paid by a number of the order $L^K/\beta=b^{-1}$, up to a small power of L^K, in the place of a power of the volume. The generating function of the small-field term is the exponential of a sum of local terms times an integral (Lemma 18.132), and along these rough directions the logarithm of that integral varies by a small amount only (Step 4 of the proof of Proposition 18.135); the local part splits along groups of entries whose supports lie apart and drops out of each cumulant that links two groups, while the sums over plaquettes that the insertions produce involve one plaquette at a time, and their size does not grow with the volume (Lemmas 18.133 and 18.134, Proposition 18.135). Finally, small pieces of the test functions turn a tuple without a common point of the supports into tuples with at least two groups (Lemma 18.137), and an exact dilation carries the bound from the labels of an interval under (Tor) to every label and every side (Proposition 18.138 and Lemma 18.139).
Setting. We use the fixed construction and source calibration of §2.3.1, and write $\mathfrak{D}$ for its choices preceding the finite-lattice data. In this subsection $\varrho_\varsigma=\varrho$, $K_{\mathrm{Q}}=K_{\mathrm{Q}}^\vee$ and $K_{\mathrm{L}}=K_{\mathrm{L}}^\vee$ are the source radius and the constants of the direct source estimate YM3_I:(2167). Use its $\mu_\star$, $\sigma_{\mathrm{src}}=\mu_\star/K_{\mathrm{Q}}$ and set $o_{\mathrm{src}}(x)=\mu_\star/(K_{\mathrm{L}}\sqrt{x})$. The constants c_ρ, E_0 and κ are those of the calibration. The old-action bound and forgetting constant are C_{old} and C_{fg} of Props. YM3_I:113.13 and YM3_I:114.3. Take $C_{\mathrm{E},0}=2048\sum_{j\ge0}e^{-j}$, the rooted count used in the proof of Lem. YM3_I:114.6.

For $\ell=2L^m$ let $T_\ell=\mathbb{R}^3/\ell\mathbb{Z}^3$, $\Lambda_{K,\ell}=a_K\mathbb{Z}^3/\ell\mathbb{Z}^3$ with $a_K=L^{-K}$, and dU the product of the bond Haar probability measures. For each positively oriented plaquette p write $x(p)$ for its barycentre

and $a_p(U) = 1 - \frac{1}{2}\operatorname{tr}\partial U(p) \in [0,2]$. Use $\rho_0 = e^{-\beta\sum_p a_p}$ and

$$\mathcal{O}_K(f) = a_K^{-1}\sum_p f(x(p))a_p, qquad \mathcal{O}_K^{(2)}(f) = (2a_K)^{-1}\sum_p f(x(p))a_p^2, \qquad \mathcal{O}'_K = \mathcal{O}_K - \mathcal{O}_K^{(2)}.$$

There are $3\ell^3 a_K^{-3}$ positive plaquettes, and $0 \le a_p^2/2 \le a_p \le 2$. Therefore both insertions have modulus at most $6\ell^3 L^{4K}\|f\|_\infty$. They are real, continuous and gauge invariant as functions of the fields, and real linear in f. Write $\langle X_1;\dots;X_n\rangle_{K,\ell,\beta}$ for the joint cumulant under the normalized Wilson measure, defined by the mixed derivative of the local logarithm of the joint moment-generating function at zero. Thus $S^T_{n;K,\ell,\beta}(\underline{f})$ is the cumulant of the $\mathcal{O}_K(f_i)$. For $n \ge 2$, the limit $S_n^{(\ell,b)}$ on tuples with no common support point is that of Thm. YM3_I:AS.

Write $\|f\|_\sharp = \max\{\|f\|_\infty, 40M\operatorname{Lip} f\}$ with the Euclidean Lipschitz constant. The spread $\mathsf{d}_\infty(\underline{f})$ is the minimum, over $x_i \in \operatorname{supp} f_i$, of $\max_{i,i'}|x_i - x_{i'}|_\infty$ on T_ℓ. Set $\mathsf{p}_n = 2\mathfrak{p}_0(n+1) + 1/2$ as in Thm. YM3_I:AR, and $\mathsf{p}_n^\natural = \max\{\mathsf{p}_n, (2\mathfrak{p}_0+2)n\}$.

Proposition 18.129 (Decoupling of the squared plaquette density under the Wilson measure; torus limits of the shifted density)**.** Let $m \in \mathbb{N}$, $\ell = 2L^m$, let $n \ge 2$ be an integer, and let b_-, b_+, d be real numbers with $0 < b_- \le b_+$ and $d > 0$. A number $C^\flat$ and an integer $K^\flat$ exist, obtained from $\mathfrak{D}$, n, ℓ, b_-, b_+ and d through the formulas in the proof that closes this subsection, such that the two bounds stated next hold whenever $b \in [b_-, b_+]$ is a label, $K \ge K^\flat$ is an integer, $\beta := L^K b$, and $\underline{f} = (f_1,\dots,f_n)$ is a tuple of real-valued Lipschitz functions on T_ℓ, each different from 0, with no point common to all of their supports and with a spread obeying $\mathsf{d}_\infty(\underline{f}) \ge d$.

(a) For every set Q with $\emptyset \ne Q \subset \{1,\dots,n\}$, with $X_i^Q := \mathcal{O}_K^{(2)}(f_i)$ for $i \in Q$ and $X_i^Q := \mathcal{O}_K(f_i)$ for $i \notin Q$: $|\langle X_1^Q;\dots;X_n^Q\rangle_{K,\ell,\beta}| \le C^\flat K^{\mathsf{p}_n^\natural} L^{-K/10}\prod_{i=1}^n \|f_i\|_\sharp$.

(b) $|\langle \mathcal{O}'_K(f_1);\dots;\mathcal{O}'_K(f_n)\rangle_{K,\ell,\beta} - S_n^{(\ell,b)}(\underline{f})| \le C^\flat K^{\mathsf{p}_n^\natural} L^{-K/10}\prod_{i=1}^n \|f_i\|_\sharp$.

Hence, as $K \to \infty$ at a fixed label $b > 0$, the cumulants in (a) converge to 0 and the cumulant of $\mathcal{O}'_K(f_1),\dots,\mathcal{O}'_K(f_n)$ converges to $S_n^{(\ell,b)}(\underline{f})$, uniformly in b on every compact subset of $(0,\infty)$ and in the tuples of spread at least d with $\prod_i \|f_i\|_\sharp \le 1$. ∎

The proof occupies the rest of the subsection; it is completed after Lemma 18.139.

The level-wise classes of sources. Use the line $x_j = L^{K-j}\mathsf{b}'$ in the setting (Th3) of §2.3.1, with its top level t_*. The field cuts Cut_t and inner balls In_t are those of Lem. YM3_I:113.10, with $\mathsf{e}_t^{\mathrm{c}} = c_\rho\varepsilon(x_t)$. Let Bc be the set of bare plaquette barycentres and identify weights of the plaquettes with functions on it. For such a source w, the relative weight is $v_j^w = -w/\mathsf{b}'$ and $x_j^w = x_j - L^{K-j}w$. For $0 \le k < K$ set

$$\|w\|_{\mathrm{lw}}^{(k)} := \max_{k\le j<K}\max\left\{\frac{|v_j^w|_\infty}{\sigma_{\mathrm{src}}}, \frac{\mathrm{sw}_j(v_j^w)}{o_{\mathrm{src}}(x_j)}\right\}, \qquad \mathsf{Src}_k^{\mathrm{lw}} := \{w : \|w\|_{\mathrm{lw}}^{(k)} < 1\}.$$

The swing is the supremum of $|v(p)-v(q)|$ over plaquette centres at sup distance at most Ma_{K-j}. The original smooth-source class $\mathsf{Src} = \{w : \|w\|_{\flat;\mathsf{Bc}} < 2\varrho\}$ uses $\|w\|_{\flat;\mathsf{Bc}} = \max\{|w|_\infty, (40M/\sqrt{3})\operatorname{Lip}_\infty w\}$. The same formula defines $\|\cdot\|_{\flat;T_\ell}$ for functions on the torus. Finally put $\beta = x_0$ and $r_1 = \mu_\star\sqrt{\beta}/(2K_{\mathrm{L}})$.

Lemma 18.130 (The level-wise norms; rough directions)**.** Use the calibrated line above and let $0 \le k < K$.

(a) $\|\cdot\|_{\mathrm{lw}}^{(k)}$ is a norm on $\mathbb{C}^{\mathsf{Bc}}$, and $\mathsf{Src}_k^{\mathrm{lw}}$ is open and convex and contains 0; for $0 \le k' \le k$ one has $\|\cdot\|_{\mathrm{lw}}^{(k)} \le \|\cdot\|_{\mathrm{lw}}^{(k')}$, so that $\mathsf{Src}_{k'}^{\mathrm{lw}} \subset \mathsf{Src}_k^{\mathrm{lw}}$.

(b) $\mathsf{Src} \subset \mathsf{Src}_0^{\mathrm{lw}}$, and $\|w\|_{\mathrm{lw}}^{(0)} \le \|w\|_{\flat;\mathsf{Bc}}/(2\varrho_\varsigma)$ for every source w.

(c) If $2K_{\mathrm{L}}\, x_k^{1/2} \ge K_{\mathrm{Q}}$, then every source w, written as $w(p) = L^{-K}\tau_p$, satisfies $\|w\|_{\mathrm{lw}}^{(k)} \le (|\tau|_\infty/r_1)\, L^{-k/2}$.

∎

Sketch of proof. (a) The map $w \mapsto v_j^w$ is linear and injective, $|\cdot|_\infty$ is a norm and sw_j a seminorm; a maximum over fewer heights is smaller. (b) For $\|w\|_{\flat;\mathsf{Bc}} < 2\varrho$, $|v_j^w|_\infty = |w|_\infty/\mathsf{b}'$ and $\mathrm{sw}_j(v_j^w) \le M\,\mathrm{Lip}_\infty(w)/x_j$. The source-room inequalities YM3_I:(2171), together with $x_j^{-1/2} \le \gamma$, give $|v_j^w|_\infty < \sigma_{\mathrm{src}}$ and $\mathrm{sw}_j(v_j^w) < o_{\mathrm{src}}(x_j)$. Thus the open $\|\cdot\|_\flat/(2\varrho)$ unit ball is contained in the open $\|\cdot\|_{\mathrm{lw}}^{(0)}$ unit ball. Homogeneity gives the stated norm inequality. (c) One has $|v_j^w|_\infty = |\tau|_\infty/\beta$ and $\mathrm{sw}_j(v_j^w) \le 2|v_j^w|_\infty$. As $o_{\mathrm{src}}(x_j) = x_j^{-1/2}\mu_\star/K_{\mathrm{L}}$ increases with j and $x_k = L^{-k}\beta$, for $j \ge k$ the second quotient is at most $2|\tau|_\infty K_{\mathrm{L}} x_k^{1/2}/(\mu_\star\beta) = (|\tau|_\infty/r_1)L^{-k/2}$; the first quotient is $|\tau|_\infty K_{\mathrm{Q}}/(\mu_\star\beta)$, which the hypothesis bounds by the same number. □

Lemma 18.131 (The flows on the level-wise classes)**.** Use the calibrated line above. Let $0 \le k < t_*$ and let $\mathcal{S}'$ be an open set containing 0 in $\mathsf{Src}_k^{\mathrm{lw}}$. At level k, an early system on $\mathcal{S}'$ is a sequence of pointed families $G^{(i)}[w]$, $1 \le i \le k$, on the fixed pair cores, bounded in the norm of rate $\kappa+1$ by E_0, jointly holomorphic in w and the open pair slices, and depending at each domain X only on the source on its plaquettes. Form the flow by the recursion YM3_I:(2172) starting with this sequence.

(a) The flow continues through level K and preserves the three conditions on the families. Its fourth potential has norm at most $7w_\star/32$. Its density and normalization increments on the cuts are those of Prop. YM3_I:114.2. The zero early sequence is admitted and gives the classical start. The empty sequence at $k = 0$ gives the chain on $\mathsf{Src}_0^{\mathrm{lw}}$. If $\mathcal{S}' \subset \mathsf{Src}_0^{\mathrm{lw}}$, the chain can be restarted at k with its own first k families.

(b) The difference estimate of Prop. YM3_I:114.3 applies to two early systems at the same source. In particular the exponent difference between the chain and the classical start at k is at most $\epsilon_{\mathrm{fg}}(t,k)$ on Cut_t whenever both flows are defined, with the constant in equation YM3_I:(2179).

(c) For $k < t \le t_*$ and $V \in \mathsf{Cut}_t$, choose a representative $U = U_t(V)$ of its regular critical orbit. The exponent is

$$\Phi_t^w(V) = -A^{\eta_t}(x_t, U) + L^{K-t}A^{\eta_t}(w, U) + \Psi_V(w), \qquad \Psi_V(w) = S[\mathfrak{f}_t[w]](U).$$

The function Ψ_V is holomorphic and $|\Psi_V| \le \mathsf{m}_t^S = C_{\mathrm{old}} L E_0 N_t/(L-1)$ on $\mathcal{S}'$, where $N_t = \ell^3 L^{3(K-t)}$. The same applies to the classical start.

(d) Every flat member $E^{(j)}[w](X, \mathbf{1}, z')$ is holomorphic in w, bounded by $E_0 e^{-(\kappa+1)d_j(X)}$, and depends only on $w|_{\mathcal{P}(X)}$, with $\mathcal{P}(X)$ the bare plaquettes whose corners lie in X.

The flows agree with the original smooth-source flows on their common source class. Restricting a flow to a smaller parameter set leaves it unchanged there. ■

Proof. The direct source lemma in YM3 I, Lem. YM3_I:114.1, applies to an arbitrary complex plaquette array v. It proves holomorphy, locality and the exact weighted action difference on the actual averaging fibre, as well as the bound

$$\mathsf{n}^{\mathrm{f}}(\mathbb{W}^{\mathrm{src}}[v]) \le 2K_{\mathrm{Q}}|v|_\infty + K_{\mathrm{L}}\sqrt{x_j}\,\mathrm{sw}_j(v)$$

at height j, including height zero. For $w \in \mathcal{S}'$ the right side at $v = v_j^w$ is at most $3\mu_\star$ at every $j \ge k$. The old array has size at most $LE_0/(L-1)$, hence its fourth-potential contribution is at most $w_\star/8$ by the calibration. The sum is at most $w_\star/8 + 3\mu_\star \le 7w_\star/32$. In the proof of Prop. YM3_I:114.2, the unperturbed interaction costs at most $E_0/4$, the normalization family at most $E_0/2$, and the change on adding the source at most $3K^{\mathrm{d}}\mu_\star \le 3E_0/16$. Consequently the new norm is at most $15E_0/16$. The localized output map is holomorphic in these parameters. Its locality and that of the input arrays give the required dependence only on plaquettes of X. These estimates inductively admit every step. The exact fibre identity of the direct source lemma and the actual cut-domain sum rule apply to this same fourth potential. They give the contact increment YM3_I:(2173) and the density YM3_I:(2175), with the fixed real Gaussian normalizations. This proves (a), including equality on restarting, which follows from the recursion.

For (b) the direct source and normalizer cancel between the two recursions. The old-array norm and the fourth-family difference estimate thus give the recurrence of Prop. YM3_I:114.3, independently of the source class. Apply the action estimate of Prop. YM3_I:113.13 to the difference and use equations YM3_I:(2179)–(2180). The same action estimate for one flow bounds its $S[\mathfrak{f}_t[w]](U)$. It is a finite sum of values of holomorphic local members at a background independent of w, so it is holomorphic. This proves (c). The induction proves (d), including evaluation at the trivial pair. Each flow is specified by the same deterministic step formula, including the same early families for the chain or the classical start. This proves agreement on the common domain. □

The small-field term at a rough source.

Lemma 18.132 (Wilson's generating function on the level-wise class)**.** Use the calibrated line with $\mathsf{b}' = b$ and choose $n \geq 2$, $u = \lceil K/[180(3n+4)] \rceil$, $s = \lceil K/9 \rceil$, $t = t_1 = K - u$, $t_0 = K - s$ with $1 \leq u < s < K$ and $t \leq t_*$. Write $x_{[d]} = L^d b$ for a height indexed by its remaining depth. Write $N_{[u]} = \ell^3 L^{3u} = N_t$ and assume $\epsilon_{\mathrm{fg}} = \epsilon_{\mathrm{fg}}(t, t_0) \leq 1/8$, $\mathsf{R}_t \leq 1/2$, where R_t is the discarded-mass bound YM3_I:(2187). Let $\mathfrak{w}_t^{\mathrm{sf}}$ be the fixed cutoff weight in Prop. YM3_I:115.2 and put

$$T(w) = \int \mathfrak{w}_t^{\mathrm{sf}} \rho_0 e^{\mathcal{O}(w)}\, dU, \qquad \mathcal{O}(w) = L^K \sum_p w(p) a_p.$$

Use the chain on $\mathsf{Src}_0^{\mathrm{lw}}$ and the classical start at t_0 on $\mathsf{Src}_{t_0}^{\mathrm{lw}}$ from Lem. 18.131. Let Φ_t^w and $\hat{\Phi}_t^w$ be their exponents on Cut_t, and $I(w)$ and $\hat{I}(w)$ their exponentials integrated over In_t against normalized Haar measure.

(a) T is entire on $\mathbb{C}^{\mathsf{Bc}}$ and $T(0) \geq \frac{1}{2} \int \rho_0\, dU > 0$.
(b) On $\mathsf{Src}_0^{\mathrm{lw}}$, $T(w) = e^{c(w)} I(w)$ with $c(w)$ the sum of the chain contact increments through t.
(c) There is a real constant $c_\star$ such that $c(w) = c_\star + \sum_{j \leq t, X, z'} e_{j,X,z'}(w)$ with $e_{j,X,z'}(w) = E^{(j)}[w](X, \mathbf{1}, z')$ holomorphic, of modulus at most $E_0 e^{-(\kappa+1) d_j(X)}$ and depending only on $w|_{\mathcal{P}(X)}$.
(d) On their respective source classes the two exponents have the form in Lem. 18.131(c), with remainders $\Psi_V(w)$ and $\hat{\Psi}_V(w)$ both bounded by m_t^S. The integrals I and $\hat{I}$ are holomorphic there. Moreover $|\Phi_t^w(V) - \hat{\Phi}_t^w(V)| \leq \epsilon_{\mathrm{fg}}$ for $w \in \mathsf{Src}_0^{\mathrm{lw}}$ and $V \in \mathsf{Cut}_t$.

■

Proof. The finite-lattice exponential has a locally uniform integrable bound since the plaquette variables and the fixed cutoff weight are bounded. This gives entireness, and equation YM3_I:(2190) at zero source gives (a). The contact increment YM3_I:(2173) and Lem. 18.131(d) give (c). Parts (b) and (c) of that lemma prove the exponent claims of (d). On any compact source set the exponential is uniformly bounded on In_t: use the cut action estimate YM3_I:(2161) for $x_t^w = x_t - L^{K-t} w$ and the bound m_t^S. Cauchy's formula and Fubini's theorem then give holomorphy of both integrals. For smooth sources the exact image identity YM3_I:(2188) and the chain density YM3_I:(2175) give (b). Both sides are holomorphic on the connected set $\mathsf{Src}_0^{\mathrm{lw}}$, and its subset Src is nonempty and open in the finite-dimensional source space. The identity theorem gives (b) throughout $\mathsf{Src}_0^{\mathrm{lw}}$. □

Two tools.

Lemma 18.133 (Sums over plaquettes of one-plaquette derivatives)**.** Let P be a nonempty finite set, $n \geq 1$, $\rho^{\mathrm{z}} \in (0, \infty)^n$ and $\rho^{\mathrm{p}} > 0$. For $0 < \theta \leq 1$ let $\mathbb{D}_\theta := \{(z, \tau) \in \mathbb{C}^n \times \mathbb{C}^{\mathsf{P}} : \ |z_i| < \theta \rho_i^{\mathrm{z}},\ |\tau_p| < \theta \rho^{\mathrm{p}}\}$, let $\partial_p := \partial/\partial \tau_p$, and for $q \in \mathsf{P}$ let $(z, \tau)^{(q)}$ be the point (z, τ) with τ_q replaced by 0. For a holomorphic function F on $\mathbb{D}_\theta$ put $\|F\|_\theta := \sup_{\mathbb{D}_\theta} |F|$, $\mathrm{osc}_\theta F := \sup\{|F(z,\tau) - F(z,\tau')| : \ (z,\tau), (z,\tau') \in \mathbb{D}_\theta\}$ and $[F]_\theta := \sup_{q \in \mathsf{P}} \sup_{\xi \in \mathbb{D}_\theta} |F(\xi) - F(\xi^{(q)})|$, the largest change of F when one plaquette variable is put to 0; these three numbers do not increase as θ decreases. Let $0 < \theta' < \theta \leq 1$, $\Delta' := (\theta - \theta') \rho^{\mathrm{p}}$,

$\xi \in \mathbb{D}_{\theta'}$ and $g \in \mathbb{C}^{\mathsf{P}}$; let $G_1, \dots, G_k$ ($k \geq 0$) and $F_1, \dots, F_l$ ($l \geq 1$) be holomorphic on $\mathbb{D}_\theta$, and let $o_1, \dots, o_k, o'_1, \dots, o'_l \geq 1$ be integers. Then $|\partial_p^o G(\xi)| \leq o!\,[G]_\theta \Delta'^{-o}$ for every holomorphic G on $\mathbb{D}_\theta$, every $p \in \mathsf{P}$ and every integer $o \geq 1$, and

$$\Big|\sum_{p\in\mathsf{P}} g(p) \prod_{j\leq k} \partial_p^{o_j} G_j(\xi) \prod_{j\leq l} \partial_p^{o'_j} F_j(\xi)\Big| \leq |g|_\infty \prod_{j\leq k} \frac{o_j!\,[G_j]_\theta}{\Delta'^{o_j}} \prod_{j\leq l} \frac{o'_j!\,\min\{\|F_j\|_\theta, \operatorname{osc}_\theta F_j\}}{\Delta'^{o'_j}};$$

the bound does not depend on how many elements P has. ■

Sketch of proof. Let e_p be the unit vector of τ_p. The function $\zeta \mapsto G(\xi+\zeta e_p) - G(\xi^{(p)})$ is holomorphic on $|\zeta| < \Delta'$, where $\xi + \zeta e_p \in \mathbb{D}_\theta$, and bounded by $[G]_\theta$, since $(\xi+\zeta e_p)^{(p)} = \xi^{(p)}$; its derivative of order $o \geq 1$ at 0 is $\partial_p^o G(\xi)$, and Cauchy's estimate gives the first bound. So $\tilde g(p) := g(p) \prod_j \partial_p^{o_j} G_j(\xi)$ satisfies $|\tilde g|_\infty \leq |g|_\infty \prod_j o_j! [G_j]_\theta \Delta'^{-o_j}$; if $\tilde g = 0$ the sum vanishes. Otherwise let $o := \sum_j o'_j$, let $g_0(p)$ be an o-th root of $\tilde g(p)$, let $(\sigma_p)_{p\in\mathsf{P}}$ be independent random variables, each uniform on the o-th roots of unity, and put $\partial_\sigma := \sum_p \sigma_p g_0(p) \partial_p$. Expanding $\prod_j \partial_\sigma^{o'_j} F_j(\xi)$ into a sum over families of o plaquettes, the mean of the product of the o factors σ equals 1 when the o plaquettes coincide and vanishes for every other family, because $\mathbb{E}\,\sigma_p^\nu$ equals 1 when o divides ν and vanishes otherwise; so $\mathbb{E}\prod_j \partial_\sigma^{o'_j} F_j(\xi)$ is the sum to be bounded. For each value of σ the function $\zeta \mapsto F_j(\xi + \zeta(\sigma_p g_0(p))_p)$ is holomorphic on $|\zeta| < \Delta'/|g_0|_\infty$, with values of F_j at points of $\mathbb{D}_\theta$ that have the coefficient tuple z of ξ; its derivative of order o'_j at 0 is $\partial_\sigma^{o'_j} F_j(\xi)$, which is also the derivative of this function minus $F_j(\xi)$. Cauchy's estimate gives $|\partial_\sigma^{o'_j} F_j(\xi)| \leq o'_j! \min\{\|F_j\|_\theta, \operatorname{osc}_\theta F_j\} (|g_0|_\infty/\Delta')^{o'_j}$, and $|g_0|_\infty^o = |\tilde g|_\infty$. □

Lemma 18.134 (Cumulants in their dependence on a source; entries with a squared plaquette action)**.** Let m be a non-zero finite measure on a measurable space, let P be a finite set, and let a_p ($p \in \mathsf{P}$) and $O_1, \dots, O_n$ be real measurable functions that are bounded; let $Q \subset \{1, \dots, n\}$, and for $i \in Q$ let $g_i \in \mathbb{R}^{\mathsf{P}}$. Put $X_i := \frac12 \sum_p g_i(p)\, a_p^2$ for $i \in Q$, $X_i := O_i$ for $i \notin Q$, and

$$\mathcal{G}(z,\tau,\lambda) := \int \exp\Big[\sum_i z_i O_i + \sum_p \tau_p a_p + \sum_i \lambda_i X_i\Big] d\mathsf{m}, \qquad T_{\mathsf{m}}(z,\tau) := \mathcal{G}(z,\tau,0),$$

an entire function on $\mathbb{C}^n \times \mathbb{C}^{\mathsf{P}} \times \mathbb{C}^n$. On the open set where $T_{\mathsf{m}} \neq 0$, for $\emptyset \neq S \subset \{1, \dots, n\}$ let $\Xi_S(z,\tau) := \partial_\lambda^S \mathcal{W}(z,\tau,0)$, $\partial_\lambda^S := \prod_{j\in S} \partial_{\lambda_j}$, where $\mathcal{W}$ is a holomorphic logarithm of $\mathcal{G}$ near $(z,\tau,0)$; $\Xi_\emptyset$ denotes any holomorphic logarithm of T_{m} near the point in question, and only its derivatives enter. Then Ξ_S is well defined and holomorphic, $\Xi_{\{1,\dots,n\}}(0,0)$ is the joint cumulant of $X_1, \dots, X_n$ under the probability measure $\mathsf{m}/\mathsf{m}(1)$, and for $S \subset \{1, \dots, n\}$ and $i \notin S$, with $\partial_p := \partial/\partial\tau_p$:

(i) if $i \notin Q$: $\Xi_{S\cup\{i\}} = \partial_{z_i} \Xi_S$;
(ii) if $i \in Q$: $\Xi_{S\cup\{i\}} = \frac12 \sum_p g_i(p) \big[\partial_p^2 \Xi_S + \sum_{S'\subset S} \partial_p \Xi_{S'}\, \partial_p \Xi_{S\setminus S'}\big]$.

■

Sketch of proof. The integrands are bounded and m is finite, so $\mathcal{G}$ is entire and may be differentiated under the integral. Where $T_{\mathsf{m}}(z,\tau) \neq 0$, $\mathcal{G}$ has no zero near $(z,\tau,0)$ and a holomorphic logarithm there; two logarithms differ by a constant, which ∂_λ^S annihilates for $S \neq \emptyset$. At $(z,\tau) = (0,0)$, $\lambda \mapsto \mathcal{G}(0,0,\lambda)$ is the generating function of $X_1, \dots, X_n$ under m, and division by $\mathsf{m}(1)$ changes the logarithm by a constant. (i) $\partial_{\lambda_i} \mathcal{G} = \partial_{z_i} \mathcal{G}$; divide by $\mathcal{G}$ and apply ∂_λ^S at $\lambda = 0$. (ii) $\partial_{\lambda_i} \mathcal{G} = \frac12 \sum_p g_i(p) \partial_p^2 \mathcal{G}$, hence $\partial_{\lambda_i} \mathcal{W} = \frac12 \sum_p g_i(p)\, e^{-\mathcal{W}} \partial_p^2 e^{\mathcal{W}} = \frac12 \sum_p g_i(p) \big[\partial_p^2 \mathcal{W} + (\partial_p \mathcal{W})^2\big]$; apply ∂_λ^S at $\lambda = 0$, and Leibniz's rule to the square, each ∂_{λ_j}, $j \in S$, falling on one of its two factors. □

Tuples in groups.

Proposition 18.135 (Cumulants with squared entries over tuples in at least two groups)**.** Use the calibrated line at b and the data and two smallness conditions of Lem. 18.132. Let $n \geq 2$ and let $f_1, \dots, f_n$ be nonzero real Lipschitz functions on T_ℓ. Put $\beta = L^K b$, and let T, c, I, Φ_t^w, $\hat\Phi_t^w$, Ψ_V,

$\hat\Psi_V$ be as in Lemma 18.132. Let $d'>0$, and let $\{1,\dots,n\}=\bigsqcup_{a\in\mathfrak{A}} C_a$ be a partition into $\#\mathfrak{A}\ge 2$ groups such that $\operatorname{dist}_\infty(\operatorname{supp} f_i,\operatorname{supp} f_{i'})\ge d'$ whenever i and i' lie in two different groups. Put

$$r_1:=\frac{\mu_\star\beta^{1/2}}{2K_{\mathrm L}},\qquad \bar{\mathsf m}:=\max\{1,\mathsf m_t^S\},$$
$$r_{\mathrm{eff}}:=\frac{r_1}{16n\bar{\mathsf m}},\qquad \Delta:=\frac{r_{\mathrm{eff}}}{4n},$$
$$C_{\mathrm{pt}}:=8e^2(3M+1)^3C_{\mathrm{E},0},\qquad \Gamma:=\max\{1,2E_0\,t\,C_{\mathrm{pt}}\},$$

$\epsilon_{\mathrm{lk}}:=4e^3E_0C_{\mathrm{E},0}N_{[u]}e^{-d'L^u/M}$, $\epsilon_{\mathrm{rd}}:=\frac32(\mathsf e_t^{\mathrm c})^2N_{[u]}L^{-t}r_{\mathrm{eff}}+\frac{3}{16n}L^{-t_0/2}$, $\epsilon_{\mathrm{osc}}:=2\epsilon_{\mathrm{lk}}+8\epsilon_{\mathrm{fg}}+4\epsilon_{\mathrm{rd}}$, with $N_{[u]}=\ell^3L^{3u}$, and assume

(Y1) $\epsilon_{\mathrm{osc}}\le\frac12$ and $\epsilon_{\mathrm{rd}}\le\frac18$;
(Y2) $\frac32(\mathsf e_t^{\mathrm c})^2N_{[u]}L^{-t}\le\bar{\mathsf m}/r_1$;
(Y3) $2K_{\mathrm L}(L^sb)^{1/2}\ge K_{\mathrm Q}$;
(Y4) $d'L^u\ge 6M$;
(Y5) $16n\,\Gamma\le r_{\mathrm{eff}}$.

Let $\emptyset\neq Q\subset\{1,\dots,n\}$, $X_i^Q:=\mathcal O_K^{(2)}(f_i)$ for $i\in Q$, $X_i^Q:=\mathcal O_K(f_i)$ for $i\notin Q$, and $\Lambda'''(F):=\int F\,\mathfrak w_t^{\mathrm{sf}}\rho_0\,dU$. Then

$$|\mathsf{cum}_{\Lambda'''}(X_1^Q,\dots,X_n^Q)|\le\epsilon_{\mathrm{osc}}\prod_{i=1}^n\mathsf A_i,$$
$$\mathsf A_i:=\frac{8n}{r_i(t)}\quad(i\notin Q),$$
$$\mathsf A_i:=\frac{2^{n+4}\Gamma^2L^K\|f_i\|_\infty}{\Delta^2}=\frac{2^{n+18}n^4K_{\mathrm L}^2\bar{\mathsf m}^2\Gamma^2\,\|f_i\|_\infty}{\mu_\star^2\,b}\quad(i\in Q),$$

with the radii of Lem. YM3_I:114.5,

$$r_i(t)=(8n\mathsf M_t^{\mathrm{rd}}\|f_i\|_{\flat;T_\ell})^{-1},\qquad \mathsf M_t^{\mathrm{rd}}=\max\{\varrho^{-1},\tfrac32(\mathsf e_t^{\mathrm c})^2N_tL^{K-t},\varrho^{-1}\mathsf m_t^S\}.$$

■

Sketch of proof. Step 1: the variables. Put $\mathsf P_i:=\{p:\ f_i(x(p))\neq0\}$, $\mathsf P^a:=\bigcup_{i\in C_a}\mathsf P_i$ and $\mathsf P:=\bigcup_a\mathsf P^a$. If some $\mathsf P_i$ is empty, the corresponding insertion vanishes identically, so the asserted bound holds. Otherwise, as $x(p)\in\operatorname{supp} f_i$ for $p\in\mathsf P_i$, the sets $\mathsf P^a$ are disjoint, and barycentres of plaquettes of two different sets $\mathsf P^a$ lie at sup distance $\ge d'$. For $(z,\tau)\in\mathbb C^n\times\mathbb C^{\mathsf P}$ let $w(z,\tau):=\sum_i z_i\,f_i\circ x+L^{-K}\tau$, the vector τ being continued by 0 off $\mathsf P$, and $w_a(z,\tau):=\sum_{i\in C_a}z_i\,f_i\circ x+L^{-K}\tau\,\mathbf 1_{\mathsf P^a}$; then $w=\sum_a w_a$ and $\mathcal O(w(z,\tau))=\sum_i z_i\mathcal O_K(f_i)+\sum_p\tau_pa_p$. On sources put $\|h\|_\star:=\max\{\frac32(\mathsf e_t^{\mathrm c})^2N_tL^{K-t}|h|_\infty,\ \bar{\mathsf m}\|h\|_{\mathrm{lw}}^{(0)}\}$, a norm, with $N_t=N_{[u]}$. By Lem. 18.130(b) and the displayed read-out radii, $\|f_i\circ x\|_\star\le\mathsf M_t^{\mathrm{rd}}\|f_i\|_{\flat;T_\ell}=(8n\,r_i(t))^{-1}$; by Lemma 18.130, (c), at $k=0$, whose hypothesis follows from (Y3) since $x_0\ge x_{t_0}=L^sb$, and by (Y2), $\|L^{-K}\tau\|_\star\le\bar{\mathsf m}|\tau|_\infty/r_1$. Take $\rho_i^{\mathrm z}:=\frac14r_i(t)$, $\rho^{\mathrm p}:=\frac12r_{\mathrm{eff}}$ and the polydiscs $\mathbb D_\theta$ of Lemma 18.133. Every $(z,\tau)\in\mathbb D_1$ then satisfies $\|w(z,\tau)\|_\star<\frac1{32}+\frac{1}{32n}<\frac1{16}$, and so does every sum of some of the $w_a(z,\tau)$.

Step 2: where the generating function does not vanish. Suppose $\|h\|_\star<1/16$. In particular h belongs to both source classes used at t. On Cut_t, equation YM3_I:(2161) gives $|L^{K-t}A^{\eta_t}(h,U)|<1/16$. The function $\hat\Psi_V$ is bounded by $\mathsf m_t^S$, so Schwarz's lemma on the line through $0,h$ gives $|\hat\Psi_V(h)-\hat\Psi_V(0)|\le2\mathsf m_t^S\|h\|_{\mathrm{lw}}^{(t_0)}<1/8$. Hence $|\hat\Phi_t^h-\hat\Phi_t^0|<3/16$. Also $|\Phi_t^h-\hat\Phi_t^h|\le\epsilon_{\mathrm{fg}}\le1/8$ by Lem. 18.132(d).

At zero source the classical start and the operators in its density recursion are positive. By YM3_I:(2175), $e^{\hat\Phi_t^0}$ is a fixed nonzero scalar times a positive density, as in the proof of Prop. YM3_I:

116.3. The inner ball is open and contains the identity, and the exponential is everywhere nonzero there. Hence $\hat I(0)\neq 0$ and $e^{\hat\Phi^0_t}/\hat I(0)$ is a probability density on the inner ball. Let $\alpha = 3/16$. Relative to this probability measure, $\hat I(h)/\hat I(0)$ is an average of numbers e^z with $|z|<\alpha$. Its argument has modulus at most α, and its real part is at least $e^{-\alpha}\cos\alpha$. Similarly

$$\left|\frac{I(h)}{\hat I(h)}-1\right| \le (e^{\epsilon_{\rm fg}}-1)\frac{e^{2\alpha}}{\cos\alpha} \le 2\epsilon_{\rm fg} \le \frac14.$$

The numerical bound uses $e^{1/8+2\alpha}/\cos\alpha < 2$. Therefore $I(h)$ and $T(h)$ are nonzero, in particular on the polydisc of Step 1.

Step 3: the local part. For a triple (j,X,z') of the sum in Lemma 18.132, (c), let $\mathsf I(X) := \{a : \mathcal P(X)\cap \mathsf P^a \neq \emptyset\}$. If $\mathsf I(X)=\emptyset$, the source $w(z,\tau)$ vanishes on $\mathcal P(X)$; if $\mathsf I(X)=\{a\}$, it agrees there with $w_a(z,\tau)$. The locality in Lemma 18.132, (c), therefore gives, at $w=w(z,\tau)$, $w_a=w_a(z,\tau)$, $(z,\tau)\in\mathbb D_1$,

$$\begin{aligned} c(w) &= c(0)+\sum_a c_a(w_a)+c_{\rm lk}(w),\\ c_a(w_a) &:= \sum_{\mathsf I(X)=\{a\}} [e_{j,X,z'}(w_a)-e_{j,X,z'}(0)],\\ c_{\rm lk}(w) &:= \sum_{\#\mathsf I(X)\ge 2} [e_{j,X,z'}(w)-e_{j,X,z'}(0)], \end{aligned}$$

and $c_a(w_a(z,\tau))$ is a function of $(z_i)_{i\in C_a}$ and $(\tau_p)_{p\in\mathsf P^a}$ only. If $\#\mathsf I(X)\ge 2$, then $\mathcal P(X)$ contains plaquettes of two different sets $\mathsf P^a$, and their barycentres are at sup distance at least $d'L^{K-j}$ in the units of level j; their corners lie in X, within $\frac12$ of the barycentres, and the diameter bound of Prop. YM3_I:45.1 gives $d_j(X)\ge D_j := d'L^{K-j}/M-3$. The rooted count in the proof of Lem. YM3_I:114.6, with rate $\kappa+1$ and size at least D_j, gives a level sum at most $2E_0C_{\mathrm{E},0}N_je^{-D_j}$. Moving one level finer multiplies this bound by $L^3\exp[-(L-1)d'L^{K-j}/M]\le 1/2$ by (Y4). Summing therefore gives $|c_{\rm lk}|\le 4e^3E_0C_{\mathrm{E},0}N_te^{-d'L^{K-t}/M}=\epsilon_{\rm lk}$. Let $c_{\rm cl}(z,\tau):=\sum_a c_a(w_a(z,\tau))$. For $q\in\mathsf P$, putting τ_q to 0 changes each source w_a at the single plaquette q; by the locality in Lemma 18.132, (c), a term $e_{j,X,z'}$ moves only when $q\in\mathcal P(X)$, and then by no more than $2E_0e^{-(\kappa+1)d_j(X)}$. If y is a corner of q, $q\in\mathcal P(X)$ and $z'\in X$, then $|y-z'|_\infty\le M(d_j(X)+2)$ in the units of level j. The same rooted count with $D=\max\{0,|y-z'|_\infty/M-2\}$ bounds the sum over these X by $C_{\mathrm{E},0}e^{2-|y-z'|_\infty/M}$, and, choosing for each site of $\mathbb T^{(j)}$ the lift nearest to a lift of y, $\sum_{z'\in\mathbb T^{(j)}}e^{-|y-z'|_\infty/M}\le\prod_{\mu\le3}\sum_{k\in\mathbb Z}e^{-|k-y_\mu|/3M}\le[2(3M+1)]^3$, by $|x|_\infty\ge\frac13\sum_\mu|x_\mu|$. Summing over the levels $j\le t$: $[c_{\rm cl}]_1\le 2E_0\,t\,C_{\rm pt}\le\Gamma$.

Step 4: the non-local part. For $\|h\|_\star<1/16$ put

$$\vartheta(h)=c_{\rm lk}(h)+\mathrm{Log}\,\frac{\hat I(h)}{\hat I(0)}+\mathrm{Log}\,\frac{I(h)}{\hat I(h)}-\mathrm{Log}\,\frac{I(0)}{\hat I(0)}.$$

All logarithms are principal and holomorphic by Step 2. On the source polydisc the grouping of Step 3 gives $T(w)=T(0)\exp[c_{\rm cl}+\vartheta(w)]$.

For two points $(z,\tau),(z,\tau')\in\mathbb D_1$ let $h=w(z,\tau)$ and $h'=w(z,\tau')$. Then $h'-h=L^{-K}(\tau'-\tau)$ with $|\tau'-\tau|_\infty<r_{\rm eff}$. The difference of the two classical-start exponents has a linear action term bounded by $\frac32(\mathsf e_t^{\rm c})^2N_tL^{-t}r_{\rm eff}$ by equation YM3_I:(2161). For the other term, Lem. 18.130(c) at $k=t_0$, using (Y3), gives

$$\|h'-h\|^{(t_0)}_{\rm lw}\le\frac{r_{\rm eff}}{r_1}L^{-t_0/2}=\frac{L^{-t_0/2}}{16n\bar{\mathfrak m}}.$$

If $h' \neq h$, restrict $\hat\Psi_V$ to $h+\zeta(h'-h)$ on the disc of radius $(1-\|h\|_{\mathrm{lw}}^{(t_0)})/\|h'-h\|_{\mathrm{lw}}^{(t_0)} > 1$. After subtracting its value at zero on this line, Schwarz's lemma and the bound $2\mathsf{m}_t^S$ give

$$|\hat\Psi_V(h') - \hat\Psi_V(h)| \le \frac{32}{15}\mathsf{m}_t^S \|h'-h\|_{\mathrm{lw}}^{(t_0)} \le \frac{3}{16n} L^{-t_0/2}.$$

The same holds when $h' = h$. This proves $|\hat\Phi_t^{h'} - \hat\Phi_t^h| \le \epsilon_{\mathrm{rd}}$. As in Step 2, with $\alpha = 3/16$,

$$\left|\frac{\hat I(h')}{\hat I(h)} - 1\right| \le (e^{\epsilon_{\mathrm{rd}}} - 1)\frac{e^{2\alpha}}{\cos\alpha} \le 2\epsilon_{\mathrm{rd}} \le \frac14.$$

The principal logarithm of this ratio is the difference of the two principal logarithms relative to $\hat I(0)$, since their arguments differ by at most $2\alpha < \pi$. Its modulus is at most $4\epsilon_{\mathrm{rd}}$ by the power series for the logarithm on $|z-1| < 1/2$. Each logarithm $\mathrm{Log}(I/\hat I)$ has modulus at most $4\epsilon_{\mathrm{fg}}$ by the same bound. The linked local term changes by at most $2\epsilon_{\mathrm{lk}}$. Thus $\mathrm{osc}_1(\vartheta\circ w) \le 2\epsilon_{\mathrm{lk}} + 4\epsilon_{\mathrm{rd}} + 8\epsilon_{\mathrm{fg}} = \epsilon_{\mathrm{osc}}$.

Step 5: splitting the recursion into a local and a non-local part. Apply Lemma 18.134 with $\mathsf{m} := \mathfrak{w}_t^{\mathrm{sf}}\rho_0\,dU$, the functions $O_i := \mathcal{O}_K(f_i)$ and a_p, $p \in \mathsf{P}$, the set Q and $g_i(p) := L^K f_i(x(p))$; its X_i are the X_i^Q, its function T_{m} is $T\circ w$, which has no zero on $\mathbb{D}_1$ (Step 2), and $\Xi_{\{1,\dots,n\}}(0,0) = \mathsf{cum}_{\Lambda''}(X_1^Q,\dots,X_n^Q)$. By Step 4 every derivative of $\Xi_\emptyset$ on $\mathbb{D}_1$ is the same derivative of $c_{\mathrm{cl}} + \vartheta\circ w$. Since the cumulant does not change under a permutation of its entries, we may and do assume $Q = \{n_0+1,\dots,n\}$. Define holomorphic functions Ξ_S^{c}, Ξ_S^ϑ on $\mathbb{D}_1$ by recursion on $\#S$: $\Xi_\emptyset^{\mathrm{c}} := c_{\mathrm{cl}}$ and $\Xi_\emptyset^\vartheta := \vartheta\circ w$; for $S \neq \emptyset$ let $i := \max S$ and $S' := S\setminus\{i\}$; if $i \notin Q$, $\Xi_S^{\mathrm{c}} := \partial_{z_i}\Xi_{S'}^{\mathrm{c}}$ and $\Xi_S^\vartheta := \partial_{z_i}\Xi_{S'}^\vartheta$; if $i \in Q$,

$$\Xi_S^{\mathrm{c}} := \frac{L^K}{2}\sum_p f_i(x(p))\Big[\partial_p^2\Xi_{S'}^{\mathrm{c}} + \sum_{S''\subset S'} \partial_p\Xi_{S''}^{\mathrm{c}}\,\partial_p\Xi_{S'\setminus S''}^{\mathrm{c}}\Big], \qquad \Xi_S^\vartheta := \Xi_S - \Xi_S^{\mathrm{c}}.$$

Induction on $\#S$, with Lemma 18.134, shows $\Xi_S = \Xi_S^{\mathrm{c}} + \Xi_S^\vartheta$ whenever $S \neq \emptyset$, and for $i \in Q$

$$\Xi_S^\vartheta = \frac{L^K}{2}\sum_p f_i(x(p))\Big[\partial_p^2\Xi_{S'}^\vartheta + \sum_{S''\subset S'} \big(\partial_p\Xi_{S''}^{\mathrm{c}}\,\partial_p\Xi_{S'\setminus S''}^\vartheta + \partial_p\Xi_{S''}^\vartheta\,\partial_p\Xi_{S'\setminus S''}^{\mathrm{c}} + \partial_p\Xi_{S''}^\vartheta\,\partial_p\Xi_{S'\setminus S''}^\vartheta\big)\Big].$$

Step 6: the local part links no two groups. Let $S \neq \emptyset$. If S is contained in no single group, Ξ_S^{c} vanishes; if $S \subset C_a$, it is a function of $(z_j)_{j\in C_a}$ and $(\tau_p)_{p\in\mathsf{P}^a}$ only. This follows by induction on $\#S$, with $i = \max S \in C_a$. If $i \notin Q$: $\partial_{z_i}c_{\mathrm{cl}} = \partial_{z_i}c_a(w_a)$ by Step 3, and $\partial_{z_i}\Xi_{S'}^{\mathrm{c}} = 0$ when $\emptyset \neq S' \subset C_{a'}$ with $a' \neq a$, or when S' lies in no group. If $i \in Q$: the sum runs over $p \in \mathsf{P}_i \subset \mathsf{P}^a$; a factor $\partial_p^o\Xi_\emptyset^{\mathrm{c}}$ is $\partial_p^o c_a(w_a)$, and a factor $\partial_p^o\Xi_{S''}^{\mathrm{c}}$ with $S'' \neq \emptyset$ vanishes unless $S'' \subset C_a$, since otherwise $\Xi_{S''}^{\mathrm{c}}$ is 0 or does not depend on τ_p; so a product that is not 0 has $S' \subset C_a$ and depends on the variables of C_a alone. As $\#\mathfrak{A} \ge 2$, $\Xi_{\{1,\dots,n\}}^{\mathrm{c}} = 0$, and $\mathsf{cum}_{\Lambda''}(X_1^Q,\dots,X_n^Q) = \Xi_{\{1,\dots,n\}}^\vartheta(0,0)$.

Step 7: estimates by induction. Let $\theta_m := 1 - m/2n$ for $0 \le m \le n$, so that $(\theta_{m-1}-\theta_m)\rho^{\mathrm{p}} = \Delta$ and $(\theta_{m-1}-\theta_m)\rho_i^{\mathrm{z}} = 1/\mathsf{A}_i$ for $i \notin Q$. We show for every S with $\#S = m$

$$[\Xi_S^{\mathrm{c}}]_{\theta_m} \le \Gamma\prod_{j\in S}\mathsf{A}_j, \qquad \mathrm{osc}_{\theta_m}\Xi_S^\vartheta \le 2\epsilon_{\mathrm{osc}}\prod_{j\in S}\mathsf{A}_j, \qquad \|\Xi_S^\vartheta\|_{\theta_m} \le \epsilon_{\mathrm{osc}}\prod_{j\in S}\mathsf{A}_j \ \text{ if } S\cap Q \neq \emptyset.$$

At $m = 0$ this is Steps 3 and 4. Let $m \ge 1$, $i = \max S$, $\theta := \theta_{m-1}$ and $\theta' := \theta_m$. Passing to a smaller polydisc can only lower the three sizes $\|\cdot\|$, osc and $[\cdot]$; so the estimates already obtained for the sets with fewer than m elements, on $\mathbb{D}_{\theta_{m''}}$ with $\theta_{m''} \ge \theta$, are valid on $\mathbb{D}_\theta$. If $i \notin Q$, then $S\cap Q = \emptyset$; for F holomorphic on $\mathbb{D}_\theta$, Cauchy's estimate in z_i on the disc of radius $1/\mathsf{A}_i$, applied to $\xi \mapsto F(\xi) - F(\xi^{(q)})$ and to $z \mapsto F(z,\tau) - F(z,\tau')$, gives $[\partial_{z_i}F]_{\theta'} \le \mathsf{A}_i[F]_\theta$ and $\mathrm{osc}_{\theta'}\partial_{z_i}F \le \mathsf{A}_i\,\mathrm{osc}_\theta F$. Let $i \in Q$ and $\Pi := \prod_{j\in S'}\mathsf{A}_j$. For Ξ_S^ϑ, Lemma 18.133 with $\Delta' = \Delta$ and $g = \frac{L^K}{2}f_i\circ x$ bounds the sum with $\partial_p^2\Xi_{S'}^\vartheta$ by $\frac{L^K}{2}\|f_i\|_\infty\cdot 2\cdot 2\epsilon_{\mathrm{osc}}\Pi\Delta^{-2}$, each of the $2\cdot 2^{m-1}$ mixed sums by $\frac{L^K}{2}\|f_i\|_\infty\Gamma\cdot 2\epsilon_{\mathrm{osc}}\Pi\Delta^{-2}$, and each

of the 2^{m-1} sums with two factors Ξ^{ϑ} by $\frac{L^K}{2}\|f_i\|_\infty(2\epsilon_{\rm osc})^2\Pi\Delta^{-2}$; as $2\epsilon_{\rm osc}\le 1\le\Gamma$ by (Y1), and as $m\le n$,

$$\|\Xi^{\vartheta}_S\|_{\theta'}\le L^K\|f_i\|_\infty\Delta^{-2}\Pi\,\epsilon_{\rm osc}(2+2^m\Gamma+2^{m-1})\le 2^{n+4}\Gamma^2L^K\|f_i\|_\infty\Delta^{-2}\,\epsilon_{\rm osc}\Pi=\epsilon_{\rm osc}\prod_{j\in S}\mathsf{A}_j,$$

and $\mathrm{osc}_{\theta'}\le 2\|\cdot\|_{\theta'}$. For $\Xi^{\rm c}_S$ let $q\in\mathsf{P}$ and $\xi\in\mathbb{D}_{\theta'}$. The summand $p=q$ of $\Xi^{\rm c}_S(\xi)-\Xi^{\rm c}_S(\xi^{(q)})$ is at most $\frac{L^K}{2}\|f_i\|_\infty\cdot 2(2\Gamma+2^{m-1}\Gamma^2)\Pi\Delta^{-2}$, by the first bound of Lemma 18.133 at ξ and at $\xi^{(q)}$. For $p\neq q$ the derivative ∂_p commutes with $\xi\mapsto\xi^{(q)}$; with $F^q_R:=\Xi^{\rm c}_R-\Xi^{\rm c}_R(\cdot^{(q)})$, holomorphic on $\mathbb{D}_\theta$ with $\|F^q_R\|_\theta\le[\Xi^{\rm c}_R]_\theta$, the difference of the terms with ∂_p^2 is $\partial_p^2F^q_{S'}(\xi)$, and the difference of the products is $\partial_p\Xi^{\rm c}_{S''}(\xi)\,\partial_pF^q_{S'\setminus S''}(\xi)+\partial_pF^q_{S''}(\xi)\,\partial_p\Xi^{\rm c}_{S'\setminus S''}(\xi^{(q)})$. Lemma 18.133 with one function F, the other factor being put into the numbers $g(p)$ (and $g(q):=0$), which its first bound controls, gives $\frac{L^K}{2}\|f_i\|_\infty 2\Gamma\Pi\Delta^{-2}$ for the first sum over $p\neq q$ and $\frac{L^K}{2}\|f_i\|_\infty 2\Gamma^2\Pi\Delta^{-2}$ for each of the 2^{m-1} ordered pairs $(S'',S'\setminus S'')$. Adding,

$$[\Xi^{\rm c}_S]_{\theta'}\le\frac{L^K}{2}\|f_i\|_\infty\Delta^{-2}\Pi(6\Gamma+2^{m+1}\Gamma^2)\le 2^{n+4}\Gamma^2L^K\|f_i\|_\infty\Delta^{-2}\Pi=\mathsf{A}_i\Pi\le\Gamma\prod_{j\in S}\mathsf{A}_j.$$

Step 8: conclusion. The point $(0,0)$ lies in $\mathbb{D}_{\theta_n}$, and $\{1,\dots,n\}$ meets Q; Steps 6 and 7 give $|\mathsf{cum}_{\Lambda''}(X^Q_1,\dots,X^Q_n)|=|\Xi^{\vartheta}_{\{1,\dots,n\}}(0,0)|\le\epsilon_{\rm osc}\prod_i\mathsf{A}_i$. The second expression of A_i, $i\in Q$, follows from $\Delta^{-2}=2^{12}n^4\bar{\mathsf{m}}^2r_1^{-2}$ and $L^Kr_1^{-2}=4K_{\rm L}^2/(\mu_\star^2b)$. □

The numbers on an interval under (Tor).

Lemma 18.136 (Arithmetic of the bound of Proposition 18.135)**.** Let $m\in\mathbb{N}$, $\ell=2L^m$, let $\mathsf{J}=[b_-,b_+]$ be an admissible label interval on T_ℓ in §2.3.1, $n\ge 2$ and $d'>0$; take $\bar{\mathsf{C}}_{\mathsf{M}}$, $\bar{\mathsf{y}}_{[K]}$ and K_0 from the proof of Thm. YM3_I:AR, with $\bar{\mathsf{y}}_{[K]}=(\log(L^Kb_+))^{2\mathfrak{p}_0}$. Use $u=\lceil K/[180(3n+4)]\rceil$ and $s=\lceil K/9\rceil$. Put $c_{\mathsf{m}}:=\max\{1,C_{\rm old}LE_0/(L-1)\}$, $c_\Gamma:=\max\{1,2E_0C_{\rm pt}\}$,

$$\begin{aligned}
C_{\rm ins}&:=\max\Big\{64n^2\bar{\mathsf{C}}_{\mathsf{M}}\big(\log(Lb_+)\big)^{2\mathfrak{p}_0},\ \frac{2^{n+18}n^4K_{\rm L}^2c_{\mathsf{m}}^2c_\Gamma^2}{\mu_\star^2\,b_-}\Big\},\\
C_{\rm sm}&:=1+8C_{\rm old}C_{\rm fg}\tfrac{L}{L-1}E_0L^{6n+4}\\
&\quad+3c_\rho^2A_0^2\frac{\mu_\star}{K_{\rm L}}\big(\log(Lb_+)\big)^{2\mathfrak{p}_0}b_-^{-1/2}L^{6n+3}+L^{6n+1},\\
\bar\epsilon_{\rm rd}&:=\tfrac34c_\rho^2A_0^2\frac{\mu_\star}{K_{\rm L}}\,\bar{\mathsf{y}}_{[K]}N_{[u]}(L^Kb_-)^{-1/2}+\tfrac{3}{16n}L^{-(K-s)/2},
\end{aligned}$$

with $\epsilon_{\rm lk}$ of Proposition 18.135 and $\epsilon_{\rm fg}$ of equation YM3_I:(2192), and let $K_{\rm gr}(d')$ be the least integer $k\ge K_0$ such that at every integer $K\ge k$

$$\bar\epsilon_{\rm rd}\le\tfrac18,\qquad 2\epsilon_{\rm lk}+8\epsilon_{\rm fg}+4\bar\epsilon_{\rm rd}\le\tfrac12,\qquad 2K_{\rm L}(L^sb_-)^{1/2}\ge K_{\rm Q},$$
$$d'L^u\ge 6M,\qquad 2^9n^2K_{\rm L}c_\Gamma c_{\mathsf{m}}\,K\,N_{[u]}\le\mu_\star(L^Kb_-)^{1/2},\qquad 2\epsilon_{\rm lk}N_{[u]}^{2n}\le\ell^{6n+3}L^{-K/10}.$$

Then $K_{\rm gr}(d')$ exists, and for every $b\in\mathsf{J}$, every integer $K\ge K_{\rm gr}(d')$, every tuple and every partition into groups as in Proposition 18.135, the calibrated conditions of Lem. 18.132 and (Y1)–(Y5) are satisfied, and for every $\emptyset\neq Q\subset\{1,\dots,n\}$

$$\epsilon_{\rm osc}\prod_{i=1}^n\mathsf{A}_i\le C_{\rm ins}^n\,C_{\rm sm}\,\ell^{6n+3}K^{(2\mathfrak{p}_0+2)n}L^{-K/10}\prod_{i=1}^n\|f_i\|_\sharp.$$

■

Sketch of proof. By the choice of K_0 in the proof of Thm. YM3_I:AR, the calibrated conditions, $\epsilon_{\rm fg} \le 1/8$ and $\mathsf{R}_t \le 1/2$ hold for every $b \in \mathsf{J}$ and $K \ge K_0$. Enlarge K_0 if needed so that $L^u b_- \ge \mathsf{t}_\natural$, and take $t_* = t$. Then $\frac{3}{2}(\mathsf{e}_t^{\rm c})^2 L^{-t} = \frac{3}{2} c_\rho^2 A_0^2 \mathsf{y}_{[u]}/\beta$, with the numbers $\mathsf{y}_{[d]} = (\log x_{[d]})^{2\mathfrak{p}_0}$, and $\mathsf{y}_{[u]} \le \mathsf{y}_{[K]} \le \bar{\mathsf{y}}_{[K]} \le (\log(Lb_+))^{2\mathfrak{p}_0} K^{2\mathfrak{p}_0}$; with $r_{\rm eff} \le r_1$ and $\beta \ge L^K b_-$ this gives $\epsilon_{\rm rd} \le \bar\epsilon_{\rm rd}$; and (Y2), which after multiplication by r_1 reads $\frac{3}{4} c_\rho^2 A_0^2 (\mu_\star/K_{\rm L}) \mathsf{y}_{[u]} N_{[u]} \beta^{-1/2} \le \bar{\mathsf{m}}$, follows from $\bar\epsilon_{\rm rd} \le \frac{1}{8}$ and $\bar{\mathsf{m}} \ge 1$. So the first four inequalities of the list give (Y1)–(Y4), with $L^s b \ge L^s b_-$ in (Y3). By the radius bound YM3_I:(2204), $8n/r_i(t_1) \le 64 n^2 \bar{\mathsf{C}}_{\mathsf{M}} (\log(Lb_+))^{2\mathfrak{p}_0} K^{2\mathfrak{p}_0} N_{[u]} \|f_i\|_\sharp$; moreover $\bar{\mathsf{m}} \le c_{\mathsf{m}} N_{[u]}$ by equation YM3_I:(2179), $\Gamma \le c_\Gamma K$ and $b \ge b_-$. As $r_{\rm eff} = \mu_\star \beta^{1/2}/(32 n K_{\rm L} \bar{\mathsf{m}})$, (Y5) is the inequality $2^9 n^2 K_{\rm L} \Gamma \bar{\mathsf{m}} \le \mu_\star \beta^{1/2}$, which the fifth inequality of the list gives, by the bounds of $\bar{\mathsf{m}}$ and of Γ just stated and by $\beta \ge L^K b_-$. Hence $\mathsf{A}_i \le C_{\rm ins} K^{2\mathfrak{p}_0} N_{[u]} \|f_i\|_\sharp$ for $i \notin Q$ and $\mathsf{A}_i \le C_{\rm ins} K^2 N_{[u]}^2 \|f_i\|_\infty$ for $i \in Q$. With $N_{[u]} \ge 1$ and $\|f_i\|_\infty \le \|f_i\|_\sharp$, each A_i is at most $C_{\rm ins} N_{[u]}^2 \|f_i\|_\sharp$ times $K^{2\mathfrak{p}_0}$ if $i \notin Q$ and times K^2 if $i \in Q$; as $K \ge 1$, $\mathfrak{p}_0 \ge 1$ and Q has at least one element, the product of these powers of K is at most $K^{2\mathfrak{p}_0(n-1)+2}$, so that $\prod_i \mathsf{A}_i \le C_{\rm ins}^n K^{2\mathfrak{p}_0(n-1)+2} N_{[u]}^{2n} \prod_i \|f_i\|_\sharp$. Write $\phi_1 = \frac{1}{180(3n+4)}$ and $\phi_2 = \frac{1}{9}$, so that $u = \lceil \phi_1 K \rceil$ and $s = \lceil \phi_2 K \rceil$. With $\phi_1 K \le u < \phi_1 K + 1$ and $\phi_2 K \le s < \phi_2 K + 1$ and $(6n+4)\phi_1 = \frac{3n+2}{90(3n+4)} \le \frac{1}{90}$ one has $u(6n+4) - s \le -\frac{K}{10} + 6n + 4$, $3u(2n+1) - \frac{K}{2} \le -\frac{K}{10} + 6n + 3$ and $6nu - \frac{1}{2}(K - s) \le -\frac{K}{10} + 6n + \frac{1}{2}$, as $\frac{K}{90} - \frac{K}{9} = -\frac{K}{10}$, $\frac{K}{90} - \frac{K}{2} < -\frac{K}{10}$ and $\frac{K}{90} - \frac{K}{2} + \frac{K}{18} = -\frac{13K}{30} \le -\frac{K}{10}$. Hence $8\epsilon_{\rm fg} N_{[u]}^{2n} = 8 C_{\rm old} C_{\rm fg} \frac{L}{L-1} E_0 \, \ell^{6n+3} L^{u(6n+4)-s}$, $4\bar\epsilon_{\rm rd} N_{[u]}^{2n}$ and, by the last inequality of the list, $2\epsilon_{\rm lk} N_{[u]}^{2n}$ are bounded by the parts of $C_{\rm sm} K^{2\mathfrak{p}_0} \ell^{6n+3} L^{-K/10}$, so $\epsilon_{\rm osc} N_{[u]}^{2n} \le C_{\rm sm} K^{2\mathfrak{p}_0} \ell^{6n+3} L^{-K/10}$. The product of the two bounds gives $\epsilon_{\rm osc} \prod_i \mathsf{A}_i \le C_{\rm ins}^n C_{\rm sm} \ell^{6n+3} K^{2\mathfrak{p}_0 n + 2} L^{-K/10} \prod_i \|f_i\|_\sharp$, and $K^{2\mathfrak{p}_0 n + 2} \le K^{(2\mathfrak{p}_0+2)n}$ because $n \ge 1$ and $K \ge 1$. Each inequality of the list is true at all large K: $\bar\epsilon_{\rm rd}$, $\epsilon_{\rm fg}$, $\epsilon_{\rm lk} N_{[u]}^{2n} L^{K/10}$ and $K N_{[u]} L^{-K/2}$ tend to 0, by these exponents, by $3\phi_1 < \frac{1}{2}$ and by $L^u \ge L^{\phi_1 K}$, while L^s and L^u tend to infinity; so $K_{\rm gr}(d')$ exists. □

Supports without a common point.

Lemma 18.137 (Cutting the test functions into small pieces)**.** Let $m \in \mathbb{N}$, $\ell = 2L^m$, $n \ge 2$, $d > 0$, and let $f_1, \dots, f_n$ be real Lipschitz functions on T_ℓ, none of them 0, with $\mathsf{d}_\infty(\underline{f}) \ge d$. Put $\mathsf{H} := \lceil 4n\ell/d \rceil$, $\mathsf{l} := \ell/\mathsf{H}$, $\psi_a^{(1)}(y) := \max\{0, 1 - \operatorname{dist}(y, a\mathsf{l} + \ell\mathbb{Z})/\mathsf{l}\}$ on $\mathbb{R}/\ell\mathbb{Z}$ for $a \in \mathbb{Z}/\mathsf{H}\mathbb{Z}$, and $\psi_\alpha(x) := \prod_{\mu \le 3} \psi_{\alpha_\mu}^{(1)}(x_\mu)$ for $\alpha \in (\mathbb{Z}/\mathsf{H}\mathbb{Z})^3$. Then $\sum_\alpha \psi_\alpha = 1$; each $\psi_\alpha f_i$ is a real Lipschitz function with $\|\psi_\alpha f_i\|_\infty \le \|f_i\|_\infty$ and $\|\psi_\alpha f_i\|_\sharp \le (1 + 600 n M/d) \|f_i\|_\sharp$; and for every $\underline{\alpha} = (\alpha_1, \dots, \alpha_n)$ with $g_i := \psi_{\alpha_i} f_i \ne 0$ for all i there is a partition of $\{1, \dots, n\}$ into at least two groups such that $\operatorname{dist}_\infty(\operatorname{supp} g_i, \operatorname{supp} g_{i'}) \ge d/2n$ whenever i and i' lie in two different groups. ■

Sketch of proof. Two points of T_ℓ lie at sup distance at most $\frac{1}{2}\ell$, so $d \le \mathsf{d}_\infty(\underline{f}) \le \frac{1}{2}\ell$; hence $\mathsf{H} \ge 8n$, $\mathsf{l} \le d/4n$ and $1/\mathsf{l} \le 4n/d + 1/\ell \le 5n/d$. Each $\psi_a^{(1)}$ is piecewise linear with values in $[0,1]$, slopes $\pm 1/\mathsf{l}$ and an arc of length $2\mathsf{l}$ as support, and these functions sum to 1 on the circle; hence ψ_α takes values in $[0,1]$, the ψ_α sum to 1, the support of ψ_α has sup diameter at most $2\mathsf{l} \le d/2n$, and, a product of numbers in $[0,1]$ moving by at most the sum of the moves of its factors, $|\psi_\alpha(x) - \psi_\alpha(y)| \le \mathsf{l}^{-1} \sum_\mu |x_\mu - y_\mu| \le 3\mathsf{l}^{-1} |x - y|_\infty \le 3\mathsf{l}^{-1} |x - y|$, the coordinate differences being taken on the circle $\mathbb{R}/\ell\mathbb{Z}$, and the sup distance being at most the Euclidean one. So $\operatorname{Lip}(\psi_\alpha f) \le \operatorname{Lip} f + 3\mathsf{l}^{-1} \|f\|_\infty$ and $\|\psi_\alpha f\|_\sharp \le (1 + 120 M/\mathsf{l}) \|f\|_\sharp \le (1 + 600 n M/d) \|f\|_\sharp$. For the groups, call i and i' neighbours when $\operatorname{dist}_\infty(\operatorname{supp} g_i, \operatorname{supp} g_{i'}) < d/2n$, and let the groups be the classes of the equivalence relation that this relation generates; supports of indices in two different classes are then at sup distance at least $d/2n$. Suppose that all indices formed one class, and pick $x_i \in \operatorname{supp} g_i \subset \operatorname{supp} f_i$. Between two indices there is a path of neighbours through at most n indices; along it each support adds at most its diameter $d/2n$ and each passage to a neighbour a distance smaller than $d/2n$, so that $|x_i - x_{i'}|_\infty < n \cdot \frac{d}{2n} + (n-1)\frac{d}{2n} < d$ for all i and i'. The tuple $(x_1, \dots, x_n)$ would then have sup diameter smaller than d, which the hypothesis $\mathsf{d}_\infty(\underline{f}) \ge d$ excludes. □

Proposition 18.138 (The bound at the labels of an interval under (Tor))**.** Let $m \in \mathbb{N}$, $\ell = 2L^m$, let $\mathsf{J} = [b_-, b_+]$ be an admissible label interval on T_ℓ, $n \geq 2$ and $d > 0$; let $\mathsf{C} = C_n(\mathsf{J})$, $\mathsf{C}' = C'_n(\mathsf{J})$ and $K_1(d) = K_1(\ell, n, \mathsf{J}, d)$ be the numbers of Thm. YM3_I:AR and Cor. YM3_I:117.1, and C_{ins}, C_{sm}, $K_{\mathrm{gr}}(\cdot)$ those of Lemma 18.136. Put

$$C^\flat_{\mathsf{J}} := (2^n - 1)\Big[\mathsf{H}^{3n}\Big(1 + \frac{600nM}{d}\Big)^n C^n_{\mathrm{ins}} C_{\mathrm{sm}}\, \ell^{6n+3} + \tfrac{1}{4}\mathsf{C}\,\ell^{3(n+1)}\Big] + \mathsf{C}'\ell^{3(n+1)}, \qquad K^\flat_{\mathsf{J}} := \max\{K_1(d), K_{\mathrm{gr}}(d/2n)\},$$

with $\mathsf{H} = \lceil 4n\ell/d \rceil$. Then the bounds (a) and (b) of Proposition 18.129 are true with $C^\flat_{\mathsf{J}}$ and $K^\flat_{\mathsf{J}}$ in the place of $C^\flat$ and $K^\flat$, for every $b \in \mathsf{J}$, every integer $K \geq K^\flat_{\mathsf{J}}$ and every tuple as there. ■

Sketch of proof. Let $b \in \mathsf{J}$, $K \geq K^\flat_{\mathsf{J}}$, $\beta = L^K b$, and let the tuple be as there. The functionals $\Lambda(F) = \int F\rho_0\, dU$ and $\Lambda'''(F) = \int F\mathfrak{w}^{\mathrm{sf}}_t\rho_0\, dU$ are positive on the gauge-invariant algebra, and $\Lambda - \Lambda'''$ is positive there by equation YM3_I:(2189). The loss in total mass is at most $\mathsf{R}_t\Lambda(1)$ by equation YM3_I:(2190). Write $\mathsf{cum}_{\Lambda'''}$ for the cumulant of the normalized second functional. After normalizing both functionals, their means of any bounded gauge-invariant function F differ by at most $2\mathsf{R}_t\|F\|_\infty$: subtract the lost integral and then account for the difference of the normalizers. In the moment formula for the joint cumulant, replace the block moments of each partition one at a time. Summing the bounds with the cumulant coefficients gives at most $2\mathsf{op}_n\mathsf{R}_t\prod_i\|X_i^Q\|_\infty$, where $\mathsf{op}_n = \sum_\pi |\pi|!$. Using the common bound on the entries gives, in particular,

$$\begin{aligned}|\langle X_1^Q;\dots;X_n^Q\rangle_{K,\ell,\beta} - \mathsf{cum}_{\Lambda'''}(X_1^Q,\dots,X_n^Q)| &\leq 4\mathsf{op}_n\mathsf{R}_t\prod_i 6\ell^3L^{4K}\|f_i\|_\infty\\ &\leq \tfrac{1}{4}\mathsf{C}\ell^{3(n+1)}K^{\mathsf{p}_n}L^{-K/10}\prod_i\|f_i\|_\sharp.\end{aligned}$$

The last inequality is the discarded-mass estimate in the proof of Thm. YM3_I:AR, using its larger prefactor $8\mathsf{op}_n\bar{\mathsf{R}}(6\ell^3L^{4(K+1)})^n$ and its choice of K_0. The entries are real linear in the f_i, and the cumulant depends real-linearly on each of its entries; with the functions ψ_α of Lemma 18.137, $\mathsf{cum}_{\Lambda'''}(X_1^Q,\dots,X_n^Q)$ is the sum over the H^{3n} tuples $\underline{\alpha}$ of the cumulants formed with the pieces $g_i = \psi_{\alpha_i}f_i$, and the terms in which some piece vanishes are 0. Each remaining choice of pieces falls into at least two groups at sup distance $\geq d/2n$, and $K \geq K_{\mathrm{gr}}(d/2n)$; Proposition 18.135 and Lemma 18.136 bound its cumulant by $C^n_{\mathrm{ins}}C_{\mathrm{sm}}\ell^{6n+3}K^{(2\mathfrak{p}_0+2)n}L^{-K/10}\prod_i\|g_i\|_\sharp$, and $\|g_i\|_\sharp \leq (1 + 600nM/d)\|f_i\|_\sharp$. As $(2\mathfrak{p}_0 + 2)n \leq \mathfrak{p}^\natural_n$, $\mathfrak{p}_n \leq \mathfrak{p}^\natural_n$ and $K \geq 1$, the cumulant in (a) is at most the bracket in the formula for $C^\flat_{\mathsf{J}}$ times $K^{\mathfrak{p}^\natural_n}L^{-K/10}\prod_i\|f_i\|_\sharp$, which gives (a). For (b), $\mathcal{O}'_K = \mathcal{O}_K - \mathcal{O}^{(2)}_K$ and the multilinearity give $\langle\mathcal{O}'_K(f_1);\dots;\mathcal{O}'_K(f_n)\rangle_{K,\ell,\beta} = \sum_{Q\subset\{1,\dots,n\}}(-1)^{\#Q}\langle X_1^Q;\dots;X_n^Q\rangle_{K,\ell,\beta}$, whose term $Q = \emptyset$ is $S^T_{n;K,\ell,\beta}(\underline{f})$; and $|S^T_{n;K,\ell,\beta}(\underline{f}) - S^{(\ell,b)}_n(\underline{f})| \leq \mathsf{C}'\ell^{3(n+1)}K^{\mathsf{p}_n}L^{-K/10}\prod_i\|f_i\|_\sharp$ for $K \geq K_1(d)$, by Cor. YM3_I:117.1 in the limit $K' \to \infty$, with the limit identified in Thm. YM3_I:AS. Adding the bounds of (a) for the $2^n - 1$ sets $Q \neq \emptyset$ and this bound, in which $K^{\mathsf{p}_n} \leq K^{\mathfrak{p}^\natural_n}$, gives (b) with the constant $C^\flat_{\mathsf{J}}$. □

Every label, every side.

Lemma 18.139 (Dilation of the cumulants of the plaquette densities)**.** Let $K, m \in \mathbb{N}$, $\ell = 2L^m$, let s be an integer with $0 \leq s < K$, let $\beta > 0$ be real, and let $f_1,\dots,f_n$ be bounded real functions on T_ℓ; for each i let $Y_{i,K}$ be one of $\mathcal{O}_K$, $\mathcal{O}^{(2)}_K$ and $\mathcal{O}'_K$, and $Y_{i,K-s}$ the density of the same kind on $\Lambda_{K-s,L^s\ell}$. With $f^{(s)}(x) = f(L^{-s}x)$,

$$\langle Y_{1,K}(f_1);\dots;Y_{n,K}(f_n)\rangle_{K,\ell,\beta} = L^{sn}\,\langle Y_{1,K-s}(f_1^{(s)});\dots;Y_{n,K-s}(f_n^{(s)})\rangle_{K-s,L^s\ell,\beta}.$$

■

Sketch of proof. The map $U \mapsto U^{(s)}$ that relabels every bond and plaquette by dilation is a bijection of $\mathcal{V}(\Lambda_{K,\ell})$ onto $\mathcal{V}(\Lambda_{K-s,L^s\ell})$ that carries the Haar measure to the Haar measure, with $a_{L^sp}(U^{(s)}) =$

$a_p(U)$ and $x(L^s p) = L^s x(p)$; it therefore carries the density $e^{-\beta \sum_p a_p}$ of the first lattice to that of the second. As $a_K^{-1} = L^s a_{K-s}^{-1}$ and $f(x(p)) = f^{(s)}(x(L^s p))$, one has $Y_K(f)(U) = L^s Y_{K-s}(f^{(s)})(U^{(s)})$ for $\mathcal{O}$ and for $\mathcal{O}^{(2)}$, and so also for their difference $\mathcal{O}'$; the cumulant is multilinear, so multiplying each of its n entries by L^s multiplies it by L^{sn}. □

Proof of Proposition 18.129. Let $s_\star$ be the least integer ≥ 0 that satisfies YM3_I:(2210) for the pair (b_-, b_+) on the side ℓ; it exists by Lem. YM3_I:118.2, and $\mathsf{J}_\star := [L^{s_\star} b_-, L^{s_\star} b_+]$ is an admissible interval on $T_{L^{s_\star}\ell}$ by equation YM3_I:(2201). Let $C^\flat_{\mathsf{J}_\star}$ and $K^\flat_{\mathsf{J}_\star}$ be the numbers of Proposition 18.138 at the side $L^{s_\star}\ell$, the interval $\mathsf{J}_\star$, the integer n and the number $L^{s_\star} d$, and put

$$C^\flat := L^{s_\star(n+\frac{1}{10})}\, C^\flat_{\mathsf{J}_\star}, \qquad K^\flat := s_\star + K^\flat_{\mathsf{J}_\star};$$

they are formed from $\mathfrak{D}$, n, ℓ, $b_\pm$ and d. Let $b \in [b_-, b_+]$, $K \geq K^\flat$, and let $\underline{f}$ be as in the statement. Then $K - s_\star \geq K^\flat_{\mathsf{J}_\star} \geq 2$; the functions $f_i^{(s_\star)}$ are real Lipschitz functions on $T_{L^{s_\star}\ell}$, none of them 0, with $\|f_i^{(s_\star)}\|_\infty = \|f_i\|_\infty$ and $\|f_i^{(s_\star)}\|_\sharp \leq \|f_i\|_\sharp$, their supports have no common point, and their spread is $L^{s_\star}\mathsf{d}_\infty(\underline{f}) \geq L^{s_\star} d$ since dilation multiplies sup distances by $L^{s_\star}$; and $L^K b = L^{K-s_\star}(L^{s_\star} b)$ with $L^{s_\star} b \in \mathsf{J}_\star$. By Lemma 18.139, each cumulant of (a) and the cumulant of (b) at $(K, \ell, L^K b, \underline{f})$ is $L^{s_\star n}$ times the corresponding cumulant at $(K - s_\star, L^{s_\star}\ell, L^{K-s_\star}(L^{s_\star} b), \underline{f}^{(s_\star)})$, and $S_n^{(\ell,b)}(\underline{f}) = L^{s_\star n} S_n^{(L^{s_\star}\ell, L^{s_\star} b)}(\underline{f}^{(s_\star)})$ by display YM3_I:(2215). Proposition 18.138 at the dilated data bounds the dilated quantities by $C^\flat_{\mathsf{J}_\star}(K - s_\star)^{\mathsf{p}^\natural_n} L^{-(K-s_\star)/10} \prod_i \|f_i\|_\sharp$, and $L^{s_\star n}(K - s_\star)^{\mathsf{p}^\natural_n} L^{-(K-s_\star)/10} \leq L^{s_\star(n+\frac{1}{10})} K^{\mathsf{p}^\natural_n} L^{-K/10}$. This gives (a) and (b); the last sentence of the Proposition follows, as $K^{\mathsf{p}^\natural_n} L^{-K/10} \to 0$ and $C^\flat$, $K^\flat$ do not depend on $b \in [b_-, b_+]$ or on the tuple. □

18.14. **One torus: the label as a variable, the laws and kernels of the block fields, the action density at coinciding points, and the classical action.** We study the label dependence and the block fields on a fixed torus T_ℓ, $\ell = 2L^m$, together with the lattice fields of smooth one-forms. Proposition 18.141 says that a torus limit $S_n^{\ell,\mathsf{b}}(X)$, at a tuple in which some two entries have disjoint supports, is real-analytic in the label on $(0, \infty)$, on every side; hence it is either identically zero or has only finitely many zeros on each compact set of labels. It also says that for test pairs (f, h) at a small scale the integrated three-point function $S_3^{\ell,\mathsf{b}}(1, f, h) = -\partial_{\mathsf{b}} S_2^{\ell,\mathsf{b}}(f, h)$ takes a positive value somewhere between two labels of a window as soon as the ratio of their squares exceeds 2, with relative bounds that are the same for all the pairs of the class. Proposition 18.142 says that at every label one of the connected functions of order three or more is non-zero at a tuple $(1, \dots, 1, f, h)$, and that a law of three points on a torus, uniform in the cutoff, makes the limit of the third connected function positive at collinear triples of bumps. According to Proposition 18.144, the laws of the block fields of a fixed depth are, on every side, real-analytic in the label, their derivatives being given by the correlations with the total action, and the mixed cumulants of the action density with a bounded Borel function of a block field obey bounds that are uniform in the cutoff, for arbitrary supports. Proposition 18.145 treats a label $\mathsf{b} \geq \gamma^{-2}$ on a side $\ell = 2L^m$ with $M\, R(\mathsf{b}) \leq L^m$; write ς_K for the square root of the specific heat at the cutoff K. Once centred, multiplied by $a_K^{3/2}$ and divided by ς_K, the smeared action density has a limit in law as K runs through all the integers, a white noise whose covariance at two test functions f, h is $\int fh$, and in this limit it is independent of the block field V_d of any fixed depth d. Without the division by ς_K, a limit in law of the same kind, with the covariance $\varsigma_0^2 \int fh$ and again independent of V_d, exists along any infinite sequence of cutoffs for which ς_K^2 tends to a number ς_0^2. Finally, $\liminf_K \varsigma_K^2 \geq \frac{3}{4}\mathsf{b}^{-2}$ holds for every real label $\mathsf{b} > 0$ and every side. Proposition 18.147 says that the conditional laws of the block field of depth $d+1$ given the block field of depth d exist at $K = \infty$, are the limits of those at the cutoffs, and turn the sequence of the block fields into a Markov chain indexed by the depth. Proposition 18.148 says that the covariance of a bounded Borel function of the block field of depth d with the smeared action

density tends, as the cutoff runs through all the integers and with an error that decays geometrically, to the integral of that function against a density $X_d(f)$ that lies in L^p for every $p<\infty$; that these densities form a martingale in the depth; and that, for f supported in one half of the torus cut by a coordinate mirror with the reflection θ, their conditional expectations with respect to the block variables on the opposite side constitute a martingale converging almost surely and in L^2, with L^2 norms at most $S_2^{\ell,\mathsf{b}}(f\circ\theta,f)^{1/2}$. Propositions 18.150 to 18.152 contain those entries of the dictionary with the classical theory that involve no evolution in time, for the action and its density, the coupling, the shell flux and the free kernels: on the lattice field of a smooth one-form the Wilson action, the action density and the shell flux are the Yang–Mills action, its density and the flux of its stress tensor, up to errors of the order of a power of the spacing; $\mathsf{b}g_{\mathrm{std}}^2=4$; and, for each $n\ge 2$, the n-th connected function of $\frac12{:}|B|^2{:}$, where B is the curvature of three free photon fields at the label b, equals $3\mathsf{b}^{-n}\mathcal{K}_{\mathrm{free}}^{(n)}$, the function of order n of the free template of Definition 18.116(3).

The scalar torus limits and the law of two points are Theorems YM3_I:AS and YM3_I:AV. Proposition 18.161 supplies holomorphic convergence and the constant-source derivatives. The block-field laws use the calibrated comparison of §2.3.1 and Corollary 2.8. Lemma 18.212 constructs the compatible thread law. The final three propositions compute the classical and Gaussian expressions directly.

Definition 18.140 (Signs on one torus)**.** Use the sourced setting $\mathfrak{s}$, the cutoff cumulants $S^T_{n;K,\ell,\beta}$ and the limits $S_n^{\ell,\mathsf{b}}$ of Definition 18.159. On $\ell=2L^m$ let $a_j=L^{-j}$ and $\Lambda_{j,\ell}=a_j\mathbb{Z}^3/\ell\mathbb{Z}^3$ for $j\ge -m$. For $j>-m$, $\mathcal{V}(\Lambda_{j,\ell})$ consists of bond fields with values in $\mathrm{SU}(2)$ and $U(\bar b)=U(b)^{-1}$. Write $\mathsf{V}_d=\mathcal{V}(\Lambda_{d,\ell})$ for $d\ge 0$. At cutoff K write $\mathbb{E}_{K,s}$ for expectation at label s and $\beta=L^K s$ and $V_d=\mathcal{M}^{K-d}U$ for $d\le K$. Its law is $\mu_d^K[s]$. Write $\mu_d[s]=\mu_d[\ell,s]$ for the limit law and $\mu_{\ell,s}$ for the thread law of Lemmas 18.212 and 18.230. The observable is $\mathcal{O}(f)=a_K^{-1}\sum_p f(x(p))a_p$, with $a_p=1-\frac12\operatorname{tr}U(p)$, and the source norm $\|f\|=\|f\|_\flat$ is specified in Definition 18.143(1). Let $\mathfrak{S}_n(T_\ell)$ be the tuples of n real C^1 functions with pairwise disjoint supports.

(1) The *setting (E)* uses a fixed choice ς of the canonical constants and auxiliary data in (Th1), (Th2) of §2.3.1, and a label $\mathsf{b}\ge\gamma^{-2}$ with $MR(\mathsf{b})\le L^m$. Denote by ϱ_ς the source radius in that calibration. The real restriction of the sourced setting uses the same canonical construction of Theorems YM3_I:D and YM3_I:AD.

(2) Use the dilation $f^{(s)}$, the tuple $X^{(s)}$, the constant insertions $(1^\nu,X)$, and tuples with a separated pair as in Definition 18.159(2), (3).

(3) Use the class $\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ and the pair kernel $\mathcal{K}_6$ of §18.4, where $\vartheta\in(0,1)$ and $20\mathsf{d}\le\ell$. In particular
$$10^{-6}\vartheta^2\|f\|_\infty\|h\|_\infty\le\mathcal{K}_6(f,h)\le(4\pi/3)^2\|f\|_\infty\|h\|_\infty,\qquad \mathsf{c}_2=\frac{9}{16\pi^2}.$$
The inequalities follow from the pair-distance bounds $[\mathsf{d},10\mathsf{d}]$, the test-integral lower bound and the support-volume upper bound.

(4) Let γ_W be the ceiling YM3_I:(2346), $\bar\varepsilon_{g,\vartheta}$ the tolerance YM3_I:(2349), and $\mathsf{d}_0(g,\vartheta)\in(0,1/200]$ the threshold YM3_I:(2350). For $0<g\le\gamma_W$ the tolerance is nondecreasing, tends to zero at zero, and stays at most $1/3$ through the threshold. Use the witness depth of YM3_I:(2321) with $C_{W,0}=\max\{1,4L^2M/A_0^2\}$ as in Theorem YM3_I:AV. This depth is formed before fixing the cutoff, label and side.

(5) For $36\mathsf{d}<\ell$, put $X_{\mathsf{d}}^\ell=(\beta_0^{\langle\ell\rangle},\beta_2^{\langle\ell\rangle},\beta_4^{\langle\ell\rangle})$, where $\beta_j(y)=(1-256|y-j\mathsf{d}e_1|^2/\mathsf{d}^2)_+^2$. These C^1 functions have supremum 1 and radius $\mathsf{d}/16$. The lifted support distances range from $15\mathsf{d}/8$ to $31\mathsf{d}/8$. Their integrals are
$$4\pi(\mathsf{d}/16)^3(1/3-2/5+1/7)=\pi\mathsf{d}^3/13440$$

and their Lipschitz constants are at most $128/(3\sqrt{3}\,\mathsf{d})$, by maximizing the radial derivative. Hence for $\vartheta \le \pi/13440$ the triple lies in $\mathfrak{T}^{(3),\mathrm{col}}_{T_\ell}(\mathsf{d};\vartheta)\cap\mathfrak{S}_3(T_\ell)$. The collinear class is contained in $\mathfrak{Q}^{(3)}_{T_\ell}(\mathsf{d};\vartheta)$, whose triples have all pairs in $\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$. The lifted kernel and the collinear bound of §18.4 give $\mathcal{K}^{(3)}_{\mathrm{free}} \ge c_3^{\mathrm{col}}\vartheta^3\prod_i\|f_i\|_\infty$ on that class, where $c_3^{\mathrm{col}} = 3.78(4\pi)^{-3}10^{-9}$. ∎

Proposition 18.141 (The torus limits as functions of the label; the sum rule; the integrated three-point function)**.** Work in a setting $\mathfrak{s}$. Let $m\in\mathbb{N}$ and $\ell = 2L^m$.

(1) *(Analytic on all of $(0,\infty)$.)* Let X be a tuple with a separated pair on T_ℓ, with $n\ge 2$ entries, and put $\varphi(\mathsf{b}) = S_n^{\ell,\mathsf{b}}(X)$, $\mathsf{b}>0$. Given $0<\mathsf{b}_-<\mathsf{b}_+$, choose an integer $s\ge 0$ with $L^s\mathsf{b}_-\ge 2\gamma^{-2}$ and $2L^{m+s}\in\mathfrak{L}\big((L^s\mathsf{b}_+/2)^{-1/2}\big)$; every sufficiently large integer qualifies. With $\upsilon_s = L^{-s}\upsilon([L^s\mathsf{b}_-,L^s\mathsf{b}_+],L^s\ell)>0$, where the width $\upsilon(\cdot,\cdot)$ of Definition 18.159(4) involves neither n nor X, the restriction of φ to $[\mathsf{b}_-,\mathsf{b}_+]$ extends to a holomorphic function on the set of the complex numbers at a distance less than υ_s from $[\mathsf{b}_-,\mathsf{b}_+]$. Hence φ is real-analytic on the whole half line $(0,\infty)$.

(2) *(Zeros; their order.)* In the setting of (1), φ is either the zero function or its zero set is discrete in $(0,\infty)$, so that each compact interval of labels contains only finitely many zeros. When φ is not constant, each label $\mathsf{b}>0$ has some $\nu\ge 1$ for which $S^{\ell,\mathsf{b}}_{n+\nu}(1^\nu,X) = (-1)^\nu\partial_{\mathsf{b}}^\nu\varphi(\mathsf{b})\ne 0$.

(3) *(The sum rule at a window.)* Let $0<g\le\gamma_W$, $\ell\in\mathfrak{L}(g)$, $\vartheta\in(0,1)$, $0<\mathsf{d}\le\mathsf{d}_0(g,\vartheta)$ and $(f,h)\in\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$. Put $\epsilon = \bar\varepsilon_{g,\vartheta}(\mathsf{d})\in[0,\frac13]$, $\mathsf{k} = \mathsf{c}_2\mathcal{K}_6(f,h)>0$, $\phi(\mathsf{b}) = S_2^{\ell,\mathsf{b}}(f,h)$ and $\psi(\mathsf{b}) = S_3^{\ell,\mathsf{b}}(1,f,h)$, and let $\mathsf{b}_{\mathrm{top}} = L(g^{-2}+\bar B)-2\bar B$ be the right end of $I(g)$. Then ϕ and ψ are real-analytic on $(0,\infty)$, $\phi' = -\psi$, and the following hold.

(a1) $|\phi(\mathsf{b}) - \mathsf{k}\,\mathsf{b}^{-2}|\le\epsilon\,\mathsf{k}\,\mathsf{b}^{-2}$ for every $\mathsf{b}\in I(g)$.

(a2) For all $\mathsf{b}_1<\mathsf{b}_2$ in $I(g)$: $\big|\int_{\mathsf{b}_1}^{\mathsf{b}_2}(\psi - 2\mathsf{k}\,\mathsf{b}^{-3})\,d\mathsf{b}\big|\le\epsilon\,\mathsf{k}\,(\mathsf{b}_1^{-2}+\mathsf{b}_2^{-2})$ and $\big|\int_{\mathsf{b}_1}^{\mathsf{b}_2}\mathsf{b}\,(\mathsf{b}\psi-2\phi)\,d\mathsf{b}\big|\le 2\epsilon\,\mathsf{k}$.

(a3) Between any two labels $\mathsf{b}_1<\mathsf{b}_2$ of $I(g)$ lies a label b'' with

$$\mathsf{k}\,\frac{(1-\epsilon)\mathsf{b}_1^{-2}-(1+\epsilon)\mathsf{b}_2^{-2}}{\mathsf{b}_2-\mathsf{b}_1}\ \le\ \psi(\mathsf{b}'')\ \le\ \mathsf{k}\,\frac{(1+\epsilon)\mathsf{b}_1^{-2}-(1-\epsilon)\mathsf{b}_2^{-2}}{\mathsf{b}_2-\mathsf{b}_1};$$

the left member is positive as soon as $\mathsf{b}_2^2>2\mathsf{b}_1^2$. The labels $\mathsf{b}_2=\mathsf{b}_{\mathrm{top}}$ and $\mathsf{b}_1=\frac12\mathsf{b}_{\mathrm{top}}$ lie in $I(g)$, and for them $\psi(\mathsf{b}'')\ge\frac83\mathsf{k}\,\mathsf{b}_{\mathrm{top}}^{-3}\ge\frac83\,10^{-6}\vartheta^2\mathsf{c}_2\,\mathsf{b}_{\mathrm{top}}^{-3}\|f\|_\infty\|h\|_\infty>0$.

(a4) At each fixed cutoff $K>s(\mathsf{d})$ the statements (a1)–(a3) remain true, with the same ϵ and k, for the functions $\mathsf{b}\mapsto S^T_{2;K,\ell,L^K\mathsf{b}}(f,h)$ and $\mathsf{b}\mapsto S^T_{3;K,\ell,L^K\mathsf{b}}(1,f,h)$ instead of ϕ and ψ.

(b) ψ does not vanish identically, its zero set is discrete in $(0,\infty)$, and ψ takes positive values inside every interval $(\mathsf{b}_1,\mathsf{b}_2)$ whose ends lie in $I(g)$ and satisfy $\mathsf{b}_2^2>2\mathsf{b}_1^2$.

The number ϵ is formed from g, ϑ, d, the radius and the choice alone, so it is one and the same at all the labels of $I(g)$; and every bound in (a1)–(a4) that carries the factor k is k times an explicit expression in ϵ and in the labels that appear in it (b, or b_1 and b_2, or $\mathsf{b}_{\mathrm{top}}$), an expression into which neither the side $\ell\in\mathfrak{L}(g)$, nor the pair in $\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ and its position, nor the cutoff $K>s(\mathsf{d})$ enters.

(4) *(Every side.)* Now let $m\in\mathbb{N}$ be arbitrary, $\ell = 2L^m$, $0<g\le\gamma_W$, $\vartheta\in(0,1)$, s an integer with $s\ge 0$ and $s\ge m_{\mathfrak{L}}(g)-m$, and $(f,h)\in\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ with $L^s\mathsf{d}\le\mathsf{d}_0(g,\vartheta)$. Then (a1)–(a3) and (b) are true on the side ℓ after three replacements: the window $I(g)$ by the dilated window $L^{-s}I(g) = \{L^{-s}\lambda:\lambda\in I(g)\}$, the number ϵ by $\bar\varepsilon_{g,\vartheta}(L^s\mathsf{d})$, and $\mathsf{b}_{\mathrm{top}}$ by $L^{-s}\mathsf{b}_{\mathrm{top}}$. ∎

Proof. Step 1. For a tuple Y with empty intersection of the supports, Theorem YM3_I:AS gives the real limits, including along moving labels by YM3_I:(2216). Proposition 18.161 gives

$\partial_{\mathsf{b}}^{\nu} S_n^{\ell,\mathsf{b}}(Y) = (-1)^{\nu} S_{n+\nu}^{\ell,\mathsf{b}}(1^{\nu}, Y)$ on every side. At a single cutoff the same identity follows by differentiating the logarithmic source generating function with weight $e^{-\mathsf{b}\mathcal{O}(1)}$. In particular $\phi' = -\psi$.

Step 2. For $g_s = (L^s\mathsf{b}_+/2)^{-1/2}$ the least side of $\mathfrak{L}(g_s)$ grows at most polynomially in s, by the formula for $m_{\mathfrak{L}}$ in Proposition YM3_I:74.1 and $R(x) \le L\max\{1, (\log x)^r\}$. Thus for all sufficiently large s the side $\ell_s = L^s\ell$ belongs to $\mathfrak{L}(g_s)$ and $L^s\mathsf{b}_- \ge 2\gamma^{-2}$. The bijective dilation preserves the separated pair, so $X^{(s)}$ is a tuple on ℓ_s.

Step 3. Proposition 18.161 gives holomorphic convergence of the cutoff cumulants of $X^{(s)}$ on the strip of width $\upsilon([L^s\mathsf{b}_-, L^s\mathsf{b}_+], \ell_s)$, with the torus limit $S_n^{\ell_s,x}(X^{(s)})$ on its real interval. The width is independent of the tuple and of n.

Step 4: back to the side ℓ; clause (1). The map $\mathsf{b} \mapsto L^s\mathsf{b}$ carries the strip of width υ_s about $[\mathsf{b}_-, \mathsf{b}_+]$ onto $\Omega_\upsilon(\mathsf{J})$, so $\Phi(\mathsf{b}) = L^{sn}F_\infty(L^s\mathsf{b})$ is holomorphic on that strip, and for $\mathsf{b} \in [\mathsf{b}_-, \mathsf{b}_+]$ the scaling law YM3_I:(2215) gives $\Phi(\mathsf{b}) = L^{sn}S_n^{L^s\ell, L^s\mathsf{b}}(X^{(s)}) = S_n^{\ell,\mathsf{b}}(X) = \varphi(\mathsf{b})$. Every $a > 0$ is an inner point of $[\frac{1}{2}a, 2a]$; at $\mathsf{b}_\pm = 2^{\pm 1}a$ the function Φ is holomorphic on a disc about a on whose real points it is φ, so φ is the sum of a convergent power series near a.

Step 5: clause (2). If the zeros of a real-analytic function on an interval accumulate at a point of the interval, the function is 0 near that point (identity theorem), and then on the whole interval, which is connected; and a compact interval cannot contain infinitely many zeros without containing one of their accumulation points (Bolzano–Weierstrass). If all the derivatives $\varphi^{(\nu)}(\mathsf{b})$, $\nu \ge 1$, vanished at one $\mathsf{b} > 0$, the power series of φ at b would be constant, $\varphi - \varphi(\mathsf{b})$ would vanish near b, and so on all of $(0, \infty)$. Step 1 identifies $\varphi^{(\nu)}(\mathsf{b})$.

Step 6: clause (3), (a1). Let $\mathsf{b} \in I(g)$. For every $K \in \mathbb{N}$ the pair $(K, L^K\mathsf{b})$ is a first-passage datum at g with the label b by Corollary YM3_I:74.2. The law of two points on the torus of every side at g, Theorem YM3_I:AV, read at this datum for every $K > s(\mathsf{d})$, gives $S^T_{2;K,\ell,L^K\mathsf{b}}(f,h) = \mathsf{c}_2\mathsf{b}^{-2}\mathcal{K}_6(f,h)(1+\varepsilon')$ with $|\varepsilon'| \le \epsilon \le \frac{1}{3}$. The witness depth involves no cutoff, so this holds for all large K; by Step 1 the left member tends to $\phi(\mathsf{b})$, and non-strict inequalities survive the limit. Analyticity of ϕ and ψ is clause (1) for the tuples (f,h) and $(1,f,h)$, which have a separated pair.

Step 7: (a2), (a3). Integrating $\phi' = -\psi$ from b_1 to b_2 and subtracting $\int_{\mathsf{b}_1}^{\mathsf{b}_2} 2\mathsf{k}\mathsf{b}^{-3} = \mathsf{k}(\mathsf{b}_1^{-2} - \mathsf{b}_2^{-2})$ shows that the first quantity in (a2) equals $[\phi(\mathsf{b}_1) - \mathsf{k}\mathsf{b}_1^{-2}] - [\phi(\mathsf{b}_2) - \mathsf{k}\mathsf{b}_2^{-2}]$; since $\frac{d}{d\mathsf{b}}(\mathsf{b}^2\phi) = -\mathsf{b}(\mathsf{b}\psi - 2\phi)$, the second equals $[\mathsf{b}_1^2\phi(\mathsf{b}_1) - \mathsf{k}] - [\mathsf{b}_2^2\phi(\mathsf{b}_2) - \mathsf{k}]$; and (a1) controls each bracket. By the mean value theorem $(\phi(\mathsf{b}_1) - \phi(\mathsf{b}_2))/(\mathsf{b}_2 - \mathsf{b}_1)$ is a value $\psi(\mathsf{b}'')$ with b'' between the two labels, and (a1) at b_1 and b_2 gives the two bounds of (a3); the lower bound is > 0 exactly when $(1-\epsilon)\mathsf{b}_2^2 > (1+\epsilon)\mathsf{b}_1^2$, which follows from $\mathsf{b}_2^2 > 2\mathsf{b}_1^2$, as $\frac{1+\epsilon}{1-\epsilon} \le 2$ for $\epsilon \le \frac{1}{3}$. The right end of $I(g)$ divided by the left end equals $L - 2\bar{B}/(g^{-2} + \bar{B}) > L - 2 \ge 11$; hence $\frac{1}{2}\mathsf{b}_{\mathrm{top}}$ exceeds $g^{-2} + \bar{B}$ and belongs to $I(g)$. For $\mathsf{b}_2 = \mathsf{b}_{\mathrm{top}} = 2\mathsf{b}_1$ the lower bound is $2(3 - 5\epsilon)\mathsf{k}\mathsf{b}_{\mathrm{top}}^{-3} \ge \frac{8}{3}\mathsf{k}\mathsf{b}_{\mathrm{top}}^{-3}$, and the lower bound for $\mathcal{K}_6$ in Definition 18.140(3) completes (a3).

Step 8: (a4), (b). At one cutoff $K > s(\mathsf{d})$ both ingredients of Step 7 are available for all $\mathsf{b} \in I(g)$, with the same ϵ: the derivative identity of Step 1 and the law of Step 6 at the datum $(K, L^K\mathsf{b})$; Step 7 uses nothing beyond them. (b): ψ is real-analytic by clause (1) and positive somewhere by (a3), so clause (2) applies, and the last assertion is a restatement of (a3).

Step 9: clause (4). As $m + s \ge m_{\mathfrak{L}}(g)$, the side $L^s\ell = 2L^{m+s}$ belongs to $\mathfrak{L}(g)$ by Proposition YM3_I:74.1. The dilation maps the test pair to scale $L^s\mathsf{d}$ and preserves $\mathcal{K}_6$ by homogeneity, as shown in §18.4. Also $1^{(s)} = 1$. Clause (3) therefore applies on the side $L^s\ell$ to the dilated pair at the scale $L^s\mathsf{d}$; call its two functions ϕ_s, ψ_s. The scaling law YM3_I:(2215) gives $\phi(\mathsf{b}) = L^{2s}\phi_s(L^s\mathsf{b})$ and $\psi(\mathsf{b}) = L^{3s}\psi_s(L^s\mathsf{b})$; as $L^{2s}(L^s\mathsf{b})^{-2} = \mathsf{b}^{-2}$, multiplying (a1) for ϕ_s at the label $L^s\mathsf{b} \in I(g)$ by L^{2s} yields (a1) for ϕ at $\mathsf{b} \in L^{-s}I(g)$. The arguments of Steps 7, 8 use only (a1), the derivative identity and the ratio of the two ends of the window, and this ratio is the same for $L^{-s}I(g)$ as for $I(g)$. □

Proposition 18.142 (At every label a higher connected function does not vanish; a law of three points gives a positive third connected function)**.** Work in a setting $\mathfrak{s}$. Let $m \in \mathbb{N}$, $\ell = 2L^m$ and $\vartheta \in (0,1)$.

(1) Given a real label $\mathsf{b}_1 > 0$, there is $\mathsf{d}_1 > 0$, depending on the setting, ℓ, b_1 and ϑ only, with the following property: whenever $0 < \mathsf{d} \le \mathsf{d}_1$ and $(f,h) \in \mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$,

$$S_2^{\ell,\mathsf{b}_1}(f,h) \;\ge\; \tfrac{2}{3}\,\mathsf{c}_2\mathsf{b}_1^{-2}\mathcal{K}_6(f,h) \;>\; \tfrac{1}{3}\,\mathsf{c}_2\mathsf{b}_1^{-2}\mathcal{K}_6(f,h) \;\ge\; S_2^{\ell,2\mathsf{b}_1}(f,h) \;>\; 0.$$

For $\vartheta \le \pi/13440$ and $36\,\mathsf{d} < \ell$ the class $\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ contains pairs.

(2) For a pair (f,h) as in (1), every label $\mathsf{b} > 0$ admits some $\nu \ge 1$ with $S_{2+\nu}^{\ell,\mathsf{b}}(1^\nu,f,h) \neq 0$. Moreover $\mathsf{b} \mapsto S_3^{\ell,\mathsf{b}}(1,f,h)$ is real-analytic on $(0,\infty)$, takes a positive value somewhere in $(\mathsf{b}_1, 2\mathsf{b}_1)$, and has a discrete set of zeros in $(0,\infty)$.

(3) *(From a law of three points.)* Let $0 < g \le \gamma$, $\ell' \in \mathfrak{L}(g)$ and $\vartheta = \pi/13440$. Suppose that there are a number $\mathsf{d}_3 > 0$ with $36\,\mathsf{d}_3 < \ell'$, a function $\epsilon_3\colon (0,\mathsf{d}_3] \to [0,\infty)$ with $\epsilon_3(\mathsf{d}) \to 0$ as $\mathsf{d} \to 0$, a number $C_3 \ge 0$ and integers $s_3(\mathsf{d})$, formed with no cutoff, such that for every first-passage datum $(K,\beta) \in \mathfrak{d}(g)$, with the label $\mathsf{b}' = a_K\beta$, every $\mathsf{d} \in (0,\mathsf{d}_3]$ with $K \ge s_3(\mathsf{d})$ and every $(f_1,f_2,f_3) \in \mathfrak{Q}^{(3)}_{T_{\ell'}}(\mathsf{d};\vartheta)$

$$\left|S^T_{3;K,\ell',\beta}(f_1,f_2,f_3) - 3\,\mathsf{b}'^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}(f_1,f_2,f_3)\right| \;\le\; \left[\epsilon_3(\mathsf{d}) + C_3\frac{a_K}{\vartheta\,\mathsf{d}}\right] 3\,\mathsf{b}'^{-3}\prod_{i=1}^{3}\|f_i\|_\infty.$$

Let $\mathsf{d}_* \in (0,\mathsf{d}_3]$ be such that $\epsilon_3(\mathsf{d}) < c_3^{\mathrm{col}}\vartheta^3$ for $0 < \mathsf{d} \le \mathsf{d}_*$. Then for every sequence $(K_j,\beta_j)_j$ of first-passage data at g with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}' \in (0,\infty)$, and for every $\mathsf{d}' \in (0,\mathsf{d}_*]$,

$$\lim_{j\to\infty} S^T_{3;K_j,\ell',\beta_j}(X^{\ell'}_{\mathsf{d}'}) = S_3^{\ell',\mathsf{b}'}(X^{\ell'}_{\mathsf{d}'}) \;\ge\; (c_3^{\mathrm{col}}\vartheta^3 - \epsilon_3(\mathsf{d}'))\,3\,\mathsf{b}'^{-3} \;>\; 0.$$

■

Proof. Clause (1). Put $\mathsf{b}_2 = 2\mathsf{b}_1$, and take an integer $s \ge 0$ with $L^s\mathsf{b}_1 \ge 2\gamma_W^{-2}$ and $\ell_s = 2L^{m+s} \in \mathfrak{L}(g'')$, $g'' = (L^s\mathsf{b}_2/2)^{-1/2}$; all large s are such, as in Step 2 of the proof of Proposition 18.141. Put $g' = (L^s\mathsf{b}_1/2)^{-1/2}$; then $g'' \le g' \le \gamma_W$, and $\ell_s \in \mathfrak{L}(g'') \subset \mathfrak{L}(g')$ by monotonicity of the least side in Proposition YM3_I:74.1. The labels $x_i = L^s\mathsf{b}_i$ satisfy $x_i \ge 2\gamma^{-2} > 2\bar{B}$. With $g_i^{-2} = x_i/2$, this gives $x_i > g_i^{-2} + \bar{B}$ and $x_i \le L(g_i^{-2} + \bar{B}) - 2\bar{B}$, hence $x_i \in I(g_i)$. Corollary YM3_I:74.2 gives the first-passage data $(K, L^K x_i)$ at $g_1 = g'$ and $g_2 = g''$ for every $K \in \mathbb{N}$. Put $\mathsf{d}_1 = L^{-s}\min\{\mathsf{d}_0(g',\vartheta), \mathsf{d}_0(g'',\vartheta)\}$, let $0 < \mathsf{d} \le \mathsf{d}_1$ and $(f,h) \in \mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$. By dilation, $(f^{(s)},h^{(s)}) \in \mathfrak{T}_{T_{\ell_s}}(L^s\mathsf{d};\vartheta)$ with the same $\mathcal{K}_6 =: \mathcal{K} > 0$. Theorem YM3_I:AV, at g' and at g'', for all K above the two witness depths, gives $S^T_{2;K,\ell_s,L^K x_1}(f^{(s)},h^{(s)}) \ge \frac{2}{3}\mathsf{c}_2 x_1^{-2}\mathcal{K}$ and $\frac{2}{3}\mathsf{c}_2 x_2^{-2}\mathcal{K} \le S^T_{2;K,\ell_s,L^K x_2}(f^{(s)},h^{(s)}) \le \frac{4}{3}\mathsf{c}_2 x_2^{-2}\mathcal{K} = \frac{1}{3}\mathsf{c}_2 x_1^{-2}\mathcal{K}$. Let $K \to \infty$ (Theorem YM3_I:AS) and return to the side ℓ by YM3_I:(2215), with $L^{2s}x_i^{-2} = \mathsf{b}_i^{-2}$. Not empty: the first two entries of X^ℓ_{d} form a pair of $\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ (Definition 18.140(5)).

Clause (2). The pairs (f,h) and the triples $(1,f,h)$ are tuples with a separated pair; by Proposition 18.141(1) the functions $\phi = S_2^\cdot(f,h)$ and $\psi = S_3^\cdot(1,f,h) = -\phi'$ are real-analytic on $(0,\infty)$. By (1), $\phi(\mathsf{b}_1) > \phi(2\mathsf{b}_1)$: ϕ is not constant, and Proposition 18.141(2) gives the integer ν. The mean value theorem gives $\mathsf{b} \in (\mathsf{b}_1, 2\mathsf{b}_1)$ with $\psi(\mathsf{b}) = (\phi(\mathsf{b}_1) - \phi(2\mathsf{b}_1))/\mathsf{b}_1 > 0$; so ψ is not identically 0, and Proposition 18.141(2) gives the last assertion.

Clause (3). Let $0 < \mathsf{d}' \le \mathsf{d}_*$ and $X = X^{\ell'}_{\mathsf{d}'}$; by Definition 18.140(5) it lies in $\mathfrak{T}^{(3),\mathrm{col}}_{T_{\ell'}}(\mathsf{d}';\vartheta) \subset \mathfrak{Q}^{(3)}_{T_{\ell'}}(\mathsf{d}';\vartheta)$, the product of the sup norms of its entries is 1, and $\mathcal{K}^{(3)}_{\mathrm{free}}(X) \ge c_3^{\mathrm{col}}\vartheta^3$. For all j with $K_j \ge s_3(\mathsf{d}')$ the hypothesis, read at the datum (K_j,β_j) with the label $\mathsf{b}_j = a_{K_j}\beta_j$, gives $S^T_{3;K_j,\ell',\beta_j}(X) \ge 3\mathsf{b}_j^{-3}[c_3^{\mathrm{col}}\vartheta^3 - \epsilon_3(\mathsf{d}') - C_3 a_{K_j}/(\vartheta\mathsf{d}')]$. The entries of X are real Lipschitz functions,

none of them 0, with pairwise disjoint supports, and $\beta_j > 0$; by YM3_I:(2216) the left member tends to $S_3^{\ell',\mathsf{b}'}(X)$, while $\mathsf{b}_j \to \mathsf{b}' > 0$ and $a_{K_j} \to 0$. □

Definition 18.143 (Sources, sourced means of a block field, mixed cumulants)**.** Let $K, m \in \mathbb{N}$, $\ell = 2L^m$, $\beta > 0$ and $\mathsf{b} = a_K\beta$.

(1) $\mathsf{Lp}(T_\ell)$ is the space of the complex Lipschitz functions w on T_ℓ, with the norm $\|w\|_\flat = \max\{\sup|w|, \frac{40}{\sqrt{3}} M \operatorname{Lip}_\infty w\}$, $\operatorname{Lip}_\infty$ being the Lipschitz number for the sup distance; and $\|1\|_\flat = 1$. For $r > 0$, $\mathsf{Src}(r) = \{w \in \mathsf{Lp}(T_\ell) : \|w\|_\flat < r\}$; a function on it is *holomorphic on the class* if $z \mapsto \Phi(w_0 + \sum_{i\le n} z_i f_i)$ is holomorphic on the open set where its argument lies in the class, for all n and all $w_0, f_i \in \mathsf{Lp}(T_\ell)$. For $w \in \mathsf{Lp}(T_\ell)$ we put $\mathcal{O}(w) = a_K^{-1}\sum_p w(x(p))\,a_p$.

(2) For an integer $0 \le d \le K$, a bounded complex Borel function F on V_d and $w \in \mathsf{Lp}(T_\ell)$ we put

$$N_K[F;w] = \int F(\mathcal{M}^{K-d}U)\, e^{-\beta\sum_p a_p(U) + \mathcal{O}(w)(U)}\, dU, \qquad Z_K[w] = N_K[1;w], \qquad \langle F\rangle_{K,w} = \frac{N_K[F;w]}{Z_K[w]} \quad (Z_K[w] \ne 0);$$

so $\langle F\rangle_{K,0} = \mu_d^K(F) = \int F\, d\mu_d^K$, and for a real number $\zeta < \mathsf{b}$, as $\mathcal{O}(\zeta) = \zeta L^K \sum_p a_p$, $\langle F\rangle_{K,\zeta} = \mu_d^K[\mathsf{b}-\zeta](F)$: a constant source shifts the label. Where the side and the label must be shown we write $\langle F\rangle_{K,w}^{\ell,\mathsf{b}}$, $N_K^{\ell,\mathsf{b}}$, $Z_K^{\ell,\mathsf{b}}$ and $\mu_d^K[\ell,\mathsf{b}]$, $\mu_d[\ell,\mathsf{b}]$.

(3) For complex Lipschitz $f_1, \dots, f_n$ the *mixed cumulant* $\langle F; \mathcal{O}(f_1); \dots; \mathcal{O}(f_n)\rangle_K$ is the cumulant $\mathsf{cum}(\mathcal{O}(f_1), \dots, \mathcal{O}(f_n), F\circ\mathcal{M}^{K-d})$ under the probability measure $Z_K[0]^{-1}e^{-\beta\sum_p a_p}\,dU$. Here the joint cumulant is the mixed derivative at zero of the local logarithm of the joint moment generating function.

(4) For real $\mathsf{b} > 0$ and integers $d \ge 0$ we put

$$Q_d(\ell,\mathsf{b}) = \exp\Big[(\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}} + 2 + c_{\mathrm{low}} + \tfrac{9}{2}\log(L^d\mathsf{b}))(L^d\ell)^3\Big],$$

where $\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}$ is the constant in the history estimate of Prop. YM3_I:83.2, and c_{low} is the constant in the real vacuum floor of Prop. YM3_I:74.4. The source energy constants E_0 and κ below can be fixed before the source radius and the coupling ceiling by Thm. YM3_I:AD. $Q_d(\ell,\mathsf{b})$ reads (d,ℓ,b) through $L^d\ell$ and $L^d\mathsf{b}$ alone: $Q_{d-s}(L^s\ell, L^s\mathsf{b}) = Q_d(\ell,\mathsf{b})$.

■

Proposition 18.144 (The laws of the block fields are real-analytic in the label; mixed cumulants with the action density, uniformly in the cutoff)**.** Work in a setting $\mathfrak{s}$, with its radius ϱ. Let $m \in \mathbb{N}$, $\ell = 2L^m$, let $d \ge 0$ be an integer, and let F be a bounded complex Borel function on V_d, gauge invariant or not.

(1) Let $\mathsf{b} \ge \gamma^{-2}$ with $M\,R(\mathsf{b}) \le L^m$, let $K \ge d+1$, $Q_d = Q_d(\ell,\mathsf{b})$ and $r_1 = 2\varrho/(Q_d+1)$. Then $Z_K[w]$ has no zero on $\|w\|_\flat < r_1$, the sourced mean $w \mapsto \langle F\rangle_{K,w}$ is a holomorphic function on the class $\mathsf{Src}(r_1)$, and

$$|\langle F\rangle_{K,w}| \le \frac{Q_d\sup|F|}{1-\|w\|_\flat/r_1} \quad (\|w\|_\flat < r_1), \qquad |\langle F\rangle_{K,w}| \le 2Q_d\sup|F| \quad \Big(\|w\|_\flat \le \frac{\varrho}{Q_d+1}\Big).$$

(2) Under the hypotheses of (1), for each $n \ge 1$ and any complex Lipschitz $f_1, \dots, f_n$ on T_ℓ, with no condition on their supports,

$$\big|\langle F; \mathcal{O}(f_1); \dots; \mathcal{O}(f_n)\rangle_K\big| \le 2Q_d\sup|F|\Big(\frac{n(Q_d+1)}{\varrho}\Big)^n \prod_{i=1}^n \|f_i\|_\flat.$$

(3) *(Every label, every side.)* Let $\mathsf{b} > 0$, and let $s \ge 0$ be an integer with $L^s\mathsf{b} \ge \gamma^{-2}$ and $M\,R(L^s\mathsf{b}) \le L^{m+s}$; every sufficiently large integer qualifies. With $d' = \max\{d,s\}$ and $Q_{d'} = Q_{d'}(\ell,\mathsf{b})$, the statements (1) and (2) are true at (ℓ,b) for every $K \ge d'+1$ once Q_d is replaced by $Q_{d'}$ and ϱ by $L^{-s}\varrho$.

(4) *(The laws at $K=\infty$ are real-analytic in the label.)* For every $\mathsf{b}>0$, $\mu_d^K[\ell,\mathsf{b}](F)\to\mu_d[\ell,\mathsf{b}](F)$ as $K\to\infty$ along the full sequence, $\mu_d[\ell,\mathsf{b}]$ being the limit law obtained from Cor. 2.8(c) and dilation. The function $\mathsf{b}\mapsto\mu_d[\ell,\mathsf{b}](F)$ is real-analytic on $(0,\infty)$. Quantitatively, fix $\mathsf{b}_0>0$, take s, d' as in (3) at b_0, and put $\mathsf{r}=L^{-s}\varrho/(Q_{d'}(\ell,\mathsf{b}_0)+1)$. Then $\mathsf{r}\le\frac{1}{8}\mathsf{b}_0$, and there is a holomorphic function Φ on $D(\mathsf{b}_0,\mathsf{r})$ with $|\Phi|\le 2Q_{d'}(\ell,\mathsf{b}_0)\sup|F|$ that agrees with $\mathsf{b}\mapsto\mu_d[\ell,\mathsf{b}](F)$ on the real segment $(\mathsf{b}_0-\mathsf{r},\mathsf{b}_0+\mathsf{r})$; Φ is the locally uniform limit, as $K\to\infty$, of $\mathsf{b}\mapsto\langle F\rangle^{\ell,\mathsf{b}_0}_{K,\mathsf{b}_0-\mathsf{b}}$, the sourced mean at the constant complex source $\mathsf{b}_0-\mathsf{b}$.

(5) *(The derivatives.)* At each label $\mathsf{b}>0$ and for each $\nu\ge1$, the limit below exists and

$$\partial_{\mathsf{b}}^{\nu}\,\mu_d[\ell,\mathsf{b}](F)=(-1)^{\nu}\lim_{K\to\infty}\langle F;\underbrace{\mathcal{O}(1);\dots;\mathcal{O}(1)}_{\nu}\rangle_K,\qquad |\partial_{\mathsf{b}}^{\nu}\,\mu_d[\ell,\mathsf{b}](F)|\le 2Q_{d'}\sup|F|\Big(\frac{\nu L^{s}(Q_{d'}+1)}{\varrho}\Big)^{\nu},$$

the cumulants being taken at $(K,\ell,L^K\mathsf{b})$, and s, d', $Q_{d'}=Q_{d'}(\ell,\mathsf{b})$ as in (3).

(6) *(A common disc for every depth.)* Under the hypotheses of (1), let $Q_0=Q_0(\ell,\mathsf{b})$. Then $Z_K[w]$ does not vanish on $\|w\|_\flat<2\varrho/(Q_0+1)$, and on the smaller ball $\|w\|_\flat\le\varrho/(Q_0+1)$ one has $|\langle F\rangle_{K,w}|\le Q_d^3\sup|F|$. Consequently the disc $D(\mathsf{b},\varrho/(Q_0+1))$, whose radius does not involve d, carries a holomorphic extension of $\mathsf{b}'\mapsto\mu_d[\ell,\mathsf{b}'](F)$ for every depth d and every F, bounded there by $Q_d^3\sup|F|$.

(7) *(A rate.)* Let J be an interval of labels under (Tor) on the side ℓ in §2.3.1, let $\mathsf{b}\in J$ with $[\mathsf{b}-\mathsf{r},\mathsf{b}+\mathsf{r}]\subset J$, $\mathsf{r}=\varrho/(Q_d(\ell,\mathsf{b})+1)$, let C_{bf}, K_{bf} and $\mathsf{p}=2\mathfrak{p}_0+\frac12$ be the numbers of Def. 2.7(5) at J, for the cutoff comparison of §2.3.1, and let $\Sigma_K=\sum_{K'\ge K}K'^{\mathsf{p}}L^{-K'/10}$. Let $\nu\ge0$ and $0<\eta\le1$. For every integer $K\ge\max\{K_{\mathrm{bf}},1260\,d,d+1\}$ with $\mathsf{C}_{\mathrm{bf}}\ell^3\Sigma_K\le 2Q_d(\ell,\mathsf{b})$,

$$\Big|(-1)^{\nu}\langle F;\underbrace{\mathcal{O}(1);\dots;\mathcal{O}(1)}_{\nu}\rangle_K-\partial_{\mathsf{b}}^{\nu}\,\mu_d[\ell,\mathsf{b}](F)\Big|\le\big(2\mathsf{C}_{\mathrm{bf}}\ell^3\Sigma_K\big)^{1-\eta}\big(4Q_d(\ell,\mathsf{b})\big)^{\eta}\Big(\frac{4\nu^2}{\pi\eta\,\mathsf{r}}\Big)^{\nu}\sup|F|,$$

the cumulants at $(K,\ell,L^K\mathsf{b})$; at $\nu=0$ the left member is $|\mu_d^K(F)-\mu_d(F)|$.

■

Sketch. Step 1: the line of a label. At $\beta=L^K\mathsf{b}$ the prescribed sequence $u_j=L^{K-j}\mathsf{b}$ has $u_{j+1}=u_j/L$ and $u_K=\mathsf{b}\ge\gamma^{-2}$. The assumption $MR(\mathsf{b})\le L^m$ supplies the room on the torus for this line, in the setting (E) of §2.3.1. The fixed source radius and coupling ceiling are those of the sourced construction. Apply Thm. YM3_I:AJ to the prescribed sequence at $k=K-d\ge1$. Its active lattice is $\Lambda_{d,\ell}$, with $u_k=L^d\mathsf{b}$ and $\mathsf{N}=(L^d\ell)^3$ sites.

Step 2: the numerator. The sum of the sourced history measures is the pushforward of $e^{-\beta\sum_p a_p+\mathcal{O}(w)}\,dU$ by $\mathcal{M}^k$. Hence $N_K[F;w]$ is the sum of their integrals against F. Pulling F back to the free history coordinates preserves its supremum bound. Prop. YM3_I:83.2 bounds the sum of the total variations there after division by $|e^{E^w_{(k)}}|$. In particular

$$|e^{-E^w_{(k)}}N_K[F;w]|\le\sup|F|\,e^{(\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}+2)\mathsf{N}}\qquad(w\in\mathsf{Src}(2\varrho)).$$

On every finite-dimensional slice the bare integral for $N_K[F;w]$ is entire, since the integrand is entire in the source coordinates and uniformly bounded in U on compact sets of those coordinates.

Step 3: the denominator. By Prop. YM3_I:83.2, $\widetilde{Z}_k(w)=e^{-E^w_{(k)}}Z_K[w]$ is holomorphic on the class with $|\widetilde{Z}_k|\le e^{(\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}+2)\mathsf{N}}$, and by the lower bound of Prop. YM3_I:74.4, $\widetilde{Z}_k(0)\ge e^{-C_{\mathrm{low}}(L^d\mathsf{b})\mathsf{N}}>0$; so $e^{(\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}+2)\mathsf{N}}/\widetilde{Z}_k(0)\le Q_d$, and $Q_d\ge1$. The function $\widetilde{Z}_k/\widetilde{Z}_k(0)-1$ is holomorphic on the class, vanishes at 0 and has modulus at most Q_d+1; the Schwarz lemma on the disc along the complex line through 0 and w gives $|\widetilde{Z}_k(w)|\ge\widetilde{Z}_k(0)(1-\|w\|_\flat/r_1)>0$ for $\|w\|_\flat<r_1$. As $e^{-E^w_{(k)}}\ne0$, $Z_K[w]\ne0$ there.

Step 4: clause (1). For $\|w\|_\flat < r_1$, $\langle F\rangle_{K,w} = e^{-E^w_{(k)}} N_K[F;w]/\widetilde{Z}_k(w)$, and Steps 2, 3 give the first bound; at $\|w\|_\flat \le \frac12 r_1$ it is at most $2Q_d \sup|F|$. On every slice numerator and denominator are holomorphic and the denominator has no zero, so the quotient is holomorphic.

Step 5: a mixed cumulant is a derivative of a sourced mean. Let $Y_i = \mathcal{O}(f_i)$, $i \le n$, $Y_{n+1} = F \circ \mathcal{M}^{K-d}$ and $\mathsf{Z}(z) = \int \exp(\sum_{i\le n+1} z_i Y_i)\, e^{-\beta\sum_p a_p}\, dU$. By definition the mixed cumulant is $\partial_1\cdots\partial_{n+1}\operatorname{Log}(\mathsf{Z}/\mathsf{Z}(0))$ at 0, taking the derivative with the largest index first. By the chain rule $\partial_{n+1}\operatorname{Log}(\mathsf{Z}/\mathsf{Z}(0)) = \partial_{n+1}\mathsf{Z}/\mathsf{Z}$ near 0, and at the points $(z',0)$, by differentiation under the integral, $\partial_{n+1}\mathsf{Z}(z',0) = N_K[F;\sum_{i\le n} z_i f_i]$ and $\mathsf{Z}(z',0) = Z_K[\sum_{i\le n} z_i f_i]$. The derivatives $\partial_1,\dots,\partial_n$ at 0 read the slice $z_{n+1}=0$ alone. So

$$\langle F;\mathcal{O}(f_1);\dots;\mathcal{O}(f_n)\rangle_K = \partial_1\cdots\partial_n\Big[z \mapsto \langle F\rangle_{K,\sum_i z_i f_i}\Big](0).$$

Step 6: clause (2). If some f_i is 0, the function does not depend on z_i, and the derivative vanishes. Otherwise put $r_i = \varrho/((Q_d+1)\,n\,\|f_i\|_\flat)$; on the polydisc $|z_i| < r_i$ the source $\sum_i z_i f_i$ has $\|\cdot\|_\flat < \varrho/(Q_d+1)$, so by clause (1) the sourced mean is holomorphic there with modulus at most $2Q_d\sup|F|$, and Cauchy's estimate with Step 5 gives (2).

Step 7: clause (3), a relabelling. All large s have the two properties, because $R(x) \le L\max\{1,(\log x)^r\}$ (Thm. YM3_I:AD) grows at most like a power of s at $x = L^s\mathsf{b}$, while L^{m+s} grows like L^s. Let D_* be the relabelling for the dilation by L^s: it renames the factors of a finite power of SU(2), so it carries the product of the Haar measures to the product of the Haar measures; it carries the plaquettes p onto plaquettes $\mathsf{D}p$ with $a_{\mathsf{D}p}(\mathsf{D}_*U) = a_p(U)$ and $x(\mathsf{D}p) = L^s x(p)$; and it commutes with the averaging map. With $w' = L^s w^{(s)}$ the observable of w' on the lattice $(L^s\ell, K-s)$ at D_*U is $L^{K-s}\sum_p L^s w(x(p))a_p(U) = \mathcal{O}(w)(U)$, and $\beta = L^K\mathsf{b} = L^{K-s}(L^s\mathsf{b})$. So, with $F' = F\circ\mathcal{M}^{d'-d}\circ\mathsf{D}_*^{-1}$ on $\mathsf{V}_{d'-s}$ of $T_{L^s\ell}$, a bounded Borel function with $\sup|F'| \le \sup|F|$,

$$N_K^{\ell,\mathsf{b}}[F;w] = N_{K-s}^{L^s\ell,L^s\mathsf{b}}[F';L^s w^{(s)}], \qquad Z_K^{\ell,\mathsf{b}}[w] = Z_{K-s}^{L^s\ell,L^s\mathsf{b}}[L^s w^{(s)}],$$

the right members at the depth $d'-s$; and $\|L^s w^{(s)}\|_\flat = \max\{L^s\sup|w|, \frac{40}{\sqrt3} M\operatorname{Lip}_\infty w\} \le L^s\|w\|_\flat$. At $(L^s\ell, L^s\mathsf{b})$ clause (1) holds with $Q_{d'-s}(L^s\ell, L^s\mathsf{b}) = Q_{d'}(\ell,\mathsf{b})$; read through these identities it is clause (1) at (ℓ,b) for $\|w\|_\flat < L^{-s}\cdot 2\varrho/(Q_{d'}+1)$, the map $w\mapsto L^s w^{(s)}$ being linear. Step 5 at (ℓ,b) and Step 6 with the radii $L^{-s}\varrho/((Q_{d'}+1)n\|f_i\|_\flat)$ give clause (2) there.

Step 8: clause (4). Cor. 2.8(c) gives total variation convergence at admitted labels and sides. For an arbitrary positive label and side, use Step 7 at $w=0$: the deeper law on the dilated torus converges by that corollary, and total variation cannot increase under the fixed block projection and inverse dilation. for probability measures μ',μ'' and a bounded complex Borel F, $|\mu'(F)-\mu''(F)| \le 2\sup|F|\sup_E|\mu'(E)-\mu''(E)|$, first for simple F and then by uniform approximation. The source room condition in Lem. YM3_I:82.5, with $x_K = \mathsf{b}$, gives $2\varrho \le \frac12\mathsf{b}$ by taking constant sources with modulus tending to 2ϱ. Let first $\mathsf{b} \ge \gamma^{-2}$ with $M\,R(\mathsf{b}) \le L^m$, and $\mathsf{r} = \varrho/(Q_d+1) \le \frac12\varrho \le \frac18\mathsf{b}$. The functions $\phi_K(\zeta) = \langle F\rangle^{\ell,\mathsf{b}}_{K,\zeta}$, $K \ge d+1$, are holomorphic on $D(0,\mathsf{r})$ with $|\phi_K| \le 2Q_d\sup|F|$ (clause (1) at the source $\zeta\cdot 1$, $\|\zeta\cdot 1\|_\flat = |\zeta|$), and at real $\zeta\in(-\mathsf{r},\mathsf{r})$ they converge to $\mu_d[\ell,\mathsf{b}-\zeta](F)$, by Definition 18.143(2) and the first sentence. By Montel's theorem and uniqueness of analytic continuation the whole sequence converges uniformly on the compact subsets of $D(0,\mathsf{r})$ to a holomorphic ϕ with $|\phi| \le 2Q_d\sup|F|$, and $\mu_d[\ell,\mathsf{b}'](F) = \phi(\mathsf{b}-\mathsf{b}')$ for real $|\mathsf{b}'-\mathsf{b}| < \mathsf{r}$. At a general label b_0, the identities of Step 7 at $w=0$, at every $K \ge d'+1$, give $\mu_d^K[\ell,\mathsf{b}](F) = \mu_{d'-s}^{K-s}[L^s\ell, L^s\mathsf{b}](F')$ for all $\mathsf{b}>0$, so $\mu_d[\ell,\mathsf{b}](F) = \mu_{d'-s}[L^s\ell,L^s\mathsf{b}](F')$; at complex constant sources they give $\langle F\rangle^{\ell,\mathsf{b}_0}_{K,\zeta} = \langle F'\rangle^{L^s\ell,L^s\mathsf{b}_0}_{K-s,L^s\zeta}$ for $|\zeta|<\mathsf{r}$. The first case, at $(L^s\ell,L^s\mathsf{b}_0)$, the depth $d'-s$ and F', gives the clause; and $\mathsf{r} \le L^{-s}\frac12\varrho \le \frac18\mathsf{b}_0$, because $2\varrho \le \frac12 L^s\mathsf{b}_0$.

Step 9: clause (5). With ϕ_K and ϕ on $D(0,\mathsf{r})$ as in Step 8 at the label b, let $0<\mathsf{r}'<\mathsf{r}$ and $\epsilon_K = \sup_{|\zeta|\le\mathsf{r}'}|\phi_K-\phi| \to 0$. The function $(\phi_K-\phi)(z_1+\cdots+z_\nu)$ on the polydisc of the

radii r'/ν has the mixed derivative $(\phi_K-\phi)^{(\nu)}(0)$ at 0, and Cauchy's estimate bounds it by $\epsilon_K(\nu/\mathsf{r}')^\nu\to 0$. By Step 5 at $f_1=\dots=f_\nu=1$ and the chain rule, $\phi_K^{(\nu)}(0)=\langle F;\mathcal{O}(1);\dots;\mathcal{O}(1)\rangle_K$; and $\partial_{\mathsf{b}'}^\nu\phi(\mathsf{b}-\mathsf{b}')|_{\mathsf{b}'=\mathsf{b}}=(-1)^\nu\phi^{(\nu)}(0)$. The bound is clause (3) at $f_i=1$, in the limit.

Step 10: clause (6). Two facts of complex analysis are used: a holomorphic function without a zero on a disc is e^{-g} with g holomorphic there, and Harnack's inequality, $u(\zeta)\le u(0)\frac{\mathsf{r}_\circ+|\zeta|}{\mathsf{r}_\circ-|\zeta|}$ for a harmonic function $u\ge 0$ on $D(0,\mathsf{r}_\circ)$. Applied at the level K, where the depth is 0, Step 3 yields $Z_K[w]\neq 0$ for $\|w\|_\flat<\mathsf{r}_\circ=2\varrho/(Q_0+1)$; consequently $\widetilde{Z}_k$, taken at the level $k=K-d$, is free of zeros on the same set. For $0<\|w\|_\flat\le\frac12\mathsf{r}_\circ$ put $\hat w=w/\|w\|_\flat$ and $\vartheta(\zeta)=\widetilde{Z}_k(\zeta\hat w)\,e^{-(\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}+2)\mathsf{N}}$ on $D(0,\mathsf{r}_\circ)$: it is holomorphic, has no zero, $|\vartheta|\le 1$, and $Q_d^{-1}\le\vartheta(0)\le 1$ (Step 3). With $\vartheta=e^{-g}$, Harnack's inequality for $u=\operatorname{Re}g=-\log|\vartheta|\ge 0$ at $|\zeta|=\|w\|_\flat\le\frac12\mathsf{r}_\circ$ gives $|\vartheta(\zeta)|\ge\vartheta(0)^3\ge Q_d^{-3}$, and with Step 2, $|\langle F\rangle_{K,w}|\le Q_d^3\sup|F|$; at $w=0$ the bound is $\sup|F|$. For the last sentence, the functions $\phi_K(\zeta)=\langle F\rangle_{K,\zeta}^{\ell,\mathsf{b}}$ are holomorphic on $|\zeta|<\mathsf{r}_\circ$, bounded by $Q_d^3\sup|F|$ on $D(0,\frac12\mathsf{r}_\circ)$, and converge at its real points, where $\mathsf{b}-\zeta>0$ by the convergence proved in Step 8. Montel's theorem and uniqueness give the continuation, as in Step 8.

Step 11: clause (7). By Cor. 2.8 and Step 8, for K as in the clause and all real $|\zeta|<\mathsf{r}$, $|\phi_K(\zeta)-\phi(\zeta)|=|\mu_d^K[\mathsf{b}-\zeta](F)-\mu_d[\mathsf{b}-\zeta](F)|\le\epsilon_K:=2\sup|F|\,\mathsf{C}_{\mathrm{bf}}\ell^3\Sigma_K$, since $\mathsf{b}-\zeta\in J$ and $\lceil K/1260\rceil\ge d$; and $|\phi_K-\phi|\le B:=4Q_d\sup|F|$ on $D(0,\mathsf{r})$. If $F=0$ there is nothing to show; otherwise $0<\epsilon_K\le B$. The two-constants bound, Lem. YM3_I:116.2, for the function $(\phi_K-\phi)(z_1+\dots+z_\nu)$ on the polydisc of the radii r/ν, whose real points are carried into $(-\mathsf{r},\mathsf{r})$, gives $|\phi_K^{(\nu)}(0)-\phi^{(\nu)}(0)|\le\epsilon_K^{1-\eta}B^\eta(\frac{4\nu}{\pi\eta})^\nu(\frac{\nu}{\mathsf{r}})^\nu$; with Step 9 this is the clause. At $\nu=0$, $|\phi_K(0)-\phi(0)|\le\epsilon_K\le\epsilon_K^{1-\eta}B^\eta$. □

Proposition 18.145 (What diverges in the action density at coinciding points is white noise, independent of the block fields)**.** Work in a setting $\mathfrak{s}$, with its radius ϱ. Let $\kappa_{\mathcal{D}}=\log 9216$ and $S(q)=2^{12}(1-e^{\kappa_{\mathcal{D}}-q})^{-1}$ for $q>\kappa_{\mathcal{D}}$. Use the constants E_0 and $\kappa>\kappa_{\mathcal{D}}+2$ of the source energy estimate in Thm. YM3_I:AD. Put

$$C_e=\frac{2E_0\,S(\kappa)}{L^3-1},\qquad C_\Gamma=\frac{1536\,M^2E_0\,S(\kappa-1)}{L^3-1},$$

numbers formed from the constants before γ alone. Let $\mathsf{b}\ge\gamma^{-2}$ and $m\in\mathbb{N}$ with $M\,R(\mathsf{b})\le L^m$, $\ell=2L^m$, $Q_d=Q_d(\ell,\mathsf{b})$ and $r_d=\varrho/(2Q_d)$. At the cutoff K the measure is the Wilson measure at $\beta=L^K\mathsf{b}$, with the mean $\mathbb{E}_K=\mathbb{E}_{K,\mathsf{b}}$; put

$$Y_K(f)=a_K^{3/2}(\mathcal{O}(f)-\mathbb{E}_K\mathcal{O}(f)),\qquad \varsigma_K^2=a_K^3\ell^{-3}S^T_{2;K,\ell,L^K\mathsf{b}}(1,1)=a_K\ell^{-3}\operatorname{Var}_K\Big(\sum_p a_p\Big)=a_K\ell^{-3}\,\partial_\beta^2\log Z_K\ \ge 0,$$

the specific heat in physical units, $Z_K=Z_K[0]$ being read as a function of β. Test functions are real Lipschitz functions on T_ℓ, with the norm $\|f\|=\|f\|_\flat$ of Definition 18.143(1); nothing is asked of their supports.

(a) *Every cumulant grows at most like a_K^{-3}.* For all $K\ge 1$, $n\ge 1$ and all $f_1,\dots,f_n$,

$$|S^T_{n;K,\ell,L^K\mathsf{b}}(f_1,\dots,f_n)|\le n^n\Big[C_e\,\ell^3a_K^{-3}(2\varrho)^{-n}+\log 2\;r_0^{-n}\Big]\prod_{i=1}^n\|f_i\|;$$

so $a_K^{3n/2}S^T_{n;K,\ell,L^K\mathsf{b}}\to 0$ for $n\ge 3$, and $\varsigma_K^2\le\frac{C_e}{2\varrho^2}+\frac{2\log 2}{\ell^3r_0^2}\,a_K^3$.

(b) *Small sources change the law of a block field only a little.* Let $d\ge 0$, $K\ge d+1$, F a bounded complex Borel function on V_d and w a complex Lipschitz function with $\|w\|_\flat<r_d$. Then $Z_K[w]\neq 0$, $|\langle F\rangle_{K,w}|\le 2Q_d\sup|F|$ and $|\langle F\rangle_{K,w}-\mu_d^K(F)|\le\frac{4Q_d}{r_d}\sup|F|\,\|w\|_\flat$.

(c) *Gaussian behaviour at a finite cutoff, with an error term.* Let $d\ge 0$, $K\ge d+1$, F as in (b), $f_1,\dots,f_J$ test functions, $t\in\mathbb{C}^J$, $w_t=\sum_i t_if_i$ and $\Sigma_K(t)=a_K^3\sum_{i,j}t_it_jS^T_{2;K,\ell,L^K\mathsf{b}}(f_i,f_j)$. If

$a_K^{3/2}\|w_t\|_\flat \le \frac12 r_d$, then

$$\Big|\mathbb{E}_K\Big[F(V_d)\,e^{\sum_i t_i Y_K(f_i)}\Big] - \mu_d^K(F)\,e^{\frac12\Sigma_K(t)}\Big| \le \sup|F|\,e^{\frac12\operatorname{Re}\Sigma_K(t)+\epsilon_K}\Big[\frac{4Q_d}{r_d}\,a_K^{3/2}\|w_t\|_\flat + \epsilon_K\Big],$$

with $\epsilon_K = 2C_e\ell^3 a_K^{3/2}(\frac{\|w_t\|_\flat}{2\varrho})^3 + 2\log 2\; a_K^{9/2}(\frac{\|w_t\|_\flat}{r_d})^3$. This error is $O(a_K^{3/2})$ for $\sup|F|\le 1$ and t in a fixed compact subset of $\mathbb{C}^J$, with a constant independent of F and t.

(d) *A white-noise covariance; the same factor ς_K^2 serves every test function.* For all test functions f, h, $a_K^3 S^T_{2;K,\ell,L^K\mathsf{b}}(f,h) - \varsigma_K^2\int_{T_\ell} fh \to 0$ as K runs through all the integers. Quantitatively: given $\varrho'>0$, one finds an integer $i=i(\varrho')\ge 0$ and a number $r'=r'(\varrho')>0$, depending only on the constants before γ, on b, ℓ and ϱ', with

$$\Big|a_K^3 S^T_{2;K,\ell,L^K\mathsf{b}}(f,f) - \varsigma_K^2\int f^2\Big| \le C_\Gamma\,\ell^3\frac{(\operatorname{Lip}_\infty f)^2}{\varrho'^2} + \frac{4\log 2\,L^{2i}}{r'^2}(\|f^2\|+\|f\|^2)a_K^3 + \tfrac12\,\ell^3\varsigma_K^2\operatorname{Lip}_\infty(f^2)\,a_K$$

for every $K > i$.

(e) *A lower bound for the specific heat.* At each real label $\mathsf{b}>0$ and on each side $\ell = 2L^m$, $m\in\mathbb{N}$, every test function f has $\liminf_{K\to\infty} a_K^3\operatorname{Var}_K\mathcal{O}(f) \ge \frac34\mathsf{b}^{-2}\int_{T_\ell} f^2$; taking $f=1$, $\liminf_K \varsigma_K^2 \ge \frac34\mathsf{b}^{-2}$.

(f) *The limit laws.* Let $G_{ij} = \int_{T_\ell} f_i f_j$. (f1) From any infinite set of cutoffs one can extract an infinite subset $\mathcal{K}$ on which ς_K^2 has a limit $\varsigma_0^2 \in [\frac34\mathsf{b}^{-2}, \frac{C_e}{2\varrho^2}]$. On such a $\mathcal{K}$, simultaneously for all $d\ge 0$, all J and all test functions $f_1,\dots,f_J$, $\mathbb{E}_K[F(V_d)\,\phi(Y_K(f_1),\dots,Y_K(f_J))] \to \mu_d(F)\int\phi\,dN(0,\varsigma_0^2 G)$ for all bounded Borel F on V_d and all ϕ that are either bounded continuous functions or polynomials; in particular $(V_d,(Y_K(f_i))_{i\le J})$ converges in distribution to $\mu_d\otimes N(0,\varsigma_0^2 G)$. (f2) For K beyond some $K_\circ$ one has $\varsigma_K>0$, and then, without passing to a subsequence, $(V_d,(Y_K(f_i)/\varsigma_K)_i)$ converges in distribution to $\mu_d\otimes N(0,G)$, together with the moments as in (f1): after the normalisation by ς_K, the centred action density converges to a standard white noise, and in the limit this noise is independent of V_d for each d.

(g) *Shifts by constants do not make $\mathcal{O}(f)$ tight.* Let $f\neq 0$ be a test function and (c_K) any sequence of real numbers; then on no infinite set of cutoffs is the family of the laws of $\mathcal{O}(f)-c_K$ under $\mathbb{E}_K$ tight.

Here $N(0,C)$ is the centred normal law with the covariance matrix C, and $\int e^{t\cdot y}\,dN(0,C)(y) = e^{\frac12 t\cdot Ct}$ for $t\in\mathbb{C}^J$. ■

Sketch. Step 1: the source energies. Throughout this sketch, $S^T_{n;K}$ abbreviates $S^T_{n;K,\ell,L^K\mathsf{b}}$. Let $d\ge 0$, $K\ge d+1$ and $k=K-d$. Use the same prescribed line as in Step 1 of the proof of Proposition 18.144. Prop. YM3_I:83.2 gives $E^w_{(k)} = E_{(k)} + \mathcal{E}_k(w)$ with $\mathcal{E}_k(w) = \sum_{j=1}^k\sum_{X\in\mathcal{D}_j} e_j(X;w)$, where each $e_j(X;\cdot)$ is holomorphic on the class $\mathsf{Src}(2\varrho)$, vanishes at 0, is real at real sources, depends on the source through its values on $X^{\sim 1}$ alone, and obeys $|e_j(X;w)| \le 2M^3E_0\frac{\|w\|_\flat}{2\varrho}e^{-\kappa d_j(X)}$; the number $E_{(k)}$ does not depend on the source. The polymers of $\mathcal{D}_j$ are unions of cubes of the partition π_j, which has $(L^{K-j}\ell/M)^3$ cubes, and the entropy estimate in the proof of Lem. YM3_I:88.1 bounds the number of size-n domains containing a given cube by $2048\,9216^n$. The geometric sum is at most $S(\kappa')$ for $\kappa'>\kappa_{\mathcal{D}}$. So

$$\sum_{j=1}^K\sum_{X\in\mathcal{D}_j} e^{-\kappa' d_j(X)} \le \frac{S(\kappa')}{M^3}\,\ell^3\sum_{j=1}^K L^{3(K-j)} \le \frac{S(\kappa')\,\ell^3 a_K^{-3}}{M^3(L^3-1)},$$

and $|\mathcal{E}_k(w)| \le C_e\ell^3 a_K^{-3}\|w\|_\flat/(2\varrho) \le C_e\ell^3 a_K^{-3}$ on the class. As in Steps 2, 3 of the proof of Proposition 18.144, $|e^{-E^w_{(k)}}N_K[F;w]| \le Q_d\sup|F|\,\widetilde{Z}_k(0)$ on the class, and $\widetilde{Z}_k = e^{-E^w_{(k)}}Z_K$ is holomorphic

there, with $|\widetilde{Z}_k| \le Q_d \widetilde{Z}_k(0)$. As $\mathcal{E}_k(0) = 0$,

$$\frac{Z_K[w]}{Z_K[0]} = e^{\mathcal{E}_k(w)}\,\frac{\widetilde{Z}_k(w)}{\widetilde{Z}_k(0)}.$$

Step 2: the small ball. Apply the Schwarz lemma to $(\widetilde{Z}_k/\widetilde{Z}_k(0) - 1)/(Q_d + 1)$ on the disc through 0 and w. Since $Q_d \ge 1$, it gives $|\widetilde{Z}_k(w)/\widetilde{Z}_k(0) - 1| \le Q_d \|w\|_\flat/\varrho \le \frac12$ for $\|w\|_\flat \le r_d$. So $\mathsf{L}_k(w) = \mathrm{Log}(\widetilde{Z}_k(w)/\widetilde{Z}_k(0))$ is formed there, $|\mathsf{L}_k| \le \sum_{n\ge1} 2^{-n}/n = \log 2$, it is holomorphic on every slice of the ball, and it is real at real sources, since $\widetilde{Z}_k(\bar w) = \overline{\widetilde{Z}_k(w)}$ by Prop. YM3_I:83.2. With $\Xi = \mathcal{E}_k + \mathsf{L}_k$: $e^{\Xi(w)} = Z_K[w]/Z_K[0] = \mathbb{E}_K e^{\mathcal{O}(w)}$ and $\Xi(0) = 0$ for $\|w\|_\flat \le r_d$; in particular $Z_K[w] \ne 0$ there.

Step 3: clause (a). Take $d = 0$ and $k = K$. If an entry is 0, the cumulant is 0: the generating function does not depend on the corresponding variable. Otherwise $S^T_{n;K,\ell,L^K\mathsf{b}}(f_1,\dots,f_n) = \partial_z^n \log Z(0)$ for $Z(z) = Z_K[\sum_i z_i f_i]$, and any holomorphic g with $e^g = Z$ on a polydisc about 0 may be used because two local logarithms differ by a constant; by Step 2, $g(z) = \log Z(0) + \Xi(\sum_i z_i f_i)$ is one on the polydisc $|z_i| < r_0/(n\|f_i\|)$. Cauchy's estimate for $\mathcal{E}_K(\sum_i z_i f_i)$ on the polydisc of the radii $2\varrho/(n\|f_i\|)$, where it is bounded by $C_e \ell^3 a_K^{-3}$, and for $\mathsf{L}_K(\sum_i z_i f_i)$ on the radii $r_0/(n\|f_i\|)$, where it is bounded by $\log 2$, gives (a). For ς_K^2: the Taylor coefficients c_n of $\zeta \mapsto \Xi(\zeta\cdot 1)$ at 0 obey $|c_n| \le C_e \ell^3 a_K^{-3}(2\varrho)^{-n} + \log 2\, r_0^{-n}$ by Cauchy's inequalities on the discs $|\zeta| < 2\varrho$ and $|\zeta| < r_0$, as $\|\zeta\cdot 1\|_\flat = |\zeta|$; and $S^T_{2;K}(1,1) = 2c_2$ is a variance, hence ≥ 0.

Step 4: clause (b). For $\|w\|_\flat < r_d$, $\langle F\rangle_{K,w} = e^{-E^w_{(k)}} N_K[F;w]/\widetilde{Z}_k(w)$, with $|\widetilde{Z}_k(w)| \ge \frac12 \widetilde{Z}_k(0)$ by Step 2; Step 1 gives $|\langle F\rangle_{K,w}| \le 2Q_d \sup|F|$. The function $w \mapsto \langle F\rangle_{K,w} = N_K[F;w]/Z_K[w]$ is holomorphic on the class $\mathsf{Src}(r_d)$, as a quotient of two functions entire on every slice whose denominator has no zero, and its value at 0 is $\mu_d^K(F)$. Applying the Schwarz lemma to the difference from its value at zero on the complex line through w, with bound $4Q_d \sup|F|$, gives the second bound.

Step 5: clause (c). Let $w_t \ne 0$, and put $\phi(\zeta) = \Xi(\zeta w_t)$ for $|\zeta|\,\|w_t\|_\flat \le r_d$. Then $e^{\phi(\zeta)} = \mathbb{E}_K e^{\zeta\mathcal{O}(w_t)}$, so $\phi'(0) = \mathbb{E}_K\mathcal{O}(w_t)$ and $\phi''(0) = \sum_{i,j} t_i t_j S^T_{2;K}(f_i,f_j)$. By Cauchy's inequalities on the discs $|\zeta| < 2\varrho/\|w_t\|_\flat$ and $|\zeta| < r_d/\|w_t\|_\flat$ the Taylor coefficients of ϕ obey $|c_n| \le C_e\ell^3 a_K^{-3}(\|w_t\|_\flat/2\varrho)^n + \log 2\,(\|w_t\|_\flat/r_d)^n$. For $|\zeta|\,\|w_t\|_\flat \le \frac12 r_d$, where $\frac12 r_d \le \frac14\varrho$, and with $\sum_{n\ge3} x^n \le 2x^3$ for $0 \le x \le \frac12$, $\phi(\zeta) = \zeta\phi'(0) + \frac12\zeta^2\phi''(0) + \mathsf{R}_3(\zeta)$ with

$$|\mathsf{R}_3(\zeta)| \le 2C_e\ell^3 a_K^{-3}\Big(\frac{|\zeta|\,\|w_t\|_\flat}{2\varrho}\Big)^3 + 2\log 2\,\Big(\frac{|\zeta|\,\|w_t\|_\flat}{r_d}\Big)^3.$$

At $\zeta = a_K^{3/2}$ and $w = a_K^{3/2} w_t$ this gives $|\mathsf{R}_3| \le \epsilon_K$, and, $\mathcal{O}$ being linear,

$$\mathbb{E}_K\Big[F(V_d)\,e^{\sum_i t_i Y_K(f_i)}\Big] = \langle F\rangle_{K,w}\,\frac{Z_K[w]}{Z_K[0]}\,e^{-\mathbb{E}_K\mathcal{O}(w)} = \langle F\rangle_{K,w}\,e^{\frac12\Sigma_K(t)+\mathsf{R}_3}.$$

Subtracting $\mu_d^K(F)e^{\frac12\Sigma_K(t)}$ and using (b), $|e^{\mathsf{R}_3}| \le e^{\epsilon_K}$, $|e^{\mathsf{R}_3} - 1| \le \epsilon_K e^{\epsilon_K}$ and $|\mu_d^K(F)| \le \sup|F|$ gives (c); by (a), $\Sigma_K(t)$ is bounded uniformly in K for t in a compact set.

Step 6: clause (d). Both members are symmetric bilinear forms in (f,h), so $f = h$ suffices. (i) *Algebra.* Given an algebra of real-valued functions containing the constants and a symmetric real bilinear form q on it, set $\Gamma_q(u) = q(u^2,1) - q(u,u)$; a direct expansion gives $\Gamma_q(u-c) = \Gamma_q(u)$ for all constants c. With $\Gamma_K = \Gamma_{S^T_{2;K}}$, $S^T_{2;K}(f,f) = S^T_{2;K}(f^2,1) - \Gamma_K(f)$. (ii) *A larger radius on a dilated torus.* Let $\varrho' > 0$. Thm. YM3_I:AD permits the source radius ϱ' after reducing the coupling ceiling to some $\gamma' > 0$, while keeping the constants preceding the radius, in particular E_0, κ, L, M, r, fixed. Use its source assignment and the all-prefix form of the energy estimates in Prop. YM3_I:83.2. Let $i \ge 0$ be the least integer with $L^i\mathsf{b} \ge \gamma'^{-2}$ and $M\,R(L^i\mathsf{b}) \le L^{m+i}$; all large integers are such, since $R(x) < L(\log x)^r$ for $x > e$ (Thm. YM3_I:AD). For $K > i$ put $K' = K - i$, $\ell' = L^i\ell$

and $\mathsf{b}' = L^i\mathsf{b}$, so that $L^K\mathsf{b} = L^{K'}\mathsf{b}'$. Steps 1, 2 hold on the lattice (ℓ', K') at the label b' in the new setting, at the depth 0, with functions $e'_j(X;W)$, $|e'_j(X;W)| \le 2M^3E_0e^{-\kappa d_j(X)}$ for $\|W\|'_\flat < 2\varrho'$, and L' with $|\mathsf{L}'| \le \log 2$ on $\|W\|'_\flat \le r' := \varrho'/(2Q_0(\ell', \mathsf{b}'))$. By the exact dilation identity of Lem. YM3_I: 118.2, $S^T_{2;K,\ell,L^K\mathsf{b}}(u,v) = L^{2i}S^T_{2;K',\ell',L^{K'}\mathsf{b}'}(u^{(i)}, v^{(i)})$ for real Lipschitz u, v, and therefore, by Step 3 on (ℓ', K'),

$$S^T_{2;K,\ell,L^K\mathsf{b}}(u,v) = L^{2i}\Big[\sum_{j=1}^{K'}\sum_{X\in\mathcal{D}'_j} q_X(u^{(i)}, v^{(i)}) + q_\infty(u^{(i)}, v^{(i)})\Big],$$

with $q_X(u',v') = \partial_1\partial_2\big[e'_j(X; z_1u' + z_2v')\big](0)$ and $q_\infty(u',v') = \partial_1\partial_2\big[\mathsf{L}'(z_1u' + z_2v')\big](0)$. (iii) *Three properties.* Each q_X and q_∞ is a symmetric bilinear form, real at real arguments: mixed derivatives of a holomorphic function commute, the chain rule along $z(c_1u_1 + c_2u_2) + z_3v'$ gives linearity, and the functions are real at real sources. If $u' = u''$ on $X^{\sim 1}$, then $q_X(u',v') = q_X(u'',v')$, by the locality of $e'_j(X;\cdot)$. Cauchy's estimate on the polydiscs of the radii $\varrho'/\|u'\|'_\flat$, $\varrho'/\|v'\|'_\flat$, respectively $r'/(2\|u'\|'_\flat)$, $r'/(2\|v'\|'_\flat)$, gives $|q_X(u',v')| \le 2M^3E_0e^{-\kappa d_j(X)}\|u'\|'_\flat\|v'\|'_\flat/\varrho'^2$ and $|q_\infty(u',v')| \le 4\log 2\,\|u'\|'_\flat\|v'\|'_\flat/r'^2$. (iv) *One polymer.* Let $\mathsf{f} = f^{(i)}$, $\lambda = \mathrm{Lip}_\infty \mathsf{f} = L^{-i}\,\mathrm{Lip}_\infty f$, $X \in \mathcal{D}'_j$ and $\mathsf{d} = d_j(X)$. A connected set of d edges of the partition meeting all cubes of X has diameter at most d times the cube side. Every point of X is within one cube side of that set, and every point of $X^{\sim 1}$ is within one cube side of X. The cube side is at most M, so $\mathrm{diam}_\infty X^{\sim 1} \le D_X := M(\mathsf{d}+4)$. Fix $y_X \in X$, put $\mathsf{g} = \mathsf{f} - \mathsf{f}(y_X)$, $\delta = \lambda D_X$ and $\tilde{\mathsf{g}} = \max\{-\delta, \min\{\delta, \mathsf{g}\}\}$. Then $\tilde{\mathsf{g}} = \mathsf{g}$ on $X^{\sim 1}$, $\|\tilde{\mathsf{g}}\|'_\flat \le 6\lambda D_X$ and $\|\tilde{\mathsf{g}}^2\|'_\flat \le 12\lambda^2 D_X^2$, as $D_X \ge 4M$; and by (i), (iii)

$$|\Gamma_{q_X}(\mathsf{f})| = |q_X(\tilde{\mathsf{g}}^2, 1) - q_X(\tilde{\mathsf{g}}, \tilde{\mathsf{g}})| \le 2M^3E_0e^{-\kappa\mathsf{d}}\,\frac{48\,\lambda^2M^2(\mathsf{d}+4)^2}{\varrho'^2} \le 1536\,M^5E_0\,\frac{\lambda^2}{\varrho'^2}\,e^{-(\kappa-1)\mathsf{d}},$$

because $(\mathsf{d}+4)^2e^{-\mathsf{d}} \le 16$ for $\mathsf{d} \ge 0$. (v) *The sum.* The count of Step 1 on (ℓ', K') at $\kappa' = \kappa - 1 > \kappa_{\mathcal{D}}$, whose right member is the same number since $\ell'^3a_{K'}^{-3} = \ell^3a_K^{-3}$, together with $L^{2i}\lambda^2 = (\mathrm{Lip}_\infty f)^2$, the bound of q_∞, $\|\mathsf{f}\|'_\flat \le \|f\|$ and $\|\mathsf{f}^2\|'_\flat \le \|f^2\|$, gives

$$a_K^3|\Gamma_K(f)| \le C_\Gamma\,\ell^3\frac{(\mathrm{Lip}_\infty f)^2}{\varrho'^2} + \frac{4\log 2\,L^{2i}}{r'^2}(\|f^2\| + \|f\|^2)a_K^3 \qquad (K > i).$$

(vi) *The lattice symmetries.* Translations by lattice points and coordinate permutations relabel the plaquettes and bonds, preserving the Wilson measure and $\mathcal{O}(1)$. Hence $S^T_{2;K}(u \circ \mathsf{r}^{-1}, 1) = S^T_{2;K}(u, 1)$ for these isometries r. They form a finite group that acts transitively on the plaquettes and carries barycentres to barycentres, so the mean of $u \circ \mathsf{r}^{-1}$ over the group takes at every barycentre the value $\bar{u}^K = (3N_K)^{-1}\sum_p u(x(p))$, $N_K = \ell^3a_K^{-3}$; and $\mathcal{O}$ reads a function at the barycentres alone. So $a_K^3S^T_{2;K}(u,1) = \varsigma_K^2\,\ell^3\,\bar{u}^K$. (vii) *A Riemann sum.* For each orientation the barycentres form a translate of $\Lambda_{K,\ell}$, and the cubes of side a_K about them tile T_ℓ; so $|\ell^3\bar{u}^K - \int u| \le \frac{1}{2}\ell^3a_K\,\mathrm{Lip}_\infty u$. At $u = f^2$, with (i), (v) and (vi), this is the display of (d); ς_K^2 is bounded by (a). As ϱ' is arbitrary, the limit is 0.

Step 7: clause (e), at every label and on every side. Let K be so large that $\beta = L^K\mathsf{b} \ge 1$. Write $a = a_K$, $A = \sum_p a_p$, and use $\|P\|_2 = (\mathrm{tr}\,P^*P)^{1/2}$; for $V \in \mathrm{SU}(2)$, $1 - \frac{1}{2}\,\mathrm{tr}\,V = \frac{1}{4}\|V - \mathbf{1}\|_2^2$, and $a_p = 1 - \frac{1}{2}\,\mathrm{tr}\,\partial U(p)$. (i) *Half of the vertical bonds.* Let $\mathcal{B}$ be the set of the bonds $\langle x, x + ae_3\rangle$ with $(x_1 + x_2)/a$ even, a parity that is well defined because ℓ/a is even. A plaquette contains either no bond in the direction e_3 or two of them, based at sites of opposite parity, so no plaquette contains two bonds of $\mathcal{B}$; every bond lies in four plaquettes; and for $b \in \mathcal{B}$ and $p \ni b$, the trace being invariant under cyclic permutations and under inversion on $\mathrm{SU}(2)$, $\mathrm{tr}\,\partial U(p) = \mathrm{tr}(U(b)S_{p,b})$, where $S_{p,b} \in \mathrm{SU}(2)$ is a product of values of U at bonds that are not in $\mathcal{B}$. With U' the variables of the bonds outside $\mathcal{B}$, put $\mathsf{S}_b = \sum_{p\ni b} S_{p,b} = \lambda_bW_b$, with $\lambda_b \in [0,4]$ and $W_b \in \mathrm{SU}(2)$ Borel in U' ($\mathrm{SU}(2)$ is the unit sphere of the quaternions, and a sum of unit quaternions is a non-negative

multiple of one), $\mathsf{S}_b^f = \sum_{p\ni b} f(x(p))S_{p,b}$, $X_b = \frac12\operatorname{tr}(U(b)\mathsf{S}_b)$ and $\alpha_b = \sum_{p\ni b} a_p = 4 - X_b$. Then $\sum_{b\in\mathcal{B}}\alpha_b \le A$, $e^{-\beta A} = c_1(U')\prod_{b\in\mathcal{B}} e^{\beta X_b}$ and $\mathcal{O}(f) = c_2(U') - a^{-1}\sum_{b\in\mathcal{B}}\frac12\operatorname{tr}(U(b)\mathsf{S}_b^f)$. Conditionally on U' the $U(b)$, $b\in\mathcal{B}$, are independent, and the formula for the variance through conditional variances gives $\operatorname{Var}_K\mathcal{O}(f) \ge a^{-2}\sum_{b\in\mathcal{B}}\mathbb{E}_K\operatorname{Var}(\frac12\operatorname{tr}(U(b)\mathsf{S}_b^f)\mid U')$. (ii) *A single bond.* Given U', $V = U(b)W_b$ has the law $\propto e^{t\cos\theta}\,dV$, with $t = \beta\lambda_b$ and $\frac12\operatorname{tr}V = \cos\theta$, $\theta\in[0,\pi]$; under the Haar measure the angle has the density $\frac{2}{\pi}\sin^2\theta$ (Weyl's formula for SU(2)), so here it has the density $\propto \sin^2\theta\, e^{t\cos\theta}$. Let $v(t)$ be the variance of $\mathsf{X} = t(1-\cos\theta)$ under this law; X has the density $\propto [\mathsf{x}(2-\mathsf{x}/t)]^{1/2}e^{-\mathsf{x}}$ on $[0,2t]$, and dominated convergence gives $v(t)\to\frac{15}{4}-\frac94 = \frac32$, the variance of the law $\propto \mathsf{x}^{1/2}e^{-\mathsf{x}}$, as $t\to\infty$. Then $\operatorname{Var}(X_b\mid U') = \lambda_b^2\operatorname{Var}(\cos\theta\mid U') = \beta^{-2}v(\beta\lambda_b)$. As $\lambda_b\le 4$, $\alpha_b = 4-\lambda_b\cos\theta_b$ is at least $4(1-\cos\theta_b)$ where $\cos\theta_b\ge 0$ and at least 4 where $\cos\theta_b<0$; so $1-\cos\theta_b\le\alpha_b$. If $\lambda_b<1$, then $X_b<1$ and $\alpha_b>3$; so $\mathbb{P}_K(\lambda_b<1)\le\frac13\mathbb{E}_K\alpha_b$. (iii) *The variation of f inside a plaquette.* With x_b the midpoint of b and $f_b = f(x_b)$: $\frac12\operatorname{tr}(U(b)\mathsf{S}_b^f) = f_bX_b + Y_b$, $Y_b = \frac12\operatorname{tr}(U(b)R_b)$, $R_b = \sum_{p\ni b}(f(x(p))-f_b)S_{p,b}$, $\|R_b\|_2\le 2\sqrt2\,a\operatorname{Lip}_\infty f$, since $|x(p)-x_b|_\infty = \frac{a}{2}$. The conditional variance is at most the conditional mean square distance from the function $\frac12\operatorname{tr}(W_b^{-1}R_b)$ of U'; as $U(b)-W_b^{-1} = (V-\mathbf{1})W_b^{-1}$ and $|\frac12\operatorname{tr}(PQ)|\le\frac12\|P\|_2\|Q\|_2$, $\operatorname{Var}(Y_b\mid U')\le 8a^2(\operatorname{Lip}_\infty f)^2\,\mathbb{E}(1-\cos\theta_b\mid U')$. With $\operatorname{Var}(A'+B')\ge(1-\epsilon)\operatorname{Var}A' - \epsilon^{-1}\operatorname{Var}B'$ for $0<\epsilon<1$: $\operatorname{Var}(f_bX_b+Y_b\mid U')\ge(1-\epsilon)f_b^2\beta^{-2}v(\beta\lambda_b) - 8\epsilon^{-1}a^2(\operatorname{Lip}_\infty f)^2\,\mathbb{E}(1-\cos\theta_b\mid U')$. (iv) *A bound on the mean action.* The function $\beta'\mapsto\log\int e^{-\beta' A}\,dU$ is convex, vanishes at 0 and has the derivative $-\langle A\rangle_{\beta'}$, so $\beta\langle A\rangle_\beta\le -\log\int e^{-\beta A}\,dU$. On the set where $\|U(b)-\mathbf{1}\|_2\le\beta^{-1/2}$ for all $3N_K$ bonds, every $a_p\le 4/\beta$, so $A\le 12N_K/\beta$; and by Weyl's formula, $\sin\theta\ge 2\theta/\pi$ and $1-\cos\theta\le\theta^2/2$, each factor of this set has the Haar measure at least $\frac{4}{3\sqrt2\pi^3}\beta^{-3/2}\ge e^{-3.5}\beta^{-3/2}$. Hence $\beta\langle A\rangle_\beta\le N_K(22.5+\frac92\log\beta)$, and $\eta_K = a^3\mathbb{E}_KA\le\ell^3\frac{a}{\mathsf{b}}(22.5+\frac92\log(L^K\mathsf{b}))\to 0$. (v) *Conclusion.* Given ϵ, let t_ϵ be such that $v\ge\frac32-\epsilon$ on $[t_\epsilon,\infty)$. For $\beta\ge t_\epsilon$, using $v\ge 0$, $a\beta^{-2} = a^3\mathsf{b}^{-2}$ and (ii)–(iv),

$$a^3\operatorname{Var}_K\mathcal{O}(f)\ge(1-\epsilon)(\tfrac32-\epsilon)\mathsf{b}^{-2}\Big[a^3\sum_{b\in\mathcal{B}}f_b^2 - \tfrac13\sup f^2\,\eta_K\Big] - 8\epsilon^{-1}(\operatorname{Lip}_\infty f)^2\,\eta_K,$$

and $|2a^3\sum_{b\in\mathcal{B}}f_b^2 - \int f^2|\le\ell^3a\operatorname{Lip}_\infty(f^2)$, the cells made of the two cubes of side a about x_b and x_b+ae_1 tiling T_ℓ. Let $K\to\infty$ and then $\epsilon\to 0$. At $f=1$, $a^3\operatorname{Var}_K\mathcal{O}(1) = \ell^3\varsigma_K^2$.

Step 8: clause (f). By (a) the numbers ς_K^2 are bounded, so every infinite set of cutoffs holds a $\mathcal{K}$ along which they converge; the limit lies in the stated interval by (a) and (e). Along $\mathcal{K}$, by (d), $\Sigma_K(t)\to\varsigma_0^2\,t\cdot Gt$ uniformly for t in compact sets; by Cor. 2.8(c), $\mu_d^K(F)\to\mu_d(F)$; with (c), $\Psi_K(t) = \mathbb{E}_K[F(V_d)e^{t\cdot Y_K}]\to\mu_d(F)e^{\frac12\varsigma_0^2t\cdot Gt}$ uniformly on the compact subsets of $\mathbb{C}^J$. The functions Ψ_K are entire, the variables being bounded at each cutoff, and Cauchy's estimate, applied to Ψ_K minus its limit on a polydisc, carries this to all the mixed moments $\mathbb{E}_K[F(V_d)\prod_i Y_K(f_i)^{\nu_i}]$; this is the case of polynomials. For $\psi\in C_c^\infty(\mathbb{R}^J)$, Fourier inversion and Fubini's theorem give $\mathbb{E}_K[F(V_d)\psi(Y_K)] = \int\hat\psi(\tau)\Psi_K(i\tau)\,d\tau$, with $\hat\psi$ integrable and the normalisation of the Fourier transform for which this is the inversion formula, and dominated convergence, with $|\Psi_K(i\tau)|\le\sup|F|$, gives the limit $\mu_d(F)\int\psi\,dN(0,\varsigma_0^2G)$. For a bounded continuous ϕ, Chebyshev's inequality with the second moments bounded by (a) cuts off the large values, and on a ball ϕ is a uniform limit of such ψ; for a bounded continuous function of the pair, its uniform continuity on the compact set $\mathsf{V}_d\times\{|y|\le\mathsf{R}\}$ reduces it to finite sums of products of indicators of Borel sets of V_d and continuous functions of y. (f2): by (e) there is $K_\circ$ with $\varsigma_K^2\ge\frac12\mathsf{b}^{-2}$ for $K\ge K_\circ$; (c) read at t/ς_K and (d) divided by ς_K^2 give the same convergence of the generating functions along the full sequence, with 1 in the place of ς_0^2, and the rest of the argument is unchanged.

Step 9: clause (g). Suppose that the laws of $\mathcal{O}(f)-c_K$ are tight along an infinite set of cutoffs; pass to a subset $\mathcal{K}$ as in (f1), and put $\sigma^2 = \varsigma_0^2\int f^2$, which is positive by (e) since f is continuous and not 0. Then $Y_K(f) = a_K^{3/2}(\mathcal{O}(f)-c_K) + s_K$ with real numbers s_K, and the first summand

tends to 0 in probability; so $|\mathbb{E}_K e^{i\tau Y_K(f)}| \to 1$, while by (f1) at $d=0$, $F=1$, the mean tends to $e^{-\frac{1}{2}\sigma^2\tau^2} < 1$ for $\tau \neq 0$. □

Definition 18.146 (Kernels; the laws of two neighbouring depths; composed kernels; the two symmetries)**.** Let W and Y be compact metrisable spaces; finite and countable products of copies of SU(2), including $\mathsf{V}_d = \mathcal{V}(\Lambda_{d,\ell})$ and $\mathsf{V} = \prod_{d\geq 0} \mathsf{V}_d$, are such spaces.

(1) A *kernel* from W to Y is a function $\kappa(W, E)$ of the points $W \in \mathsf{W}$ and of the Borel sets $E \subset \mathsf{Y}$ such that $\kappa(W, \cdot)$ is a Borel probability measure for every W and $\kappa(\cdot, E)$ is a Borel function for every E. For a bounded Borel function F on $\mathsf{W}\times\mathsf{Y}$ we put $(\kappa F)(W) = \int F(W,V)\,\kappa(W, dV)$; for a Borel probability measure μ on W, $\mu\otimes\kappa$ is the measure $B \mapsto \int \kappa(W, B_W)\,\mu(dW)$ on $\mathsf{W}\times\mathsf{Y}$, where $B_W = \{V : (W,V) \in B\}$. If P is a Borel probability measure on $\mathsf{W}\times\mathsf{Y}$ with the first marginal μ, a *kernel of* P is a kernel κ with $P = \mu\otimes\kappa$: it gives the distribution of the second coordinate when the first one is known. For two Borel probability measures on one space, $\|\lambda - \lambda'\| = \sup_E |\lambda(E) - \lambda'(E)|$, the supremum over the Borel sets.

(2) Let $m \in \mathbb{N}$, $\ell = 2L^m$, $\mathsf{b} > 0$ and $d \geq 0$. The averaging map $\mathcal{M}\colon \mathsf{V}_{d+1} \to \mathsf{V}_d$ is the Borel block map of Prop. YM3_I:4.5; the cutoff and the level enter its definition only through the two lattices $\mathbb{T}^{(k)} = \Lambda_{d+1,\ell}$ and $\mathbb{T}^{(k+1)} = \Lambda_{d,\ell}$, so it is one map at all the cutoffs $K \geq d+1$, and $\mathcal{M}^{K-d} = \mathcal{M}\circ\mathcal{M}^{K-d-1}$. Put $\mathrm{gr}_d(V) = (\mathcal{M}V, V)$; for $K \geq d+1$ let $P_d^K = (\mathrm{gr}_d)_*\mu_{d+1}^K$, the law under $\mathbb{E}_{K,\mathsf{b}}$ of the pair (V_d, V_{d+1}) of the block fields, and let $P_d = (\mathrm{gr}_d)_*\mu_{d+1}$, with the limit laws of Proposition 18.144(4). Their first marginals are $\mathcal{M}_*\mu_{d+1}^K = \mu_d^K$ and $\mathcal{M}_*\mu_{d+1} = \mu_d$. Where the side and the label must be shown we write $\mu_d[\ell, \mathsf{b}]$, $P_d[\ell, \mathsf{b}]$ and $\kappa_d[\ell, \mathsf{b}]$.

(3) For $0 \leq d < D$ and kernels κ_j from V_j to V_{j+1}, $d \leq j < D$, the *composed kernel* is

$$\kappa_{d\to D}(W, E) = \int \kappa_d(W, dV_{d+1}) \int \kappa_{d+1}(V_{d+1}, dV_{d+2}) \cdots \int \kappa_{D-2}(V_{D-2}, dV_{D-1})\,\kappa_{D-1}(V_{D-1}, E).$$

On V, $\mathcal{F}_d$ is the σ-algebra generated by $(V_0, \dots, V_d)$, and $\iota_{d,D}(V) = (\mathcal{M}^{D-d}V, \dots, \mathcal{M}V, V)$ for $V \in \mathsf{V}_D$.

(4) A gauge transformation v of $\Lambda_{d+1,\ell}$, a map from its sites to SU(2), acts on V_{d+1} by $V \mapsto V^v$, $V^v(b) = v(b_-)V(b)v(b_+)^{-1}$, and its restriction $v|_d$ to the sites of $\Lambda_{d,\ell}$ acts on V_d; the set $\mathcal{G}_{d+1}$ of all these maps is the compact group of these transformations, with its Haar probability measure dv, and $(V^u)^v = V^{vu}$. Iso_d is the finite group induced on T_ℓ by translations through $a_d\mathbb{Z}^3$ and signed coordinate permutations, acting on fields by $(\mathsf{r}V)(b) = V(\mathsf{r}^{-1}b)$ and on gauge transformations by $(\mathsf{r}u)(x) = u(\mathsf{r}^{-1}x)$; $\mathsf{Iso}_d \subset \mathsf{Iso}_{d+1}$ since $a_d\mathbb{Z}^3 \subset a_{d+1}\mathbb{Z}^3$. For a set E of fields, E^v and $\mathsf{r}E$ are its images.

■

Proposition 18.147 (The kernels from one depth to the next at $K=\infty$; the sequence of the block fields as a Markov chain indexed by the depth)**.** Use the block laws of Proposition 18.144(4). Let $m \in \mathbb{N}$, $\ell = 2L^m$, $\mathsf{b} > 0$, and $d \geq 0$ be an integer. The laws μ_d satisfy $\mathcal{M}_*\mu_{d+1} = \mu_d$ since the identity holds at every cutoff and the limits are in total variation. Define the thread measure $\mu_{\ell,\mathsf{b}}$ on V by its finite laws $(\iota_{0,D})_*\mu_D$. These laws are consistent by the preceding identity. Kolmogorov's extension theorem gives a unique Borel probability measure with those finite laws, and the countably many identities $V_j = \mathcal{M}V_{j+1}$ then hold simultaneously almost surely.

(a) *Existence and uniqueness.* (a1) At each cutoff $K \geq d+1$ the pair law P_d^K has a kernel κ_d^K, so that $\mathbb{E}_{K,\mathsf{b}}F(V_d, V_{d+1}) = \int \mu_d^K(dW) \int \kappa_d^K(W, dV)\,F(W,V)$ whenever F is bounded and Borel on $\mathsf{V}_d \times \mathsf{V}_{d+1}$. The limit pair law P_d, which is the joint law of V_d and V_{d+1} under $\mu_{\ell,\mathsf{b}}$, has a kernel κ_d. A kernel of P_d^K is determined as a measure-valued function outside a Borel μ_d^K-null set, and a kernel of P_d outside a Borel μ_d-null set. (a2) The measure $\kappa_d(W, \cdot)$ is carried by the fibre $\mathcal{M}^{-1}\{W\}$ for all W outside a μ_d-null set, and likewise at every cutoff.

(b) *Convergence, for any kernels.* Whatever kernels κ_d^K ($K \ge d+1$) and κ_d as in (a1) are chosen, the function $\Delta_K(W) = \|\kappa_d^K(W,\cdot) - \kappa_d(W,\cdot)\|$ is Borel on V_d, takes values in $[0,1]$, and satisfies

$$\int \Delta_K \, d\mu_d = \|\mu_d \otimes \kappa_d^K - \mu_d \otimes \kappa_d\| \le \|\mu_d - \mu_d^K\| + \|\mu_{d+1}^K - \mu_{d+1}\| \le 2\,\|\mu_{d+1}^K - \mu_{d+1}\| \xrightarrow[K\to\infty]{} 0$$

as K runs through all the integers. Replacing μ_d by μ_d^K, both as the measure against which Δ_K is integrated and as the first factor of the two products, keeps the chain valid. In the other direction, $\|\mu_{d+1}^K - \mu_{d+1}\| \le \|\mu_d^K - \mu_d\| + \int \Delta_K \, d\mu_d$. When $\mathsf{b} \ge \gamma^{-2}$ and $M\,R(\mathsf{b}) \le L^m$, every $K \ge K_{\rm bf}$ with $\lceil K/1260 \rceil \ge d+1$ has

$$2\,\|\mu_{d+1}^K - \mu_{d+1}\| \le 2\,\mathsf{C}_{\rm bf}\,\ell^3 \sum_{K' \ge K} K'^{\mathsf{p}} L^{-K'/10} \le 2\,\mathsf{C}_{\rm bf}\,\Sigma_0\,\ell^3 K^{\mathsf{p}} L^{-K/10},$$

where $\mathsf{C}_{\rm bf}$, $K_{\rm bf}$ and $\mathsf{p} = 2\mathfrak{p}_0 + \frac12$ are the numbers of Def. 2.7(5) at the interval $\{\mathsf{b}\}$ and $\Sigma_0 = \sum_{j\ge0}(1+j)^{\mathsf{p}} L^{-j/10}$. (b2) Outside some Borel μ_d-null set $\mathsf{N} \subset \mathsf{V}_d$ the series $\sum_K L^{\theta K}\Delta_K(W)$ converges for every real $\theta < \frac{1}{10}$; thus at every $W \notin \mathsf{N}$, $\Delta_K(W) = o(L^{-\theta K})$ for each such θ, with no subsequence taken. (b3) For $D > d$ the composed kernels give the conditional law of V_D given V_d: $\kappa_{d\to D}^K$, built from the κ_j^K, at each cutoff $K \ge D$, and $\kappa_{d\to D}$, built from the κ_j, under $\mu_{\ell,\mathsf{b}}$; and $\int \|\kappa_{d\to D}^K(W,\cdot) - \kappa_{d\to D}(W,\cdot)\|\,\mu_d(dW) \le \|\mu_d - \mu_d^K\| + \|\mu_D^K - \mu_D\| \le 2\|\mu_D^K - \mu_D\|$.

(c) *The Markov chain.* Let κ_j be a kernel of P_j for every $j \ge 0$. (c1) Whenever $0 \le d \le D$ and F is a bounded Borel function of $(V_d,\dots,V_D)$,

$$\int F(V_d,\dots,V_D)\,d\mu_{\ell,\mathsf{b}} = \int \mu_d(dV_d) \int \kappa_d(V_d,dV_{d+1}) \cdots \int \kappa_{D-1}(V_{D-1},dV_D)\,F(V_d,\dots,V_D).$$

(c2) For $D > d$ and a bounded Borel function H on $\mathsf{V}_{d+1}\times\cdots\times\mathsf{V}_D$, the function $h(W) = \int \kappa_d(W,dV_{d+1}) \cdots \int \kappa_{D-1}(V_{D-1},dV_D)\,H$ is a bounded Borel function on V_d, and $h(V_d)$, which reads V_d alone, serves under $\mu_{\ell,\mathsf{b}}$ as the conditional expectation of $H(V_{d+1},\dots,V_D)$ with respect to $\mathcal{F}_d$, the σ-algebra of all the depths up to d. (c3) $\mu_{\ell,\mathsf{b}}$ is the only Borel probability measure on V for which (c1) holds at $d=0$ for every D: it is the Markov chain that starts with the law μ_0 and moves from the depth j to the depth $j+1$ by κ_j. (c4) Likewise at a fixed cutoff K: under $\mathbb{E}_{K,\mathsf{b}}$ the sequence $(V_0,\dots,V_K) = (\mathcal{M}^K U,\dots,\mathcal{M}U,U)$ satisfies (c1)–(c3), with the laws μ_d^K and kernels κ_d^K of P_d^K, $0 \le d \le D \le K$. Read towards smaller depths, each chain has no randomness: $V_d = \mathcal{M}V_{d+1}$ almost surely.

(d) *Covariance.* (d1) Let κ_d be a kernel of P_d, v a gauge transformation of $\Lambda_{d+1,\ell}$ and $\mathsf{r} \in \mathsf{Iso}_d$. Outside a Borel μ_d-null set of W, the identities $\kappa_d(W^{v|_d}, E^v) = \kappa_d(W,E)$ and $\kappa_d(\mathsf{r}W, \mathsf{r}E) = \kappa_d(W,E)$ are true for every Borel set $E \subset \mathsf{V}_{d+1}$. (d2) Some kernel of P_d satisfies these identities with no exceptional set: for every $W \in \mathsf{V}_d$, every v, every $\mathsf{r} \in \mathsf{Iso}_d$ and every E. Both statements carry over to the cutoffs $K \ge d+1$, with P_d^K, μ_d^K and κ_d^K.

(e) *Every label, every side; scaling.* (e1) Let $s \ge 0$ be an integer with $L^s\mathsf{b} \ge \gamma^{-2}$ and $M\,R(L^s\mathsf{b}) \le L^{m+s}$; every sufficiently large integer qualifies. Then each $K \ge d+1$ with $K - s \ge K'_{\rm bf}$ and $\lceil (K-s)/1260 \rceil \ge \max\{d+1-s, 0\}$ has

$$\int \Delta_K \, d\mu_d \le 2\,\mathsf{C}'_{\rm bf}\,\Sigma_0\,(L^s\ell)^3 (K-s)^{\mathsf{p}} L^{-(K-s)/10},$$

with $\mathsf{C}'_{\rm bf}$ and $K'_{\rm bf}$ taken from Def. 2.7(5) on the side $L^s\ell$ at the interval $\{L^s\mathsf{b}\}$; in particular (b2) is true at every label and on every side. (e2) Let $0 \le s \le d$ be integers and the kernels arbitrary, and let D_* be the relabelling of Proposition 18.144, Step 7, for the dilation by L^s. Outside a $\mu_d[\ell,\mathsf{b}]$-null set of W,

$$\kappa_d[\ell,\mathsf{b}](W,E) = \kappa_{d-s}[L^s\ell, L^s\mathsf{b}](\mathsf{D}_*W, \mathsf{D}_*E) \qquad \text{for every Borel set } E \subset \mathsf{V}_{d+1}.$$

For $s = d$ this says that each step of the chain, from the depth d to $d+1$, is, once relabelled, the first step, from the depth 0 to 1, of the chain on the side $L^d\ell$ at the label $L^d\mathsf{b}$.

■

Sketch. Step 1: kernels exist and are unique. Let P be a Borel probability measure on $\mathsf{W}\times\mathsf{Y}$ with the first marginal μ. The space $C_{\mathbb{R}}(\mathsf{Y})$ is separable; let $\mathcal{Q}$ be a countable dense subspace over $\mathbb{Q}$ that holds 1. For $g\in\mathcal{Q}$, the real measure $A\mapsto\int \mathbf{1}_A(W)g(V)\,dP$ on W is bounded by $\|g\|_\infty\mu$; let h_g be a real Radon–Nikodym density of it with respect to μ. Each of the countably many relations $h_{qg+q'g'}=qh_g+q'h_{g'}$, $|h_g|\le\|g\|_\infty$, $h_1=1$ ($q,q'\in\mathbb{Q}$) says of an integrable function that its integral over every Borel set is 0, respectively ≥ 0, so it holds off a Borel μ-null set; let N be the union of these sets. For $W\notin\mathsf{N}$ the map $g\mapsto h_g(W)$ is linear over $\mathbb{Q}$, bounded by the sup norm and equal to 1 at 1; it extends to a positive linear form on $C_{\mathbb{R}}(\mathsf{Y})$, the integral of a Borel probability measure $\kappa(W,\cdot)$ by the theorem of Riesz; for $W\in\mathsf{N}$ let $\kappa(W,\cdot)$ be the second marginal of P. The bounded Borel functions g on Y for which $W\mapsto\int g\,d\kappa(W,\cdot)$ is a Borel function and $\int\mathbf{1}_A(W)g(V)\,dP=\int_A(\int g\,d\kappa(W,\cdot))\mu(dW)$ for all Borel A form a vector space that holds $\mathcal{Q}$ and is closed under bounded pointwise limits, so it holds all of them; at $g=\mathbf{1}_E$ this is the measurability in W and $P(A\times E)=(\mu\otimes\kappa)(A\times E)$, and the products of Borel sets generate. The same argument shows that κF is a bounded Borel function for every bounded Borel F on $\mathsf{W}\times\mathsf{Y}$ and that $\int F\,d(\mu\otimes\kappa)=\int\kappa F\,d\mu$. Two kernels of P give the same integral to each $g\in\mathcal{Q}$ off a null set, hence, $\mathcal{Q}$ being dense, the same measure there.

Step 2: the distance of two kernels. For a Borel function h with values in $[0,1]$, $|\int h\,d\lambda-\int h\,d\lambda'|\le\|\lambda-\lambda'\|$, by the step functions $\frac1n\sum_{i\le n}\mathbf{1}_{\{h>i/n\}}$, which lie between $h-\frac1n$ and h. Let $g_1=0,g_2,\dots$ number the functions $\min\{\max\{g,0\},1\}$, $g\in\mathcal{Q}$. Then $\|\lambda-\lambda'\|=\sup_i(\int g_i\,d\lambda-\int g_i\,d\lambda')$ for all Borel probability measures λ,λ' on Y: for a Borel set E, approximate $\mathbf{1}_E$ in $L^1(\lambda+\lambda')$ by a continuous function, cut it off at 0 and 1, and approximate that uniformly by some g_i. Hence $\Delta(W)=\|\kappa(W,\cdot)-\kappa'(W,\cdot)\|=\sup_i(\kappa-\kappa')(1\otimes g_i)(W)$ is a Borel function. Let $A_{n,i}$, $i\le n$, be the Borel sets on which i is the first index $\le n$ at which $(\kappa-\kappa')(1\otimes g_i)$ is largest, and $F_n=\sum_{i\le n}\mathbf{1}_{A_{n,i}}\otimes g_i$, with values in $[0,1]$. By Step 1 and the first remark on $\mathsf{W}\times\mathsf{Y}$, $\int\max_{i\le n}(\kappa-\kappa')(1\otimes g_i)\,d\mu=\int F_n\,d(\mu\otimes\kappa)-\int F_n\,d(\mu\otimes\kappa')\le\|\mu\otimes\kappa-\mu\otimes\kappa'\|$, and monotone convergence gives $\int\Delta\,d\mu\le\|\mu\otimes\kappa-\mu\otimes\kappa'\|$; the reverse inequality is $|\int[\kappa(W,B_W)-\kappa'(W,B_W)]\,\mu(dW)|\le\int\Delta\,d\mu$.

Step 3: clause (b). Images under Borel maps do not raise $\|\cdot\|$, and $P_d^K(\mathsf{V}_d\times E)-P_d(\mathsf{V}_d\times E)=\mu_{d+1}^K(E)-\mu_{d+1}(E)$; so $\|P_d^K-P_d\|=\|\mu_{d+1}^K-\mu_{d+1}\|=:\epsilon_K$, and $\|\mu_d^K-\mu_d\|\le\epsilon_K$. For a Borel set $B\subset\mathsf{V}_d\times\mathsf{V}_{d+1}$ put $h=\kappa_d^K\mathbf{1}_B$, with values in $[0,1]$; as $\mu_d^K\otimes\kappa_d^K=P_d^K$ and $\mu_d\otimes\kappa_d=P_d$,

$$(\mu_d\otimes\kappa_d^K)(B)-(\mu_d\otimes\kappa_d)(B)=\Big[\int h\,d\mu_d-\int h\,d\mu_d^K\Big]+[P_d^K(B)-P_d(B)],$$

of modulus at most $\|\mu_d-\mu_d^K\|+\epsilon_K$; this uses no property of κ_d^K besides $\mu_d^K\otimes\kappa_d^K=P_d^K$, so its values on a μ_d^K-null set do not matter. With Step 2 this is the chain of (b). With $h'=\kappa_d\mathbf{1}_B$ the same computation gives the variant with μ_d^K, and $P_d^K(B)-P_d(B)=[\int h\,d\mu_d^K-\int h\,d\mu_d]+[(\mu_d\otimes\kappa_d^K)(B)-(\mu_d\otimes\kappa_d)(B)]$ gives the converse. The convergence $\epsilon_K\to0$ is Proposition 18.144(4). For the rate, $\{\mathsf{b}\}$ is an interval of labels under (Tor) on the side ℓ in §2.3.1, and Cor. 2.8 at the depth $d+1$ gives $\epsilon_K\le\mathsf{C}_{\mathrm{bf}}\ell^3\sum_{K'\ge K}K'^{\mathsf{p}}L^{-K'/10}$; as $K+j\le K(1+j)$, the sum is at most $K^{\mathsf{p}}L^{-K/10}\Sigma_0$, and $\Sigma_0<\infty$ because $(1+j)^{\mathsf{p}}L^{-j/20}$ is bounded.

Step 4: (b2). Let $\theta_n=\frac{1}{10}-\frac1n$, $n>10$. By the rate, $\sum_K L^{\theta_nK}\int\Delta_K\,d\mu_d\le2\sum_K L^{\theta_nK}\epsilon_K<\infty$, the finitely many K below the range adding finite terms; by monotone convergence $\int\sum_K L^{\theta_nK}\Delta_K\,d\mu_d<\infty$, so the series converges off a Borel null set N_n. Put $\mathsf{N}=\bigcup_n\mathsf{N}_n$; for $\theta<\frac{1}{10}$ take $\theta_n\ge\theta$. At a general label and side the same argument runs with (e1).

Step 5: clause (a). Step 1 gives the kernels and their uniqueness. Under $\mu_{\ell,\mathsf{b}}$ the law of $(V_0,\dots,V_{d+1})$ is the image of μ_{d+1} under $\iota_{0,d+1}$, so that of (V_d,V_{d+1}) is the image of μ_{d+1} under gr_d, which is P_d. (a2): the set $\mathsf{G}=\{(W,V):W=\mathcal{M}V\}$ is Borel, $\mathcal{M}$ being Borel and the diagonal closed;

its sections are the fibres $\mathcal{M}^{-1}\{W\}$, and $\mathrm{gr}_d^{-1}\mathsf{G} = \mathsf{V}_{d+1}$. So $1 = P_d(\mathsf{G}) = \int \kappa_d(W, \mathcal{M}^{-1}\{W\})\,\mu_d(dW)$, and the Borel function $1 - \kappa_d(W, \mathcal{M}^{-1}\{W\}) \geq 0$, whose integral is 0, vanishes almost everywhere; the same at the cutoff.

Step 6: clause (c) and (b3). As in Step 5, the law of $(V_d, \dots, V_D)$ under $\mu_{\ell,\mathsf{b}}$ is $(\iota_{d,D})_*\mu_D$. We show $\int F \circ \iota_{d,D}\, d\mu_D = \int \mu_d(dV_d) \int \kappa_d(V_d, dV_{d+1}) \cdots F$ by induction on D. As $\iota_{d,D+1}(V) = (\iota_{d,D}(\mathcal{M}V), V)$ and $P_D = \mu_D \otimes \kappa_D$, $\int F \circ \iota_{d,D+1}\, d\mu_{D+1} = \int \mu_D(dW) \int \kappa_D(W, dV)\, F(\iota_{d,D}(W), V)$; the inner integral is a bounded Borel function of $\iota_{d,D}(W)$, whose last entry is W, and the hypothesis of the induction applies to it. This is (c1). (c2): for $F = \Phi(V_0, \dots, V_d)H(V_{d+1}, \dots, V_D)$ the factor Φ is not integrated in the inner integrals of (c1) from the depth 0, so the iterated integral is that of $\Phi(V_0, \dots, V_d)h(V_d)$, and (c1) on the depths $0, \dots, d$ gives $\int \Phi H\, d\mu_{\ell,\mathsf{b}} = \int \Phi\, h(V_d)\, d\mu_{\ell,\mathsf{b}}$ for all bounded Borel Φ, in particular for the indicators of the sets of $\mathcal{F}_d$. (c3): a measure for which (c1) holds at $d = 0$ for all D has the images $(\iota_{0,D})_*\mu_D$ under $V \mapsto (V_0, \dots, V_D)$, so it is $\mu_{\ell,\mathsf{b}}$ since its finite laws determine it on the product Borel σ-algebra. (c4): the same induction at the cutoff K, with μ_K^K the Wilson measure and $\mathcal{M}_*\mu_{j+1}^K = \mu_j^K$. The last sentence: the threads have full measure, and at a cutoff it is the definition of the block fields. (b3): (c1) for $F = \mathbf{1}_A(V_d)\mathbf{1}_E(V_D)$ gives $\mu_D(\{V \in E : \mathcal{M}^{D-d}V \in A\}) = \int_A \kappa_{d\to D}(W, E)\,\mu_d(dW)$; $\kappa_{d\to D}$ is a kernel, measurable by Step 1 and σ-additive by monotone convergence; the same at the cutoff, and Step 3 with $\mathcal{M}^{D-d}$ in the place of $\mathcal{M}$ gives the bound.

Step 7: clause (d). (d1), gauge: $\mathcal{M}(V^v) = \mathcal{M}(V)^{v|_d}$ (Prop. YM3_I:4.5); $V \mapsto V^v$ and $W \mapsto W^{v|_d}$ are homeomorphisms, and μ_{d+1} is gauge invariant by covariance and invariance of the cutoff laws, followed by total variation convergence, so $\mu_d = \mathcal{M}_*\mu_{d+1}$ is invariant under $W \mapsto W^{v|_d}$. Put $\kappa^v(W, E) = \kappa_d(W^{v|_d}, E^v)$, a kernel (its measurability by Step 1, the map $W \mapsto W^{v|_d}$ being continuous). For Borel sets A, E,

$$\begin{aligned}(\mu_d \otimes \kappa^v)(A \times E) &= \int \mathbf{1}_{A^{v|_d}}(W')\,\kappa_d(W', E^v)\,\mu_d(dW') \\ &= \mu_{d+1}(\{V \in E^v : \mathcal{M}V \in A^{v|_d}\}) \\ &= \mu_{d+1}(\{V \in E : \mathcal{M}V \in A\}^v) = P_d(A \times E),\end{aligned}$$

so κ^v is a kernel of P_d, and Step 1 gives (d1). Isometries: $\mathsf{r} \in \mathsf{Iso}_d \subset \mathsf{Iso}_{d+1}$ acts on V_d and V_{d+1} by homeomorphisms, and $\mathcal{M}(\mathsf{r}V) = \mathsf{r}\mathcal{M}(V)$ ([7, Lem. G.1]). The Wilson measure at the cutoff K is invariant under r, which is induced by an isometry of $a_K\mathbb{Z}^3$; with $\mathcal{M}^{K-d-1}(\mathsf{r}U) = \mathsf{r}\mathcal{M}^{K-d-1}(U)$, $\mathsf{r}_*\mu_{d+1}^K = \mu_{d+1}^K$, and in the limit in total variation $\mathsf{r}_*\mu_{d+1} = \mu_{d+1}$. The computation above, with r in the place of v, gives the second equality. (d2): put $\bar\kappa(W, E) = \int_{\mathcal{G}_{d+1}} \kappa_d(W^{v|_d}, E^v)\,dv$. The integrand is $\int \kappa_d(W^{v|_d}, dV)\,\mathbf{1}_E(V^{v^{-1}})$, a bounded Borel function of (v, W) by Step 1, the maps $(v, W) \mapsto W^{v|_d}$ and $(v, V) \mapsto V^{v^{-1}}$ being continuous; so $\bar\kappa(\cdot, E)$ is Borel by Fubini's theorem, and $\bar\kappa(W, \cdot)$ is a probability measure by monotone convergence. By Fubini's theorem and (d1), $\mu_d \otimes \bar\kappa = \int dv\,(\mu_d \otimes \kappa^v) = P_d$. For every gauge transformation u and every W, $\bar\kappa(W^{u|_d}, E^u) = \int \kappa_d(W^{(vu)|_d}, E^{vu})\,dv = \bar\kappa(W, E)$, dv being invariant under $v \mapsto vu$. Next put $\bar{\bar\kappa}(W, E) = |\mathsf{Iso}_d|^{-1} \sum_{\mathsf{r}\in\mathsf{Iso}_d} \bar\kappa(\mathsf{r}W, \mathsf{r}E)$; each term is a kernel of P_d by the isometry part of (d1), so the mean is one; it is invariant under Iso_d at every W, the group acting by $\mathsf{r}(\mathsf{r}'V) = (\mathsf{r}\mathsf{r}')V$; and it keeps the gauge covariance at every W, because $\mathsf{r}(V^u) = (\mathsf{r}V)^{\mathsf{r}u}$ by the formula for the gauge action on an oriented bond and $(\mathsf{r}u)|_d = \mathsf{r}(u|_d)$, r carrying $\Lambda_{d,\ell}$ onto itself. At the cutoff K the same argument runs with μ_{d+1}^K, which is gauge invariant as the image of the gauge-invariant Wilson measure under the gauge-covariant map $\mathcal{M}^{K-d-1}$.

Step 8: clause (e). The relabelling D_* of Proposition 18.144, Step 7, for the dilation by L^s renames the factors of a finite power of SU(2), so it carries the Haar measure to the Haar measure; $a_{\mathsf{D}p}(\mathsf{D}_*U) = a_p(U)$; it commutes with $\mathcal{M}$; and $L^K\mathsf{b} = L^{K-s}(L^s\mathsf{b})$. Hence $(\mathsf{D}_*)_*\mu_j^K[\ell, \mathsf{b}] = \mu_{j-s}^{K-s}[L^s\ell, L^s\mathsf{b}]$ for $s \leq j \leq K$ and $K > s$, and D_*, a bijection, keeps $\|\cdot\|$. (e1): if $d + 1 \geq s$, $\|\mu_{d+1}^K[\ell, \mathsf{b}] - \mu_{d+1}[\ell, \mathsf{b}]\| = \|\mu_{d+1-s}^{K-s}[L^s\ell, L^s\mathsf{b}] - \mu_{d+1-s}[L^s\ell, L^s\mathsf{b}]\|$, and Cor. 2.8 on the side $L^s\ell$ at the

interval $\{L^s\mathsf{b}\}$, with the tail sum of Step 3, bounds it; if $d+1<s$, $\mu^K_{d+1}=(\mathcal{M}^{s-d-1})_*\mu^K_s$, the same holds at $K=\infty$ by consistency, and the bound at the depth s applies. With Step 3 this is (e1); that all large integers s have the two properties follows from $R(x)<L(\log x)^r$ for $x>e$ (Thm. YM3_I:AD). (e2): passing to the limit in the identity of the laws, $(\mathsf{D}_*)_*\mu_j[\ell,\mathsf{b}]=\mu_{j-s}[L^s\ell,L^s\mathsf{b}]$ for $j\ge s$. Let κ' be a kernel of $P_{d-s}[L^s\ell,L^s\mathsf{b}]$ and $\kappa''(W,E)=\kappa'(\mathsf{D}_*W,\mathsf{D}_*E)$, a kernel from V_d to V_{d+1} on T_ℓ. For Borel sets A, E, by $\mathcal{M}\mathsf{D}_*=\mathsf{D}_*\mathcal{M}$,

$$\begin{aligned}&(\mu_d[\ell,\mathsf{b}]\otimes\kappa'')(A\times E)\\&\quad=\int_{\mathsf{D}_*A}\kappa'(W',\mathsf{D}_*E)\,\mu_{d-s}[L^s\ell,L^s\mathsf{b}](dW')\\&\quad=\mu_{d+1-s}[L^s\ell,L^s\mathsf{b}](\{V'\in\mathsf{D}_*E:\mathcal{M}V'\in\mathsf{D}_*A\})\\&\quad=\mu_{d+1}[\ell,\mathsf{b}](\{V\in E:\mathcal{M}V\in A\}),\end{aligned}$$

so κ'' is a kernel of $P_d[\ell,\mathsf{b}]$, and Step 1 gives (e2). □

Proposition 18.148 (The covariance of a block function with the action density; a density in every L^p; a martingale in the depth; one half of the torus across a mirror)**.** Work in setting (E) of Definition 18.140(1) at label b and side ℓ. Use the calibration radius ϱ_ς, denoted by ϱ in the proof. Write $\mu_d=\mu_d[\ell,\mathsf{b}]$ and let $\mu_{\ell,\mathsf{b}}$ be the thread law. Use the filtration $\mathcal{F}_d$ of Definition 18.146(3) and the torus limit $S_2^{\ell,\mathsf{b}}$ of Theorem YM3_I:AS for separated pairs. For real Lipschitz f on T_ℓ, put $\|f\|_\sharp=\max\{\sup|f|,40M\operatorname{Lip}f\}$. For $K\ge\max\{d,2\}$ and bounded complex Borel F on V_d define

$$\mathsf{c}_K(F;f)=\mathbb{E}_{K,\mathsf{b}}\Big[F(V_d)\big(\mathcal{O}(f)-\mathbb{E}_{K,\mathsf{b}}\mathcal{O}(f)\big)\Big].$$

For an integer $n\ge1$ let $\alpha_n=\frac{1}{60(3n+4)}$, $\gamma_n=\frac{1}{20}-\alpha_n$, $\theta_n=1-20\alpha_n$ and $u_n(K)=\lceil K/(180(3n+4))\rceil$; so $\gamma_1=\frac{1}{21}$ and $\theta_1=\frac{20}{21}$. Let $c_0=3\mathfrak{p}_0+\frac14$ and $c_1=4\mathfrak{p}_0+\frac12$. Let $\bar K_n=\max\{K_{\rm bf},K_0\}$, where $K_{\rm bf}$ is the integer of Definition 2.7(5) and K_0 the uniform smallness threshold in Theorem YM3_I:AR at n, both at the interval $\{\mathsf{b}\}$, and let $K_*(d,n)$ be the least integer $K\ge\bar K_n$ with $u_n(K)\ge d$; $K_*(d)=K_*(d,1)$.

(a1) *The limit.* At each depth $d\ge0$ a unique finite signed Borel measure $\xi_{d,f}$ on V_d satisfies

$$\Big|\mathsf{c}_K(F;f)-\int F\,d\xi_{d,f}\Big|\le\mathsf{C}_1\,K^{c_0}L^{-K/21}\sup|F|\,\|f\|_\sharp$$

for all integers $K\ge K_*(d)$ and all bounded complex Borel F on V_d, whether gauge invariant or not; here C_1 depends on the choice, ℓ and b and on nothing else, in particular not on d, K, F or f. Moreover $\xi_{d,f}(\mathsf{V}_d)=0$, $\xi_{d,f}$ is gauge invariant and depends real linearly on f, and $\mathcal{M}_*\xi_{d+1,f}=\xi_{d,f}$.

(a2) *The density.* Given $d\ge0$, an integer $n\ge1$ and a real $\eta\in(0,\theta_n)$, one has $|\xi_{d,f}(E)|\le\mathsf{C}\|f\|_\sharp\,\mu_d(E)^{\theta_n-\eta}$ for all Borel sets $E\subset\mathsf{V}_d$, with a constant $\mathsf{C}=\mathsf{C}(d,n,\eta)$ depending only on the choice, ℓ, b, d, n and η. Hence $\xi_{d,f}$ has a density $X_d(f)$ with respect to μ_d, real and determined up to a μ_d-null set, with $\int X_d(f)\,d\mu_d=0$ and $X_d(f)\in L^p(\mu_d)$ for every $p<\infty$, $\|X_d(f)\|_{L^p(\mu_d)}\le\mathsf{C}'(d,p)\|f\|_\sharp$; and $\mathsf{c}_K(F;f)\to\int F\,X_d(f)\,d\mu_d$ for every bounded Borel F.

(a3) *The martingale.* Under $\mu_{\ell,\mathsf{b}}$ the sequence $(X_d(f)(V_d))_{d\ge0}$ is a martingale with respect to $(\mathcal{F}_d)_{d\ge0}$; its mean is 0, and each of its terms lies in $L^p(\mu_{\ell,\mathsf{b}})$ for all $p<\infty$.

(a4) *The growth in the depth.* Let $n\ge1$ be an integer and $1\le p<3(3n+4)$. Then $\|X_d(f)\|_{L^p(\mu_d)}\le\mathsf{C}_4\,(1+d)^{c_1}L^{3d}\,\|f\|_\sharp$ at every depth $d\ge0$, where C_4 depends on the choice, ℓ, b, n and p, but not on d.

(b) *Across a mirror.* Let $d_0\ge0$ be an integer, $\mu\in\{1,2,3\}$, $c\in\frac{a_{d_0}}{2}\mathbb{Z}$, θ the map of T_ℓ induced by $x\mapsto x-2(x_\mu-c)e_\mu$, $\mathbb{E}_+=\{c<x_\mu<c+\frac{\ell}{2}\}$ and $\mathbb{E}_-=\theta\mathbb{E}_+$, and let $f\ne0$ with $\operatorname{supp}f\subset\mathbb{E}_+$. For $D\ge d_0$ let $\mathcal{G}_D$ be the σ-algebra on V generated by the block variables $V_d(c')$, $d_0\le d\le D$, c' a bond of $\Lambda_{d,\ell}$ with both end points in $\mathbb{E}_-$; $\mathcal{G}_\infty=\sigma(\bigcup_D\mathcal{G}_D)$; and

$\Psi_D = \mathbb{E}_{\mu_{\ell,\mathsf{b}}}[X_D(f)(V_D) \mid \mathcal{G}_D]$. A bounded $\mathcal{G}_D$-measurable function is $H = h\big((V_d(c'))_{(d,c')}\big)$ with a bounded Borel function h; put $H^\theta = h\big((V_d(\theta c'))_{(d,c')}\big)$.

(b1) The Ψ_D, $D \ge d_0$, have mean 0 and form a martingale with respect to $(\mathcal{G}_D)$; and $\lim_K \mathbb{E}_{K,\mathsf{b}}\big[h\big(((\mathcal{M}^{K-d}U)(c'))_{(d,c')}\big)\big(\mathcal{O}(f) - \mathbb{E}_{K,\mathsf{b}}\mathcal{O}(f)\big)\big] = \int H\,\Psi_D\,d\mu_{\ell,\mathsf{b}}$.

(b2) We have $S_2^{\ell,\mathsf{b}}(f\circ\theta, f) \ge 0$ and

$$\Big|\int H\Psi_D\,d\mu_{\ell,\mathsf{b}}\Big|^2 \le \Big(\int H\,\overline{H^\theta}\,d\mu_{\ell,\mathsf{b}}\Big)\,S_2^{\ell,\mathsf{b}}(f\circ\theta, f) \le \|H\|^2_{L^2(\mu_{\ell,\mathsf{b}})}\,S_2^{\ell,\mathsf{b}}(f\circ\theta, f),$$

where the first factor in the middle is a real number ≥ 0. In particular the L^2 norms of all the Ψ_D are bounded by $S_2^{\ell,\mathsf{b}}(f\circ\theta, f)^{1/2}$.

(b3) There is a $\mathcal{G}_\infty$-measurable $\Psi_\infty(f)$, of mean 0 and with $\|\Psi_\infty(f)\|_{L^2} \le S_2^{\ell,\mathsf{b}}(f\circ\theta, f)^{1/2}$, such that $\Psi_D \to \Psi_\infty(f)$ both $\mu_{\ell,\mathsf{b}}$-almost surely and in L^2, and $\Psi_D = \mathbb{E}[\Psi_\infty(f) \mid \mathcal{G}_D]$. Among the elements of $L^2(\mathcal{G}_\infty)$ it is characterised by its integrals against the bounded $\mathcal{G}_D$-measurable H, $D \ge d_0$, which are the limits in (b1); and it depends real linearly on f within the Lipschitz functions supported in $\mathbb{E}_+$.

■

Proof. Step 1: a gauge-invariant function at a larger depth. Let $\bar F(V) = \int F(V^v)\,dv$, the mean over the gauge transformations of $\Lambda_{d,\ell}$; it is bounded, Borel and gauge invariant. For a gauge transformation v of $\Lambda_{d,\ell}$ let $\tilde v$ be the bare gauge transformation equal to v at the sites of $\Lambda_{d,\ell}$ and to $\mathbf{1}$ elsewhere; $\mathcal{M}^{K-d}(U^{\tilde v}) = (\mathcal{M}^{K-d}U)^v$ (Proposition YM3_I:4.5), the Wilson density and $\mathcal{O}(f)$ are gauge invariant, and dU is invariant under $U \mapsto U^{\tilde v}$; so $\mathsf{c}_K(F; f) = \mathsf{c}_K(F(\cdot^v); f)$, and, integrating over v, $\mathsf{c}_K(F; f) = \mathsf{c}_K(\bar F; f)$. For $d \le u \le K$, $\mathsf{c}_K(F; f)$ is also the covariance at the depth u of the function $F \circ \mathcal{M}^{u-d}$, gauge invariant when F is (Proposition YM3_I:4.5).

Step 2. Take $f \ne 0$, $n \ge 1$ and $K \ge K_0$. Use $u = u_n(K)$, $s = \lceil K/9\rceil$, and the two lattices $\mathrm{A} = (\ell, K)$, $\mathrm{B} = (\ell, K+1)$ at the common label. Use the hypotheses of the adjacent-cutoff comparison as in Theorem YM3_I:AR. Its extra spread condition concerns contact derivatives. The quotient below cancels the contact terms identically. For a mark $\bullet$ put $t^\bullet = K^\bullet - u$, and use the common source radius $r = r_1(t^{\mathrm{A}}) = (8nM^{\mathrm{rd}}_{t^{\mathrm{A}}}\|f\|_\flat)^{-1}$ from the polydisc of Lemma YM3_I:114.5, taking all n test functions equal to f and using just the first source coordinate. Use the common depth-u space and inner set $\mathsf{In}_{[u]}$ of Section YM3_I:116. Let F now be a bounded gauge-invariant function on that space, $Y_0 = F(\mathcal{M}^{t^\bullet}U)$, $Y_1 = \mathcal{O}(f)$, and $s_1^\bullet = 6\ell^3 L^{4K^\bullet}\|f\|_\infty$. The last number bounds $|Y_1|$ since $0 \le a_p \le 2$ and there are $3(\ell L^{K^\bullet})^3$ plaquettes.

For this lattice write $\Lambda_0(G) = \int G\rho_0\,dU$ and $\Lambda_1(G) = \int G\mathfrak{w}^{\mathrm{sf}}_{t^\bullet}\rho_0\,dU$. By YM3_I:(2189)–(2190), Λ_1 and $\Lambda_0 - \Lambda_1$ are positive on bounded gauge-invariant functions and the latter has mass at most $R_{t_1}\Lambda_0(1)$. In particular $\Lambda_1(1) \ge \Lambda_0(1)/2$. Write the normalized Λ_0 as the convex combination of the normalized Λ_1 and the normalized remainder, with remainder weight at most R_{t_1}. The normalized moments of any bounded G in the two expectations differ by at most $2R_{t_1}\|G\|_\infty$. Apply this to Y_0Y_1, Y_0 and Y_1, and telescope the product of the latter two means. The covariance error is at most $12R_{t_1}\sup|F|\,s_1^\bullet$.

Step 3. Put $q^\bullet(\zeta) = \Lambda_1(Y_0e^{\zeta Y_1})/\Lambda_1(e^{\zeta Y_1})$ near zero. Its derivative is the covariance for the normalized Λ_1. The exact pushforward YM3_I:(2188) and the density formula YM3_I:(2175) give

$$\Lambda_1(h(\mathcal{M}^{t^\bullet}U)e^{\zeta Y_1}) = e^{c^\bullet(\zeta)}\int_{\mathsf{In}_{[u]}} h(V)e^{\Phi^{\bullet,\zeta f}(V)}\,dV \qquad (|\zeta| < r)$$

for bounded Borel h. In the ratio $q^\bullet$ the prefactor, including the contact energies, cancels.

Step 4. The density $e^{c^\bullet(0)+\Phi^{\bullet,0}}$ is nonnegative by the pushforward identity. Put $\delta(V) = \Phi^{\bullet,\zeta f}(V) - \Phi^{\bullet,0}(V)$. By YM3_I:(2184), $|\delta| \le 1/4$ on the disc. The denominator, after the scalar prefactor is removed, differs from its zero-source value by at most $e^{1/4} - 1$ times the modulus of that value.

Thus it has no zeros. Bounding the numerator by $e^{1/4}$ times its zero-source integral with $|Y_0|$ gives

$$|q^\bullet(\zeta)| \le \frac{e^{1/4}}{2-e^{1/4}}\frac{\Lambda_1(|Y_0|)}{\Lambda_1(1)} < 1.794\frac{\Lambda_1(|Y_0|)}{\Lambda_1(1)}.$$

Step 5. For real $x \in (-r, r)$ the chain and the classical start define positive measures on $\mathsf{In}_{[u]}$. Their field-dependent exponents differ by at most ϵ_{fg} by YM3_I:(2180) and YM3_I:(2192). Up to a positive scalar, their densities differ by at most $(e^{\epsilon_{\mathrm{fg}}}-1)$ times the classical-start density. If positive measures P, Q satisfy $|(P-Q)(h)| \le \delta Q(1)\|h\|_\infty$, their normalized means differ by at most $2\delta\|h\|_\infty$, by adding and subtracting $P(h)/Q(1)$. Thus the chain and classical-start normalized values differ by at most $5\epsilon_{\mathrm{fg}} \sup|F|$.

For the two classical starts use the common space at depth s and its common map $\mathcal{M}^{s-u}$ to depth u. In the proof of Proposition YM3_I:116.1 each positive density gives mass at most ϵ_{sh} times its own mass to the set where the other density vanishes, by YM3_I:(2198). On their common positive set the gauge factors coincide and the log ratio of the starts is bounded by ϵ_{cl}. In particular the mass for B is at most twice the mass for A. Splitting the two integrals over the common set and the two exceptional sets bounds their difference, also with a multiplier $F(\mathcal{M}^{s-u}V)$, by $(2\epsilon_{\mathrm{cl}} + 3\epsilon_{\mathrm{sh}})\sup|F|$ times the mass for A. The same normalization argument gives

$$|q^{\mathrm{B}}(x) - q^{\mathrm{A}}(x)| \le \mathfrak{o}'_K \sup|F|, \qquad \mathfrak{o}'_K = 10\epsilon_{\mathrm{fg}} + 8\epsilon_{\mathrm{cl}} + 12\epsilon_{\mathrm{sh}}.$$

Step 6. The holomorphic difference on the disc is bounded by $4\sup|F|$ there and by $\mathfrak{o}'_K \sup|F|$ on the diameter. Apply Lemma YM3_I:116.2 with one variable and $\sigma = 1/2$. Use the discarding error on each lattice and Step 1 to pass to any $d \le u_n(K)$. This proves

$$\text{(P1)} \qquad |\mathsf{c}_{K+1}(F;f) - \mathsf{c}_K(F;f)| \le \sup|F|\Big[\frac{16}{\pi}(\mathfrak{o}'_K)^{1/2}r^{-1} + 144\,\ell^3 L^{4K+4}\,R_{t_1}\|f\|_\infty\Big].$$

For a Borel set $E \subset \mathsf{V}_d$, apply Step 4 to $F = \bar{\mathbf{1}}_E \circ \mathcal{M}^{u-d}$ on A. Cauchy's inequality and $\Lambda_1 \le \Lambda_0$ for nonnegative gauge-invariant functions give $|(q^{\mathrm{A}})'(0)| \le 3.6 r^{-1}\mu_d^K(E)$, using gauge invariance of μ_d^K to integrate $\bar{\mathbf{1}}_E$. The single-lattice discarding error then gives

$$\text{(P2)} \qquad |\mathsf{c}_K(\mathbf{1}_E;f)| \le 3.6\, r^{-1}\mu_d^K(E) + 72\,\ell^3 L^{4K}\,R_{t_1}\|f\|_\infty.$$

By YM3_I:(2204) and $N_{[u]} \le \ell^3 L^3 L^{\alpha_n K}$, $r^{-1} \le \mathsf{A}_1 K^{2\mathfrak{p}_0} L^{\alpha_n K}\|f\|_\sharp$. Here A_1 is formed from ℓ, b, n and the fixed constants. The bounds $4u - s \le -K/10 + 4$ and $(7s-K)/2 \le -K/9 + 7/2$ of YM3_I:(2205) in YM3_I:(2192)–(2194) imply that ϵ_{fg} and ϵ_{cl} are at most constants times $K^{\mathsf{p}}L^{-K/10}$, with $\mathsf{p} = 2\mathfrak{p}_0 + 1/2$. The majorants of ϵ_{sh} and R_{t_1} in the proof of Theorem YM3_I:AR decay faster than any exponential at fixed side and label. Hence choose $\mathsf{A}_2, \mathsf{A}_3$ independent of K, d, F, f with $\mathfrak{o}'_K \le \mathsf{A}_2 K^{\mathsf{p}} L^{-K/10}$ and $144\ell^3 L^{4K+4} R_{t_1} \le \mathsf{A}_3 L^{-K/10}$. Since $\mathsf{p}/2 + 2\mathfrak{p}_0 = c_0$, the bracket in (P1) is at most $\mathsf{A}_4 K^{c_0} L^{-\gamma_n K}\|f\|_\sharp$ with $\mathsf{A}_4 = (16/\pi)\mathsf{A}_2^{1/2}\mathsf{A}_1 + \mathsf{A}_3$. For summation use $\sum_{k\ge K} k^c L^{-\gamma k} \le K^c L^{-\gamma K}\mathsf{S}(c,\gamma)$ with $\mathsf{S}(c,\gamma) = \sum_{j\ge 0}(1+j)^c L^{-\gamma j}$, from $K + j \le K(1+j)$ for $K \ge 1$.

Step 7: clause (a1). At $f = 0$ everything vanishes. Let $f \ne 0$, $n = 1$, $K \ge K_*(d)$; every $k \ge K$ has $k \ge K_0$ and $u_1(k) \ge d$. Summing (P1) over $K \le k < K'$: $|\mathsf{c}_{K'}(F;f) - \mathsf{c}_K(F;f)| \le \mathsf{C}_1 K^{c_0} L^{-K/21}\sup|F|\|f\|_\sharp$ with $\mathsf{C}_1 = \mathsf{A}_4\mathsf{S}(c_0, \frac{1}{21})$ at $n = 1$. So $\mathsf{c}(F;f) = \lim_K \mathsf{c}_K(F;f)$ exists with the bound of (a1). Each $\xi^K(E) = \mathsf{c}_K(\mathbf{1}_E;f)$ is a finite signed measure, and $\xi_{d,f}(E) = \mathsf{c}(\mathbf{1}_E;f)$ is finitely additive and, as the limit is uniform in E, σ-additive: for Borel sets $R_N \downarrow \emptyset$ and $\eta' > 0$ take K with $\sup_E|\xi_{d,f}(E) - \xi^K(E)| \le \eta'$, and use $\xi^K(R_N) \to 0$. It is bounded, and $\int F\, d\xi_{d,f} = \mathsf{c}(F;f)$ by uniform approximation of F by simple functions. Uniqueness holds because a signed measure is determined by the integrals of indicators. The total mass vanishes because $\mathsf{c}_K(1;f) = 0$; gauge invariance comes from Step 1; linearity in f from that of $\mathcal{O}(f)$; and as $\mathcal{M}^{K-d} = \mathcal{M} \circ \mathcal{M}^{K-d-1}$, the covariance of $\mathbf{1}_{\mathcal{M}^{-1}E}$ computed at the depth $d+1$ equals that of $\mathbf{1}_E$ computed at the depth d, which gives $\mathcal{M}_*\xi_{d+1,f} = \xi_{d,f}$ in the limit.

Step 8: clause (a2). Let $f \neq 0$, $0 < \eta < \theta_n$, $K \geq K_*(d,n)$, E a Borel set and $\mu = \mu_d(E)$. As in Step 7 at n, $|\xi_{d,f}(E) - \mathsf{c}_K(\mathbf{1}_E; f)| \leq \mathsf{A}_4\mathsf{S}(c_0,\gamma_n)K^{c_0}L^{-\gamma_n K}\|f\|_\sharp$. By (P2), the bound of r^{-1} and $72\ell^3 L^{4K}R_{t_1} \leq \frac{1}{2}\mathsf{A}_3 L^{-K/10}$: $|\mathsf{c}_K(\mathbf{1}_E; f)| \leq 3.6\mathsf{A}_1 K^{2\mathfrak{p}_0}L^{\alpha_n K}\|f\|_\sharp \mu_d^K(E) + \frac{1}{2}\mathsf{A}_3 L^{-K/10}\|f\|_\sharp$. By Corollary 2.8(b), (c), eq. 2.xvii and the tail sum, as $\lceil K/1260\rceil = u_1(K) \geq u_n(K) \geq d$: $\mu_d^K(E) \leq \mu + \mathsf{C}_{\mathrm{bf}}\ell^3\mathsf{S}(\mathsf{p}, \frac{1}{10})K^{\mathsf{p}}L^{-K/10}$. With $2\mathfrak{p}_0 + \mathsf{p} = c_1 \geq c_0$ and $\alpha_n - \frac{1}{10} \leq -\gamma_n$:

$$|\xi_{d,f}(E)| \leq \mathsf{A}_5\|f\|_\sharp K^{c_1}\big[L^{\alpha_n K}\mu + L^{-\gamma_n K}\big] \qquad (K \geq K_*(d,n)),$$

$\mathsf{A}_5 = 3.6\mathsf{A}_1(1 + \mathsf{C}_{\mathrm{bf}}\ell^3\mathsf{S}(\mathsf{p}, \frac{1}{10})) + \frac{1}{2}\mathsf{A}_3 + \mathsf{A}_4\mathsf{S}(c_0,\gamma_n)$, formed without d. If $\mu = 0$, let $K \to \infty$. Let $0 < \mu \leq 1$ and $\Lambda = \log_L \frac{1}{\mu}$; the two terms are of equal size at $K = 20\Lambda$, because $\alpha_n + \gamma_n = \frac{1}{20}$. If $\lceil 20\Lambda\rceil \geq K_*$, take $K = \lceil 20\Lambda\rceil$: the bracket is at most $2L\mu^{\theta_n}$ and $K^{c_1} \leq \mathsf{a}_\eta\mu^{-\eta}$ with $\mathsf{a}_\eta = \sup_{\Lambda\geq 0}(1+20\Lambda)^{c_1}L^{-\eta\Lambda}$. Otherwise $1 \leq (L^{K_*/20}\mu)^{\theta_n}$; take $K = K_*$. So (a2) holds with $\mathsf{C} = 2\mathsf{A}_5\max\{L\mathsf{a}_\eta, K_*^{c_1}L^{K_*/20}\}$, $K_* = K_*(d,n)$, using $\alpha_n + \frac{\theta_n}{20} = \frac{1}{20}$. The density: since $\xi_{d,f}(E) = 0$ whenever $\mu_d(E) = 0$, the Radon–Nikodym theorem gives $X = X_d(f) \in L^1(\mu_d)$. With $\vartheta = \theta_n - \eta$, $q = \frac{1}{1-\vartheta}$ and $\mathsf{c} = \mathsf{C}\|f\|_\sharp$: $\lambda\mu_d(X > \lambda) \leq \xi_{d,f}(\{X > \lambda\}) \leq \mathsf{c}\,\mu_d(X > \lambda)^\vartheta$, so $\mu_d(X > \lambda) \leq (\mathsf{c}/\lambda)^q$, the same for $-X$, and $\int |X|^p\,d\mu_d \leq \mathsf{c}^p(1 + \frac{2p}{q-p})$ for $p < q$, by $\int |X|^p = p\int_0^\infty \lambda^{p-1}\mu_d(|X| > \lambda)\,d\lambda$. As $\frac{1}{1-\theta_n} = 3(3n+4) \to \infty$, every $p < \infty$ is reached.

Step 9: clause (a4). Let $f \neq 0$, $1 \leq p < 3(3n+4)$, $a = \mathsf{A}_5\|f\|_\sharp$, $K_* = K_*(d,n)$ and $\lambda_K = 2aK^{c_1}L^{\alpha_n K}$. For $K \geq K_*$ and $\lambda \geq \lambda_K$, the bound of Step 8 at $E = \{X > \lambda\}$ gives $\lambda\mu_d(E) \leq \frac{1}{2}\lambda_K\mu_d(E) + aK^{c_1}L^{-\gamma_n K}$, so $\mu_d(|X| > \lambda) \leq 2L^{-K/20}$. Splitting $[0,\infty)$ at the λ_K, $K \geq K_*$, and using $K + 1 \leq 2K$ and $\delta = \frac{1}{20} - p\alpha_n > 0$: $\int |X|^p\,d\mu_d \leq \lambda_{K_*}^p[1 + 2^{1+pc_1}L^{p\alpha_n}\mathsf{S}(pc_1,\delta)]$. As $K_* = \max\{\bar K_n, 180(3n+4)(d-1)+1\}$ and $\alpha_n\cdot 180(3n+4) = 3$: $K_* \leq (\bar K_n + 180(3n+4))(1+d)$ and $\alpha_n K_* \leq \alpha_n\bar K_n + 3d$, which gives (a4) with $\mathsf{C}_4 = 2\mathsf{A}_5(\bar K_n + 180(3n+4))^{c_1}L^{\alpha_n\bar K_n}[1 + 2^{1+pc_1}L^{p\alpha_n}\mathsf{S}(pc_1,\delta)]^{1/p}$.

Step 10: clause (a3). Under $\mu_{\ell,\mathsf{b}}$ the law of $(V_0,\dots,V_{d+1})$ is the image of μ_{d+1} under $\iota_{0,d+1}$, so for a bounded Borel Φ on $\mathsf{V}_0 \times \cdots \times \mathsf{V}_d$, by the consistency in (a1),

$$\int \Phi(V_0,\dots,V_d)\,X_{d+1}(f)(V_{d+1})\,d\mu_{\ell,\mathsf{b}} = \xi_{d+1,f}(\Phi\circ\iota_{0,d}\circ\mathcal{M}) = \xi_{d,f}(\Phi\circ\iota_{0,d}) = \int \Phi(V_0,\dots,V_d)\,X_d(f)(V_d)\,d\mu_{\ell,\mathsf{b}};$$

so $\mathbb{E}[X_{d+1}(f)(V_{d+1}) \mid \mathcal{F}_d] = X_d(f)(V_d)$; the integrability is (a2), and the mean is 0.

Step 11. For $K \geq d_0$, $c \in \frac{a_K}{2}\mathbb{Z}$ gives a coordinate lattice mirror at depth K. The same holds at each depth $d \geq d_0$. The reflection exchanges the two halves and commutes with blocking by Proposition YM3_I:4.5. The double-block dependence in that proposition confines a blocked bond to the bare bonds in the two endpoint blocks. Each endpoint block at depth d has coordinate half-width $(a_d - a_K)/2$, by summing the half-widths of its nested blocks. If an endpoint lies strictly in the positive half, its two distances to the boundary are positive multiples of $a_d/2$. Thus a blocked bond with both endpoints there reads only bonds in that half. For the plaquettes with $f(x(p)) \neq 0$, the positive distance of the compact support to the boundary ensures the same claim for every sufficiently large K. The Wilson law is reflection invariant by permutation of the bonds and their orientations. The plaquette barycentres transform with the plaquettes and their actions are unchanged, so reflection takes $\mathcal{O}(f)$ to $\mathcal{O}(f\circ\theta)$. Commutation with blocking and total variation convergence give the reflection invariance of μ_D^K and μ_D. (iv) *Schwarz at a cutoff.* Let $D \geq d_0$, h bounded Borel, $\pi(V) = ((\mathcal{M}^{D-d}V)(c'))_{(d,c')}$ on V_D, the pairs (d,c') as in the definition of $\mathcal{G}_D$, $H_D = h\circ\pi$, and take $K \geq \max\{D,2\}$ sufficiently large for the support condition above. Put $F_1(U) = \overline{H_D(\theta\mathcal{M}^{K-D}U)}$ and $F_2 = \mathcal{O}(f) - \mathbb{E}_{K,\mathsf{b}}\mathcal{O}(f)$; both read only bonds of the positive half, $\overline{F_1(\theta U)} = H_D(\mathcal{M}^{K-D}U)$, and $F_2(\theta U)$ is the centred $\mathcal{O}(f\circ\theta)$. The reflection-positive form from Proposition YM3_I:91.4 is positive semidefinite on these functions, so Cauchy–Schwarz gives

$$|\mathsf{c}_K(H_D; f)|^2 \leq \int H_D\,\overline{H_D\circ\theta}\,d\mu_D^K \cdot S^T_{2;K,\ell,L^K\mathsf{b}}(f\circ\theta, f).$$

(v) *Three limits.* $\mathsf{c}_K(H_D;f)\to\int H_D X_D(f)\,d\mu_D$ by (a1), (a2); the middle factor converges, the laws converging in total variation; and $S^T_{2;K,\ell,L^K\mathsf{b}}(f\circ\theta,f)\to S_2^{\ell,\mathsf{b}}(f\circ\theta,f)$ by Theorem YM3_I: AS, as $f\circ\theta$ and f are real Lipschitz, not 0, with supports in the disjoint sets $\mathbb{E}_-$ and $\mathbb{E}_+$. So both factors of the limit are ≥ 0, and the Cauchy–Schwarz inequality in $L^2(\mu_D)$ with $\theta_*\mu_D=\mu_D$ gives the second inequality. (vi) *The martingale and its bound.* On the threads, which have full measure, $V_d=\mathcal{M}^{D-d}V_D$, so $H=H_D(V_D)$ almost surely; $\mathcal{G}_D\subset\mathcal{G}_{D+1}$ and $\mathcal{G}_D\subset\mathcal{F}_D$; by the tower property and (a3), $\mathbb{E}[\Psi_{D+1}\mid\mathcal{G}_D]=\mathbb{E}[\mathbb{E}[X_{D+1}(f)(V_{D+1})\mid\mathcal{F}_D]\mid\mathcal{G}_D]=\Psi_D$, and $\int H\Psi_D=\int H_D X_D(f)\,d\mu_D=\lim_K\mathsf{c}_K(H_D;f)$, which is (b1). The first inequality of (b2) is (iv)–(v) read on the threads; it extends to all bounded $\mathcal{G}_D$-measurable H by uniform approximation. At $H_N=\Psi_D\mathbf{1}\{|\Psi_D|\le N\}$ it gives $\|H_N\|_2^2\le\|H_N\|_2 S_2^{\ell,\mathsf{b}}(f\circ\theta,f)^{1/2}$, and monotone convergence gives $\|\Psi_D\|_2\le S_2^{\ell,\mathsf{b}}(f\circ\theta,f)^{1/2}$. (vii) *Clause (b3).* Doob's theorem for martingales bounded in L^2 gives $\Psi_\infty(f)$, the convergence almost surely and in L^2, and $\Psi_D=\mathbb{E}[\Psi_\infty(f)\mid\mathcal{G}_D]$; the norm and the mean pass to the limit. If $\Phi\in L^2(\mathcal{G}_\infty)$ has $\int H\Phi=0$ for all bounded $\mathcal{G}_D$-measurable H and all D, the sets $G\in\mathcal{G}_\infty$ with $\int_G\Phi=0$ form a Dynkin system that holds the π-system $\bigcup_D\mathcal{G}_D$, so $\Phi=0$. Linearity: $\xi_{D,f}$ is linear in f, so are $X_D(f)$ up to null sets, Ψ_D and the limit. □

Definition 18.149 (Smooth one-forms, their holonomies and their lattice fields)**.** Let $K,m\in\mathbb{N}$, $\ell=2L^m$, $a=a_K$ and $\Lambda=\Lambda_{K,\ell}$; so $\ell\ge 2$, $0<a\le 1$ and $\ell/a\in\mathbb{N}$. $\mathfrak{g}$ is the space of the traceless hermitian 2×2 matrices with $\langle X,Y\rangle=\frac12\operatorname{tr}(XY)$ and $|X|=\langle X,X\rangle^{1/2}$; for $X\in\mathfrak{g}$, $X^2=|X|^2\mathbf{1}$, so $|X|$ is the operator norm $\|X\|$. For a 2×2 matrix M put $\mathbf{w}(M)=\frac{1}{2i}(M-M^*)$ and $\mathbf{c}(M)=\frac12\operatorname{Re}\operatorname{tr}M$; on SU(2), $\mathbf{w}$ is the vector part of YM3_I:(2103). In fact $V=\mathbf{c}(V)\mathbf{1}+i\mathbf{w}(V)$ and $\mathbf{c}(V)^2+|\mathbf{w}(V)|^2=1$, and $a_p=1-\mathbf{c}(\partial U(p))$.

(1) By a *one-form of class* C^k we mean a triple $Q=(Q_1,Q_2,Q_3)$ of functions $Q_\mu\in C^k(T_\ell;\mathfrak{g})$; $\|Q\|_{C^k}=\max_\mu\max_{|\kappa|\le k}\sup|\partial^\kappa Q_\mu|$, and $\|\chi\|_{C^k}$ is defined in the same way for a function χ.

(2) Let $\gamma\colon[t_0,t_1]\to T_\ell$ be continuous and of class C^1 on finitely many pieces, and let H_γ be the solution of $H'(t)=H(t)\,iQ_\lambda(\gamma(t))\,\gamma'^\lambda(t)$, $H(t_0)=\mathbf{1}$; the *holonomy* is $\operatorname{hol}_Q(\gamma)=H_\gamma(t_1)\in\mathrm{SU}(2)$. It does not depend on the parametrisation, $\operatorname{hol}_Q(\gamma_1\gamma_2)=\operatorname{hol}_Q(\gamma_1)\operatorname{hol}_Q(\gamma_2)$ for γ_1 followed by γ_2, and the reversed path has the inverse holonomy. The *lattice field* $U[Q]\in\mathcal{V}(\Lambda)$ is $U[Q](\langle x,x'\rangle)=\operatorname{hol}_Q$ of the straight segment of length a from x to x'; thus the ordered product of its bonds along any lattice path Γ is $\operatorname{hol}_Q(\Gamma)$. For a signed direction α write $e_\alpha=\operatorname{sgn}(\alpha)e_{|\alpha|}$. When $|\alpha|\ne|\alpha'|$, let $W_x(\alpha,\alpha')$ be the product along the loop from x with steps $ae_\alpha,ae_{\alpha'},-ae_\alpha,-ae_{\alpha'}$. Its underlying plaquette is $p(x;\alpha,\alpha')$. In particular $\partial U[Q](p_{\mu\nu}(x))=W_x(\mu,\nu)(U[Q])$.

(3) $F_{\mu\nu}=\partial_\mu Q_\nu-\partial_\nu Q_\mu+i[Q_\mu,Q_\nu]$, $D_\lambda\Psi=\partial_\lambda\Psi+i[Q_\lambda,\Psi]$ for $\mathfrak{g}$-valued Ψ, $(d^*_Q F)_\mu=\sum_\nu D_\nu F_{\mu\nu}$; $\mathrm{YM}(f)=\frac12\int_{T_\ell}f\sum_{\mu<\nu}|F_{\mu\nu}|^2$ for a bounded Borel function f; $B_k=\frac12\sum_{i,j}\epsilon_{kij}F_{ij}$; and the stress tensor is $T_{\alpha\rho}=\sum_\mu\langle F_{\alpha\mu},F_{\rho\mu}\rangle-\delta_{\alpha\rho}\frac12\sum_{\mu<\nu}|F_{\mu\nu}|^2$.

(4) For $Q\in C^{k+1}$, $\Phi_k=\Phi_k(Q)=\max\sup_x|D_{\lambda_1}\cdots D_{\lambda_k}F_{\mu\nu}(x)|$, maximised over all choices of the indices.

(5) For $g\in C^1(T_\ell;\mathrm{SU}(2))$ and a one-form Q of class C^0 put $Q^g_\mu=gQ_\mu g^{-1}-ig\,\partial_\mu g^{-1}$, a one-form of class C^0. Then $\operatorname{hol}_{Q^g}(\gamma)=g(\gamma(t_0))\operatorname{hol}_Q(\gamma)g(\gamma(t_1))^{-1}$, as the two sides, read as functions of the end point, satisfy one differential equation with one initial value; so $U[Q^g]=U[Q]^{g|_\Lambda}$. If moreover $g\in C^2$ and $Q\in C^1$, then $Q^g\in C^1$, $F^{Q^g}=\mathrm{Ad}(g)F^Q$, and $D^{Q^g}_\lambda(\mathrm{Ad}(g)\Psi)=\mathrm{Ad}(g)D^Q_\lambda\Psi$ for $\Psi\in C^1(T_\ell;\mathfrak{g})$, where D^Q is the D of (3) formed with Q; if $g\in C^{k+2}$ and $Q\in C^{k+1}$, then $Q^g\in C^{k+1}$, and the first identity, the second applied k times and $|\mathrm{Ad}(g)X|=|X|$ give $\Phi_k(Q^g)=\Phi_k(Q)$.

For a positively oriented bond $b=\langle x,x+ae_\mu\rangle$ and a plaquette p containing b, there is a unique α with $|\alpha|\ne\mu$ and $p=p(x;\mu,\alpha)$. Put $W_{b,p}=W_x(\mu,\alpha)$ and $x_b=x+\frac{a}{2}e_\mu$. The displacement and

elementary density of YM3_I:(2103), YM3_I:(2104) are

$$\mathbf{u}_{b,\rho}=-\tfrac12\{\mathbf{w}(W_x(\mu,\rho))-\mathbf{w}(W_x(\mu,-\rho))\}\quad(\rho\neq\mu),\qquad \mathbf{u}_{b,\mu}=0,\qquad \mathfrak{d}_{b,p,\rho}=\langle\mathbf{u}_{b,\rho},\mathbf{w}(W_{b,p})\rangle.$$

Here ρ ranges over the positive coordinate indices. Use central lifts $y\in[-\ell/2,\ell/2)^3$ for positions paired with ωy. A function has margin $2a$ if its support is contained in $(-\ell/2+2a,\ell/2-2a)^3$. The differences and the three sums of the shell insertion YM3_I:(2106) are

$$\begin{aligned}
\nabla^{\mathrm c}_\mu\chi(y)&=\frac{\chi(y+ae_\mu/2)-\chi(y-ae_\mu/2)}{a},\\
\nabla^{\mathrm s}_\omega\chi(y)&=\sum_\rho(\omega y)_\rho\frac{\chi(y+ae_\rho)-\chi(y-ae_\rho)}{2a},\\
S_1&=\beta\sum_p a_p\nabla^{\mathrm s}_\omega\chi(x(p)),\\
S_2&=\frac{\beta}{a}\sum_{p,\,b\subset\partial p,\,\rho}[\chi(x_b)-\chi(x(p))](\omega x_b)_\rho\,\mathfrak{d}_{b,p,\rho},\\
S_3&=\tfrac32\sum_{p=p_{\mu\nu},\,\mu<\nu}a_p[(\omega x(p))_\mu\nabla^{\mathrm c}_\mu\chi(x(p))+(\omega x(p))_\nu\nabla^{\mathrm c}_\nu\chi(x(p))],\\
\mathfrak{B}_{\omega,\chi}&=S_1-S_2-S_3.
\end{aligned}$$

Every bond in S_2 has the positive orientation. All positions in a local displacement use a common lift.

■

Proposition 18.150 (Tools: the numbers Φ_k, transport, planar loops, a rectangle, a square seen from its centre, Riemann sums)**.** In the setting of Definition 18.149:

(a) For $Q\in C^{k+1}$ and $N=\|Q\|_{C^{k+1}}$, $\Phi_k\le 2^{k^2+k+1}(1+N)^{k+2}$; in particular $\Phi_0\le 2(1+N)^2$, $\Phi_1\le 8(1+N)^3$, $\Phi_2\le 128(1+N)^4$.

(b) *Transport.* Let $Q\in C^1$, γ as in Definition 18.149(2) and $\Psi\in C^1(T_\ell;\mathfrak g)$; inside each piece the transported value $\mathrm{Ad}(H_\gamma(t))\Psi(\gamma(t))$ has the t-derivative $\mathrm{Ad}(H_\gamma(t))(\gamma'^\lambda D_\lambda\Psi)(\gamma(t))$. For $Q\in C^k$, $\Psi\in C^k$, $c\in T_\ell$, $z\in\mathbb R^3$ and $R(t)$ the holonomy of $s\mapsto c+sz$, $0\le s\le t$, the function $\varphi(t)=\mathrm{Ad}(R(t))\Psi(c+tz)$ has $\varphi^{(j)}(t)=\mathrm{Ad}(R(t))((z\cdot D)^j\Psi)(c+tz)$ for $j\le k$.

(c) *Planar loops.* Take $Q\in C^1$, a point $c\in T_\ell$, two directions $\mu\neq\nu$ and a loop $y=y^\mu e_\mu+y^\nu e_\nu\colon[0,1]\to\mathbb R^3$, continuous and C^1 on finitely many pieces, with $y(0)=y(1)=0$; put $m=y^\mu y'^\nu-y^\nu y'^\mu$ and $|m|_1=\int_0^1|m|$. For $0\le r,t\le1$ write $H(r,t)$ for the holonomy along $s\mapsto c+ry(s)$, $s\in[0,t]$, and $V(r)=H(r,1)$. Then $V(0)=\mathbf1$, $V'(r)V(r)^{-1}=ir\int_0^1\mathrm{Ad}(H(r,t))F_{\mu\nu}(c+ry(t))\,m(t)\,dt$, and $\|V(r)-\mathbf1\|\le\frac12r^2|m|_1\Phi_0$.

(d) *A rectangle seen from a corner.* For $x\in T_\ell$, $\mu\neq\nu$, real a_1,a_2 and Rect the holonomy of $x\to x+a_1e_\mu\to x+a_1e_\mu+a_2e_\nu\to x+a_2e_\nu\to x$: $\|\mathrm{Rect}-\mathbf1\|\le|a_1a_2|\Phi_0$ for $Q\in C^1$, and $\|\mathrm{Rect}-\exp(ia_1a_2F_{\mu\nu}(x))\|\le\frac23|a_1a_2|(2|a_1|+|a_2|)\Phi_1$ for $Q\in C^2$.

(e) *A square seen from its centre.* For $Q\in C^3$, $\mu\neq\nu$, $x\in T_\ell$, $c=x+\frac a2(e_\mu+e_\nu)$, T the holonomy of the segment from c to x and W the holonomy of $x\to x+ae_\mu\to x+ae_\mu+ae_\nu\to x+ae_\nu\to x$: $\|TWT^{-1}-\exp(ia^2F_{\mu\nu}(c))\|\le\frac14a^4(\Phi_2+4\Phi_0^2)$.

(f) *Riemann sums.* For $c_0\in\mathbb R^3$: $|\int_{T_\ell}\psi-a^3\sum_{c\in\Lambda+c_0}\psi(c)|\le\frac{5}{16}\ell^3a^2\max_{\kappa,\lambda}\sup|\partial_\kappa\partial_\lambda\psi|$ for $\psi\in C^2(T_\ell)$, and $\le\frac{\sqrt3}{2}\ell^3a\,\mathrm{Lip}\,\psi$ for Lipschitz ψ, Lip for the euclidean distance.

■

Proof. Step 0: matrix facts. For $V\in\mathrm{SU}(2)$: $(V-\mathbf1)^*(V-\mathbf1)=2(1-\mathbf c(V))\mathbf1$, so $\|V-\mathbf1\|^2=2(1-\mathbf c(V))$; $|\mathbf w(V)|^2=(1-\mathbf c(V))(1+\mathbf c(V))\le\|V-\mathbf1\|^2$; for $X\in\mathfrak g$, $e^{iX}=\cos|X|\,\mathbf1+i\frac{\sin|X|}{|X|}X$, so $\|e^{iX}-\mathbf1\|\le|X|$ and $|\mathbf w(e^{iX})-X|=||X|-\sin|X||\le\frac16|X|^3$; $\|\mathbf w(M)\|\le\|M\|$; $|[X,Y]|\le2|X||Y|$;

$\|\operatorname{Ad}(V)-\operatorname{Ad}(V')\|\le 2\|V-V'\|$; $\partial_\lambda\langle\Psi,\Psi'\rangle=\langle D_\lambda\Psi,\Psi'\rangle+\langle\Psi,D_\lambda\Psi'\rangle$. *Comparison:* let Ξ,Ξ_0 be continuous $\mathfrak{g}$-valued functions on $[0,r]$ and V,V_0 solutions of $V'=i\Xi V$, $V_0'=i\Xi_0V_0$ with $V(0)=V_0(0)\in\mathrm{SU}(2)$; then both take values in SU(2), $(V_0^{-1}V)'=V_0^{-1}i(\Xi-\Xi_0)V$, and so $\|V(r)-V_0(r)\|\le\int_0^r|\Xi-\Xi_0|$.

Step 1: (a). By Leibniz' rule and $|[X,Y]|\le 2|X||Y|$, $\|F\|_{C^k}\le 2N+2^{k+1}N^2\le 2^{k+1}(1+N)^2$, and $\|D_\lambda\Psi\|_{C^{j-1}}\le(1+2^jN)\|\Psi\|_{C^j}$; so $\Phi_k\le\prod_{j=1}^k(1+2^jN)\cdot 2^{k+1}(1+N)^2\le 2^{k^2}(1+N)^k\,2^{k+1}(1+N)^2$.

Step 2: (b) and a variation formula. If $\partial_tH=H\,iA(t;r)$, $H(t_0)=\mathbf{1}$, with A and ∂_rA continuous on pieces, then $X=\partial_rH\,H^{-1}$ has $X(t_0)=0$ and $\partial_tX=\operatorname{Ad}(H)\,i\partial_rA$, so $\partial_rH(t)H(t)^{-1}=i\int_{t_0}^t\operatorname{Ad}(H)\partial_rA$. At $A=Q_\lambda(\gamma)\gamma'^\lambda$, $\frac{d}{dt}(H\Psi H^{-1})=H(iA\Psi+\gamma'^\lambda\partial_\lambda\Psi-\Psi iA)H^{-1}$, which is the transport; the formula for $\varphi^{(j)}$ follows by induction, $z\cdot D\Psi$ being of class C^{k-1}. For a family of paths $\sigma(r,t)$ with fixed end points and $A=Q_\beta(\sigma)\partial_t\sigma^\beta$, the same computation shows that ∂_rA differs from $\operatorname{Ad}(H)^{-1}\partial_t[\operatorname{Ad}(H)(Q_\alpha\partial_r\sigma^\alpha)]$ by $F_{\alpha\beta}\partial_r\sigma^\alpha\partial_t\sigma^\beta$, and the total derivative integrates to 0, as $\partial_r\sigma=0$ at the ends; so the derivative of the holonomy of the loop in r is $i\int\operatorname{Ad}(H)F_{\alpha\beta}\partial_r\sigma^\alpha\partial_t\sigma^\beta$, times the holonomy.

Step 3: (c). At $\sigma(r,t)=c+ry(t)$, $\partial_r\sigma=y$ and $\partial_t\sigma=ry'$, and $F_{\alpha\beta}y^\alpha ry'^\beta=rF_{\mu\nu}m$; this is the formula. The bound is the comparison with $V_0=\mathbf{1}$: $\|V(r)-\mathbf{1}\|\le\int_0^r r'|m|_1\Phi_0\,dr'$.

Step 4: (d). Parametrise each of the four sides by $u\in[0,1]$: $y=ua_1e_\mu$, $a_1e_\mu+ua_2e_\nu$, $(1-u)a_1e_\mu+a_2e_\nu$, $(1-u)a_2e_\nu$, with $m=0,a_1a_2,a_1a_2,0$; so $|m|_1=2|a_1a_2|$, and (c) gives the first bound. A point of the second or of the third side is reached after a path length of at most $r(2|a_1|+|a_2|)$, so by (b) $|\operatorname{Ad}(H(r,t))F_{\mu\nu}(x+ry(t))-F_{\mu\nu}(x)|\le r(2|a_1|+|a_2|)\Phi_1$ where $m\neq 0$. So $V'V^{-1}=i[2ra_1a_2F_{\mu\nu}(x)+e(r)]$ with $|e(r)|\le 2r^2|a_1a_2|(2|a_1|+|a_2|)\Phi_1$, while $V_0(r)=\exp(ir^2a_1a_2F_{\mu\nu}(x))$ has $V_0'V_0^{-1}=i\,2ra_1a_2F_{\mu\nu}(x)$; the comparison and $\int_0^1 2r^2\,dr=\frac{2}{3}$ give the second bound.

Step 5: (e). Let y go straight from 0 to the corner $y_0=-\frac{a}{2}(e_\mu+e_\nu)$, then once around the square $[-\frac{a}{2},\frac{a}{2}]^2$ of the (μ,ν)-plane, starting in the direction e_μ and parametrised by arc length, and then straight back to 0; then $V(1)=TWT^{-1}$. On the segments $m=0$, on the boundary $m=\frac{a}{2}$; so $\int m=|m|_1=2a^2$, and $\int y^\lambda m=0$ by the symmetry $y\mapsto -y$ of the boundary. For a point $z=ry(t)$ of the boundary let $R(z)$ be the holonomy of the segment from c to $c+z$; $H(r,t)R(z)^{-1}$ is the holonomy of a planar loop with $|m|_1\le 2a^2$, so $\|H(r,t)R(z)^{-1}-\mathbf{1}\|\le r^2a^2\Phi_0$ by (c), and $|\operatorname{Ad}(H(r,t))F_{\mu\nu}(c+z)-\operatorname{Ad}(R(z))F_{\mu\nu}(c+z)|\le 2r^2a^2\Phi_0^2$. By (b) and Taylor's formula, $\operatorname{Ad}(R(z))F_{\mu\nu}(c+z)=F_{\mu\nu}(c)+z^\lambda D_\lambda F_{\mu\nu}(c)+\rho(z)$ with $|\rho(z)|\le\frac{1}{2}(|z^\mu|+|z^\nu|)^2\Phi_2\le\frac{1}{2}r^2a^2\Phi_2$. Into (c): $V'V^{-1}=ir[2a^2F_{\mu\nu}(c)+e(r)]$, the term with $D_\lambda F$ vanishing, with $|e(r)|\le r^2a^4(\Phi_2+4\Phi_0^2)$; the comparison with $\exp(ir^2a^2F_{\mu\nu}(c))$ and $\int_0^1 r^3\,dr=\frac{1}{4}$ give (e).

Step 6: (f). T_ℓ is the disjoint union of the $(\ell/a)^3$ cubes $c+[-\frac{a}{2},\frac{a}{2})^3$, $c\in\Lambda+c_0$. For $\psi\in C^2$ the first-order term of Taylor's formula integrates to 0 over a cube, and $\int z_\kappa^2\,dz=\frac{a^5}{12}$, $\int|z_\kappa||z_\lambda|\,dz=\frac{a^5}{16}$ for $\kappa\neq\lambda$, with $\frac{1}{2}(\frac{3}{12}+\frac{6}{16})=\frac{5}{16}$; for Lipschitz ψ, $|\psi(c+z)-\psi(c)|\le\frac{\sqrt{3}}{2}a\operatorname{Lip}\psi$. □

Proposition 18.151 (On the lattice field of a smooth one-form: the Wilson action, the action density, the elementary densities and the shell flux)**.** In the setting of Definition 18.149, let Q be a one-form, $N=\|Q\|_{C^3}$, and put $\mathsf{K}_1=\frac{1}{4}\Phi_0\Phi_2+\Phi_0^3+\frac{7}{24}a^2\Phi_0^4$ and $\mathsf{K}_2=5\Phi_0\Phi_1+\frac{1}{3}a^3\Phi_0^4$.

(1) *A single plaquette.* For $Q\in C^3$ and $p=p_{\mu\nu}(x)$: $0\le a_p(U[Q])\le\frac{1}{2}a^4\Phi_0^2$ and $|a_p(U[Q])-\frac{1}{2}a^4|F_{\mu\nu}(x(p))|^2|\le a^6\mathsf{K}_1$, $\mathsf{K}_1\le 77(1+N)^8$.

(2) *The action.* For $Q\in C^3$, $\mathsf{b}>0$ and $\beta=\mathsf{b}/a$: $|\beta A(U[Q])-\mathsf{b}\,\mathrm{YM}(1)|\le 3\mathsf{b}\ell^3a^2[\mathsf{K}_1+\frac{5}{16}(\Phi_0\Phi_2+\Phi_1^2)]\le 531\,\mathsf{b}\,\ell^3a^2(1+N)^8$, where $A=\sum_p a_p$.

(3) *The action density.* For $Q\in C^3$ and a complex Lipschitz function f on T_ℓ: $|\mathcal{O}(f)(U[Q])-\mathrm{YM}(f)|\le 3\ell^3[a^2\mathsf{K}_1\|f\|_\infty+\frac{\sqrt{3}}{2}a(\frac{1}{2}\Phi_0^2\operatorname{Lip}f+\sqrt{3}\Phi_0\Phi_1\|f\|_\infty)]\le(303+\frac{1}{7M})\,\ell^3a\,\|f\|_\sharp\,(1+N)^8$.

(4) *The coupling.* The Pauli matrices $\sigma_1,\sigma_2,\sigma_3$ form an orthonormal basis of $\mathfrak{g}$. Requiring $\mathsf{b}\cdot\frac12|F|^2=\frac{1}{2g_{\rm std}^2}\sum_c(F^c)^2$ for all $F=\sum_c F^c\sigma_c/2$ with real F^c fixes $g_{\rm std}>0$ as $g_{\rm std}=2\mathsf{b}^{-1/2}$; thus $\mathsf{b}\,g_{\rm std}^2=4$.

(5) *The elementary densities.* Let $Q\in C^2$ and $x\in\Lambda$. (a) For $\mu,\rho\in\mathbb{D}$ with $|\mu|\neq|\rho|$ and $\mathbb{D}=\{\pm1,\pm2,\pm3\}$: $|\mathbf{w}(W_x(\mu,\rho)(U[Q]))|\le a^2\Phi_0$ and $|\mathbf{w}(W_x(\mu,\rho)(U[Q]))-\operatorname{sgn}(\mu)\operatorname{sgn}(\rho)a^2F_{|\mu||\rho|}(x)|\le 2a^3\Phi_1+\frac16a^6\Phi_0^3$. (b) For $b=\langle x,x+ae_\mu\rangle$, $1\le\mu\le3$, $\alpha\in\mathbb{D}$ with $|\alpha|\neq\mu$, $p=p(x;\mu,\alpha)$ the underlying plaquette and $1\le\rho\le3$: $|\mathfrak{d}_{b,p,\rho}(U[Q])|\le a^4\Phi_0^2$ and

$$|a^{-4}\mathfrak{d}_{b,p,\rho}(U[Q])+\operatorname{sgn}(\alpha)\langle F_{\mu\rho},F_{\mu|\alpha|}\rangle(x_b)|\le a\,\mathsf{K}_2,\qquad \mathsf{K}_2\le 86(1+\|Q\|_{C^2})^8,$$

Here $\mathfrak{d}_{b,p,\rho}$ and x_b are as in Definition 18.149.

(6) *The shell flux.* Let $Q\in C^3$, $\mathsf{b}>0$, $\beta=\mathsf{b}/a$ and $\omega\in\mathfrak{so}(3)$, write $\|\omega\|_{\rm op}=\max\{|\omega v|:v\in\mathbb{R}^3,\ |v|=1\}$ for the operator norm of ω on euclidean $\mathbb{R}^3$, and let $\chi\in C^2(\mathbb{R}^3)$ be real with margin $2a$ as in Definition 18.149. For the shell flux $\mathfrak{B}_{\omega,\chi}$, use the integral over $[-\frac{\ell}{2},\frac{\ell}{2})^3$ and $\mathsf{K}_3=\frac92a\mathsf{K}_1+9\mathsf{K}_2+\frac{63}{2}\Phi_0^2+\frac{135}{4}\Phi_0\Phi_1$:

$$\begin{aligned}&\Big|\mathfrak{B}_{\omega,\chi}(U[Q])+\mathsf{b}\int\sum_{\alpha,\rho}\partial_\alpha\chi(y)\,(\omega y)_\rho\,T_{\alpha\rho}(y)\,dy\Big|\\&\quad\le\ell^4a\|\omega\|_{\rm op}\|\chi\|_{C^2}\big[\tfrac{27}{8}\Phi_0^2+\mathsf{b}\,\mathsf{K}_3\big]\\&\quad\le 3000\,(1+\mathsf{b})\,\ell^4a\|\omega\|_{\rm op}\|\chi\|_{C^2}(1+N)^8;\end{aligned}$$

the sum S_3 has modulus at most $\frac{27}{8}\ell^4a\|\omega\|_{\rm op}\|\chi\|_{C^1}\Phi_0^2$.

(7) *The tensor.* For $Q\in C^2$: (a) $T_{\alpha\rho}=T_{\rho\alpha}=\frac12\delta_{\alpha\rho}|B|^2-\langle B_\alpha,B_\rho\rangle$ with $|B|^2=\sum_k|B_k|^2=\sum_{\mu<\nu}|F_{\mu\nu}|^2$; (b) $\sum_\alpha\partial_\alpha T_{\alpha\rho}=-\sum_\mu\langle(d_Q^*F)_\mu,F_{\rho\mu}\rangle$; (c) for $\chi\in C^1$ vanishing outside a compact subset of $(-\frac{\ell}{2},\frac{\ell}{2})^3$, $-\int\sum\partial_\alpha\chi(\omega y)_\rho T_{\alpha\rho}=-\int\chi\sum_{\rho,\mu}(\omega y)_\rho\langle(d_Q^*F)_\mu,F_{\rho\mu}\rangle=-\frac{d}{dt}\big|_{t=0}\mathrm{YM}(1)(Q+t\,\delta Q)$ with $\delta Q_\mu=\chi\sum_\rho(\omega y)_\rho F_{\rho\mu}$. Thus, for $Q\in C^3$, $\omega\in\mathfrak{so}(3)$, $\mathsf{b}>0$, $\beta=\mathsf{b}/a$ and a real $\chi\in C^2(\mathbb{R}^3)$ whose support is a compact subset of $(-\frac{\ell}{2},\frac{\ell}{2})^3$, so that χ has the margin $2a$ once K is large, the shell flux at $U[Q]$ tends, as $K\to\infty$ with ℓ held fixed, to the negative of the derivative of $\mathsf{b}\,\mathrm{YM}(1)$ along the rotation field cut off by χ, a number that vanishes where $d_Q^*F=0$.

■

Proof. (1). $\partial U[Q](p)=W$ of Proposition 18.150(e) and $n:=a_p=1-\mathbf{c}(W)=1-\mathbf{c}(V)$ with $V=TWT^{-1}$. By Step 0 of the proof of Proposition 18.150 and its clause (d), $n=\frac12\|W-\mathbf{1}\|^2\le\frac12a^4\Phi_0^2$. By its clause (e) and Step 0, $|\mathbf{w}(V)-a^2F_{\mu\nu}(c)|\le\frac14a^4(\Phi_2+4\Phi_0^2)+\frac16a^6\Phi_0^3$, with $c=x(p)$; as $|\mathbf{w}(V)|\le\|V-\mathbf{1}\|\le a^2\Phi_0$, $||\mathbf{w}(V)|^2-a^4|F_{\mu\nu}(c)|^2|\le2a^2\Phi_0$ times that; and $|\mathbf{w}(V)|^2=n(2-n)$ gives $n-\frac12|\mathbf{w}(V)|^2=\frac12n^2\le\frac18a^8\Phi_0^4$. Together, $|n-\frac12a^4|F_{\mu\nu}(c)|^2|\le a^6\mathsf{K}_1$; Proposition 18.150(a) and $a\le1$ give $\mathsf{K}_1\le(64+8+\frac{14}{3})(1+N)^8$.

(2). $\beta A=\frac{\mathsf{b}}{a}\sum_p a_p$, and there are $3(\ell/a)^3$ plaquettes; by (1), putting $\frac12a^4|F_{\mu\nu}(x(p))|^2$ in the place of every a_p changes βA by at most $3\mathsf{b}\ell^3a^2\mathsf{K}_1$. The barycentres of the plaquettes with the directions $\mu<\nu$ are the points of $\Lambda+\frac{a}{2}(e_\mu+e_\nu)$, and Proposition 18.150(f) applies to $\psi=\frac12|F_{\mu\nu}|^2$, with $\partial_\kappa\partial_\lambda\psi=\langle D_\kappa D_\lambda F_{\mu\nu},F_{\mu\nu}\rangle+\langle D_\lambda F_{\mu\nu},D_\kappa F_{\mu\nu}\rangle$, of modulus at most $\Phi_0\Phi_2+\Phi_1^2$. Numbers: $3[77+\frac{5}{16}(256+64)]=531$.

(3). $\mathcal{O}(f)=a^{-1}\sum_p f(x(p))a_p$ (Definition 18.143(1)); the same substitution changes it by at most $3\ell^3a^2\mathsf{K}_1\|f\|_\infty$, and the Riemann sums of $\psi=f\cdot\frac12|F_{\mu\nu}|^2$, with $\operatorname{Lip}\psi\le\frac12\Phi_0^2\operatorname{Lip}f+\sqrt3\Phi_0\Phi_1\|f\|_\infty$, as $|\partial_\lambda\frac12|F|^2|=|\langle D_\lambda F,F\rangle|\le\Phi_0\Phi_1$, cost the rest. With $\operatorname{Lip}f\le\|f\|_\sharp/(40M)$, $a\le1$, $\Phi_0\Phi_1\le16(1+N)^5$ and $\Phi_0^2\le4(1+N)^4$: $3[77+24+\frac{\sqrt3}{40M}]\le303+\frac{1}{7M}$.

(4). $\sigma_c\sigma_e+\sigma_e\sigma_c=2\delta_{ce}\mathbf{1}$, so $\langle\sigma_c,\sigma_e\rangle=\delta_{ce}$ and $|\sum_c F^c\sigma_c/2|^2=\frac14\sum_c(F^c)^2$; the identity reads $\frac{\mathsf b}{8}\sum(F^c)^2=\frac{1}{2g_{\rm std}^2}\sum(F^c)^2$.

(5). (a) $W_x(\mu,\rho)(U[Q])$ is the Rect of Proposition 18.150(d) with the directions $|\mu|,|\rho|$, $a_1=\operatorname{sgn}(\mu)a$ and $a_2=\operatorname{sgn}(\rho)a$; Step 0 of its proof gives both bounds. (b) If $\rho=\mu$, the two sides are 0: $\mathbf{u}_{b,\mu}=0$ by definition, and $F_{\mu\mu}=0$. Let $\rho\neq\mu$ and $\eta_0=2a^3\Phi_1+\frac16 a^6\Phi_0^3$; by (a), $\mathbf{w}(W_x(\mu,\pm\rho))=\pm a^2F_{\mu\rho}(x)+r_\pm$ and, with the based holonomy $W_{b,p}$, $\mathbf{w}(W_{b,p})=\mathbf{w}(W_x(\mu,\alpha))=\operatorname{sgn}(\alpha)a^2F_{\mu|\alpha|}(x)+r_\alpha$, all $|r|\le\eta_0$. Substituting in the density formula gives

$$\mathfrak{d}_{b,p,\rho}=-\operatorname{sgn}(\alpha)a^4\langle F_{\mu\rho},F_{\mu|\alpha|}\rangle(x)-a^2\langle F_{\mu\rho}(x),r_\alpha\rangle-\tfrac12\langle r_+-r_-,\mathbf{w}(W_{b,p})\rangle,$$

the last two terms of modulus at most $2a^2\Phi_0\eta_0$; moving the point from x to $x_b=x+\frac a2e_\mu$ costs $a\Phi_0\Phi_1$, as $|\partial_\mu\langle F_{\mu\rho},F_{\mu|\alpha|}\rangle|\le2\Phi_0\Phi_1$. Sum: $a^{-4}\cdot2a^2\Phi_0\eta_0+a\Phi_0\Phi_1=a\mathsf K_2$. And $|\mathfrak{d}_{b,p,\rho}|\le\frac12(|\mathbf{w}(W_x(\mu,\rho))|+|\mathbf{w}(W_x(\mu,-\rho))|)\,|\mathbf{w}(W_{b,p})|\le a^4\Phi_0^2$.

(6). Read all points at their central lifts $y\in[-\frac\ell2,\frac\ell2)^3$; there $|y|\le\frac{\sqrt3}{2}\ell$, hence $\sum_\rho|(\omega y)_\rho|\le\sqrt3\,|\omega y|\le\frac32\ell\|\omega\|_{\rm op}$, and near the faces of the cube, within the sup distance $2a$, the function χ and all its derivatives are 0, so that the shifted values of χ in $\nabla^{\rm s}_\omega$, $\nabla^{\rm c}_\mu$ and S_2 are those of χ on $\mathbb{R}^3$. Use the three sums $\mathfrak{B}_{\omega,\chi}=S_1-S_2-S_3$ and $-\mathsf b\int\sum\partial_\alpha\chi(\omega y)_\rho T_{\alpha\rho}=I_1-I_2$, with $I_1=\mathsf b\int\frac12\sum_{\mu<\nu}|F_{\mu\nu}|^2\,(\omega y\cdot\nabla\chi)$ and $I_2=\mathsf b\int\sum_{\alpha,\rho}\partial_\alpha\chi(\omega y)_\rho\sum_\mu\langle F_{\alpha\mu},F_{\rho\mu}\rangle$. *$S_3$:* as $|\nabla^{\rm c}_\mu\chi|\le\|\chi\|_{C^1}$ and $a_p\le\frac12a^4\Phi_0^2$, $|S_3|\le\frac32\cdot3(\ell/a)^3\cdot\frac12a^4\Phi_0^2\cdot\frac32\ell\|\omega\|_{\rm op}\|\chi\|_{C^1}=\frac{27}{8}\ell^4a\|\omega\|_{\rm op}\|\chi\|_{C^1}\Phi_0^2$, which is the last assertion. *S_1-I_1:* as $|\nabla^{\rm s}_\omega\chi|\le\frac32\ell\|\omega\|_{\rm op}\|\chi\|_{C^1}$, (1) shows that putting $\frac12a^4|F_{\mu\nu}(x(p))|^2$ in the place of a_p costs at most $\frac92\mathsf b\ell^4a^2\|\omega\|_{\rm op}\|\chi\|_{C^1}\mathsf K_1$; next, since $|(2a)^{-1}[\chi(y+ae_\rho)-\chi(y-ae_\rho)]-\partial_\rho\chi(y)|\le\frac a2\|\chi\|_{C^2}$, putting $\omega y\cdot\nabla\chi$ in the place of $\nabla^{\rm s}_\omega\chi$ costs at most $\frac98\mathsf b\ell^4a\|\omega\|_{\rm op}\|\chi\|_{C^2}\Phi_0^2$; finally, for $\psi_{\mu\nu}=\frac12|F_{\mu\nu}|^2(\omega y\cdot\nabla\chi)$ one has $|\partial_\lambda(\omega y\cdot\nabla\chi)|\le\sqrt3\|\omega\|_{\rm op}\|\chi\|_{C^1}+\frac32\ell\|\omega\|_{\rm op}\|\chi\|_{C^2}\le\frac52\ell\|\omega\|_{\rm op}\|\chi\|_{C^2}$, because $\ell\ge2$, so $|\partial_\lambda\psi_{\mu\nu}|\le\ell\|\omega\|_{\rm op}\|\chi\|_{C^2}[\frac54\Phi_0^2+\frac32\Phi_0\Phi_1]$, the euclidean Lipschitz number of $\psi_{\mu\nu}$ is at most $\sqrt3$ times this, and Proposition 18.150(f) bounds the three Riemann sums by $\frac92\mathsf b\ell^4a\|\omega\|_{\rm op}\|\chi\|_{C^2}[\frac54\Phi_0^2+\frac32\Phi_0\Phi_1]$. *$S_2-I_2$:* a plaquette together with one of its four bonds corresponds one to one, through $p=p(x;\mu,\alpha)$, to a pair (b,α) of a positively oriented bond $b=\langle x,x+ae_\mu\rangle$ and an $\alpha\in\mathbb D$ with $|\alpha|\neq\mu$; there are $12(\ell/a)^3$ such pairs, and $x(p)=x_b+\frac a2e_\alpha$, $W_{b,p}=W_x(\mu,\alpha)$; so $S_2=\frac{\mathsf b}{a^2}\sum_{(b,\alpha)}\sum_\rho[\chi(x_b)-\chi(x_b+\frac a2e_\alpha)](\omega x_b)_\rho\,\mathfrak{d}_{b,p,\rho}$. Here $\chi(x_b)-\chi(x_b+\frac a2e_\alpha)=-\frac a2\operatorname{sgn}(\alpha)\partial_{|\alpha|}\chi(x_b)+r_\chi$, $|r_\chi|\le\frac{a^2}{8}\|\chi\|_{C^2}$, and by (5) $\mathfrak{d}_{b,p,\rho}=-\operatorname{sgn}(\alpha)a^4\langle F_{\mu\rho},F_{\mu|\alpha|}\rangle(x_b)+a^4r_{\mathfrak d}$, $|r_{\mathfrak d}|\le a\mathsf K_2$; the product of the main terms is $\frac{a^5}{2}\partial_{|\alpha|}\chi(x_b)\langle F_{\mu\rho},F_{\mu|\alpha|}\rangle(x_b)$, since $\operatorname{sgn}(\alpha)^2=1$, the remaining part of the product is at most $a^6[\frac12\|\chi\|_{C^1}\mathsf K_2+\frac18\|\chi\|_{C^2}\Phi_0^2]$ in modulus, and with $\sum_\rho|(\omega x_b)_\rho|\le\frac32\ell\|\omega\|_{\rm op}$ these remainders cost at most $18\mathsf b\ell^4a\|\omega\|_{\rm op}[\frac12\|\chi\|_{C^1}\mathsf K_2+\frac18\|\chi\|_{C^2}\Phi_0^2]$. The main term is $\mathsf b\sum_\mu a^3\sum_{x_b}\psi_\mu(x_b)$, a Riemann sum over $\Lambda+\frac a2e_\mu$ of $\psi_\mu=\sum_{\nu\neq\mu}\sum_\rho(\omega y)_\rho\partial_\nu\chi\langle F_{\mu\rho},F_{\mu\nu}\rangle$, the two $\alpha=\pm\nu$ giving the same term; the three ways in which ∂_λ can fall on ψ_μ give $|\partial_\lambda\psi_\mu|\le2[\sqrt3\|\chi\|_{C^1}\Phi_0^2+\frac32\ell\|\chi\|_{C^2}\Phi_0^2+3\ell\|\chi\|_{C^1}\Phi_0\Phi_1]\|\omega\|_{\rm op}\le2\ell\|\omega\|_{\rm op}\|\chi\|_{C^2}[\frac52\Phi_0^2+3\Phi_0\Phi_1]$, so the Riemann sums cost at most $9\mathsf b\ell^4a\|\omega\|_{\rm op}\|\chi\|_{C^2}[\frac52\Phi_0^2+3\Phi_0\Phi_1]$; and $\mathsf b\sum_\mu\int\psi_\mu=I_2$, as $F_{\mu\mu}$ vanishes and $\langle F_{\mu\rho},F_{\mu\nu}\rangle=\langle F_{\nu\mu},F_{\rho\mu}\rangle$. *Sum:* with $\|\chi\|_{C^1}\le\|\chi\|_{C^2}$, the costs that carry the factor $\mathsf b$ add up to $\mathsf b\ell^4a\|\omega\|_{\rm op}\|\chi\|_{C^2}$ times $\frac92a\mathsf K_1+9\mathsf K_2+(\frac98+\frac{45}{8}+\frac94+\frac{45}{2})\Phi_0^2+(\frac{27}{4}+27)\Phi_0\Phi_1=\mathsf K_3$, and S_3 adds $\frac{27}{8}\Phi_0^2$; with the bounds of (1), (5), with Proposition 18.150(a) and $a\le1$, $\mathsf K_3\le(\frac{693}{2}+774+126+540)(1+N)^8<1787(1+N)^8$ and $\frac{27}{8}\Phi_0^2\le\frac{27}{2}(1+N)^8$, which gives the second inequality.

(7). (a) $F_{\alpha\mu}=\sum_k\epsilon_{\alpha\mu k}B_k$ and $\sum_\mu\epsilon_{\alpha\mu k}\epsilon_{\rho\mu l}=\delta_{\alpha\rho}\delta_{kl}-\delta_{\alpha l}\delta_{k\rho}$ give $\sum_\mu\langle F_{\alpha\mu},F_{\rho\mu}\rangle=\delta_{\alpha\rho}|B|^2-\langle B_\rho,B_\alpha\rangle$. (b) $\partial_\alpha\sum_\mu\langle F_{\alpha\mu},F_{\rho\mu}\rangle=\langle D_\alpha F_{\alpha\mu},F_{\rho\mu}\rangle+\langle F_{\alpha\mu},D_\alpha F_{\rho\mu}\rangle$, summed over repeated indices, and the identity $D_\lambda F_{\mu\nu}+D_\mu F_{\nu\lambda}+D_\nu F_{\lambda\mu}=0$ follows by the Jacobi identity for $\partial_\lambda+iQ_\lambda$, whose commutator with $\partial_\mu+iQ_\mu$ is $iF_{\lambda\mu}$. Contracting with $F_{\alpha\mu}$ gives $\partial_\rho\frac14\sum_{\mu,\nu}|F_{\mu\nu}|^2=\langle F_{\alpha\mu},D_\alpha F_{\rho\mu}\rangle$; so $\partial_\alpha T_{\alpha\rho}=\langle D_\alpha F_{\alpha\mu},F_{\rho\mu}\rangle=-\langle(d_Q^*F)_\mu,F_{\rho\mu}\rangle$. (c) Integration by parts gives $\int\chi[\omega_{\rho\alpha}T_{\alpha\rho}+(\omega y)_\rho\partial_\alpha T_{\alpha\rho}]$, and the first term vanishes, ω being antisymmetric and T symmetric; and $\frac{d}{dt}|_0\mathrm{YM}(1)(Q+t\delta Q)=$

$\int\sum_{\mu,\nu}\langle F_{\mu\nu}, D_\mu\delta Q_\nu\rangle = \int\sum_\nu\langle(d^*_Q F)_\nu, \delta Q_\nu\rangle$. With (6): for $Q\in C^3$, $\omega\in\mathfrak{so}(3)$, $\mathsf{b}>0$ and a real $\chi\in C^2(\mathbb{R}^3)$ that vanishes outside a compact subset of $(-\frac{\ell}{2},\frac{\ell}{2})^3$, and so has the margin $2a_K$ for all large K, the shell flux at $U[Q]$ with $\beta=\mathsf{b}/a_K$ differs from $-\mathsf{b}\int\sum\partial_\alpha\chi(\omega y)_\rho T_{\alpha\rho}$ by at most $3000\,(1+\mathsf{b})\,\ell^4 a_K\|\omega\|_{\mathrm{op}}\|\chi\|_{C^2}(1+N)^8$, and so tends to it as $K\to\infty$, ℓ being fixed. □

Proposition 18.152 (Three free photons: the connected functions of half the Wick square of their curvature form the free template)**.** Let $\mathsf{b}>0$, Π the orthogonal projection of $L^2(\mathbb{R}^3;\mathbb{R}^3)$ with the Fourier multiplier $\delta_{ik}-k_ik_k/|k|^2$, $\mathsf{g}(x)=(4\pi|x|)^{-1}$, and $G(x)=\mathbb{K}_3(x)$.

(1) *Gaussian quadratic forms.* Fix $n\geq 2$, real symmetric $m\times m$ matrices $A_1,\dots,A_n$, and a centred Gaussian vector ξ with values in $\mathbb{R}^m$ and covariance Σ, which is allowed to be degenerate. The joint cumulant of $\frac12\xi^{\mathsf{T}}A_1\xi,\dots,\frac12\xi^{\mathsf{T}}A_n\xi$ is $\frac12\sum_\pi\operatorname{tr}(\Sigma A_1\Sigma A_{\pi2}\cdots\Sigma A_{\pi n})$, the sum over the $(n-1)!$ orders π of $2,\dots,n$; adding constants to the quadratic forms leaves it unchanged.

(2) *The field and the photons.* (a) A centred Gaussian process $B(\varphi)$, depending linearly on $\varphi=(\varphi^c)_{c=1,2,3}\in L^2(\mathbb{R}^3;\mathbb{R}^3)^3$, exists with the covariance $\mathbb{E}\,B(\varphi)B(\psi)=\mathsf{b}^{-1}\sum_c\langle\varphi^c,\Pi\psi^c\rangle_{L^2}$. (b) For bounded Borel $\varphi,\psi\in L^2(\mathbb{R}^3;\mathbb{R}^3)$ whose compact supports are at a positive distance, $\langle\varphi,\Pi\psi\rangle=\iint\varphi_i(x)G_{ik}(x-y)\psi_k(y)\,dx\,dy$; the entries $G_{ik}=\partial_i\partial_k\mathsf{g}$ are harmonic off the origin, and $G(-x)=G(x)=G(x)^{\mathsf{T}}$. (c) For $\zeta\geq0$, $\mathcal{A}$ denotes a centred Gaussian process indexed by the triples $\varphi=(\varphi^c)_{c=1,2,3}\in\mathcal{S}(\mathbb{R}^3;\mathbb{R}^3)^3$ of Schwartz vector fields, whose covariance is $\mathbb{E}\,\mathcal{A}(\varphi)\mathcal{A}(\psi)=\mathsf{b}^{-1}\sum_c\int\overline{\hat\varphi^c_i(k)}\,|k|^{-2}[\delta_{ik}-(1-\zeta)k_ik_k/|k|^2]\,\hat\psi^c_k(k)\frac{dk}{(2\pi)^3}$; for $\zeta>0$ this is the inverse Hessian of the quadratic action $\frac{\mathsf{b}}{2}\int|\operatorname{curl}\mathcal{A}|^2+\frac{\mathsf{b}}{2\zeta}\int(\operatorname{div}\mathcal{A})^2$. For every ζ, the process $\varphi\mapsto\mathcal{A}(\operatorname{curl}\varphi)$, $\varphi\in\mathcal{S}(\mathbb{R}^3;\mathbb{R}^3)^3$, with the curl applied colour by colour, and the restriction of B of (a) to these Schwartz triples have one and the same covariance; in this sense $B=\operatorname{curl}\mathcal{A}$ in law. (d) For $Q=\sum_c\mathcal{A}^c\sigma_c$ with real one-forms $\mathcal{A}^c\in C^1$, the terms of second order in $\mathcal{A}$ of $\mathrm{YM}(f)(Q)$ sum to $\frac12\int f\sum_c|\operatorname{curl}\mathcal{A}^c|^2$; so $\mathsf{b}\,\mathrm{YM}(1)$ has at second order the action $\mathsf{b}\cdot\frac12\int|\operatorname{curl}\mathcal{A}^c|^2$ of three photons, and $\mathrm{YM}(f)$ has at second order $\frac12\int f|B|^2$, $B^c=\operatorname{curl}\mathcal{A}^c$.

(3) *The connected functions of* $\frac12{:}|B|^2{:}$. Let $\varrho\in C^\infty_c(\mathbb{R}^3)$ be ≥0, of integral 1 and supported in $\{|x|\leq1\}$, $\varrho_\varepsilon(x)=\varepsilon^{-3}\varrho(x/\varepsilon)$, $B^c_{\varepsilon,k}(x)=B(\varrho_\varepsilon(x-\cdot)e_k\otimes e^c)$, $C^\varepsilon_{ik}(x-y)=\langle\varrho_\varepsilon(x-\cdot)e_i,\Pi\varrho_\varepsilon(y-\cdot)e_k\rangle$, and for a bounded Borel f with compact support $\mathcal{O}_\varepsilon(f)=\frac12\int f(x)[|B_\varepsilon(x)|^2-\mathbb{E}|B_\varepsilon(x)|^2]\,dx$, a Bochner integral in L^p for every $p<\infty$. Let $n\geq2$ and $f_1,\dots,f_n$ bounded Borel functions with compact supports at pairwise distances $\geq\delta_0>0$. For random variables $Y_1,\dots,Y_n$ with moments of every order, $\kappa_n(Y_1,\dots,Y_n)$ denotes their joint cumulant; the $\mathcal{O}_\varepsilon(f_i)$ are such variables. (a) For every $\varepsilon>0$, $\kappa_n(\mathcal{O}_\varepsilon(f_1),\dots,\mathcal{O}_\varepsilon(f_n))=\frac32\mathsf{b}^{-n}\sum_\pi\int\prod_i f_i(x_i)\operatorname{tr}[C^\varepsilon(x_1-x_{\pi2})C^\varepsilon(x_{\pi2}-x_{\pi3})\cdots C^\varepsilon(x_{\pi n}-x_1)]\,dx$. (b) For radial ϱ and $\varepsilon<\delta_0/2$ one has the identity $\kappa_n(\mathcal{O}_\varepsilon(f_1),\dots,\mathcal{O}_\varepsilon(f_n))=3\,\mathsf{b}^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}(f_1,\dots,f_n)$, with the functional of Definition 18.116(3). (c) For any ϱ as above and $\varepsilon\leq\delta_0/4$, the modulus of the difference of the two members in (b) is at most $104\,n!\,(4/\pi)^{n-1}\mathsf{b}^{-n}\varepsilon\,\delta_0^{-3n-1}\prod_i\|f_i\|_{L^1}$; so the limit $\varepsilon\to0$ exists and depends on b and G alone, and this limit is what we call the connected function of $\frac12{:}|B|^2{:}$ at $(f_1,\dots,f_n)$. (d) For a continuous real $f\neq0$ with compact support, $\varepsilon^3\operatorname{Var}\mathcal{O}_\varepsilon(f)$ tends to a positive number, so $\operatorname{Var}\mathcal{O}_\varepsilon(f)\to\infty$: it is the set of the connected functions evaluated at tuples with separated supports that has a limit, not the variable $\mathcal{O}_\varepsilon(f)$.

(4) *The dictionary.* The connected functions of (3) form the free template $S^{\mathrm{fr}}[3,\mathsf{b}]$ of Definition 18.116(3). For $n=2$ one gets $\mathsf{c}_2\mathsf{b}^{-2}\mathcal{K}_6(f,h)$, $\mathsf{c}_2=\frac{9}{16\pi^2}$; for $n=3$ one gets $3\mathsf{b}^{-3}\mathcal{K}^{(3)}_{\mathrm{free}}$, where the kernel k_3 of $\mathcal{K}^{(3)}_{\mathrm{free}}$ is $k_3(x_1,x_2,x_3)=-\dfrac{3+9\,\mathsf{q}_\triangle(x_1,x_2,x_3)}{(4\pi)^3|x_1-x_2|^3|x_2-x_3|^3|x_3-x_1|^3}$, $\mathsf{q}_\triangle$ being the product of the cosines of the angles of the triangle. So, for every order $n\geq2$, the function $S^{\mathrm{fr}}_n[3,\mathsf{b}]=3\mathsf{b}^{-n}\mathcal{K}^{(n)}_{\mathrm{free}}$ of the free template is the connected function of order n

of $\frac12{:}|B|^2{:}$, where $B^c=\operatorname{curl}\mathcal{A}^c$ for three independent free photon fields $\mathcal{A}^c$ on $\mathbb{R}^3$ with the action $\mathsf{b}\cdot\frac12\int|\operatorname{curl}\mathcal{A}|^2$, at the label b. By (2)(d), point by point, the density $\mathsf{b}\cdot\frac12\sum_c|\operatorname{curl}\mathcal{A}^c|^2$ of their action and the density $\frac12 f|B|^2$ are the parts of second order in $\mathcal{A}$ of the integrands $\frac{\mathsf{b}}{2}\sum_{\mu<\nu}|F_{\mu\nu}|^2$ of $\mathsf{b}\,\mathrm{YM}(1)$ and $\frac12 f\sum_{\mu<\nu}|F_{\mu\nu}|^2$ of $\mathrm{YM}(f)$, formed at $Q=\sum_c\mathcal{A}^c\sigma_c$, while on the lattice of a torus T_ℓ the functions βA and $\mathcal{O}(f)$ stand for $\mathsf{b}\,\mathrm{YM}(1)$ and $\mathrm{YM}(f)$ (Proposition 18.151(2), (3)).

■

Proof. (1). Write $\xi=\Sigma^{1/2}\zeta$ with ζ standard Gaussian and $A(t)=\sum_j t_jA_j$; for small t the symmetric matrix $M=\Sigma^{1/2}A(t)\Sigma^{1/2}$ has norm <1, and diagonalising it gives $\mathbb{E}\exp(\frac12\zeta^{\mathsf{T}}M\zeta)=\prod_i(1-m_i)^{-1/2}$. The logarithm of the generating function is therefore $-\frac12\log\det(\mathbf{1}-M)=\frac12\sum_{k\ge1}\frac1k\operatorname{tr}\big((\Sigma A(t))^k\big)$, analytic near 0, and the joint cumulant is the coefficient of $t_1\cdots t_n$, carried by the term $k=n$ alone: $\frac{1}{2n}\sum_{\varsigma\in S_n}\operatorname{tr}(\Sigma A_{\varsigma1}\cdots\Sigma A_{\varsigma n})$. The cyclic rotations split S_n into classes of size n, each of which contains a single permutation fixing 1. Adding constants to the forms only adds a linear function of t to the logarithm.

(2). (a) Since Π is an orthogonal projection, the covariance form is symmetric and ≥0, and a Gaussian process with it exists. (b) For $\varphi,\psi\in C_c^\infty$ Plancherel's theorem gives $\langle\varphi,\Pi\psi\rangle=\int\varphi\cdot\psi-\iint(\operatorname{div}\varphi)(x)\mathsf{g}(x-y)(\operatorname{div}\psi)(y)\,dx\,dy$, as g has the Fourier transform $|k|^{-2}$. When the supports are disjoint, $\int\varphi\cdot\psi=0$, and integrating by parts in x and in y yields the kernel $\partial_i\partial_k\mathsf{g}(x-y)=G_{ik}(x-y)$, with $\partial_i\partial_k(4\pi|x|)^{-1}=(4\pi)^{-1}(3x_ix_k|x|^{-5}-\delta_{ik}|x|^{-3})$. For bounded Borel φ,ψ one approximates by mollified functions whose supports keep a distance $\ge\frac{\delta}{2}$; both sides pass to the limit, the left one in L^2 and the right one in L^1. Off the origin $\Delta G_{ik}=\partial_i\partial_k\Delta\mathsf{g}=0$. (c) The matrix $|k|^{-2}[\Pi(k)+\zeta kk^{\mathsf{T}}/|k|^2]$ is positive semidefinite and locally integrable in k; since $(\operatorname{curl}\varphi)^\wedge=ik\times\hat\varphi$ is orthogonal to k, the part with kk^{T} does not contribute, and $\overline{(k\times\hat\varphi)}\cdot(k\times\hat\psi)=|k|^2\,\overline{\hat\varphi}\cdot\Pi(k)\hat\psi$. (d) $F_{\mu\nu}=\sum_c(\partial_\mu\mathcal{A}^c_\nu-\partial_\nu\mathcal{A}^c_\mu)\sigma_c+i[Q_\mu,Q_\nu]$, and the commutator is of second order in $\mathcal{A}$; as $\langle\sigma_c,\sigma_e\rangle=\delta_{ce}$, the second-order part of $|F_{\mu\nu}|^2$ is $\sum_c(\partial_\mu\mathcal{A}^c_\nu-\partial_\nu\mathcal{A}^c_\mu)^2$, whose sum over $\mu<\nu$ is $\sum_c|\operatorname{curl}\mathcal{A}^c|^2$.

(3). Translation is continuous in L^2, so $B^c_{\varepsilon,k}(x)$ depends continuously on x in L^2 of the probability space, and, Gaussian variables having all their moments bounded by powers of the second one, also in every L^p. So the Bochner integral defining $\mathcal{O}_\varepsilon(f)$ makes sense, and the joint cumulant, continuous and multilinear on L^n, may be taken under the integral sign: $\kappa_n(\mathcal{O}_\varepsilon(f_1),\dots)=\int\prod_i f_i(x_i)\,\kappa_n(\frac12|B_\varepsilon(x_1)|^2,\dots,\frac12|B_\varepsilon(x_n)|^2)\,dx$. (a) Use (1) for the Gaussian vector ξ of the $9n$ numbers $B^c_{\varepsilon,k}(x_j)$, with A_j selecting the nine coordinates that belong to x_j; the covariance of ξ is made of the blocks $\mathsf{b}^{-1}\mathbf{1}_3\otimes C^\varepsilon(x_j-x_{j'})$, and the trace over the colours contributes the factor 3. No distance between the points x_j or between the supports enters this computation, coinciding points giving a degenerate Σ, which (1) admits; so the formula of (a) holds at all bounded Borel $f_1,\dots,f_n$ with compact supports. (b) For $|x-y|>2\varepsilon$, (2)(b) gives $C^\varepsilon(x-y)=\int\eta_\varepsilon(z)G(x-y-z)\,dz$ with $\eta_\varepsilon(z)=\int\varrho_\varepsilon(u)\varrho_\varepsilon(u-z)\,du$, a probability density supported in $|z|\le2\varepsilon$, radial when ϱ is. Averaging the harmonic function G_{ik} over spheres centred at $x-y$ returns its value there, so $C^\varepsilon(x-y)=G(x-y)$. Where $\prod_i f_i(x_i)\ne0$ all the distances are $\ge\delta_0>2\varepsilon$; the orders π of $2,\dots,n$ correspond to the cyclic orders ς with $\varsigma(1)=1$, and $\frac32\sum_\pi\operatorname{tr}[G\cdots G]=3k_n$ by the definition of k_n. The integral is therefore $3\mathsf{b}^{-n}\mathcal{K}^{(n)}_{\text{free}}$. (c) For a unit vector e, $\|\partial_eG(u)\|\le\frac{9}{4\pi|u|^4}$, and $\|G(u)\|=\frac{2}{4\pi|u|^3}$; so for $|x|\ge\delta_0\ge4\varepsilon$ and $|z|\le2\varepsilon$, $\|C^\varepsilon(x)\|,\|G(x)\|\le\frac{4}{\pi\delta_0^3}$ and $\|C^\varepsilon(x)-G(x)\|\le\frac{72\varepsilon}{\pi\delta_0^4}$. The trace of a 3×3 matrix is at most 3 times its norm; expanding the difference of the two products of n factors as a telescoping sum and multiplying by $\frac32\mathsf{b}^{-n}(n-1)!\prod\|f_i\|_{L^1}$ gives the bound, as $\frac92\cdot\frac{72}{\pi}<104$. (d) At $n=2$, $f_1=f_2=f$, the formula of (a), valid at coinciding supports as noted at the end of the proof of (a), reads $\operatorname{Var}\mathcal{O}_\varepsilon(f)=\frac32\mathsf{b}^{-2}\iint f(x)f(y)\operatorname{tr}C^\varepsilon(x-y)^2\,dx\,dy$, as C^ε is even; $C^\varepsilon(x)=\varepsilon^{-3}C^1(x/\varepsilon)$, so $\varepsilon^3\operatorname{Var}\mathcal{O}_\varepsilon(f)\to\frac32\mathsf{b}^{-2}\|\operatorname{tr}(C^1)^2\|_{L^1}\int f^2>0$, by Plancherel's theorem and $\operatorname{tr}\Pi(k)^2=2$.

(4). The template identity is (3)(b), (c) with Definition 18.116(3). For a unit vector $e \in \mathbb{R}^3$ let $D(e) = 3ee^{\mathsf{T}} - \mathbf{1}$, and for $u \neq 0$ let $\hat{u} = u/|u|$; then $G(u) = (4\pi)^{-1}|u|^{-3}D(\hat{u})$, and $D(-e) = D(e)$. For $n = 2$, $\mathrm{Cyc}(2)$ consists of a single cyclic order, and at $u = x_1 - x_2$ the matrix $D(\hat{u})^2 = 3\hat{u}\hat{u}^{\mathsf{T}} + \mathbf{1}$ has the trace 6, so $k_2 = \frac{1}{2} \cdot \frac{6}{(4\pi)^2}|u|^{-6}$ and $3k_2 = \mathsf{c}_2|u|^{-6}$. For $n = 3$ the two cyclic orders yield equal traces, as G is symmetric and even, so $k_3 = \operatorname{tr} G(x_1 - x_2)G(x_2 - x_3)G(x_3 - x_1)$; with the unit vectors $\mathsf{e}_1, \mathsf{e}_2, \mathsf{e}_3$ of $x_1 - x_2$, $x_2 - x_3$, $x_3 - x_1$, $\operatorname{tr} D(\mathsf{e}_1)D(\mathsf{e}_2)D(\mathsf{e}_3) = 27(\mathsf{e}_1 \cdot \mathsf{e}_2)(\mathsf{e}_2 \cdot \mathsf{e}_3)(\mathsf{e}_3 \cdot \mathsf{e}_1) - 9[(\mathsf{e}_1 \cdot \mathsf{e}_2)^2 + (\mathsf{e}_2 \cdot \mathsf{e}_3)^2 + (\mathsf{e}_3 \cdot \mathsf{e}_1)^2] + 6$, and the scalar products are minus the cosines of the angles of the triangle; with $\cos^2 A + \cos^2 B + \cos^2 C = 1 - 2\cos A \cos B \cos C$ this is $-(3 + 9\mathsf{q}_{\triangle})$. The last sentence is (2)(c), (d) with Proposition 18.151(2), (3). □

18.15. **On one torus: the torus limits in the label, the statistic on one thread, and other plaquette weights.** We use the block fields and the Wilson measure of Definition 18.140 on a fixed torus T_ℓ. Proposition 18.154 takes the torus limits as functions of the label: they are real-analytic on $(0, \infty)$ and extend to a complex strip whose width is fixed by the side and the interval of labels, their derivatives in the label are insertions of the constant function 1, and the law of two points turns into a sum rule for the three-point function with one entry 1. Proposition 18.155 takes the background action statistic T_d^K at $K = K(d)$, the cutoff that Corollary 18.213 attaches to the depth d, and compares $T_d = T_d^{K(d)}$ with the number $m_d(\mathsf{b}) = \int T_d \, d\mu_d^{K(d)}[\mathsf{b}]$, an integral against the law of the block field at that same cutoff: on almost every thread the two differ by at most a constant times $(dN_d)^{1/2}$ once d exceeds a depth that depends on the thread; hence $m_d(\mathsf{b})$ is of the form $N_d[\varkappa_0\mathsf{b}^{-1} + \varkappa_1 L^{-d}\mathsf{b}^{-2} + o(L^{-d})]$ precisely when $L^d[N_d^{-1}T_d - \varkappa_0\mathsf{b}^{-1}]$ tends to $\varkappa_1\mathsf{b}^{-2}$ on almost every thread, and when $m_d(\mathsf{b})$ is of this form its coefficient $\varkappa_1$ can be found from one thread alone; it shows besides that the singularity of the thread measure against the laws of Gaussian lattice fields, and the smallness of their affinity, hold for every gauge-invariant law in its place. Proposition 18.158, with Lemmas 18.156 and 18.157 on a real source in the chain of the main text, carries the laws of the block fields from Wilson's plaquette weight to the weights $e^{-\beta s}\hat{m}(s)e^{-h(s)}$, in which $\hat{m}(s) = \int e^{-\tau s} m(d\tau)$ for a probability measure m that lives on a short interval, and $0 \leq h(s) \leq M_h s^4$; they include the mixed action whose adjoint coupling is positive and small. The label stays the same, and at the cutoff K' the error is at most a constant times $L^{-K'/11}$.

Definition 18.153 (Signs)**.** Use the fixed constants ς of §2.3.1 and write ϱ_ς for its source radius. Let $\ell = 2L^m$, $m \geq 1$, and use V_d, $\mathcal{M}$, $\mu_d^K[s]$, $\mu_d[s]$ and $\mu_{\ell,s}$ of Definition 18.140, with $a_d = L^{-d}$ and $N_d = \ell^3 L^{3d}$. For an admitted interval $J = [\mathsf{b}_-, \mathsf{b}_+]$ on this side put $d_\natural = \min\{d \geq 1 : L^d\mathsf{b}_- \geq \mathsf{t}_\natural\}$. For $K > d \geq d_\natural$ and $t = K - d$, let $\mathsf{Cut}_t[s]$ and $\mathsf{In}_t[s]$ be the cut and inner ball of Lem. YM3_I:113.10 on the line $x_j = L^{K-j}s$. If $U_t(V)$ is the critical background over V, define

$$T_d^K(V) = \begin{cases} L^K \sum_p a_p(U_t(V)), & V \in \mathsf{Cut}_t[\mathsf{b}_-], \\ 0, & V \notin \mathsf{Cut}_t[\mathsf{b}_-]. \end{cases}$$

The critical orbit is independent of the label and the action is constant on it. The cut and the action are Borel and gauge invariant by Lem. YM3_I:113.10 and Prop. YM3_I:114.2. Use the constants c_{A}, C_{old} and $C_{\mathrm{E},0}$ of YM3_I:(2163) and put

$$\mathsf{Q}' = \max\left\{\varrho_\varsigma^{-1}, \tfrac{3}{2}c_\rho^2\ell^3 \sup_{u \geq 1} \varepsilon(L^u\mathsf{b}_-)^2, \varrho_\varsigma^{-1}C_{\mathrm{old}}\tfrac{L}{L-1}E_0\ell^3\right\},$$

$$\Xi_u[s] = \frac{c_{\mathrm{A}}\alpha_0\varepsilon_{\mathcal{W}}}{2Mc_\rho\varepsilon(L^u s)}, \qquad \theta_0 = c'A_0^2(\log L)^{2\mathfrak{p}_0},$$

$$\rho[s](u) = 2M^{-3}\ell^3 L^{3u}\exp[(C_{\mathrm{maj}}^{\Sigma} + 2 + C_{\mathrm{low}}(s))\ell^3 - \theta_0 u^2].$$

The constants of the cut are those of §2.3.1. By the action estimate YM3_I:(2161), $0 \leq T_d^K \leq \mathsf{Q}'L^{4d}$. Take $u_\flat$ to be the least integer $u \geq d_\natural$ with $\theta_0(2u+1) \geq 3\log L$ and $\rho[\mathsf{b}_+](u) \leq 1/4$. The Gaussian decay in u ensures that this integer exists and that $\rho[s](u) \leq 1/4$ for every $s \in J$ and $u \geq u_\flat$.

(1) *Tuples and limits.* Use the norms $\|f\|_\sharp$ and $\|f\| = \|f\|_\flat$ of Definitions 18.159(3) and 18.143(1). A tuple has $n \geq 2$ real Lipschitz entries with empty intersection of their supports. For nonzero entries, its spread $\mathsf{d}_\infty(\underline{f})$ is the minimum of the maximum pairwise sup distance over one point from each support, as in Definition 18.159(2). It is positive by compactness. Write $\underline{f}^{+\nu} = (1^\nu, \underline{f})$ and $\underline{f}^{(s)}$ for the dilated tuple on $T_{L^s\ell}$. The scalar cutoff cumulants and their torus limits $S_n^{\ell,\mathsf{b}}(\underline{f})$ are those of Thm. YM3_I:AS. For compact $J \subset (0,\infty)$ and $r > 0$ set $\Omega_r(J) = \{\zeta : \operatorname{dist}(\zeta, J) < r\}$.

(2) *Distances of laws.* Let P, Q be probability measures on one measurable space, with densities p, q against a σ-finite measure λ. Their total variation is $\|P - Q\| = \sup_E |P(E) - Q(E)| = \frac{1}{2}\int |p - q|\, d\lambda$, and their affinity is $\operatorname{aff}(P, Q) = \int (pq)^{1/2} d\lambda$; neither of the two depends on λ.

(3) *Gauge.* $\mathcal{G}_d$ is the compact group of the gauge transformations of the lattice of depth d, acting by $V^u(x,y) = u(x)V(x,y)u(y)^{-1}$ on the bond from x to y, and du is its Haar probability measure. A Borel probability measure P on V_d is *gauge invariant* if it is its own image under $V \mapsto V^u$ for every $u \in \mathcal{G}_d$; $\mathscr{I}_d$ is the σ-algebra of the Borel sets of V_d that every $u \in \mathcal{G}_d$ maps onto themselves; and the *gauge average* of a Borel probability measure ν on V_d is $\bar\nu = \int \nu^u\, du$, where ν^u is the image of ν under $V \mapsto V^u$. A site $a_d k$, $k \in \mathbb{Z}^3$, is *even* if $k_1 + k_2 + k_3$ is even; as ℓL^d is even this is a property of the site of T_ℓ, there are $\frac{1}{2}N_d$ even sites, and the two ends of a bond have different parities. For an even site y we write c_y for the bond from y to $y + a_d e_1$, and we put

$$E_d = \{V \in \mathsf{V}_d :\ |V(c_y) - \mathbf{1}|_{\mathrm{op}} \leq 1 \text{ for every even site } y\}, \qquad h_0 = \tfrac{1}{3} - \tfrac{\sqrt{3}}{4\pi} = 0.1955\ldots,$$

$|\cdot|_{\mathrm{op}}$ being the operator norm of 2×2 matrices.

(4) *Gaussian lattice fields.* Let $c > 0$. Let $A = (A^1, A^2, A^3)$ be three independent centred Gaussian fields indexed by the vector fields $\varphi \in L^2(T_\ell; \mathbb{R}^3)$, with

$$\mathbb{E}\, A^a(\varphi) A^{a'}(\psi) = \delta_{aa'}\, c^{-1}\ell^{-3} \sum_{k \in (2\pi/\ell)\mathbb{Z}^3 \setminus \{0\}} |k|^{-2}\, \overline{\hat\varphi(k)} \cdot \Pi(k) \hat\psi(k), \qquad \hat\varphi(k) = \int_{T_\ell} \varphi(x) e^{-ik\cdot x} dx, \qquad \Pi(k) = 1 - \frac{kk^{\mathsf{T}}}{|k|^2},$$

the field of the covariance $c^{-1}(d^*d)^{-1}$ on the orthogonal complement of the closed one-forms. For the bond b from x to $x + a_d e_\mu$ let $q_b(z) = a_d^{-3} \big|\{\tau \in [0, a_d] :\ z - x - \tau e_\mu \in [-\frac{1}{2}a_d, \frac{1}{2}a_d)^3\}\big|\, e_\mu$, so that $A^a(q_b)$ is the mean, over the shifts by the points of a cube of side a_d, of the line integral of the component μ of A^a along the shifted bond; put $B^a(b) = A^a(q_b)$, $B(b) = (B^a(b))_a$, and $V_d^{\mathrm{qf}}(b) = \exp(i \sum_a B^a(b)\sigma_a)$, σ_a the Pauli matrices, with $V_d^{\mathrm{qf}}(b^{-1}) = V_d^{\mathrm{qf}}(b)^{-1}$. The *quasi-free law* $\nu_d[c]$ is the law of V_d^{qf} on V_d, and $\nu[c]$ is the law on $\mathsf{V} = \prod_{d \geq 0} \mathsf{V}_d$ of the family $(V_d^{\mathrm{qf}})_{d \geq 0}$, all of whose members are built from one field A.

■

Proposition 18.154 (The torus limits as functions of the label)**.** Let $\ell = 2L^m$ be a side and $\underline{f} = (f_1, \ldots, f_n)$ a tuple on T_ℓ none of whose entries is 0.

(1) *(Each cutoff.)* Use the real construction of Definition 18.159(1). For every $K \in \mathbb{N}$ the function $\mathsf{b} \mapsto S^T_{n;K,\ell,L^K\mathsf{b}}(\underline{f})$ is real-analytic on $(0,\infty)$, and $\partial_{\mathsf{b}}^\nu S^T_{n;K,\ell,L^K\mathsf{b}}(\underline{f}) = (-1)^\nu S^T_{n+\nu;K,\ell,L^K\mathsf{b}}(\underline{f}^{+\nu})$ for every $\nu \geq 0$ and $\mathsf{b} > 0$.

(2) *(The limit is smooth.)* Under the same constants the function $\mathsf{b} \mapsto S_n^{\ell,\mathsf{b}}(\underline{f})$ is infinitely differentiable on $(0,\infty)$, with

$$\partial_{\mathsf{b}}^\nu S_n^{\ell,\mathsf{b}}(\underline{f}) = (-1)^\nu S_{n+\nu}^{\ell,\mathsf{b}}(\underline{f}^{+\nu}) \qquad (\nu \geq 0,\ \mathsf{b} > 0),$$

and for every ν the derivative of order ν at the cutoff K tends to the derivative of order ν of the limit as $K \to \infty$, uniformly on the compact subsets of $(0,\infty)$. With a rate: let $0 < \mathsf{b}_- \leq \mathsf{b}_+$, let $s \geq 0$ be an integer with $L^s\mathsf{b}_- \geq \gamma^{-2}$ and $M\, R(L^s\mathsf{b}_+) \leq L^{m+s}$ (all large s are such by Lem. YM3_I:118.2), let $0 < \mathsf{d} \leq \mathsf{d}_\infty(\underline{f})$, and let C'_s, $K_{1,s}(\mathsf{d})$ be the numbers of

Theorem YM3_I:AS formed for $n+\nu$ entries, with $\mathsf{p}_{n+\nu} = 2\mathfrak{p}_0(n+\nu+1)+\frac{1}{2}$; then for all $\mathsf{b} \in [\mathsf{b}_-, \mathsf{b}_+]$ and all integers $K \ge K_{1,s}(\mathsf{d}) + s$

$$|\partial_{\mathsf{b}}^{\nu} S^{T}_{n;K,\ell,L^K\mathsf{b}}(\underline{f}) - \partial_{\mathsf{b}}^{\nu} S^{\ell,\mathsf{b}}_{n}(\underline{f})| \le L^{s(n+\nu)}\, \mathsf{C}'_s\, (L^s\ell)^{3(n+\nu+1)} (K-s)^{\mathsf{p}_{n+\nu}} L^{-(K-s)/10} \prod_{i=1}^{n} \|f_i\|_\sharp,$$

and the two numbers C'_s, $K_{1,s}(\mathsf{d})$ serve all tuples of n entries with spread at least d and all labels of the interval.

(3) *(Lipschitz in the label.)* Under the same constants and with the same $\mathsf{b}_\pm$, s, d, put $r = n+1$, $Y = \underline{f}^{+1}$ and let $k_* = K_{1,s}(\mathsf{d})$ and C'_s here be the constants for r entries. Write $\mathsf{op}_r = \sum_\pi |\pi|!$ over partitions of $\{1,\dots,r\}$ and set

$$\mathsf{L} = \mathsf{op}_r \prod_{i=1}^{r} (6\ell^3 L^{4(k_*+s)} \|Y_i\|_\infty) + L^{sr}\mathsf{C}'_s (L^s\ell)^{3(r+1)} k_*^{\mathsf{p}_r} L^{-k_*/10} \prod_{i=1}^{r} \|Y_i\|_\sharp.$$

Then then $|S^{T}_{n;K,\ell,L^K\mathsf{b}}(\underline{f}) - S^{T}_{n;K,\ell,L^K\mathsf{b}'}(\underline{f})| \le \mathsf{L}|\mathsf{b}-\mathsf{b}'|$ for all $K \in \mathbb{N}$ and $\mathsf{b}, \mathsf{b}' \in [\mathsf{b}_-, \mathsf{b}_+]$, and the same bound holds for the limits.

(4) *(A strip.)* Let the constants be a sourced setting $\mathfrak{s}$ with radius ϱ from Definition 18.159(1). Let $0 < \mathsf{b}_- < \mathsf{b}_+$, and let $s \ge 0$ be an integer with

$$L^s\mathsf{b}_- \ge 2\gamma^{-2}, \qquad 2L^{m+s} \in \mathfrak{L}\big((\tfrac{1}{2}L^s\mathsf{b}_+)^{-1/2}\big);$$

all large s are such. Put

$$\upsilon_s = \tfrac{1}{4} L^{-s} \varrho \exp\Big[-\Big(C_{\mathrm{S}} + C_{\mathrm{st}} + \tfrac{9}{2}\log\big(L(\tfrac{1}{2}L^s\mathsf{b}_+ + B_\sharp)\big)\Big)(L^s\ell)^3\Big],$$

with the source stability constants C_{S} and C_{st} of Definition 18.159(4). There is exactly one holomorphic function $\Phi[\underline{f}]$ on $\Omega_{\upsilon_s}([\mathsf{b}_-, \mathsf{b}_+])$ that equals $S^{\ell,\mathsf{b}}_n(\underline{f})$ at the points $\mathsf{b} \in [\mathsf{b}_-, \mathsf{b}_+]$; it is bounded, and it equals $S^{\ell,\mathsf{b}}_n(\underline{f})$ at every real point b of its domain. Consequently $\mathsf{b} \mapsto S^{\ell,\mathsf{b}}_n(\underline{f})$ is real-analytic on $(0,\infty)$; for $\mathsf{b} \in [\mathsf{b}_-, \mathsf{b}_+]$ and real t with $|t| < \upsilon_s$

$$S^{\ell,\mathsf{b}+t}_n(\underline{f}) = \sum_{\nu \ge 0} \frac{(-t)^\nu}{\nu!}\, S^{\ell,\mathsf{b}}_{n+\nu}(\underline{f}^{+\nu}), \qquad |S^{\ell,\mathsf{b}}_{n+\nu}(\underline{f}^{+\nu})| \le \nu!\, \upsilon_s^{-\nu} \sup|\Phi[\underline{f}]|;$$

and for every $\mathsf{b} \ge \gamma^{-2}$ the interval $(\mathsf{b}-2\varrho, \mathsf{b}+2\varrho)$ lies in $(0,\infty)$, so the limit is real-analytic on it.

(5) *(A sum rule with one insertion of* 1*.)* Let the constants be a setting $\mathfrak{s}$, let $0 < g \le \gamma_W$ with the ceiling γ_W of YM3_I:(2346), $\ell \in \mathfrak{L}(g)$, $\vartheta \in (0,1)$, $0 < \mathsf{d} \le \mathsf{d}_0(g,\vartheta)$ with d_0 of YM3_I:(2350), and let $(f,h) \in \mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ be a test pair of Definition 18.159(5). Let $\mathsf{b}_1 > 0$ with $\mathsf{b}_1 \in I(g)$ and $2\mathsf{b}_1 \in I(g)$. Then $(1,f,h)$ is a tuple on T_ℓ none of whose entries is 0, and

$$\int_{\mathsf{b}_1}^{2\mathsf{b}_1} S^{\ell,\mathsf{b}}_3(1,f,h)\, d\mathsf{b} = S^{\ell,\mathsf{b}_1}_2(f,h) - S^{\ell,2\mathsf{b}_1}_2(f,h) \ge \tfrac{1}{3}\,\mathsf{c}_2\mathsf{b}_1^{-2}\mathcal{K}_{\mathrm{free}}(f,h) \ge \tfrac{1}{3}\,10^{-6}\vartheta^2\,\mathsf{c}_2\mathsf{b}_1^{-2}\|f\|_\infty\|h\|_\infty > 0,$$

with the constant c_2 and the pair kernel $\mathcal{K}_{\mathrm{free}} = \mathcal{K}_6$ of Definition 18.159(5). Hence $\mathsf{b} \mapsto S^{\ell,\mathsf{b}}_3(1,f,h)$ is not identically 0 on $(0,\infty)$, and its zeros have no limit point in $(0,\infty)$.

■

Proof. The exact finite-cutoff derivative and its convergence follow from Prop. 18.160. The constant insertions do not alter the spread and have $\|1\|_\sharp = 1$. For the explicit rate, apply Cor. YM3_I:117.1 on the dilated torus to $(\underline{f}^{+\nu})^{(s)}$, whose spread is at least $L^s\mathsf{d}$. One can use the weaker threshold formed at spread d because $s \ge 0$. The dilation identity YM3_I:(2209) supplies the factor $L^{s(n+\nu)}$, and the dilated entries have no larger norms. This proves clauses (1) and (2).

For clause (3), the cumulant partition formula and the bound $|\mathcal{O}(f)| \le 6\ell^3 L^{4K}\|f\|_\infty$ give the first term of L when $K \le k_* + s$, including at $K = k_* + s$. For $K \ge k_* + s$, apply YM3_I:(2207) at

the base cutoff k_* on the dilated torus, comparing with cutoff $K-s$, and use the same dilation as above. This costs at most the second term of L. It follows that the absolute value of the first derivative in the label is at most L at every cutoff. Integration gives the Lipschitz inequality, which survives the limit in clause (2).

For clause (4), Prop. 18.161 applies to every empty-intersection tuple. Its proof uses a finite partition of unity into small cubes, so each nonzero piece has a separated pair, and takes the same holomorphic width for all pieces. The width in the present statement is exactly the width there, since $X_{g(L^s\mathsf{b}_+)} = L(L^s\mathsf{b}_+/2 + B_\sharp)$. The same proposition gives the bounds and the absolutely convergent series with constant entries. The canonical source room gives $2\varrho \le \gamma^{-2} - \bar{B} < \gamma^{-2}$, so the indicated real interval about every $\mathsf{b} \ge \gamma^{-2}$ is positive.

Finally integrate $\partial_{\mathsf{b}} S_2^{\ell,\mathsf{b}}(f,h) = -S_3^{\ell,\mathsf{b}}(1,f,h)$ on $[\mathsf{b}_1, 2\mathsf{b}_1]$. The two-point estimates of Prop. 18.141(3)(a1) at the endpoints, with relative error at most $1/3$, give

$$S_2^{\ell,\mathsf{b}_1}(f,h) - S_2^{\ell,2\mathsf{b}_1}(f,h) \ge \mathsf{c}_2 \mathsf{b}_1^{-2} \mathcal{K}_6(f,h) \left[(1-\tfrac{1}{3}) - \tfrac{1}{4}(1+\tfrac{1}{3})\right] = \tfrac{1}{3}\mathsf{c}_2 \mathsf{b}_1^{-2} \mathcal{K}_6(f,h).$$

The lower bound for the kernel is in Definition 18.159(5). The integral is positive, so the analytic integrand has only isolated zeros in $(0,\infty)$. □

Proposition 18.155 (The statistic on one thread; what gauge invariance alone gives)**.** Use Definition 18.153 with an admitted interval $J = [\mathsf{b}_-, \mathsf{b}_+]$ on the side ℓ. For $d \ge d_\natural$ let $K(d)$ be the cutoff of Corollary 18.213, and put $T_d = T_d^{K(d)}$, $m_d^K(s) = \int T_d^K \, d\mu_d^K[s]$ and $m_d(s) = m_d^{K(d)}(s)$ for $s \in J$. Set

$$\mathsf{v}_d = 2E_0 C_{\mathrm{E},0} L^{-3} N_d, \qquad \mathsf{A} = 8E_0 C_{\mathrm{E},0} \varrho_\varsigma^{-2} L^{-3} \log L.$$

(1) *(Tails at a cutoff.)* Let $\mathsf{b} \in J$ and let $u_\flat \le d' < d < K$ be integers with $\Xi_d[\mathsf{b}_-] \ge 2$. For every real λ with $0 \le \lambda \le \mathsf{v}_d/(8\varrho_\varsigma^2 \mathsf{Q}' L^{4d'})$,

$$\mu_d^K[\mathsf{b}]\Big(\big|T_d^K - m_d^K(\mathsf{b})\big| \ge \lambda + 2\rho[\mathsf{b}](d')\,\mathsf{Q}' L^{4d}\Big) \le 4\exp\Big[-\frac{\varrho_\varsigma^2 \lambda^2}{2\mathsf{v}_d}\Big] + 2\rho[\mathsf{b}](d').$$

(2) *(On one thread.)* For every $\mathsf{b} \in J$ and $\mu_{\ell,\mathsf{b}}$-almost every thread V there is an integer d_V with

$$\big|T_d(V_d) - m_d(\mathsf{b})\big| \le (\mathsf{A}\, d\, N_d)^{1/2} + 1 \qquad \text{for all } d \ge d_V.$$

(3) *(The mean and one thread.)* Let $\mathsf{b} \in J$ and $\varkappa_0 \in \mathbb{R}$, and put $\xi_d(V) = L^d[N_d^{-1} T_d(V_d) - \varkappa_0 \mathsf{b}^{-1}]$ and $x_d = L^d[N_d^{-1} m_d(\mathsf{b}) - \varkappa_0 \mathsf{b}^{-1}]$. For $\mu_{\ell,\mathsf{b}}$-almost every V, $|\xi_d(V) - x_d| \le \mathsf{A}^{1/2} d^{1/2} \ell^{-3/2} L^{-d/2} + \ell^{-3} L^{-2d}$ for all large d; so for every real y the event $\{\xi_d \to y\}$ has the $\mu_{\ell,\mathsf{b}}$-probability 1 if $x_d \to y$ and 0 otherwise. In particular, for real $\varkappa_1$ the expansion

$$m_d(\mathsf{b}) = N_d[\varkappa_0 \mathsf{b}^{-1} + \varkappa_1 L^{-d} \mathsf{b}^{-2} + o(L^{-d})] \qquad (d \to \infty)$$

holds if and only if $\xi_d \to \varkappa_1 \mathsf{b}^{-2}$ $\mu_{\ell,\mathsf{b}}$-almost surely; and if it holds with $\varkappa_0 > 0$, then $\mu_{\ell,\mathsf{b}}$-almost surely

$$L^d\Big(\frac{\varkappa_0 N_d}{T_d(V_d)} - \mathsf{b}\Big) \to -\frac{\varkappa_1}{\varkappa_0}, \qquad L^d\Big[\frac{T_d(V_d)}{N_d} - \frac{T_{d+1}(V_{d+1})}{N_{d+1}}\Big] \to \frac{\varkappa_1}{\mathsf{b}^2}\Big(1 - \frac{1}{L}\Big).$$

(4) *(Gauge invariance alone.)* Let P be a gauge-invariant Borel probability measure on V_d. Under P the variables $V(c_y)$, y an even site, are independent, and each has the Haar law of SU(2); hence $P(E_d) = h_0^{N_d/2}$.

(5) *(Against the quasi-free laws.)* For every $c > 0$ and every $d \ge 0$, $\nu_d[c](\mathsf{V}_d \setminus E_d) \le 3N_d e^{-c/(12a_d)}$, and for every gauge-invariant Borel probability measure P on V_d

$$\mathrm{aff}(P, \nu_d[c]) \le h_0^{N_d/4} + (3N_d)^{1/2} e^{-c/(24a_d)} \le e^{-c/(48a_d)},$$

the second inequality from an integer d_c on, which depends on c and ℓ alone; for any $\mathsf{b} > 0$ the last member is $\exp[-k\ell^3/(\mathsf{b}^2 a_d)]$ with $k = c\mathsf{b}^2/(48\ell^3)$. The Borel set $\mathbf{E} = \{V \in \mathsf{V} : V_d \in$

E_d for all large $d\}$ has $\nu[c](\mathbf{E}) = 1$ for every $c > 0$, and $\mathbf{P}(\mathbf{E}) = 0$ for every Borel probability measure $\mathbf{P}$ on V whose images under the maps $V \mapsto V_d$ are gauge invariant. In particular $\mu_{\ell,\mathsf{b}}$ and $\nu[c]$ are mutually singular for all real $\mathsf{b} > 0$ and $c > 0$. What (4) and (5) assert on V_d uses of P only that it is gauge invariant; it applies to $P = \mu_d[\mathsf{b}]$ and, unchanged, to $P = \bar{\nu}_d[c']$, $c' > 0$, the average of a quasi-free law over the gauge group.

(6) *(On the invariant sets.)* Let P be a gauge-invariant and ν any Borel probability measure on V_d. Then ν and $\bar{\nu}$ agree on $\mathscr{I}_d$, and

$$\mathrm{aff}(P, \bar{\nu}) = \mathrm{aff}\big(P|_{\mathscr{I}_d}, \nu|_{\mathscr{I}_d}\big) \geq \mathrm{aff}(P, \nu).$$

■

Sketch. Step 1: the generating function of the statistic. Set $t = K - d$ and $t' = K - d'$ and take $t_* = t'$ in the calibration. Let $\tilde{\nu}$ and $\hat{\nu}$ be the laws of V_d and $V_{d'}$ under the normalized weight $\mathfrak{w}^{\mathrm{sf}}_{t'}\rho_0\, dU$ of Prop. YM3_I:115.2. The discarded fraction is at most $\mathsf{R}_{t'} \leq \rho[\mathsf{b}](d') \leq 1/4$ by YM3_I:(2187), since $\log L^{d'}\mathsf{b} \geq d' \log L$ and $2\mathfrak{p}_0 \geq 2$. The weight includes the cut at level $t < t'$. The cut criterion in Section YM3_I:113.4 and the decreasing ε give $\mathsf{Cut}_t[\mathsf{b}] \subset \mathsf{Cut}_t[\mathsf{b}_-]$. Thus $T_d^K = \mathcal{O}(1)(U_t(V))$ on the support of the cutoff density at level t.

Start the recursion YM3_I:(2172) at level t with the unsourced chain's first t families, held constant as the source z varies on $|z| < 2\varrho_\varsigma$. These satisfy all the early-family hypotheses of Prop. YM3_I:114.2. Write $\Phi_j^{[z]}$ for the exponents of this run. At level t the old array is independent of z, so the linear weighted-action term gives $\Phi_t^{[z]} - \Phi_t^{[0]} = zT_d^K$ on the cut. At $z = 0$ the run is the original chain from t on by the restart identity. Factor $\mathfrak{w}^{\mathrm{sf}}_{t'}$ at level t: the weight through the cut at t produces the chain's density at t, and the remaining factors depend on V_d and its later averages. Apply the exact density recursion YM3_I:(2175) to the frozen early system from t to t' and restrict to $\mathsf{In}_{t'}[\mathsf{b}]$. Divide by its value at $z = 0$. The contact increments YM3_I:(2173) have source-independent normalization terms, so this yields

$$\tilde{\nu}(e^{zT_d^K}) = e^{\mathsf{c}(z)-\mathsf{c}(0)}\hat{J}_0(z), \qquad \hat{J}_0(z) = \int e^{\Phi_{t'}^{[z]} - \Phi_{t'}^{[0]}}\, d\hat{\nu},$$

where c is the sum of the flat members of levels $t+1$ through t'. The rooted bound of Lem. YM3_I:114.6 gives $|\mathsf{c}| \leq 2E_0C_{\mathrm{E},0}L^{-3}N_d = \mathsf{v}_d$ on $|z| < 2\varrho_\varsigma$. Apply Lem. YM3_I:114.5 to this early system at $f = 1$ and level t'. It gives $|\hat{J}_0 - 1| \leq e^{1/4} - 1 < 0.2841$ on $|z| < r' = (8\mathsf{M}^{\mathrm{rd}}_{t'})^{-1}$. Its readout constant satisfies $\varrho_\varsigma^{-1} \leq \mathsf{M}^{\mathrm{rd}}_{t'} \leq \mathsf{Q}'L^{4d'}$ by the definition of Q' and $\varepsilon(L^{d'}\mathsf{b}) \leq \varepsilon(L^{d'}\mathsf{b}_-)$. The upper bound on $|\hat{J}_0 - 1|$ holds at $|z| = r'$ by continuity. The argument proves this identity and the stated tail bound for every $u_\flat \leq d' < d < K$.

Step 2: an exponential moment and a tail bound under $\tilde{\nu}$. Let $\tilde{m} = \tilde{\nu}(T_d^K)$; it is the real part of $(\mathsf{c})'(0) + \hat{J}_0'(0)$. For real z with $|z| \leq r'$ the left member of the identity of Step 1 is positive, and Cauchy's bounds of the Taylor coefficients, on the radius $2\varrho_\varsigma$ for c and on the radius r' for $\hat{J}_0 - 1$, give

$$\log \tilde{\nu}\big(e^{z(T_d^K - \tilde{m})}\big) \leq \mathsf{v}_d\, \frac{(z/2\varrho_\varsigma)^2}{1 - |z|/2\varrho_\varsigma} + \log 1.2841 + 0.2841 \leq \frac{\mathsf{v}_d z^2}{2\varrho_\varsigma^2} + 0.54.$$

For $0 \leq \lambda \leq \mathsf{v}_d r'/\varrho_\varsigma^2$, Markov's inequality at $z = \pm\lambda\varrho_\varsigma^2/\mathsf{v}_d$ gives $\tilde{\nu}(|T_d^K - \tilde{m}| \geq \lambda) \leq 2e^{0.54}\exp[-\varrho_\varsigma^2\lambda^2/(2\mathsf{v}_d)]$, and $2e^{0.54} < 4$.

Step 3: back to the Wilson measure; clause (1). On the gauge-invariant algebra, the difference between the Wilson probability and its unnormalized restriction to the cutoff weight is positive by YM3_I:(2189) and has mass at most $\rho[\mathsf{b}](d')$. For a bounded function F on this algebra, first remove that difference and then rescale the remaining mass to one. The change in its expectation is at most $2\rho[\mathsf{b}](d')\|F\|_\infty$. Apply this to the statistic with $0 \leq T_d^K \leq \mathsf{Q}'L^{4d}$ and to the indicator of $\{|T_d^K - \tilde{m}| \geq \lambda\}$. The first use bounds $|m_d^K(\mathsf{b}) - \tilde{m}|$ by $2\rho[\mathsf{b}](d')\mathsf{Q}'L^{4d}$, and the second transfers the tail. The permitted range of λ follows from $r' \geq (8\mathsf{Q}'L^{4d'})^{-1}$.

Step 4: clause (2). Take $d' = \lfloor d/5 \rfloor$, $K = K(d)$ and $\lambda_d = (\mathsf{A}\, dN_d)^{1/2}$. For all large d: $d' \ge u_\flat$ and $\Xi_d[\mathsf{b}_-] \ge 2$; λ_d, of the order $d^{1/2}L^{3d/2}$, lies below $\mathsf{v}_d/(8\varrho_\varsigma^2 \mathsf{Q}' L^{4d'})$, of the order $L^{11d/5}$; and $2\rho[\mathsf{b}](d')\mathsf{Q}'L^{4d} \le 1$, because $\theta_0 d'^2$ beats every multiple of d. As $\varrho_\varsigma^2\lambda_d^2/(2\mathsf{v}_d) = 2d\log L$, clause (1) and Corollary 18.213 give

$$\mu_d[\mathsf{b}](|T_d - m_d(\mathsf{b})| > \lambda_d + 1) \le 4L^{-2d} + 2\rho[\mathsf{b}](\lfloor d/5 \rfloor) + L^{-d},$$

a summable sequence. The map $V \mapsto V_d$ carries $\mu_{\ell,\mathsf{b}}$ to $\mu_d[\mathsf{b}]$ (Lemma 18.212(b)), and the lemma of Borel and Cantelli gives clause (2).

Step 5: clause (3). $|\xi_d - x_d| = L^d N_d^{-1}|T_d - m_d(\mathsf{b})|$, and clause (2) with $N_d = \ell^3 L^{3d}$ gives the bound, which tends to 0; so ξ_d converges exactly when the number x_d does, and to the same limit. The expansion says $x_d \to \varkappa_1 \mathsf{b}^{-2}$. If it holds with $\varkappa_0 > 0$, then almost surely $T_d/N_d = \varkappa_0 \mathsf{b}^{-1} + L^{-d}\xi_d$ with $\xi_d \to \varkappa_1 \mathsf{b}^{-2}$; so $T_d > 0$ for large d, $\varkappa_0 N_d/T_d = \mathsf{b}(1 + \mathsf{b}\varkappa_0^{-1}L^{-d}\xi_d)^{-1} = \mathsf{b} - \mathsf{b}^2\varkappa_0^{-1}L^{-d}\xi_d + O(L^{-2d})$, and $L^d[T_d/N_d - T_{d+1}/N_{d+1}] = \xi_d - L^{-1}\xi_{d+1}$.

Step 6: clause (4). Let $u \in \mathcal{G}_d$ be random, with independent Haar values at the even sites and the value $\mathbf{1}$ at the odd sites, independent of V, which has the law P. As P is invariant under every fixed gauge transformation, V^u has the law P. The bond c_y goes from the even site y to an odd site, so $V^u(c_y) = u(y)V(c_y)$; given V these are independent and Haar distributed, by the invariance of the Haar measure under left translations, the bonds c_y being distinct. An element of SU(2) with the eigenvalues $e^{\pm i\theta}$, $0 \le \theta \le \pi$, has $|g - \mathbf{1}|_{\mathrm{op}} = 2\sin(\theta/2)$, and the class angle has the Haar density $\frac{2}{\pi}\sin^2\theta$; so the Haar measure of $\{|g - \mathbf{1}|_{\mathrm{op}} \le 1\} = \{\theta \le \pi/3\}$ is $\frac{2}{\pi}\int_0^{\pi/3}\sin^2\theta\, d\theta = h_0$.

Step 7: one bond of the quasi-free field. For the bond b from x to $x + a_d e_\mu$, $|\hat{q}_b(k)| = a_d|\operatorname{sinc}(k_\mu a_d/2)|\prod_{\nu=1}^3 |\operatorname{sinc}(k_\nu a_d/2)| \le a_d \prod_\nu \min\{1, 2/(a_d|k_\nu|)\}$, with $\operatorname{sinc} v = v^{-1}\sin v$. With $p = a_d k \in (2\pi/n_s)\mathbb{Z}^3$, $n_s = \ell L^d$, and $\Pi_{\mu\mu} \le 1$,

$$\operatorname{Var} B^a(b) \le \frac{a_d}{c}\, n_s^{-3} \sum_{p \ne 0} |p|^{-2} \prod_{\nu=1}^3 \min\{1, 4p_\nu^{-2}\}.$$

Write $p = \kappa + 2\pi j$ with $\kappa \in (-\pi, \pi]^3$, $j \in \mathbb{Z}^3$. For the terms with $j = 0$ write $\kappa = 2\pi n/n_s$: the shell $|n|_\infty = r$ holds $24r^2 + 2$ points, all with $|n| \ge r$, so these terms add up to at most $(n_s/2\pi)^2(12n_s + \pi^2/3) \le 13n_s^3/(4\pi^2)$, as $n_s \ge 4$. The terms with $j \ne 0$ have $|p| \ge \pi$, and $\sum_{j_\nu \in \mathbb{Z}} \min\{1, 4(\kappa_\nu + 2\pi j_\nu)^{-2}\} \le 1 + \frac{8}{\pi^2}\sum_{m \ge 1,\ m \text{ odd}} m^{-2} = 2$ for $|\kappa_\nu| \le \pi$; so they add up to at most $8n_s^3/\pi^2$. Hence $\operatorname{Var} B^a(b) \le \frac{45}{4\pi^2}\frac{a_d}{c} \le \frac{2a_d}{c}$, and, the three colours being independent, $\mathbb{P}(|B(b)| > 1) \le 3 \cdot 2\exp[-\frac{1}{3}/(2 \cdot 2a_d/c)] = 6e^{-c/(12a_d)}$. As $i\sum_a B^a\sigma_a$ has the eigenvalues $\pm i|B|$, $|V_d^{\mathrm{qf}}(b) - \mathbf{1}|_{\mathrm{op}} = 2|\sin(|B(b)|/2)| \le |B(b)|$; a union over the $\frac{1}{2}N_d$ even sites gives $\nu_d[c](\mathsf{V}_d \setminus E_d) \le 3N_d e^{-c/(12a_d)}$.

Step 8: clause (5). Splitting the affinity over E_d and its complement, the inequality of Cauchy and Schwarz on each part gives $\operatorname{aff}(P, \nu_d[c]) \le P(E_d)^{1/2} + \nu_d[c](\mathsf{V}_d \setminus E_d)^{1/2}$, and Steps 6 and 7 give the first bound. As $N_d = \ell^3 a_d^{-3}$, the first term is $\exp[-\frac{1}{4}\ell^3 a_d^{-3}\log h_0^{-1}]$ and the second is a power of a_d^{-1} times $e^{-c/(24a_d)}$; both are below $\frac{1}{2}e^{-c/(48a_d)}$ from a threshold on that depends on c and ℓ alone. The set $\mathbf{E}$ is a lim inf of cylinder sets, hence Borel. As $\sum_d \nu_d[c](\mathsf{V}_d \setminus E_d) < \infty$, $\nu[c](\mathbf{E}) = 1$ by Borel and Cantelli; if the images $\mathbf{P}_d$ of $\mathbf{P}$ are gauge invariant, $\sum_d \mathbf{P}_d(E_d) = \sum_d h_0^{N_d/2} < \infty$, so $\mathbf{P}$-almost surely $V_d \notin E_d$ for all large d, and $\mathbf{P}(\mathbf{E}) = 0$. The images of $\mu_{\ell,\mathsf{b}}$ are the gauge-invariant laws $\mu_d[\mathsf{b}]$, for every $\mathsf{b} > 0$ (Lemma 18.230). Steps 6–8 use of the law only its gauge invariance, and a gauge average is gauge invariant, since $(\nu^u)^{u'} = \nu^{u'u}$ and the Haar measure is invariant.

Step 9: clause (6). For $E \in \mathscr{I}_d$ and $u \in \mathcal{G}_d$, $\nu^u(E) = \nu(\{V : V^u \in E\}) = \nu(E)$; so $\bar{\nu} = \nu$ on $\mathscr{I}_d$. Let $\lambda = \frac{1}{2}(P + \bar{\nu})$, a gauge-invariant law. If p is a density of a gauge-invariant law against λ, so is $V \mapsto p(V^u)$ for every u, and so is the average $\int p(V^u)\, du$, which is gauge invariant and hence $\mathscr{I}_d$-measurable; with such densities for P and $\bar{\nu}$, $\operatorname{aff}(P, \bar{\nu})$ is computed on $\mathscr{I}_d$, where it equals $\operatorname{aff}(P|_{\mathscr{I}_d}, \nu|_{\mathscr{I}_d})$. To compare with $\operatorname{aff}(P, \nu)$, let $\lambda_\nu = \frac{1}{2}(P + \nu)$, a probability measure

against which P and ν have densities p' and q' on all Borel sets. For a sub-σ-algebra $\mathscr{A}$ the conditional means $\mathbb{E}_{\lambda_\nu}[p'|\mathscr{A}]$ and $\mathbb{E}_{\lambda_\nu}[q'|\mathscr{A}]$ exist, λ_ν being finite, and they serve as densities of the restrictions $P|_{\mathscr{A}}$ and $\nu|_{\mathscr{A}}$ with respect to $\lambda_\nu|_{\mathscr{A}}$; the conditional inequality of Cauchy and Schwarz gives $\mathbb{E}_{\lambda_\nu}[(p'q')^{1/2}|\mathscr{A}] \le (\mathbb{E}_{\lambda_\nu}[p'|\mathscr{A}]\,\mathbb{E}_{\lambda_\nu}[q'|\mathscr{A}])^{1/2}$ λ_ν-almost everywhere, and integrating both members against λ_ν gives $\mathrm{aff}(P,\nu) \le \mathrm{aff}(P|_{\mathscr{A}}, \nu|_{\mathscr{A}})$. At $\mathscr{A} = \mathscr{I}_d$ this is the inequality of clause (6). □

Lemma 18.156 (A rough real source lies in the class; the chain forgets a source in the sup norm)**.** Use the calibrated line $x_j = L^{K'-j}\mathsf{b}'$ and top level t_* of §2.3.1 on (ℓ, K'). Use the cuts of Lem. YM3_I:113.10 with $\mathsf{e}^{\mathrm{c}}_j = c_\rho \varepsilon(x_j)$, and the barycentre source class $\mathsf{Src} = \mathsf{Src}_{\mathsf{Bc}}(2\varrho_\varsigma, 2\varrho_\varsigma)$ as in YM3_I:(1497). Here Bc is the set of bare plaquette barycentres, $|w|_\infty$ is the maximum modulus, and Lip_∞ uses the torus sup distance. Let $E^{(i)}[w]$, $\mathsf{c}_i(w)$, Φ^w_t be the chain families, contact increments and exponents in YM3_I:(2172)–(2175). Write $v^w_j = -w/\mathsf{b}'$, $\mathsf{s}^{\mathrm{abs}}_j = (1+\beta_{\mathrm{s}})\delta(x_j)/\alpha_0$, $\Delta_i(w) = \|E^{(i)}[w] - E^{(i)}[0]\|_{i,\kappa+1}$ and $n_t(w) = \sum_{i=1}^{t} L^{-(t-i)}\Delta_i(w)$. Put

$$C_n = 2C_{\mathrm{fg}}K^{\mathrm{d}}\big(\tfrac{13}{12}K^\vee_{\mathrm{Q}} + \tfrac{3}{2}K^\vee_{\mathrm{L}}\big), \qquad C_{\mathrm{src}} = \tfrac{3}{8} + C_{\mathrm{old}}C_n, \qquad \epsilon_{\mathrm{src}}(D;\vartheta) = C_{\mathrm{src}}\,\ell^3 L^{4D}\vartheta,$$

with K^{d} of Section YM3_I:114.1, C_{fg} of Prop. YM3_I:114.3 and C_{old} of YM3_I:(2163); C_n and C_{src} are formed from the constants alone.

(1) Let $\tau \ge 0$, and let w be a complex weight of the bare plaquettes with $|w(p) - w(p')| \le 2\tau L^{-K'}$ for all bare plaquettes p, p'. Then $\mathrm{Lip}_\infty(w; \mathsf{Bc}) \le 4\tau$; hence $w \in \mathsf{Src}_{\mathsf{Bc}}(2\varrho_0, 2\varrho_0)$ whenever $\varrho_0 > 0$, $|w|_\infty < 2\varrho_0$ and $\tau < \sqrt{3}\varrho_0/(80M)$.

(2) For $w \in \mathsf{Src}$ and $0 \le j < t_*$,

$$\Delta_{j+1}(w) \le K^{\mathrm{d}}K_\Lambda \mathsf{s}^{\mathrm{abs}}_j\, n_j(w) + K^{\mathrm{d}}\big(2K^\vee_{\mathrm{Q}} + 2K^\vee_{\mathrm{L}}x_j^{1/2}\big)\,|w|_\infty/\mathsf{b}'.$$

(3) For $w \in \mathsf{Src}$, $1 \le t \le t_*$ and $D = K' - t$: $n_t(w) \le C_n|w|_\infty L^{(D+1)/2}$, and $|\Phi^w_t(V) - \Phi^0_t(V)| \le \epsilon_{\mathrm{src}}(D; |w|_\infty)$ at every $V \in \mathsf{Cut}_t$.

■

Proof. Distinct plaquette barycentres in the periodic lattice differ in some coordinate by at least $a_{K'}/2$. This proves the Lipschitz estimate and the source admission in (1).

At level j, keep the early array fixed and remove the direct source potential. The fourth-family Lipschitz estimate YM3_I:(1603), in the range verified in the proof of Prop. YM3_I:114.2, bounds the change in the next family by $K^{\mathrm{d}}\mathsf{n}^{\mathrm{f}}(\mathbb{W}^{\mathrm{src}}[v^w_j])$. By YM3_I:(2167) and $\mathrm{sw}_j(v) \le 2|v|_\infty$, this is at most $K^{\mathrm{d}}(2K^\vee_{\mathrm{Q}} + 2K^\vee_{\mathrm{L}}\sqrt{x_j})|w|_\infty/\mathsf{b}'$. With the source removed, the change from the old array at w to that at zero is at most $K^{\mathrm{d}}K_\Lambda \mathsf{s}^{\mathrm{abs}}_j n_j(w)$ by the one-step bound in the proof of Prop. YM3_I:114.3. The old array is empty if $j = 0$. The triangle inequality proves (2).

For (3), put $q_j = K^{\mathrm{d}}K_\Lambda \mathsf{s}^{\mathrm{abs}}_j$ and let σ_j be the second summand of (2). Then $n_{j+1} \le (L^{-1} + q_j)n_j + \sigma_j$, with $n_0 = 0$. By YM3_I:(2176)–(2177), the product from $i = j+1$ to $t-1$ of $L^{-1} + q_i$ is at most $C_{\mathrm{fg}}L^{-(t-1-j)}$. Summing the two geometric series, with $D = K' - t$, gives

$$n_t \le 2C_{\mathrm{fg}}K^{\mathrm{d}}|w|_\infty \left(\frac{K^\vee_{\mathrm{Q}}}{\mathsf{b}'}\frac{L}{L-1} + \frac{K^\vee_{\mathrm{L}}}{\sqrt{\mathsf{b}'}}\frac{L^{(D+1)/2}}{1 - L^{-1/2}}\right) \le C_n|w|_\infty L^{(D+1)/2},$$

using $L \ge 13$ and $\mathsf{b}' \ge 4$. The action term in the exponent changes by $L^D A^{\eta_t}(w, U_t(V))$ and has modulus at most $\frac{3}{8}N_D L^D|w|_\infty$, by YM3_I:(2161) and $2\mathsf{e}^{\mathrm{c}}_t \le 1$. The remaining change is at most $C_{\mathrm{old}}N_D n_t(w)$ by YM3_I:(2164). Since $D \ge 1$ and $N_D = \ell^3 L^{3D}$, these bounds give $\epsilon_{\mathrm{src}}(D; |w|_\infty)$. □

Lemma 18.157 (A real source: floor, tails and discarding; the laws of the block fields)**.** Use the fixed choices of Definition 18.153 and the sourced construction of Definition 18.159(1) with radius ϱ, with common real data. Choose the calibration to satisfy Lem. YM3_I:82.5 as well as Section YM3_I:115, using the same $\eth \in (0,1)$. The history summability thresholds are imposed

before the torus, cutoff and label. For an admitted interval $J = [\mathsf{b}_-, \mathsf{b}_+]$ put $\varrho_\wedge = \min\{\varrho, \varrho_\varsigma\}$ and $\mathsf{Src}_\wedge = \mathsf{Src}_{\mathsf{Bc}}(2\varrho_\wedge, 2\varrho_\wedge)$. For $K' > d_\natural$ and $\mathsf{b}' \in J$ take $t_* = K' - d_\natural$. At depth $D = K' - t$ the mass bound YM3_I:(2187) is

$$\mathsf{R}(D;\mathsf{b}') = 2M^{-3}\ell^3 L^{3D}\exp\bigl[-c' A_0^2(\log L^D \mathsf{b}')^{2\mathfrak{p}_0}\bigr]\exp\bigl[(\mathsf{C}^\Sigma_{\mathrm{maj}} + 2 + C_{\mathrm{low}}(\mathsf{b}'))\ell^3\bigr],$$

with C_{low} of YM3_I:(1538). Let $D_1 \ge d_\natural$ be the least integer from which $\mathsf{R}(D;\mathsf{b}') \le 1/2$ holds for all $\mathsf{b}' \in J$. The exponential decay in D makes this threshold finite. Use the source history constants $c^{\mathrm{S}}_\star$ and $\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}$ of YM3_I:(1725)–(1726), and put $\lambda_L = (6L^3+1)\log 2$, $c'_{\mathrm{S}} = (1-\eth)c^{\mathrm{S}}_\star$ and $\mathsf{e}_1 = 4E_0 C_{\mathrm{E},0}\ell^3 L^{3(D_1-1)}$. For $\vartheta \ge 0$ set

$$\mathsf{R}^{\mathrm{src}}(D;\mathsf{b}',\vartheta) = 4M^{-3}\ell^3 L^{3D}\exp\bigl[-c'_{\mathrm{S}} A_0^2(\log L^D \mathsf{b}')^{2\mathfrak{p}_0}\bigr]\exp\bigl[(\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}} + \lambda_L + 2 + C_{\mathrm{low}}(\mathsf{b}'))\ell^3 + \mathsf{e}_1 + \epsilon_{\mathrm{src}}(D_1;\vartheta)\bigr],$$

with ϵ_{src} of Lem. 18.156. Let $K' > D_1$, $\mathsf{b}' \in J$ and $w \in \mathsf{Src}_\wedge$ be real with $|w|_\infty \le \vartheta$. Put $\rho_0^w = \exp[-\sum_p (L^{K'}\mathsf{b}' - L^{K'}w(p))a_p]$, $Z[w] = \int \rho_0^w\, dU$, $P^w = Z[w]^{-1}\rho_0^w\, dU$ and $Z = Z[0]$. Use $\mathfrak{w}^{\mathrm{sf}}_t$ of Prop. YM3_I:115.2, the cut Cut_0 of Section YM3_I:113.4 and $a_t(w) = \sum_{0<i\le t}(\mathsf{c}_i(w) - \mathsf{c}_i(0))$.

(1) *(Floor.)* Every $a_t(w)$ is real, and with $t_\flat = K' - D_1$, $Z[w] \ge \frac{1}{2}e^{a_{t_\flat}(w) - \epsilon_{\mathrm{src}}(D_1;\vartheta)}Z$.

(2) *(Discarding.)* For $1 \le t \le t_*$ and $D = K' - t$, $0 \le Z[w] - \int \mathfrak{w}^{\mathrm{sf}}_t \rho_0^w\, dU \le \mathsf{R}^{\mathrm{src}}(D;\mathsf{b}',\vartheta)\, Z[w]$; and $P^w(\mathsf{V}_{K'} \setminus \mathsf{Cut}_0) \le \mathsf{R}^{\mathrm{src}}(K'-1;\mathsf{b}',\vartheta)$.

(3) *(Block laws.)* For $d_\natural \le D < K'$ and $0 \le d \le D$,

$$\bigl\|(\mathcal{M}^{K'-d})_* P^w - \mu_d^{K'}[\mathsf{b}']\bigr\| \le \eta(D;\mathsf{b}',\vartheta) := \mathsf{R}^{\mathrm{src}}(D;\mathsf{b}',\vartheta) + \mathsf{R}(D;\mathsf{b}') + 2\epsilon_{\mathrm{src}}(D;\vartheta).$$

(4) *(Mixtures; a thin factor.)* Take a Borel set $\mathcal{S} \subset \mathsf{Src}_\wedge$ whose members are real sources with $|w|_\infty \le \vartheta$, a positive Borel measure $\pi_0 \ne 0$ of finite mass on $\mathcal{S}$, and a bounded, gauge-invariant Borel function $H \ge 0$ on $\mathsf{V}_{K'}$ such that $H \le \delta_0$ on Cut_0; put $\Psi = \int \rho_0^w\, \pi_0(dw)$. Then $P = \Psi e^{-H}dU / \int \Psi e^{-H} dU$ is a gauge-invariant law, and for $d_\natural \le D < K'$ and $0 \le d \le D$

$$\bigl\|(\mathcal{M}^{K'-d})_* P - \mu_d^{K'}[\mathsf{b}']\bigr\| \le \delta_0 + \mathsf{R}^{\mathrm{src}}(K'-1;\mathsf{b}',\vartheta) + \eta(D;\mathsf{b}',\vartheta).$$

■

Proof. Step 1: the common regular families. The constant-coupling line has zero increments and meets the sequence and room requirements of YM3_I:(1524). A real barycentre source extends to a real function on T_ℓ with the same Lipschitz bound and supremum bound. For example, take the infimum of the functions $w(p) + \Lambda|x - x(p)|_\infty$ for $\Lambda = \mathrm{Lip}_\infty w$ and clip to the range of w. The sourced history construction of Thm. YM3_I:AJ therefore applies. It uses the same real data as the small-field chain. Its ordinary regular recursion YM3_I:(1683) uses the one-lattice companion and the real localized normalizer. For $j \ge 1$ compare the companion in YM3_I:(1635) with YM3_I:(2165). The weighted Wilson family in both formulas uses the same vertex brackets of the actual shift and the same reference plaquette for each nonpivot bond. The last paragraph of p. 799 identifies these weighted members on the one-lattice cores. The formula at $j = 0$ uses the same pivot completion by YM3_I:(1652). The companion is $-\mathbb{W}^{\mathrm{src}}[v_j^w]$ in both cases. The pointed term with this companion is the same local integral by Props. YM3_I:77.3 and YM3_I:77.4, with the normalization terms independent of w. The counterterms are zero on this line. Thus induction on j identifies the regular families in (1683) and (2172). The source contribution to the vacuum through level t in YM3_I:(1736)–(1737) equals $a_t(w)$ by YM3_I:(2173), so it is real at real sources.

Step 2: the floor. At depth $D = K' - t$ the image of $\mathfrak{w}^{\mathrm{sf}}_t \rho_0^w\, dU$ is a positive measure by YM3_I:(2188). On the inner ball its density is that of YM3_I:(2175). Taking the ratio of the densities at w and 0, and using Lemma 18.156(3), bounds it between $e^{a_t(w) - \epsilon_{\mathrm{src}}(D;\vartheta)}$ and $e^{a_t(w) + \epsilon_{\mathrm{src}}(D;\vartheta)}$. The same bounds hold if the exponents are read through their real parts, since the density ratio is positive. At $t_\flat = K' - D_1$ the zero-source restricted mass is at least $Z/2$ by YM3_I:(2190). The sourced restricted mass is at most $Z[w]$ by YM3_I:(2189), tested with the positive gauge-invariant function ρ_0^w/ρ_0. This proves (1).

Step 3: the vacuum comparison. Let $E^w_{(K')}$ be the sourced vacuum of YM3_I:(1737). Its difference from $E_{(K')}$ is $a_{t_\flat}(w)$ plus the flat-family differences for $j > t_\flat$. At level j the norm bound in YM3_I:(1729) and the rooted sum used in Prop. YM3_I:83.2 bound those flat differences by $2E_0C_{\mathrm{E},0}N_{K'-j}$. Their sum is at most e_1, since $\sum_{u=0}^{D_1-1} N_u \le 2\ell^3 L^{3(D_1-1)}$. The zero-source floor YM3_I:(1538) and clause (1) give

$$e^{E^w_{(K')}} \le 2Z[w]\exp[\mathsf{e}_1 + C_{\mathrm{low}}(\mathsf{b}')\ell^3 + \epsilon_{\mathrm{src}}(D_1;\vartheta)].$$

Step 4: the sourced rare histories. The sourced histories are positive at real w, since their measures are images of ρ_0^w multiplied by the fixed real nonnegative history weights of Prop. YM3_I:73.5. For each $h \in \mathcal{H}_{K'}$ denote the mass by $m_h(w)$ and its history label by $S(h)$. The creation estimate YM3_I:(1734) and deficit estimate YM3_I:(1735) give the hypotheses of YM3_I:(1452), applied to $f(h) = e^{\mathcal{E}^w_{K',S(h)}} m_h(w)$ and $e(S) = -\sum_n \mathfrak{E}'^w_n(S)$, with the sourced constants. Equation YM3_I:(1735) identifies $f(h)e^{e(S(h))}$ with $e^{-E^w_{(K')}} m_h(w)$. All vacuum exponents here are real by conjugation. In the proof of Prop. YM3_I:67.5, for fixed creation sets W_j the multiplicity bound YM3_I:(1447) cancels the binary factors, leaving at most $e^{\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}\ell^3}$ times the product of $e^{-c'_{\mathrm{S}}p_0(g_j)^2}$ over the created cells. If the bad region at level t is nonempty, at least one cell was created by level t. Mark one such cell and sum over it and then over the unrestricted creation sets. Exactly as in Lem. YM3_I:115.1, the resulting bound is

$$\sum_{h:Z_t(h)\neq\varnothing} m_h(w) \le e^{E^w_{(K')}} \Pi_{K'}(\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}, c'_{\mathrm{S}}) \sum_{j\le t} \#\mathcal{P}_j e^{-c'_{\mathrm{S}}p_0(g_j)^2}.$$

Here $\mathcal{P}_j$ is the level-j partition into candidate cells. The threshold in Lem. YM3_I:82.5 admits Prop. YM3_I:67.6 at the sourced constants, including $Y^{\mathrm{S}}(c'_{\mathrm{S}})$. Thus the stopped sum is at most $2M^{-3}N_D e^{-c'_{\mathrm{S}}A_0^2(\log x_t)^{2\mathfrak{p}_0}}$ and $\Pi_{K'}(\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}, c'_{\mathrm{S}})$ is at most $e^{(\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}+2)\ell^3}$, by YM3_I:(1451). Enlarging its first argument by λ_L keeps both bounds valid and gives the stated constant.

Step 5: discarding. The inequalities YM3_I:(2189), with $F = \rho_0^w/\rho_0$, compare the sourced partition function and the empty-history and cutoff masses. The fixed history weights have the prefix refinement used in the proof of Prop. YM3_I:115.2. The descendants of the empty prefix through level t are exactly the histories with $Z_t = \varnothing$. This property concerns their weights and holds also after multiplication by ρ_0^w. Thus the lost mass is nonnegative and at most the rare-history sum of Step 4. Step 3 yields $\mathsf{R}^{\mathrm{src}}(D;\mathsf{b}',\vartheta)Z[w]$. The cutoff weight at $t=1$ contains $\mathbf{1}_{\mathsf{Cut}_0}$; apply YM3_I:(2189) with $F = \mathbf{1}_{\mathsf{Cut}_0}\rho_0^w/\rho_0$ to bound its mass by the sourced mass of Cut_0. This proves (2).

Step 6: the block laws. Test the cutoff and full image laws at level t against an invariant function G with $0 \le G \le 1$. The positive difference in YM3_I:(2189) at $F = G\circ\mathcal{M}^t$ times ρ_0^w/ρ_0 shows that the full normalized law is a convex combination of the normalized restricted law and the law of the removed mass on this algebra. Its difference from the restricted law on G is at most the discarded fraction from clause (2). At zero source use YM3_I:(2190) instead. The ratio of the two normalized restricted densities is between $e^{-2\epsilon_{\mathrm{src}}(D;\vartheta)}$ and $e^{2\epsilon_{\mathrm{src}}(D;\vartheta)}$ by Step 2, so their variation distance is at most $1 - e^{-2\epsilon_{\mathrm{src}}(D;\vartheta)} \le 2\epsilon_{\mathrm{src}}(D;\vartheta)$. The full laws are gauge invariant, and gauge averaging an indicator reduces the supremum to such invariant tests by eq. 2.xx. This proves (3) for $d = D$. Taking the image under $\mathcal{M}^{D-d}$ cannot increase total variation.

Step 7: clause (4). The map $(w,U) \mapsto \rho_0^w(U)$ is continuous and positive, and Fubini's theorem gives $\Psi dU/\int \Psi dU = \int P^w\,\pi(dw)$ with $\pi \propto Z[w]\pi_0(dw)$. For $w \in \mathcal{S}$ let $P^w_H = e^{-H}P^w/P^w(e^{-H})$; its density ϕ against P^w is at least $e^{-H} \ge e^{-\delta_0}$ on Cut_0, so $\|P^w_H - P^w\| = \int(1-\phi)_+ dP^w \le (1-e^{-\delta_0}) + P^w(\mathsf{V}_{K'} \setminus \mathsf{Cut}_0) \le \delta_0 + \mathsf{R}^{\mathrm{src}}(K'-1;\mathsf{b}',\vartheta)$. In the same way $P = \int P^w_H\,\pi'(dw)$ with $\pi' \propto Z[w]P^w(e^{-H})\pi_0(dw)$; a mixture of gauge-invariant laws is gauge invariant, the total variation between a mixture and a fixed law is at most the supremum of the total variations of the mixed laws, and clause (3) ends the argument. □

Proposition 18.158 (The block fields under the plaquette weights $e^{-\beta s}\hat m(s)e^{-h(s)}$)**.** Let the constants be a setting $\mathfrak s$ with the radius ϱ, let $J=[\mathsf b_-,\mathsf b_+]$ be an interval of labels on the side ℓ, take the numbers of Lemmas 18.156 and 18.157, and put $\tau_\star=\sqrt3\,\varrho_\wedge/(80M)$. Let $\lambda\in\mathbb R$, $0\le\tau_0<\tau_\star$, $M_h\ge0$ and $\tau_1=|\lambda|+\tau_0$. For $K'\in\mathbb N$, $\mathsf b\in J$ and $\beta=L^{K'}\mathsf b$ let

$$\Psi_{K'}(U)=\prod_p e^{-\beta s_p}\,\hat m_p(s_p)\,e^{-h(s_p)},\qquad s_p=a_p(U),\qquad \hat m_p(s)=\int e^{-\tau s}m_p(d\tau),$$

the product over the bare plaquettes, where each m_p is a Borel probability measure on $[\lambda-\tau_0,\lambda+\tau_0]$ (one measure m for all p keeps the invariance under the lattice isometries) and h is a Borel function on $[0,2]$ with $0\le h(s)\le M_hs^4$; let $P_{\Psi_{K'}}=\Psi_{K'}dU/\int\Psi_{K'}dU$. Let K_0 be the least integer with $K_0\ge8D_1+8$, $\tau_1L^{-K_0}<2\varrho_\wedge$ and $\epsilon_{\rm src}(D_1;\tau_1L^{-K_0})\le1$, and put

$$\mathsf C_R=\sup_{D\ge1,\ \mathsf b'\in J}L^{8D}\mathsf R(D;\mathsf b'),\qquad \mathsf C'_R=\sup\bigl\{L^{8D}\mathsf R^{\rm src}(D;\mathsf b',\vartheta):\ D\ge1,\ \mathsf b'\in J,\ \epsilon_{\rm src}(D_1;\vartheta)\le1\bigr\},$$

$$\eta_\Psi(K')=(\mathsf C_R+2\mathsf C'_R)L^{-K'}+2C_{\rm src}\ell^3\tau_1L^{4-K'/2}+\tfrac{3}{16}M_h(c_\rho A_0)^8\ell^3\mathsf b_-^{-4}(\log L^{K'}\mathsf b_+)^{8\mathfrak p_0}L^{-K'};$$

both suprema are finite.

(1) For $K'\ge K_0$ and $K=\lceil K'/8\rceil$, $\bigl\|(\mathcal M^{K'-K})_*P_{\Psi_{K'}}-\mu_K^{K'}[\mathsf b]\bigr\|\le\eta_\Psi(K')$.

(2) *(Every block field, at the same label.)* For every integer $d\ge0$ and every integer $K'\ge\max\{K_0,8d,K_{\rm bf},1260d\}$, with $K_{\rm bf}$ and τ_J of Corollary 18.213,

$$\bigl\|(\mathcal M^{K'-d})_*P_{\Psi_{K'}}-\mu_d[\mathsf b]\bigr\|\le\eta_\Psi(K')+\tau_J(K')\le C_\Psi L^{-K'/11};$$

both laws are gauge invariant, so this total variation over all Borel sets of $\mathsf V_d$ equals the one over the sets of $\mathscr J_d$; C_Ψ depends on ς, ϱ, ℓ, J, τ_1 and M_h, and on no label of J.

(3) *(Functions of one block field.)* For bounded Borel functions $f_1,\dots,f_n$ on $\mathsf V_d$ and K' as in (2), the joint cumulants of $f_1(V_d),\dots,f_n(V_d)$ under $P_{\Psi_{K'}}$ and under $\mu_d[\mathsf b]$ differ by at most $2\bigl(\sum_\pi|\pi|!\bigr)\prod_i\sup|f_i|\,\bigl(\eta_\Psi(K')+\tau_J(K')\bigr)$, the sum over the partitions π of $\{1,\dots,n\}$.

(4) *(The mixed action.)* Let $0<\beta_A<\frac{3}{32}\min\{\tau_\star,\frac12\}^2$ and $a=(32\beta_A/3)^{1/2}$. The plaquette weight $\exp[-\beta(1-\frac12\operatorname{tr}\partial U(p))-\beta_A(1-\frac13\operatorname{tr}_{\rm ad}\partial U(p))]$ equals $e^{-\beta s_p}\hat m(s_p)e^{-h(s_p)}$ with $m=\frac34\delta_\lambda+\frac18(\delta_{\lambda+a}+\delta_{\lambda-a})$, $\lambda=\frac83\beta_A$, $\tau_0=a$, and $0\le h(s)\le\frac{1}{96}a^4\cosh(1)\,s^4$; so (1)–(3) hold for it.

(5) *(Four numbers that suffice.)* Let $u\in C^4([0,2])$ be real with $u(0)=0$, $u_k=u^{(k)}(0)/k!$ and $M_4=\frac{1}{24}\sup|u''''|$, and let a be real with $0<a\le\frac12$, $2a<\tau_\star$ and

$$0<32u_2\le a^2,\qquad 256|u_3|\le a^3,\qquad 2u_2a^2-6.4|u_3|a\ge80M_4.$$

Then $e^{-\beta s+u(s)}=e^{-\beta s}\hat m(s)e^{-h(s)}$ on $[0,2]$, with a probability measure m of at most six atoms in $[\lambda-2a,\lambda+2a]$, $|\lambda|\le|u_1|+a/32$, and $0\le h(s)\le(a^4/100+M_4)s^4$; so (1)–(3) hold for the weight $e^{-\beta s+u(s)}$, with $\tau_0=2a$.

■

Sketch. Step 1: the weight as a mixture of sources. With $w(\tau)(p)=-L^{-K'}\tau_p$ for $\tau=(\tau_p)_p$, Fubini's theorem gives

$$\prod_p e^{-\beta s_p}\hat m_p(s_p)=\int\exp\Bigl[-\sum_p(\beta+\tau_p)\,a_p(U)\Bigr]\bigotimes_p m_p(d\tau_p)=\int\rho_0^{w(\tau)}(U)\bigotimes_p m_p(d\tau_p),$$

ρ_0^w taken at the label $\mathsf b$; the constant λ stays in the source, and the label does not move. Here $|w(\tau)|_\infty\le\tau_1L^{-K'}=:\vartheta<2\varrho_\wedge$ and $|w(\tau)(p)-w(\tau)(p')|\le2\tau_0L^{-K'}$, so $w(\tau)\in\mathsf{Src}_\wedge$ by Lemma 18.156(1), as $\tau_0<\tau_\star$; the map $\tau\mapsto w(\tau)$ is continuous, so the image π_0 of $\bigotimes_p m_p$ is a probability measure on a compact set of real sources of $\mathsf{Src}_\wedge$. The factor $H=\sum_p h(s_p)$ is bounded, Borel and gauge invariant. On Cut_0, $\varpi(U)<c_\rho\varepsilon(x_0)$ with $x_0=L^{K'}\mathsf b$; since $\det\partial U(p)=1$,

$a_p = \frac{1}{2}\det(\partial U(p) - \mathbf{1}) \le \frac{1}{2}|\partial U(p) - \mathbf{1}|^2$, by the 2×2 determinant identity $\det(g-1) = 2 - \operatorname{tr} g$; with the $3\ell^3 L^{3K'}$ bare plaquettes this gives $H \le \delta_0$ on Cut_0, with

$$\delta_0 = 3\ell^3 L^{3K'} M_h \tfrac{1}{16} c_\rho^8 \varepsilon(x_0)^8 \le \tfrac{3}{16} M_h (c_\rho A_0)^8 \ell^3 \mathsf{b}_-^{-4} (\log L^{K'} \mathsf{b}_+)^{8\mathfrak{p}_0} L^{-K'}.$$

Step 2: clause (1). For $K' \ge K_0$, $K = \lceil K'/8 \rceil$ satisfies $D_1 + 1 \le K \le \frac{1}{8}K' + 1 < K'$, so Lemma 18.157(4) applies at $D = d = K$ and bounds the distance by $\delta_0 + \mathsf{R}^{\mathrm{src}}(K'-1;\mathsf{b},\vartheta) + \mathsf{R}^{\mathrm{src}}(K;\mathsf{b},\vartheta) + \mathsf{R}(K;\mathsf{b}) + 2\epsilon_{\mathrm{src}}(K;\vartheta)$. As $\epsilon_{\mathrm{src}}(D_1;\vartheta) \le 1$ and $8K \ge K'$, the three middle terms are at most $(\mathsf{C}_R + 2\mathsf{C}'_R)L^{-K'}$, and $4K \le \frac{1}{2}K' + 4$ gives $2\epsilon_{\mathrm{src}}(K;\vartheta) = 2C_{\mathrm{src}}\ell^3 L^{4K}\tau_1 L^{-K'} \le 2C_{\mathrm{src}}\ell^3\tau_1 L^{4-K'/2}$. The two suprema are finite, because $(\log L^D \mathsf{b}')^{2\mathfrak{p}_0} \ge (D\log L)^{2\mathfrak{p}_0}$, $2\mathfrak{p}_0 \ge 2$, beats every multiple of D.

Step 3: clauses (2) and (3). For $K' \ge 8d$, $K \ge d$; the image under $\mathcal{M}^{K-d}$ does not raise the total variation and carries $\mu_K^{K'}[\mathsf{b}]$ to $\mu_d^{K'}[\mathsf{b}]$, and Corollary 18.213 adds $\tau_J(K')$ for $K' \ge K_{\mathrm{bf}}$ and $\lceil K'/1260 \rceil \ge d$. Every term of $\eta_\Psi(K') + \tau_J(K')$ is at most a constant times $K'^{\mathfrak{p}} L^{-K'/10}$, which gives $C_\Psi L^{-K'/11}$. Both laws are gauge invariant. By Step 1, $P_{\Psi_{K'}}$ is the law P of Lemma 18.157(4), which is gauge invariant on $\mathsf{V}_{K'}$; the averaging map is gauge covariant by YM3_I:(37)–(39), so the image of $P_{\Psi_{K'}}$ under $\mathcal{M}^{K'-d}$ is gauge invariant on V_d; and $\mu_d[\mathsf{b}]$ is gauge invariant by Lemma 18.212(b), whose hypotheses $\mathsf{b} \ge \gamma^{-2}$ and $M\,R(\mathsf{b}) \le M\,R(\mathsf{b}_+) \le L^m$ hold on J. For gauge-invariant laws the gauge average of indicators eq. 2.xx makes the total variation over $\mathscr{I}_d$ equal to the one over all Borel sets. For (3): the means of a product of bounded functions under two laws differ by at most twice the total variation times the product of the suprema, and the joint cumulant is $\sum_\pi (-1)^{|\pi|-1}(|\pi|-1)! \prod_{B\in\pi} m_B$ in the mixed moments m_B; replacing the $|\pi|$ factors one at a time gives the bound.

Step 4: clause (4). For $g \in \mathrm{SU}(2)$, $\operatorname{tr}_{\mathrm{ad}} g = (\operatorname{tr} g)^2 - 1$; with $s = 1 - \frac{1}{2}\operatorname{tr} g$ this is $4(1-s)^2 - 1$, so $1 - \frac{1}{3}\operatorname{tr}_{\mathrm{ad}} g = \frac{1}{3}(8s - 4s^2)$, and the weight is $e^{-(\beta+\lambda)s} e^{\theta s^2}$ with $\lambda = \frac{8}{3}\beta_A$ and $\theta = \frac{4}{3}\beta_A$. Let $q = \frac{1}{4}$, so that $\frac{1}{2}qa^2 = \theta$, and $g_0(y) = \log(1 + q(\cosh y - 1)) - \frac{1}{2}qy^2$; then $e^{\theta s^2} = (1 - q + q\cosh(as))e^{-g_0(as)}$, and $1 - q + q\cosh(as) = \int e^{-\tau s} m^\circ(d\tau)$ with $m^\circ = \frac{3}{4}\delta_0 + \frac{1}{8}(\delta_a + \delta_{-a})$. Let $0 \le y = as \le 2a \le 1$. From $\log(1+x) \le x$ and $\cosh y - 1 - \frac{1}{2}y^2 = \sum_{k\ge 2} y^{2k}/(2k)! \le \frac{1}{24}y^4 \cosh y$, as $(2k)! \ge 24\,(2k-4)!$, we get $g_0(y) \le \frac{q}{24}y^4 \cosh 1$. From $\log(1+x) \ge x - \frac{1}{2}x^2$, $\cosh y - 1 - \frac{1}{2}y^2 \ge \frac{1}{24}y^4$ and $\cosh y - 1 \le \frac{1}{2}y^2 e^{y^2/12}$, which follows from $2\cdot 12^{k-1}(k-1)! \le (2k)!$ coefficient by coefficient, we get $g_0(y) \ge \frac{q}{24}y^4(1 - 3qe^{y^2/6}) \ge \frac{q}{24}y^4(1 - \frac{3}{4}e^{1/6}) \ge 0$. So $h(s) = g_0(as)$ lies between 0 and $\frac{1}{96}a^4\cosh(1)s^4$, and $e^{-\lambda s}\int e^{-\tau s} m^\circ(d\tau) = \hat{m}(s)$ for the translate m of m° by λ, which lies in $[\lambda - a, \lambda + a]$; and $a < \min\{\tau_\star, \frac{1}{2}\}$.

Step 5: clause (5). Let σ be the sign of u_3 and $y_3 = 6|u_3|/a^3 \le \frac{6}{256}$. The function $\varphi(q') = q'(1-q')(1-2q')$ increases on $[0, \frac{1}{32}]$ from 0 to $\frac{930}{32768} > 0.0283 > y_3$, so there is $q' \in [0, \frac{1}{32}]$ with $\varphi(q') = y_3$, and $q'(1-q') = y_3/(1-2q') \le \frac{16}{15}y_3$. Put $q = 2u_2/a^2 - q'(1-q')$; then $q \le \frac{1}{16}$ and $qa^4 \ge 2u_2a^2 - 6.4|u_3|a \ge 80M_4 \ge 0$. Let $X_1 \in \{0, \pm a\}$ with the weights $1-q, \frac{q}{2}, \frac{q}{2}$ and $X_2 \in \{0, \sigma a\}$ with the weights $1-q', q'$ be independent, let m° be the law of $-(X_1 + X_2)$, which has at most six atoms in $[-2a, 2a]$, and $\psi(s) = \log\int e^{-\tau s} m^\circ(d\tau) = \log \mathbb{E} e^{s(X_1+X_2)}$. At $s = 0$, $\psi'(0) = \sigma a q'$, $\frac{1}{2}\psi''(0) = \frac{1}{2}a^2(q + q'(1-q')) = u_2$, and $\frac{1}{6}\psi'''(0) = \frac{1}{6}\sigma a^3\varphi(q') = u_3$. For $s \in [0,2]$, $\psi''''(s)$ is the fourth cumulant of $X_1 + X_2$ under the law tilted by $e^{s(X_1+X_2)}$, the sum of the fourth cumulants of the two tilted variables. The tilted X_1 has the moments $\mu_1 = a\delta$, $\mu_2 = a^2 Q$, $\mu_3 = a^3\delta$, $\mu_4 = a^4 Q$, with $|\delta| \le Q = q\cosh(as)/(1 + q(\cosh(as) - 1)) \in [q, q\cosh 1] \subset [q, 0.0965]$; by $\kappa_4 = \mu_4 - 4\mu_3\mu_1 - 3\mu_2^2 + 12\mu_2\mu_1^2 - 6\mu_1^4$ its fourth cumulant lies in $[a^4Q(1-7Q-6Q^3), a^4Q(1+12Q^2)] \subset [0.3qa^4, 1.72qa^4]$. The tilted X_2 is σa times a Bernoulli variable whose parameter p is at most $eq' \le 0.085$, and its fourth cumulant $a^4 p(1-p)(1-6p(1-p))$ lies in $[0, 2.72q'a^4]$. Put $\lambda = \psi'(0) - u_1$ and $h(s) = \psi(s) - \psi'(0)s - u(s) + u_1 s$. Then h and its first three derivatives vanish at 0, and $h'''' = \psi'''' - u''''$ lies in $[0.3qa^4 - 24M_4, (1.72q + 2.72q')a^4 + 24M_4]$, whose lower end is ≥ 0; Taylor's

formula with the integral remainder gives $0 \le h(s) \le [\frac{1}{24}(\frac{1.72}{16} + \frac{2.72}{32})a^4 + M_4]s^4 \le (\frac{a^4}{100} + M_4)s^4$. Finally $e^{u(s)} = e^{-\lambda s}e^{\psi(s)}e^{-h(s)}$, where $e^{-\lambda s}e^{\psi(s)} = \hat{m}(s)$ for the translate m of m° by λ, and $|\lambda| \le |u_1| + aq' \le |u_1| + a/32$. □

18.16. **One torus: derivatives in the label as entries 1, analyticity at every label, and the sign of $S_3(1,f,h)$ between two labels.** The statements of this subsection concern the torus limits $S_n^{\ell,\mathsf{b}}$ of one side $\ell = 2L^m$, taken as functions of the label b on the whole half-line $(0,\infty)$. Proposition 18.160 says that for every tuple X on T_ℓ, at each cutoff and in the limit, a derivative in the label puts the constant function 1 in front of X as one more entry and changes the sign, $\partial_{\mathsf{b}}^{\nu} S_n^{\ell,\mathsf{b}}(X) = (-1)^{\nu} S_{n+\nu}^{\ell,\mathsf{b}}(1^{\nu}, X)$; that, for each order ν, the ν-th derivative at the cutoff K converges as $K \to \infty$ to the ν-th derivative of the limit, uniformly on every compact set of labels; and that $\int_{\mathsf{b}'}^{\mathsf{b}} S_3^{\ell,t}(1,f,h)\,dt = S_2^{\ell,\mathsf{b}'}(f,h) - S_2^{\ell,\mathsf{b}}(f,h)$ for two functions f,h with disjoint supports. Proposition 18.161 says that in a setting $\mathsf{b} \mapsto S_n^{\ell,\mathsf{b}}(X)$ is a real-analytic function of the label on the whole half-line, whatever the tuple X, whether two of its supports are disjoint or only the intersection of all of them is empty: about each compact interval of positive labels it extends to a holomorphic function on a strip whose width depends neither on X nor on n, and within that width it is the sum of its power series in the shift t of the label, in which the coefficient of t^{ν} is the torus limit of the tuple with ν entries 1 put in front, multiplied by $(-1)^{\nu}/\nu!$. Proposition 18.162 works at a reference coupling $0 < g \le \gamma_W$, on a side of $\mathfrak{L}(g)$, with a test pair (f,h) at a scale d and the tolerance $\epsilon = \bar{\varepsilon}_{g,\vartheta}(\mathsf{d})$ of the main text's law of two points: for any two labels $\mathsf{b}_1 < \mathsf{b}_2$ of the window $I(g)$ with $(\mathsf{b}_2/\mathsf{b}_1)^2 > (1+\epsilon)/(1-\epsilon)$ the function $t \mapsto S_3^{\ell,t}(1,f,h)$ takes a positive value between them, bounded below by a number given in closed form; since ϵ tends to 0 with d, any two labels of the window have this property at all the pairs of all the scales below a threshold formed from g, ϑ and $\mathsf{b}_2/\mathsf{b}_1$, and the classes of these pairs are not empty; and the zeros of $t \mapsto S_3^{\ell,t}(1,f,h)$ do not accumulate at any point of $(0,\infty)$. Proposition 18.163 admits any two positive labels $\mathsf{b}_1 < \mathsf{b}_2$ and treats all the sides $2L^m$, $m \in \mathbb{N}$, together: at every scale up to a first threshold the class of test pairs is not empty, and for each of its pairs the proposition gives the law of two points at b_1 and at b_2, and a label $t \in (\mathsf{b}_1, \mathsf{b}_2)$ at which $S_3^{\ell,t}(1,f,h)$ equals $(S_2^{\ell,\mathsf{b}_1}(f,h) - S_2^{\ell,\mathsf{b}_2}(f,h))/(\mathsf{b}_2 - \mathsf{b}_1)$, the difference quotient of $\mathsf{b} \mapsto S_2^{\ell,\mathsf{b}}(f,h)$ over $[\mathsf{b}_1, \mathsf{b}_2]$ with its sign reversed, and is bounded below by an expression in the two tolerances; for the scales up to a second, smaller threshold this lower bound is in turn at least a positive number given in closed form; the two thresholds and the two tolerances serve every m.

The cutoff differentiation uses the exact Wilson weight, and the passage to the limit uses locally uniform convergence from Theorem YM3_I:AS. The source factorization of Theorem YM3_I:AD gives a common strip. The two-point law in Theorem YM3_I:AV, together with the integral identity in Proposition 18.160, gives the sign conclusions. The Taylor coefficients are the cumulants with constant entries.

Definition 18.159 (Label, tuples, and the width of a strip)**.** (1) Use the canonical construction of Theorem YM3_I:D and the scalar torus cumulants $S^T_{n;K,\ell,\beta}$ for the Wilson action. In a sourced setting $\mathfrak{s}$ also use the fixed radius ϱ and the common constants of Theorem YM3_I:AD, with the canonical source room of [7, Lem. N.1]. This choice has $2\varrho \le \gamma^{-2} - \bar{B}$ by the source-radius inequality of the canonical construction. Write $S_n^{\ell,\mathsf{b}}(X)$ for the limit of the torus cumulants at $\beta = L^K\mathsf{b}$ through all cutoffs, as in Theorem YM3_I:AS. Use $X_g = L(g^{-2} + B_\sharp)$, $\bar{B} = LB_\sharp/(L-1)$, $I(g) = (g^{-2} + \bar{B}, X_g - \bar{B}]$, and the first-passage data and sides $\mathfrak{L}(g)$ of Proposition YM3_I:74.1.

(2) A tuple on T_ℓ has $n \ge 2$ real Lipschitz entries whose supports have empty intersection. For $\nu \ge 0$, $(1^\nu, X)$ prepends ν copies of the constant function 1. For a tuple with no identically zero entry put $\mathsf{d}_\infty(X) = \min_{x_i \in \operatorname{supp} f_i} \max_{i,j} |x_i - x_j|_\infty$ with torus sup distance. This minimum is positive by compactness and empty intersection. Such a tuple has a separated

pair if two supports are disjoint. In that case put $\hat{\mathsf{d}}(X) = \max_{i<j} \operatorname{dist}_\infty(\operatorname{supp} f_i, \operatorname{supp} f_j)$, with distance between sets measured in the torus sup metric.

(3) Put $f^{(s)}(x) = f(L^{-s}x)$ on $T_{L^s\ell}$ and $X^{(s)} = (f_i^{(s)})_i$. This dilation multiplies distances by L^s, preserves the supremum and decreases the Lipschitz constant. Thus $\|f^{(s)}\|_\sharp \le \|f\|_\sharp$, where $\|f\|_\sharp = \max\{\|f\|_\infty, 40M \operatorname{Lip} f\}$. It takes supports to the corresponding dilated supports, so it preserves the empty-intersection condition and multiplies $\hat{\mathsf{d}}(X)$ by L^s.

(4) An interval above the floor is $\mathsf{J} = [x_-, x_+]$ with $x_- \ge 2\gamma^{-2}$, and its sides are $\mathfrak{L}(g(x_+))$ with $g(x) = (x/2)^{-1/2}$. On a side λ set

$$Q = \exp[(C_{\mathrm{S}} + C_{g(x_+)})\lambda^3], \qquad \upsilon(\mathsf{J},\lambda) = \frac{\varrho}{4Q}, \qquad C_{g(x_+)} = C_{\mathrm{st}} + \frac{9}{2}\log X_{g(x_+)}.$$

Here C_{S} and C_g are the canonical source stability constants of [7, Lem. N.1]. Put

$$\mathsf{M}_n(d;\mathsf{J},\lambda) = \left(\frac{n}{\varrho}\right)^n 27 C_{\mathrm{S}} S(\kappa) C'_\Sigma(\kappa - \log 9216, 4)\left(\frac{\lambda}{d}\right)^3 + \log 2\left(\frac{n}{\upsilon(\mathsf{J},\lambda)}\right)^n,$$

where $S(\kappa)$ is the counting constant of Lemma YM3_I:88.1 and C'_Σ is from YM3_I:(1776). For a real interval J write $\Omega_r(J) = \{\zeta : \operatorname{dist}(\zeta, J) < r\}$.

(5) For $0 < \vartheta < 1$ and $20d \le \ell$, $\mathfrak{T}_{T_\ell}(d;\vartheta)$ consists of nonnegative Lipschitz pairs (f,h), neither zero, each supported in a closed ball of radius d, at mutual support distance between d and $6d$. Each entry satisfies $\int f \ge \vartheta \|f\|_\infty d^3$ and $\operatorname{Lip} f \le \|f\|_\infty/(\vartheta d)$. Put $\mathsf{c}_2 = 9/(16\pi^2)$ and $\mathcal{K}_6(f,h) = \iint f(x)h(y)|x-y|^{-6}\,dx\,dy$, using the torus distance. All cross distances lie in $[d, 10d]$. The integral bounds and the volumes of the two balls give

$$10^{-6}\vartheta^2 \|f\|_\infty \|h\|_\infty \le \mathcal{K}_6(f,h) \le (4\pi/3)^2 \|f\|_\infty \|h\|_\infty.$$

The class is nonempty: take the translates of $(1 - |x|/d)_+$ centered at 0 and $3de_1$, periodized to T_ℓ. Each has mass $\pi d^3/3 > d^3$ and Lipschitz constant $1/d$. Dilation by L^s maps a test pair to the class at $L^s d$ with the same ϑ and the same $\mathcal{K}_6$, by change of variables. Use the ceiling γ_W, the witness depth $s(d)[g]$, the tolerance $\bar{\varepsilon}_{g,\vartheta}(d)$ and the threshold $d_0(g,\vartheta)$ of Theorem YM3_I:AV and YM3_I:(2349). The tolerance is nondecreasing, tends to zero at zero and is at most $1/3$ on the indicated range.

■

Proposition 18.160 (Derivatives in the label at a cutoff and in the limit; their integrals over labels)**.** Use the real construction of Definition 18.159(1). Let $m \in \mathbb{N}$, $\ell = 2L^m$, $n \ge 2$, and let $X = (f_1, \dots, f_n)$ be a tuple on T_ℓ.

(1) *(One cutoff.)* For every $K \in \mathbb{N}$ the function $\mathsf{b} \mapsto S^T_{n;K,\ell,L^K\mathsf{b}}(X)$ is real-analytic on $(0,\infty)$, and

$$\partial_{\mathsf{b}}^\nu S^T_{n;K,\ell,L^K\mathsf{b}}(X) = (-1)^\nu S^T_{n+\nu;K,\ell,L^K\mathsf{b}}(1^\nu, X) \qquad (\nu \ge 0,\ \mathsf{b} > 0).$$

(2) *(The limit.)* The function $\mathsf{b} \mapsto S^{\ell,\mathsf{b}}_n(X)$ is of class C^∞ on $(0,\infty)$, and

$$\partial_{\mathsf{b}}^\nu S^{\ell,\mathsf{b}}_n(X) = (-1)^\nu S^{\ell,\mathsf{b}}_{n+\nu}(1^\nu, X) \qquad (\nu \ge 0,\ \mathsf{b} > 0).$$

For every $\nu \ge 0$ and every compact set $\mathsf{J}' \subset (0,\infty)$, $\sup_{\mathsf{b}\in\mathsf{J}'} \left|\partial_{\mathsf{b}}^\nu S^T_{n;K,\ell,L^K\mathsf{b}}(X) - \partial_{\mathsf{b}}^\nu S^{\ell,\mathsf{b}}_n(X)\right| \to 0$ as $K \to \infty$.

(3) *(Over an interval of labels.)* For all $0 < \mathsf{b}' < \mathsf{b}$,

$$\int_{\mathsf{b}'}^{\mathsf{b}} S^{\ell,t}_{n+1}(1,X)\,dt = S^{\ell,\mathsf{b}'}_n(X) - S^{\ell,\mathsf{b}}_n(X).$$

If f, h are real Lipschitz functions on T_ℓ with disjoint supports, then for all $0 < \mathsf{b}' < \mathsf{b}$

$$\int_{\mathsf{b}'}^{\mathsf{b}} S^{\ell,t}_3(1,f,h)\,dt = S^{\ell,\mathsf{b}'}_2(f,h) - S^{\ell,\mathsf{b}}_2(f,h), \qquad \int_{\mathsf{b}'}^{\mathsf{b}} t\,[t\,S^{\ell,t}_3(1,f,h) - 2S^{\ell,t}_2(f,h)]\,dt = \mathsf{b}'^2 S^{\ell,\mathsf{b}'}_2(f,h) - \mathsf{b}^2 S^{\ell,\mathsf{b}}_2(f,h).$$

The three identities hold as well at every cutoff K, each torus limit $S_k^{\ell,u}(Y)$ being replaced by $S^T_{k;K,\ell,L^K u}(Y)$.

■

Sketch. Step 1: an entry 0. If an entry of X is 0, so is an entry of each tuple $(1^\nu, X)$; the cumulants of such a tuple then vanish for all K and all $\beta > 0$, hence so do its torus limits at all labels (Theorem YM3_I:AS), and every member of (1)–(3) is 0. From here on no entry of X is 0, and then no entry of any $(1^\nu, X)$ is 0.

Step 2: the label as a constant source. For fixed K set $\mathcal{O}(f) = a_K^{-1}\sum_p f(x(p))a_p$ and

$$\mathcal{Z}_K(\zeta, z) = \int e^{-\zeta\mathcal{O}(1)+\sum_i z_i\mathcal{O}(f_i)}\, dU.$$

This is entire because the action and all insertions are bounded on the finite lattice. It is positive for real ζ, z. At any real $\mathsf{b} > 0$, the mixed derivative of $\log\mathcal{Z}_K(\mathsf{b}, z)$ in the z_i at zero is $S^T_{n;K,\ell,L^K\mathsf{b}}(X)$, since dividing by $\mathcal{Z}_K(\mathsf{b}, 0)$ adds a constant to the logarithm. The same derivative defines a holomorphic function of ζ where $\mathcal{Z}_K(\zeta, 0) \neq 0$. A local logarithm near each $(\zeta, 0)$ suffices, since the derivative is independent of its branch. A source z_0 for the entry 1 replaces ζ by $\zeta - z_0$. Differentiating once and then repeating yields the identity of (1) for every ν.

Step 3: the limit; clause (2). Put $\phi_{\nu,K}(\mathsf{b}) = (-1)^\nu S^T_{n+\nu;K,\ell,L^K\mathsf{b}}(1^\nu, X)$ and $\phi_\nu(\mathsf{b}) = (-1)^\nu S^{\ell,\mathsf{b}}_{n+\nu}(1^\nu, X)$. The tuple $(1^\nu, X)$ has $n + \nu \geq 2$ entries, none of them 0, and the intersection of its supports is empty; so by Theorem YM3_I:AS its torus limit exists at every label and is continuous in the label, and $\phi_{\nu,K} \to \phi_\nu$ uniformly on each compact subset of $(0, \infty)$. By (1), $\phi_{\nu,K}$ is continuously differentiable and $\phi'_{\nu,K} = \phi_{\nu+1,K}$. A sequence of C^1 functions on a compact interval that converges at every point, while the derivatives converge uniformly, has a C^1 limit, and differentiation commutes with the passage to the limit; so $\phi'_\nu = \phi_{\nu+1}$ in the interior of every compact interval of $(0, \infty)$, hence on $(0, \infty)$. By induction on ν, ϕ_0 has derivatives of every order and $\phi_0^{(\nu)} = \phi_\nu$. The uniform convergence of the derivatives is the convergence $\phi_{\nu,K} \to \phi_\nu$ just used.

Step 4: clause (3). By (2) at $\nu = 1$, ϕ_0 is continuously differentiable on $[\mathsf{b}', \mathsf{b}]$ with the derivative $t \mapsto -S^{\ell,t}_{n+1}(1, X)$, a continuous function, and integrating this derivative over $[\mathsf{b}', \mathsf{b}]$ gives the first identity. Two real Lipschitz functions with disjoint supports form a tuple (f, h) on T_ℓ, and $(1, f, h) = (1^1, (f, h))$; this gives the second identity. For the third, with $\phi(t) = S_2^{\ell,t}(f, h)$ and $\psi(t) = S_3^{\ell,t}(1, f, h)$, $\frac{d}{dt}[t^2\phi(t)] = 2t\phi(t) + t^2\phi'(t) = -t[t\psi(t) - 2\phi(t)]$, a continuous function, which is integrated in the same way. At a cutoff, (1) takes the place of (2) in these three arguments. □

Proposition 18.161 (Analyticity in the label on the whole half-line; the series of the entries 1)**.** Work in a setting $\mathfrak{s}$. Let $m \in \mathbb{N}$, $\ell = 2L^m$, $n \geq 2$, and let $X = (f_1, \dots, f_n)$ be a tuple on T_ℓ.

(1) *(A strip about a compact interval.)* Let $0 < \mathsf{b}_- < \mathsf{b}_+$, and fix an integer $s \geq 0$ such that

$$(\dagger) \qquad L^s\mathsf{b}_- \geq 2\gamma^{-2}, \qquad 2L^{m+s} \in \mathfrak{L}\big((L^s\mathsf{b}_+/2)^{-1/2}\big).$$

By the first inequality of (†), $(L^s\mathsf{b}_+/2)^{-1/2} < (L^s\mathsf{b}_-/2)^{-1/2} \leq \gamma$, so that the set of sides in the second condition is defined. If an integer $s \geq 0$ satisfies $L^s \geq \max\{2\gamma^{-2}/\mathsf{b}_-,\ L(\frac{1}{2}\mathsf{b}_+ + \bar{B})\}$, $L^{m+s/2} \geq L^2M\,(4r/e)^r$ and $L^{m+s} \geq L^2MC_{\mathrm{s}}$, then it satisfies (†); and these three inequalities hold for every s beyond some integer. Put $\mathsf{J}_s = [L^s\mathsf{b}_-, L^s\mathsf{b}_+]$ and $\upsilon_s = L^{-s}\upsilon(\mathsf{J}_s, L^s\ell)$. Then the real points of $\Omega_{\upsilon_s}([\mathsf{b}_-, \mathsf{b}_+])$, the numbers of $(\mathsf{b}_- - \upsilon_s, \mathsf{b}_+ + \upsilon_s)$, are positive, and a unique holomorphic function $\Phi[X]$ on $\Omega_{\upsilon_s}([\mathsf{b}_-, \mathsf{b}_+])$ takes the value $S_n^{\ell,\mathsf{b}}(X)$ at each real point b of this set; $\Phi[X]$ is bounded. The width υ_s is formed from the values of the constants before γ, from ϱ, s, b_+ and ℓ, and depends neither on n, nor on X, nor on a cutoff. If X has a separated pair, then $|\Phi[X]| \leq L^{sn}\,\mathsf{M}_n\big(L^s\hat{\mathsf{d}}(X); \mathsf{J}_s, L^s\ell\big)\prod_{i=1}^n \|f_i\|_\sharp$ on $\Omega_{\upsilon_s}([\mathsf{b}_-, \mathsf{b}_+])$.

(2) *(Every label.)* The function $\mathsf{b} \mapsto S_n^{\ell,\mathsf{b}}(X)$ is real-analytic at every point of $(0, \infty)$.

(3) *(The series of the entries 1.)* In the situation of (1) let $\mathsf{b} \in [\mathsf{b}_-, \mathsf{b}_+]$. Then $|S^{\ell,\mathsf{b}}_{n+\nu}(1^\nu, X)| \le \nu!\, \upsilon_s^{-\nu} \sup|\Phi[X]|$ for every $\nu \ge 0$, the supremum being taken over $\Omega_{\upsilon_s}([\mathsf{b}_-, \mathsf{b}_+])$, and whenever t is real and $|t| < \upsilon_s$,

$$S^{\ell,\mathsf{b}+t}_n(X) = \sum_{\nu=0}^{\infty} \frac{(-t)^\nu}{\nu!}\, S^{\ell,\mathsf{b}}_{n+\nu}(1^\nu, X),$$

with an absolutely convergent series.

■

Sketch. Step 1: the integer s. Let s satisfy the three inequalities; put $c = \frac{1}{2}\mathsf{b}_+$ and $g_s = (L^s c)^{-1/2}$. From the first, $L^s \mathsf{b}_- \ge 2\gamma^{-2}$; then $L^s c \ge \frac{1}{2} L^s \mathsf{b}_- \ge \gamma^{-2} \ge 4$, so $g_s \le \frac{1}{2}$ and $\mathfrak{L}(g_s)$ is defined. With $Y = L(g_s^{-2} + \bar{B}) = L(L^s c + \bar{B})$ we have $Y \ge 4L > e$, and, because $1 \le L^s$ and $L(c + \bar{B}) \le L^s$, also $Y \le L^s\, L(c + \bar{B}) \le L^{2s}$; so $0 < \log Y \le 4y$ with $y = \frac{1}{2} s \log L$. Raising $y/r \le e^{y/r - 1}$, a case of $u \le e^{u-1}$ for real u, to the power r gives $y^r \le (r/e)^r e^y = (r/e)^r L^{s/2}$, hence $(\log Y)^r \le (4r/e)^r L^{s/2}$, and the second and third inequalities yield $L^2 M \max\{(\log Y)^r, C_{\mathrm{S}}\} \le L^{m+s}$. The room formula in Proposition YM3_I:74.1 bounds the smallest side of $\mathfrak{L}(g_s)$, the number $2L^{m_{\mathfrak{L}}(g_s)}$, strictly by $2L^2 M \max\{(\log Y)^r, C_{\mathrm{S}}\}$; therefore $m_{\mathfrak{L}}(g_s) < m + s$, and $2L^{m+s} \in \mathfrak{L}(g_s)$ by the room condition. Since L^s, $L^{m+s/2}$ and L^{m+s} tend to infinity with s while the numbers they are compared with are fixed, the three inequalities hold for all large s.

Step 2: a uniform complex neighborhood on T_{ℓ_s}. By (†) the interval J_s is above the floor and $\ell_s = L^s \ell$ is a side of it. Use Q and υ from Definition 18.159(4). Because $2\upsilon \le \varrho/2$ and the lower endpoint of J_s is at least $2\gamma^{-2}$, every point at distance at most 2υ from J_s has positive real part. Fix $x \in \mathsf{J}_s$. For $g(x)^{-2} = x/2$ the label x lies in $I(g(x))$: the left endpoint is $x/2 + \bar{B} < x$, and the right endpoint is at least $Lx/2$. Thus $(K, L^K x)$ is first passage for each K by Corollary YM3_I:74.2. The side is admissible there by monotonicity of the room condition in Proposition YM3_I:74.1. For a tuple $Y = (h_i)$ on T_{ℓ_s} with nonzero entries, write $\mathcal{Z}_K$ for the finite-lattice integral in the proof of Proposition 18.160, with side ℓ_s and entries h_i. Use the source $w = \xi + \sum_i z_i h_i$ on the ball $|\xi| + \sum_i |z_i| \|h_i\|_\sharp < 2\varrho$. The factorization of Theorem YM3_I:AD at $(K, L^K x)$ gives

$$\frac{\mathcal{Z}_K(x - \xi, z)}{\mathcal{Z}_K(x, 0)} = e^{\mathcal{E}(w)} H(\xi, z), \qquad \mathcal{E}(w) = \sum_{j,X} e_j(X; w), \qquad H(\xi, z) = \frac{\widetilde{Z}(w)}{\widetilde{Z}(0)}.$$

Here $H(0,0) = 1$ and $|H| \le Q$, since $C_{g(x)} \le C_{g(\sup \mathsf{J}_s)}$. Schwarz's lemma on each radial complex line, applied to $(H - 1)/(Q + 1)$, gives

$$|H(\xi, z) - 1| \le \frac{Q + 1}{2\varrho} \left(|\xi| + \sum_i |z_i| \|h_i\|_\sharp \right).$$

It follows that H is nonzero when the parentheses are less than 4υ, and that $|\log H| \le \log 2$ when they are at most 2υ, by the series for $\log(1 + (H - 1))$.

Step 3: the uniform bound for a separated pair. Fix $|\xi| < \upsilon$. Cauchy's inequality on $|z_i| < \upsilon/(n\|h_i\|_\sharp)$ bounds the mixed derivative of $\log H$ at zero by $\log 2\, (n/\upsilon)^n \prod_i \|h_i\|_\sharp$. For the source energies use instead the radii $\varrho/(n\|h_i\|_\sharp)$, which still lie in the source ball. Each term contributes at most $(n/\varrho)^n C_{\mathrm{S}} e^{-\kappa d_j(X)} \prod_i \|h_i\|_\sharp$. It contributes zero unless the one-layer enlargement of X meets both supports in a separated pair, by source locality. Choose a pair with sup separation $d = \hat{\mathsf{d}}(Y)$. At level $j = K - r$ Lemma YM3_I:88.1 bounds the sum of the exponential factors of contributing domains by

$$27 S(\kappa) (\ell_s L^r / M)^3 e^{-(\kappa - \log 9216)[L^r d/M - 4]_+}.$$

Summing this over r by YM3_I:(1777) and adding the logarithm estimate gives $\mathsf{M}_n(d; \mathsf{J}_s, \ell_s) \prod_i \|h_i\|_\sharp$. The mixed log derivative of $\mathcal{Z}_K$ does not depend on the local branch, so these functions agree on overlaps of the discs $|x - \zeta| < \upsilon$ and define a bounded holomorphic function on $\Omega_\upsilon(\mathsf{J}_s)$ for each K.

On the real points it is the torus cumulant of Y. Theorem YM3_I:AS gives convergence at every such real point. Montel's theorem gives locally uniform subsequential limits. The identity theorem makes them equal, since they agree on the interval J_s, and hence the whole sequence converges locally uniformly to F_∞. It obeys the same bound. Apply this argument to $Y = X^{(s)}$.

Step 4: from T_{ℓ_s} to T_ℓ. Put $\Phi[X](\zeta) = L^{sn}F_\infty(L^s\zeta)$ for $\zeta \in \Omega_{\upsilon_s}([\mathsf{b}_-, \mathsf{b}_+])$, holomorphic by Step 2. At a real point b of this set, Step 3 and the scaling law YM3_I:(2215) give $\Phi[X](\mathsf{b}) = L^{sn}S_n^{L^s\ell, L^s\mathsf{b}}(X^{(s)}) = S_n^{\ell,\mathsf{b}}(X)$. The bound of (1) follows from that of Step 3, since $\hat{\mathsf{d}}(X^{(s)}) = L^s\hat{\mathsf{d}}(X)$ and $\|f_i^{(s)}\|_\sharp \le \|f_i\|_\sharp$. For uniqueness: being convex, the set $\Omega_{\upsilon_s}([\mathsf{b}_-, \mathsf{b}_+])$ is connected, and it contains a real interval; a holomorphic function on it vanishing on that interval vanishes identically, by the identity theorem. If an entry of X is 0, $\Phi[X] = 0$ has the required properties (Theorem YM3_I:AS).

Step 5: every tuple. Let no entry of X be 0, and put $\delta_X = \mathsf{d}_\infty(X) > 0$. Choose an integer $N \ge 3$ for which the mesh $\mathsf{w} = \ell/N$ satisfies $4\mathsf{w} < \delta_X$, and let $\mathrm{tent}(u) = \max\{0, 1 - |u|\}$; the translates $\mathrm{tent}(u - j)$, $j \in \mathbb{Z}$, add up to 1 at every real u. For $\alpha \in \{0, \dots, N-1\}^3$ define χ_α at a point $x \in T_\ell$ with a lift $\tilde{x}$ by $\chi_\alpha(x) = \prod_{\mu=1}^3 \sum_{j \equiv \alpha_\mu \pmod N} \mathrm{tent}(\tilde{x}_\mu/\mathsf{w} - j)$. A change of $\tilde{x}_\mu$ by $\ell = N\mathsf{w}$ shifts the index j by N and leaves the inner sum unchanged, so χ_α is well defined on T_ℓ. In an inner sum the terms that are not 0 live on disjoint intervals and vary at a rate at most $1/\mathsf{w}$; therefore χ_α takes its values in $[0,1]$ and is Lipschitz. The sum over α is $\prod_\mu \sum_{j\in\mathbb{Z}} \mathrm{tent}(\tilde{x}_\mu/\mathsf{w} - j) = 1$. If $\chi_\alpha(x) \ne 0$, each $\tilde{x}_\mu$ lies within w of a number $j\mathsf{w}$ with $j \equiv \alpha_\mu$, so x is at a sup distance less than w from the point p_α with the lift $\mathsf{w}\alpha$; consequently $\operatorname{supp}\chi_\alpha$ has sup diameter at most $2\mathsf{w}$. Each $f_i\chi_\alpha$ is a real Lipschitz function supported in $A_i = \operatorname{supp} f_i$, the closed sets $A_1, \dots, A_n$ have an empty intersection, and $f_i = \sum_\alpha f_i\chi_\alpha$. Since $S_n^{\ell,\mathsf{b}}$ is multilinear on the product of the spaces of real Lipschitz functions supported in $A_1, \dots, A_n$ (Proposition YM3_I:118.3),

$$S_n^{\ell,\mathsf{b}}(X) = \sum_{\alpha_1,\dots,\alpha_n} S_n^{\ell,\mathsf{b}}(f_1\chi_{\alpha_1}, \dots, f_n\chi_{\alpha_n}) \qquad (\mathsf{b} > 0).$$

Let a term have no entry 0, and suppose that every two of its supports intersect. Pick x_i in the support of its i-th entry for each i, and, for $i \ne i'$, a point y common to the supports of the i-th and the i'-th entries; then $|x_i - x_{i'}|_\infty \le |x_i - y|_\infty + |y - x_{i'}|_\infty \le 4\mathsf{w} < \delta_X$ for all i, i', although $x_i \in \operatorname{supp} f_i$ for every i, which contradicts the definition of δ_X as a least value. So each term either has an entry 0 and vanishes at every label, or has a separated pair and falls under Steps 3 and 4 with the same s and the same strip, which depend neither on the tuple nor on n. The sum of the functions Φ of the terms of the second kind is holomorphic and bounded on $\Omega_{\upsilon_s}([\mathsf{b}_-, \mathsf{b}_+])$ and equals $S_n^{\ell,\mathsf{b}}(X)$ at its real points; its uniqueness follows as in Step 4.

Step 6: clauses (2) and (3). Let $\mathsf{b}_0 > 0$. Clause (1) with $\mathsf{b}_\pm = 2^{\pm1}\mathsf{b}_0$ and an integer s satisfying (†) provides a holomorphic function on a disc about b_0 equal to $S_n^{\ell,\cdot}(X)$ at the real points of the disc; such a function is the sum of its Taylor series on a smaller disc, which is (2). For (3) let $\mathsf{c}_\Phi = \sup|\Phi[X]| < \infty$. As $D(\mathsf{b}, \upsilon_s) \subset \Omega_{\upsilon_s}([\mathsf{b}_-, \mathsf{b}_+])$, $\Phi[X](\zeta) = \sum_{\nu\ge0} c_\nu(\zeta - \mathsf{b})^\nu$ on this disc, and Cauchy's inequalities give $|c_\nu| \le \mathsf{c}_\Phi\upsilon_s^{-\nu}$. Along the real axis the derivatives of $\Phi[X]$ at b are those of $S_n^{\ell,\cdot}(X)$, so $\nu!\,c_\nu = \partial_\mathsf{b}^\nu S_n^{\ell,\mathsf{b}}(X) = (-1)^\nu S_{n+\nu}^{\ell,\mathsf{b}}(1^\nu, X)$ by Proposition 18.160(2). Setting $\zeta = \mathsf{b} + t$ with real t, $|t| < \upsilon_s$, gives (3), the terms being at most $\mathsf{c}_\Phi(|t|/\upsilon_s)^\nu$ in modulus. □

Proposition 18.162 (The three-point function with an entry 1 between two labels of a window)**.** Work in a setting $\mathfrak{s}$. Let $0 < g \le \gamma_W$, $\ell \in \mathfrak{L}(g)$, $\vartheta \in (0,1)$, $0 < \mathsf{d} \le \mathsf{d}_0(g,\vartheta)$ and $(f,h) \in \mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$. Put $\epsilon = \bar{\varepsilon}_{g,\vartheta}(\mathsf{d})$, so that $0 \le \epsilon \le \frac13$, $\mathsf{k} = \mathsf{c}_2\mathcal{K}_6(f,h)$, $\phi(\mathsf{b}) = S_2^{\ell,\mathsf{b}}(f,h)$ and $\psi(\mathsf{b}) = S_3^{\ell,\mathsf{b}}(1,f,h)$ for $\mathsf{b} > 0$, and let $\mathsf{b}_{\mathrm{top}} = L(g^{-2} + \bar{B}) - 2\bar{B}$ be the right end of $I(g)$.

(1) (f,h) and $(1,f,h)$ are tuples on T_ℓ with a separated pair, and $\mathsf{k} \ge 10^{-6}\vartheta^2\mathsf{c}_2\|f\|_\infty\|h\|_\infty > 0$. Each of ϕ and ψ is a real-analytic function of the label on $(0,\infty)$, $\phi' = -\psi$, and $\int_{\mathsf{b}'}^{\mathsf{b}} \psi(t)\,dt = \phi(\mathsf{b}') - \phi(\mathsf{b})$ for $0 < \mathsf{b}' < \mathsf{b}$.

(2) *(The law of two points on the window.)* $|\phi(\mathsf{b}) - \mathsf{k}\,\mathsf{b}^{-2}| \le \epsilon\,\mathsf{k}\,\mathsf{b}^{-2}$ for every $\mathsf{b} \in I(g)$.

(3) *(Integrals.)* Whenever $\mathsf{b}_1 < \mathsf{b}_2$ lie in $I(g)$, $\left|\int_{\mathsf{b}_1}^{\mathsf{b}_2}(\psi(\mathsf{b}) - 2\mathsf{k}\,\mathsf{b}^{-3})\,d\mathsf{b}\right| \le \epsilon\,\mathsf{k}\,(\mathsf{b}_1^{-2} + \mathsf{b}_2^{-2})$ and $\left|\int_{\mathsf{b}_1}^{\mathsf{b}_2}\mathsf{b}\,(\mathsf{b}\,\psi(\mathsf{b}) - 2\phi(\mathsf{b}))\,d\mathsf{b}\right| \le 2\epsilon\,\mathsf{k}$.

(4) *(A positive value between two labels.)* Whenever $\mathsf{b}_1 < \mathsf{b}_2$ lie in $I(g)$, some $t \in (\mathsf{b}_1, \mathsf{b}_2)$ satisfies

$$\mathsf{k}\,\frac{(1-\epsilon)\mathsf{b}_1^{-2} - (1+\epsilon)\mathsf{b}_2^{-2}}{\mathsf{b}_2 - \mathsf{b}_1} \le \psi(t) \le \mathsf{k}\,\frac{(1+\epsilon)\mathsf{b}_1^{-2} - (1-\epsilon)\mathsf{b}_2^{-2}}{\mathsf{b}_2 - \mathsf{b}_1}.$$

If $(\mathsf{b}_2/\mathsf{b}_1)^2 > (1+\epsilon)/(1-\epsilon)$, the lower bound is a positive number, so that $\psi(t) > 0$ and $\int_{\mathsf{b}_1}^{\mathsf{b}_2}\psi > 0$. As $(1+\epsilon)/(1-\epsilon) \le 2$, this happens whenever $\mathsf{b}_2^2 > 2\mathsf{b}_1^2$; for instance $\mathsf{b}_1 = \frac{1}{2}\mathsf{b}_{\mathrm{top}}$ and $\mathsf{b}_2 = \mathsf{b}_{\mathrm{top}}$ are two labels of $I(g)$, and for this choice $\psi(t) \ge 2(3-5\epsilon)\mathsf{k}\,\mathsf{b}_{\mathrm{top}}^{-3} \ge \frac{8}{3}\mathsf{k}\,\mathsf{b}_{\mathrm{top}}^{-3}$.

(5) *(Any two labels of the window, at small scales.)* Let $\mathsf{b}_1 < \mathsf{b}_2$ lie in $I(g)$, and put $\rho = \mathsf{b}_2/\mathsf{b}_1$, $\eta_\rho = \frac{\rho^2-1}{2(\rho^2+1)}$ and

$$\mathsf{d}_\bullet(g,\vartheta,\rho) = \tfrac{1}{2}\sup\{\mathsf{d}' \in (0, \mathsf{d}_0(g,\vartheta)] :\ \bar{\varepsilon}_{g,\vartheta}(\mathsf{d}') \le \eta_\rho\}.$$

Then $0 < \mathsf{d}_\bullet(g,\vartheta,\rho) \le \frac{1}{2}\mathsf{d}_0(g,\vartheta)$; for every $\mathsf{d}' \in (0, \mathsf{d}_\bullet(g,\vartheta,\rho)]$ the class $\mathfrak{T}_{T_\ell}(\mathsf{d}';\vartheta)$ is not empty, and every pair (f',h') of it has a label $t \in (\mathsf{b}_1,\mathsf{b}_2)$ with

$$S_3^{\ell,t}(1,f',h') \ge \tfrac{1}{2}\,\mathsf{c}_2\,\mathcal{K}_6(f',h')\,\frac{\mathsf{b}_1+\mathsf{b}_2}{\mathsf{b}_1^2\mathsf{b}_2^2} \ge \tfrac{1}{2}\,10^{-6}\vartheta^2\,\mathsf{c}_2\,\frac{\mathsf{b}_1+\mathsf{b}_2}{\mathsf{b}_1^2\mathsf{b}_2^2}\,\|f'\|_\infty\|h'\|_\infty > 0.$$

Every open interval that lies in $I(g)$ and is not empty contains two labels $\mathsf{b}_1 < \mathsf{b}_2$; so at all the pairs of all the scales up to $\mathsf{d}_\bullet(g,\vartheta,\mathsf{b}_2/\mathsf{b}_1)$ the function $t \mapsto S_3^{\ell,t}(1,f',h')$ takes a positive value in that interval.

(6) *(Zeros.)* ψ is not identically 0, and its zeros do not accumulate at any point of $(0,\infty)$, so that every compact interval of positive labels holds finitely many of them; the set $\{\psi > 0\}$ is open, and it contains a point of each interval $(\mathsf{b}_1,\mathsf{b}_2)$ whose ends lie in $I(g)$ and satisfy $(\mathsf{b}_2/\mathsf{b}_1)^2 > (1+\epsilon)/(1-\epsilon)$.

(7) *(One cutoff.)* Let $K > s(\mathsf{d})[g]$. Then (2)–(4) remain true when ϕ and ψ are replaced by $\phi_K(\mathsf{b}) = S^T_{2;K,\ell,L^K\mathsf{b}}(f,h)$ and $\psi_K(\mathsf{b}) = S^T_{3;K,\ell,L^K\mathsf{b}}(1,f,h)$, ϵ and k being unchanged; and $\phi_K' = -\psi_K$ on $(0,\infty)$.

The numbers ϵ, $\mathsf{d}_0(g,\vartheta)$ and $\mathsf{d}_\bullet(g,\vartheta,\rho)$ are formed from the setting, g, ϑ, d and ρ alone. So one and the same number ϵ enters the bounds of (2)–(4) and (7) for all the sides $\ell \in \mathfrak{L}(g)$, all the pairs of $\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ wherever they lie on the torus, all the labels of $I(g)$ and all the cutoffs $K > s(\mathsf{d})[g]$. ■

Sketch. Step 1: clause (1). The two functions of a test pair are non-negative and Lipschitz, neither vanishes identically, and their supports are at a distance at least $\mathsf{d} > 0$; so f and h are real Lipschitz functions, not 0, with disjoint supports, and the constant function 1 is real, Lipschitz and not 0. Hence (f,h) and $(1,f,h)$ are tuples on T_ℓ with a separated pair. The lower bound for k is Definition 18.159(5). Proposition 18.161(2) for the two tuples gives the analyticity, and Proposition 18.160(2), (3) the identity $\phi' = -\psi$ and the integral.

Step 2: clause (2). Let $\mathsf{b} \in I(g)$. As $g \le \gamma_W \le \gamma$, each pair $(K, L^K\mathsf{b})$, $K \in \mathbb{N}$, is a first-passage datum at g, and its label is b (Corollary YM3_I:74.2). For $K > s(\mathsf{d})[g]$, Theorem YM3_I:AV, the law of two points on the tori of the sides at g, applied at this datum, at the side $\ell \in \mathfrak{L}(g)$, at the scale $\mathsf{d} \in (0, \mathsf{d}_0(g,\vartheta)]$ and at the pair (f,h), gives $S^T_{2;K,\ell,L^K\mathsf{b}}(f,h) = \mathsf{c}_2\mathsf{b}^{-2}\mathcal{K}_6(f,h)(1+\varepsilon')$ with $|\varepsilon'| \le \epsilon$, that is, $|S^T_{2;K,\ell,L^K\mathsf{b}}(f,h) - \mathsf{k}\,\mathsf{b}^{-2}| \le \epsilon\,\mathsf{k}\,\mathsf{b}^{-2}$. The witness depth does not depend on K or on b, so this holds for all large K; as $K \to \infty$ the cumulant converges, by Theorem YM3_I:AS applied to the tuple (f,h) of clause (1), none of whose entries is 0, and its limit is $\phi(\mathsf{b})$ (YM3_I:(2212)); the inequality, whose right side is free of K, persists.

Step 3: clause (3). Integrating ψ and $2\mathsf{k}\,\mathsf{b}^{-3}$ over $[\mathsf{b}_1,\mathsf{b}_2]$ with the help of (1), one finds that the quantity inside the first modulus of (3) equals $[\phi(\mathsf{b}_1) - \mathsf{k}\mathsf{b}_1^{-2}] - [\phi(\mathsf{b}_2) - \mathsf{k}\mathsf{b}_2^{-2}]$, a difference of two numbers that (2) bounds. By the last identity of Proposition 18.160(3) the quantity inside

the second modulus equals $[\mathsf{b}_1^2\phi(\mathsf{b}_1)-\mathsf{k}]-[\mathsf{b}_2^2\phi(\mathsf{b}_2)-\mathsf{k}]$, and (2) times b^2 bounds each of the two brackets by $\epsilon\mathsf{k}$.

Step 4: clause (4). Applied to ϕ on the interval $[\mathsf{b}_1,\mathsf{b}_2]$, the mean value theorem and $\phi'=-\psi$ give a $t\in(\mathsf{b}_1,\mathsf{b}_2)$ with $\psi(t)=(\phi(\mathsf{b}_1)-\phi(\mathsf{b}_2))/(\mathsf{b}_2-\mathsf{b}_1)$; inserting $(1-\epsilon)\mathsf{k}\mathsf{b}_i^{-2}\le\phi(\mathsf{b}_i)\le(1+\epsilon)\mathsf{k}\mathsf{b}_i^{-2}$, $i=1,2$, from (2) gives the lower and the upper bound. As $\epsilon<1$, the lower bound is positive precisely if $(1-\epsilon)\mathsf{b}_2^2>(1+\epsilon)\mathsf{b}_1^2$, and then also $\int_{\mathsf{b}_1}^{\mathsf{b}_2}\psi=\phi(\mathsf{b}_1)-\phi(\mathsf{b}_2)>0$. If $\epsilon\le\frac13$, then $(1+\epsilon)/(1-\epsilon)\le2$. The right end of $I(g)$ divided by its left end is $\mathsf{b}_{\mathrm{top}}/(g^{-2}+\bar B)=L-2\bar B/(g^{-2}+\bar B)>L-2\ge11$, because $g^{-2}>0$; hence $\frac12\mathsf{b}_{\mathrm{top}}>g^{-2}+\bar B$, and both $\frac12\mathsf{b}_{\mathrm{top}}$ and $\mathsf{b}_{\mathrm{top}}$ belong to $I(g)$. For this choice $\mathsf{b}_1^{-2}=4\mathsf{b}_{\mathrm{top}}^{-2}$ and $\mathsf{b}_2-\mathsf{b}_1=\frac12\mathsf{b}_{\mathrm{top}}$, so the lower bound equals $2(3-5\epsilon)\mathsf{k}\,\mathsf{b}_{\mathrm{top}}^{-3}\ge\frac83\mathsf{k}\,\mathsf{b}_{\mathrm{top}}^{-3}$.

Step 5: clause (5). Since $\bar\varepsilon_{g,\vartheta}$ has the limit 0 at 0 and $\eta_\rho>0$, the set whose supremum defines $\mathsf{d}_\bullet(g,\vartheta,\rho)$ is not empty, and that supremum lies in $(0,\mathsf{d}_0(g,\vartheta)]$. For $0<\mathsf{d}'\le\mathsf{d}_\bullet(g,\vartheta,\rho)$ the set has an element $\mathsf{d}''>\mathsf{d}'$, and monotonicity gives $\epsilon'=\bar\varepsilon_{g,\vartheta}(\mathsf{d}')\le\bar\varepsilon_{g,\vartheta}(\mathsf{d}'')\le\eta_\rho$. For $(f',h')\in\mathfrak{T}_{T_\ell}(\mathsf{d}';\vartheta)$, clause (4) applies with ϵ' and $\mathsf{k}'=\mathsf{c}_2\mathcal{K}_6(f',h')$; moreover $\epsilon'(\mathsf{b}_1^{-2}+\mathsf{b}_2^{-2})\le\eta_\rho(\rho^2+1)\mathsf{b}_2^{-2}=\frac12(\rho^2-1)\mathsf{b}_2^{-2}=\frac12(\mathsf{b}_1^{-2}-\mathsf{b}_2^{-2})$, so the lower bound of (4) is at least $\frac12\mathsf{k}'(\mathsf{b}_1^{-2}-\mathsf{b}_2^{-2})/(\mathsf{b}_2-\mathsf{b}_1)=\frac12\mathsf{k}'(\mathsf{b}_1+\mathsf{b}_2)\mathsf{b}_1^{-2}\mathsf{b}_2^{-2}$, and Definition 18.159(5) gives the last inequality. As $20\,\mathsf{d}'\le\frac{1}{10}<\ell$, the explicit tent pairs of Definition 18.159(5) give nonemptiness.

Step 6: clause (6). By (1) and (4), ψ is real-analytic on $(0,\infty)$ and takes a positive value. Suppose that the zeros of ψ accumulate at some $a>0$, and expand $\psi(t)=\sum_j c_j(t-a)^j$ near a. Were some c_j different from 0, with j_0 the smallest index of such a coefficient, one would have $\psi(t)=(t-a)^{j_0}\chi(t)$ near a, χ continuous with $\chi(a)=c_{j_0}\neq0$, and ψ would have no zero near a other than a; so $\psi=0$ on a neighbourhood of a. Hence the points of $(0,\infty)$ having a neighbourhood on which ψ vanishes form an open set U, which is also closed in $(0,\infty)$, because the zeros accumulate at every point of its closure. The half-line is connected and ψ is not identically 0, so U is empty; therefore the zeros of ψ do not accumulate in $(0,\infty)$. Infinitely many zeros in a compact interval of positive labels would accumulate at a point of it (Bolzano–Weierstrass); so there are finitely many. Continuity makes $\{\psi>0\}$ open, and (4) gives its points in the intervals of (6).

Step 7: clause (7) and the dependence. Let $K>s(\mathsf{d})[g]$. By Proposition 18.160(1), ϕ_K is real-analytic on $(0,\infty)$ with $\phi_K'=-\psi_K$, and Proposition 18.160(3) holds at the cutoff K; Step 2, stopped before the limit $K\to\infty$, is (2) for ϕ_K, and Steps 3 and 4 use nothing beyond these facts. The tolerance and the threshold depend on ϱ, $\varsigma^{\mathrm S}$, g and ϑ only (YM3_I:(2349)); ϵ is the value of the tolerance at d, and $\mathsf{d}_\bullet(g,\vartheta,\rho)$ is built from these and ρ; none of them depends on a side, a pair, the place of a pair, a label or a cutoff. □

Proposition 18.163 (Two positive labels on every side at once)**.** Work in a setting $\mathfrak{s}$. Let $\vartheta\in(0,1)$ and $0<\mathsf{b}_1<\mathsf{b}_2$, and put $\rho=\mathsf{b}_2/\mathsf{b}_1$ and $\eta_\rho=\frac{\rho^2-1}{2(\rho^2+1)}$. Fix an integer $s\ge0$ such that

$$(\ddagger)\qquad L^s\mathsf{b}_1\ge2\gamma_W^{-2},\qquad 2L^{1+s}\in\mathfrak{L}(g_2),\qquad \text{where } g_i=(L^s\mathsf{b}_i/2)^{-1/2}\ (i=1,2).$$

The first inequality of (‡) alone gives $g_2^{-2}>g_1^{-2}=\frac12L^s\mathsf{b}_1\ge\gamma_W^{-2}$, that is, $0<g_2<g_1\le\gamma_W\le\gamma$; hence the set $\mathfrak{L}(g_2)$ in the second condition is defined, and so are the thresholds $\mathsf{d}_0(g_i,\vartheta)$ and the tolerances $\bar\varepsilon_{g_i,\vartheta}$ used below (Definition 18.159(5)). If an integer $s\ge0$ satisfies $L^s\ge\max\{2\gamma_W^{-2}/\mathsf{b}_1,\ L(\frac12\mathsf{b}_2+\bar B)\}$, $L^{1+s/2}\ge L^2M\,(4r/e)^r$ and $L^{1+s}\ge L^2MC_{\mathrm s}$, then it satisfies (‡); and these three inequalities hold for every s beyond some integer. Put $\mathsf{d}_1=L^{-s}\min\{\mathsf{d}_0(g_1,\vartheta),\mathsf{d}_0(g_2,\vartheta)\}$, $\epsilon_i(\mathsf{d})=\bar\varepsilon_{g_i,\vartheta}(L^s\mathsf{d})$ for $0<\mathsf{d}\le\mathsf{d}_1$ and $i=1,2$, and

$$\mathsf{d}_\circ=\tfrac12\sup\{\mathsf{d}\in(0,\mathsf{d}_1]:\ \max\{\epsilon_1(\mathsf{d}),\epsilon_2(\mathsf{d})\}\le\eta_\rho\}.$$

Then $0<\mathsf{d}_\circ\le\frac12\mathsf{d}_1$; for every $m\in\mathbb{N}$, $\ell=2L^m$, and every $\mathsf{d}\in(0,\mathsf{d}_1]$ the class $\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ is not empty; and every pair (f,h) of this class has the following properties.

(1) $|S_2^{\ell,\mathsf{b}_i}(f,h)-\mathsf{c}_2\mathsf{b}_i^{-2}\mathcal{K}_6(f,h)|\le\epsilon_i(\mathsf{d})\,\mathsf{c}_2\mathsf{b}_i^{-2}\mathcal{K}_6(f,h)$ for $i=1,2$, and $\epsilon_i(\mathsf{d})\le\frac13$.

(2) Some $t \in (\mathsf{b}_1, \mathsf{b}_2)$ has

$$S_3^{\ell,t}(1,f,h) = \frac{S_2^{\ell,\mathsf{b}_1}(f,h) - S_2^{\ell,\mathsf{b}_2}(f,h)}{\mathsf{b}_2 - \mathsf{b}_1} \geq \mathsf{c}_2 \mathcal{K}_6(f,h)\, \frac{(1-\epsilon_1(\mathsf{d}))\mathsf{b}_1^{-2} - (1+\epsilon_2(\mathsf{d}))\mathsf{b}_2^{-2}}{\mathsf{b}_2 - \mathsf{b}_1}.$$

(3) If $\mathsf{d} \leq \mathsf{d}_\circ$, the right member of (2) is at least $\frac{1}{2}\mathsf{c}_2\mathcal{K}_6(f,h)(\mathsf{b}_1+\mathsf{b}_2)\mathsf{b}_1^{-2}\mathsf{b}_2^{-2} \geq \frac{1}{2}\,10^{-6}\vartheta^2\mathsf{c}_2(\mathsf{b}_1+\mathsf{b}_2)\mathsf{b}_1^{-2}\mathsf{b}_2^{-2}\|f\|_\infty\|h\|_\infty > 0$.

If s is taken to be the least integer satisfying (‡), then s, d_1, $\mathsf{d}_\circ$ and the functions ϵ_1, ϵ_2 are formed from the setting, ϑ, b_1 and b_2 alone; they depend on no side, no test pair, no place of a pair on the torus and no cutoff, so that one threshold $\mathsf{d}_\circ$ of the scale serves all the sides $2L^m$, $m \in \mathbb{N}$. ■

Sketch. Step 1: the integer s. Let s satisfy the three inequalities. The first entry of the maximum in the first of them yields $L^s\mathsf{b}_1 \geq 2\gamma_W^{-2}$, the inequality that (‡) asks for. As $\gamma_W \leq \gamma$, that first inequality implies the first inequality of Proposition 18.161(1) for $\mathsf{b}_- = \mathsf{b}_1$ and $\mathsf{b}_+ = \mathsf{b}_2$, and at $m = 1$ the second and the third coincide with those of that proposition. So Step 1 of its proof applies with $m = 1$; it draws from the first entry of the maximum the bounds $L^s\mathsf{b}_2/2 \geq L^s\mathsf{b}_1/2 \geq \gamma^{-2} \geq 4$ and from the second entry the bound $L(\frac{1}{2}\mathsf{b}_2 + \bar{B}) \leq L^s$, and it gives $2L^{1+s} \in \mathfrak{L}((L^s\mathsf{b}_2/2)^{-1/2}) = \mathfrak{L}(g_2)$, the membership that (‡) asks for. All three inequalities hold for large s, as there.

Step 2: couplings, windows and sides. Let $i \in \{1,2\}$ and $x_i = L^s\mathsf{b}_i$. Then $g_i^{-2} = \frac{1}{2}x_i \geq \frac{1}{2}L^s\mathsf{b}_1 \geq \gamma_W^{-2}$, so $g_i \leq \gamma_W \leq \gamma$, and $g_2 < g_1$ because $\mathsf{b}_1 < \mathsf{b}_2$. As $x_i \geq 2\gamma^{-2}$, $\{x_i\}$ is an interval of labels above the floor with $g(x_i) = g_i$; the endpoint formulas give $g_i^{-2} + \bar{B} < x_i \leq X_{g_i} - \bar{B}$, and Corollary YM3_I:74.2 shows that $(K, L^K x_i)$ is, for each cutoff K, a first-passage datum at g_i whose label is x_i. The monotonicity of the room condition gives $m_{\mathfrak{L}}(g_1) \leq m_{\mathfrak{L}}(g_2)$, and (‡) gives $1 + s \geq m_{\mathfrak{L}}(g_2)$; so for every $m \in \mathbb{N}$, $m + s \geq m_{\mathfrak{L}}(g_i)$, and $\ell_s = L^s\ell = 2L^{m+s} \in \mathfrak{L}(g_i)$ by the room condition.

Step 3: the classes; clause (1). Let $0 < \mathsf{d} \leq \mathsf{d}_1$. As $\mathsf{d}_1 \leq \frac{1}{200}$, $20\,\mathsf{d} \leq \frac{1}{10} < \ell$; so the class $\mathfrak{T}_{T_\ell}(\mathsf{d};\vartheta)$ is defined, and it is not empty by the explicit tent pairs of Definition 18.159(5). Let (f,h) be a pair of this class. By change of variables under dilation, $(f^{(s)}, h^{(s)}) \in \mathfrak{T}_{T_{\ell_s}}(L^s\mathsf{d};\vartheta)$ and $\mathcal{K}_6(f^{(s)}, h^{(s)}) = \mathcal{K}_6(f,h)$; also $L^s\mathsf{d} \leq \mathsf{d}_0(g_i,\vartheta)$. Theorem YM3_I:AV, applied at g_i, at the datum $(K, L^K x_i)$, at the side $\ell_s \in \mathfrak{L}(g_i)$, at the scale $L^s\mathsf{d}$ and at the pair $(f^{(s)}, h^{(s)})$, yields for every $K > s(L^s\mathsf{d})[g_i]$

$$|S^T_{2;K,\ell_s,L^K x_i}(f^{(s)}, h^{(s)}) - \mathsf{c}_2 x_i^{-2}\mathcal{K}_6(f,h)| \leq \epsilon_i(\mathsf{d})\,\mathsf{c}_2 x_i^{-2}\mathcal{K}_6(f,h),$$

together with $\epsilon_i(\mathsf{d}) \leq \frac{1}{3}$. The functions $f^{(s)}, h^{(s)}$ are real Lipschitz, not 0, with disjoint supports, so the cumulant converges to $S_2^{\ell_s,x_i}(f^{(s)}, h^{(s)})$ as $K \to \infty$ (Theorem YM3_I:AS), and the inequality persists. The scaling law YM3_I:(2215) gives $S_2^{\ell,\mathsf{b}_i}(f,h) = L^{2s}S_2^{\ell_s,x_i}(f^{(s)}, h^{(s)})$, and $L^{2s}x_i^{-2} = \mathsf{b}_i^{-2}$.

Step 4: clauses (2), (3) and the dependence. As in Step 1 of the proof of Proposition 18.162, (f,h) and $(1,f,h)$ are tuples on T_ℓ; the mean value theorem with $\partial_{\mathsf{b}}S_2^{\ell,\mathsf{b}}(f,h) = -S_3^{\ell,\mathsf{b}}(1,f,h)$ (Proposition 18.160(2)) provides t, and (1) at b_1 and at b_2 provides the bound. The functions ϵ_1, ϵ_2 are non-decreasing with the limit 0 at 0, so the set defining $\mathsf{d}_\circ$ is not empty, and for $\mathsf{d} \leq \mathsf{d}_\circ$, by the argument of Step 5 of that proof, $\max_i \epsilon_i(\mathsf{d}) \leq \eta_\rho$; then $\rho^2\epsilon_1(\mathsf{d}) + \epsilon_2(\mathsf{d}) \leq \eta_\rho(\rho^2+1) = \frac{1}{2}(\rho^2-1)$, and $(1-\epsilon_1(\mathsf{d}))\mathsf{b}_1^{-2} - (1+\epsilon_2(\mathsf{d}))\mathsf{b}_2^{-2} = \mathsf{b}_2^{-2}[\rho^2 - 1 - \rho^2\epsilon_1(\mathsf{d}) - \epsilon_2(\mathsf{d})] \geq \frac{1}{2}(\mathsf{b}_1^{-2} - \mathsf{b}_2^{-2})$; dividing by $\mathsf{b}_2 - \mathsf{b}_1$ and using Definition 18.159(5) gives (3). The condition (‡) involves no side, and $\mathsf{d}_0(g_i,\vartheta)$ and $\bar{\varepsilon}_{g_i,\vartheta}$ depend on the setting, g_i and ϑ only (YM3_I:(2349)); this gives the last assertion. □

18.17. **Reconstruction data fixed by one ball; spacing-first limits at every label; a ceiling on the lowest mass and the growth of the Källén–Lehmann measure; one vacuum from ergodic states.** We study reconstruction from local data, spacing-first limits and spectral bounds. Proposition 18.166 says that two functionals that are reconstruction data and agree at the separated tuples supported in one non-empty open set, for instance in one ball, are equal, so that they have one Hilbert space, one Hamiltonian and one field; that at one order n agreement at the tuples

supported near one configuration of n distinct points gives equality at that order, because the kernels of the order n are one holomorphic function on a connected domain; that the members of $A[b]$, their components and centred components, the limits of convergent Gibbs sequences at every reference coupling with their components, and all real dilates of these are reconstruction data; and that reconstruction data with one first and one second number form a normal family. Proposition 18.168 says that at a label $b \in I(g)$ the torus limits along every sequence of sides have limit points at all separated tuples, each of them a continuum limit at g along growing tori with the label b; so $\mathrm{SF}(b)$ is not empty. Proposition 18.169 carries this to every real label and every sequence of sides, and lists what every spacing-first limit has: invariance under all translations and the cubic group, reflection positivity at every coordinate plane, bounds and the growth condition with numbers that read no cutoff, side or sequence, regularity, a separable Hilbert space with a semigroup and two momenta, and the law of two points with its label. Proposition 18.170 says that the Källén–Lehmann measure ρ of every component of every member of $A[b]$ obeys $4.7 \cdot 10^{-9}\, b^{-2} M^5 \le \rho([0,M]) \le 0.973\, b^{-2} M^5$ for $M \ge 1.36\, C_0/b$; that at a reference coupling $g \le \gamma_W$ and for every $\vartheta \in (0, \vartheta_1]$ the lowest mass of every component of the limit of every convergent Gibbs sequence at g is at most $m_\circ / d_0(g,\vartheta)$, with $m_\circ < 2.59$; that, at such g and ϑ, every continuum limit S at g along growing tori has $\dim\ker H_S \ge 2$ or a point of $\operatorname{spec} H_S$ in $(0, m_\circ/d_0(g,\vartheta)]$; and that every spacing-first limit S at a real label b has $\dim\ker H_S \ge 2$ or a point of $\operatorname{spec} H_S$ in $(0, C_0/b]$. Proposition 18.171 says that the limit of a convergent Gibbs sequence whose states are ergodic infinitely often has one vacuum; under the uniform finite-size hypothesis, the one limit at a label that a uniformly small finite-size effect gives has one vacuum as soon as one of its defining sequences of states has ergodic states infinitely often.

The analytic kernels are those of Proposition YM3_I:108.3. Use Theorem YM3_I:AP for Gibbs-frame reconstruction, Theorem YM3_I:AL for the canonical decomposition, and Theorems YM3_I:AS and YM3_I:AW for moving-label torus limits and continuum two-point bounds.

Definition 18.164 (Further signs)**.** Use the common construction and source calibration of §2.3.1. Write $\mathfrak{L} = \{2L^m : m \ge 1\}$ and $Q_\ell = (-\ell/4, \ell/4)^3$. Use $\mathfrak{d}(g)$, $\mathfrak{L}(g)$ and $I(g)$ from Proposition YM3_I:74.1 and Corollary YM3_I:74.2. The labels of first-passage data lie in $I^{\mathrm{lab}}(g) = [g^{-2}, L(g^{-2} + \bar B)]$. Use γ_W, $\bar\varepsilon_{g,\vartheta}(d)$ and $d_0(g,\vartheta)$ of Definition 18.140(4). Put

$$\alpha = (5/3)^6, \quad c_2 = 9/(16\pi^2), \quad m_\circ = \tfrac14 \log 31250, \quad \kappa_0 = L(\gamma_W^{-2} + \bar B), \quad \vartheta_1 = 3\sqrt{3}/8,$$
$$g_1 = \gamma_W, \quad g_2 = (\gamma_W^{-2} + 2\bar B/L)^{-1/2}, \quad g_3 = (2\gamma_W^{-2})^{-1/2},$$
$$d^\star = \min_i d_0(g_i, \vartheta_1), \quad k_0 = 6d^\star/\kappa_0, \quad C_0 = m_\circ \kappa_0 / d^\star.$$

For $b \in I(g)$ write $\mathfrak{d}_b = \{(K, L^K b) : K \ge 1\}$. Set $K_{\mathrm{free}}(f,h) = \iint f(x) h(y) |x-y|^{-6}\, dx\, dy$. Use the two-point test class of §18.4 with C^1 entries for separated moments. Write $\mathfrak{S}(O) = \bigcup_{n\ge0} \mathfrak{S}_n(O)$ for the separated tuples of real $C^1_c(O)$ functions, including the empty tuple. Use the product, translations and norm from Definition 18.205. For $s > 0$ set $X_{(s)} = (f_i(s\,\cdot))_i$ and $(\mathrm{dil}_s\sigma)(X) = s^{-|X|}\sigma(X_{(s)})$. Write $X^{[z]} = X_{(L^{-z})}$.

For $\zeta = (K, \ell, \beta)$ put $\mathsf{a}(\zeta; X) = S^T_{n;K,\ell,\beta}(X^{\langle\ell\rangle})$, with periodized tests. For $X \in \mathfrak{S}_n(Q_\ell)$ put $\mathsf{B}(\ell, b; X) = S^{\ell,b}_n(X^{\langle\ell\rangle})$ at the torus limit of Theorem YM3_I:AS. A growing-torus sequence at g has $K, \ell \to \infty$ with $(K,\beta) \in \mathfrak{d}(g)$ and $\ell \in \mathfrak{L}(g)$. Its pointwise separated-cumulant limits form $\mathrm{GT}(g)$. Use $\mathcal{G}^{\mathrm{tor}}_{(K,\beta)}$ for weak limits of periodic extensions at the fixed pair as $\ell \to \infty$. Every such limit is a periodic Gibbs state by the local DLR equations, which pass to the weak limit on continuous cylinder functions, and it inherits the lattice symmetries. The analogous limits using states in $\mathcal{G}^{\mathrm{tor}}_{(K,\beta)}$ form $\mathrm{VF}(g)$. At $b \in I(g)$, GT_b and VF_b specify the subclasses with $\beta = L^K b$. Use the cube cumulant bound table $C^g_n(d; R)$ and its class $\mathcal{K}(g)$ from Propositions YM3_I:91.13 and YM3_I:92.1. For the sharper infinite-volume table use the torus constants of YM3_I:(1795)–(1797) and YM3_I:

(1799)–(1804), evaluated with $(\rho_*, C_e, \kappa_e, E_+, C_{\mathrm{low}}) = (2\varrho, C_{\mathrm{S}}, \kappa, C_{\mathrm{S}}, C_g)$ from [7, Lem. N.1]. In that notation put

$$C_n^{g,\infty}(d;R) = \min\{C_n^{\infty}(d;R), A(d)B(R)^n(n!)^{\varkappa_\star}\}.$$

The canonical growth constants at g are

$$k_{\mathrm{E}} = 10, \qquad \mathsf{c}_{\mathrm{E}} = 1, \qquad \mathsf{C}_{\mathrm{E}}^{\mathrm{c},g} = C_{\neq}^3 MB(1)\sqrt{A_{\mathrm{PL}}}, \qquad \varkappa_{\mathrm{E}} = \varkappa_\star + 9,$$

where $C_{\neq} = 10^{53}$ as in Proposition YM3_I:93.3. They result from $A(d) \le A_{\mathrm{PL}} \max(1, d^{-4})$ and the Schwinger extension estimate in Proposition YM3_I:93.4.

For $\mathfrak{q} = (a_j, \beta_j)_j$ with $a_j \to 0$ and $a_j\beta_j \to b > 0$, let $\mathsf{K}_{\mathfrak{q}}$ be the set of pointwise limits of self-centred moments σ_{ν_j} for periodic Gibbs states at these pairs. Their union is $A[b]$, and $E[b]$ is its one-vacuum subclass. The canonical decomposition, its component evaluations, and the iterated plateaux are those of Theorem YM3_I:AL. One vacuum means that the decomposition has one component. Put $A_J = \bigcup_{b\in J} A[b]$. A Gibbs sequence at g uses $a_j = L^{-K_j}$, $K_j \to \infty$, and $(K_j, \beta_j) \in \mathfrak{d}(g)$. For compact $J \subset (0,\infty)$ a cover W_J is a finite family (z_i, g_i) such that for each $c \in [\min J/(2L), 2\max J]$ some $L^{z_i}c \in I(g_i)^\circ$. Write $s_- = \min_i L^{-z_i}$ and $s_+ = \max_i L^{1-z_i}$. Given $c > 0$, choose z so that $g = (L^z c/2)^{-1/2} \le \gamma$ and $L^z c/2 > \bar{B}$. Since $L \ge 13$, $L^z c$ lies in the interior of $I(g)$. These windows are open and compactness gives the cover. One may require all $g_i \le \gamma_W$ by increasing z in the same construction.

(1) *Families.* For a family $S = (S_n)_{n\ge 2}$ of symmetric multilinear maps S_n on $\mathfrak{S}_n(\mathbb{R}^3)$, σ_S is its centred functional: $\sigma_S(\varnothing) = 1$, $\sigma_S((f)) = 0$, and $\sigma_S(X) = \sum_\pi \prod_{I\in\pi} S_{|I|}(X_I)$ for $|X| \ge 2$, the sum over the partitions π of $\{1,\dots,|X|\}$ into blocks of at least two elements; so $\sigma_S(f,h) = S_2(f,h)$. Where σ_S is reflection positive and H_{σ_S} is formed by Proposition YM3_I:94.1 we write $\mathcal{H}(S) = \mathcal{H}(\sigma_S)$ and $H_S = H_{\sigma_S}$. With $(\mathrm{dil}_s S)_n(X) = s^{-n} S_n(X_{(s)})$, $\sigma_{\mathrm{dil}_s S} = \mathrm{dil}_s \sigma_S$, because $\sum_{I\in\pi} |I| = |X|$.

(2) *Spacing-first limits at a real label.* For real $b > 0$, $\mathrm{SF}(b)$ is the set of the families $S = (S_n)_{n\ge 2}$ of maps $S_n \colon \mathfrak{S}_n(\mathbb{R}^3) \to \mathbb{R}$ for which there are sides $\ell_k \in \mathfrak{L}$ with $\ell_k \to \infty$ such that $\mathsf{B}(\ell_k, b; X) \to S_n(X)$ as $k \to \infty$ for all $n \ge 2$ and $X \in \mathfrak{S}_n(\mathbb{R}^3)$; the number $\mathsf{B}(\ell_k, b; X)$ is formed as soon as $X \in \mathfrak{S}_n(Q_{\ell_k})$, that is for all large k, and S is then taken along (ℓ_k). Restricting the sides to $\mathfrak{L}(g)$ does not change this set, since $\mathfrak{L}(g)$ is a tail.

(3) *Symmetries and coordinate planes.* W_3 is the cubic group of the 48 signed permutations of the coordinates, and $W_2 \subset W_3$ the subgroup of the 8 elements that fix e_3. For $\mu \in \{1,2,3\}$ and $c \in \mathbb{R}$, $\theta_{\mu,c}$ is the reflection $x \mapsto x - 2(x_\mu - c)e_\mu$; a functional σ is reflection positive at $\{x_\mu = c\}$ from the side $\{\epsilon(x_\mu - c) > 0\}$, $\epsilon \in \{1,-1\}$, if $\sigma(\theta_{\mu,c}\bar{F} \cdot F) \ge 0$ for every F in the complex span of the separated tuples supported in that side.

(4) *Ergodic states.* A periodic Gibbs state $\nu \in \mathcal{G}_{a,\beta}$, which is invariant under all translations of $a\mathbb{Z}^3$ by Proposition YM3_I:103.4, is ergodic if $\nu(E) \in \{0,1\}$ for every Borel set E of configurations with $\tau_v E = E$ for all $v \in a\mathbb{Z}^3$; these sets form the σ-algebra $\mathcal{I}$.

(5) *Reconstruction and the data kernels.* The reconstruction data with $(C_\wp, \wp, c_0)$ satisfy (Rec1)–(Rec4) of Section YM3_I:107. They are Euclidean invariant and reflection positive with a separable reflection Hilbert space, its strongly continuous translation semigroup and commuting momenta, joint spectrum in $E \ge |q|$, and the estimate

$$|\sigma(\theta\bar{F} \cdot (h) \cdot F')| \le C_\wp \eta^{-\wp} \|h\|_1 \|[\tau_{-\eta e_3} F]\| \, \|[\tau_{-\eta e_3} F']\|$$

for $0 < \eta \le 1$, F, F' supported above η and h supported in $|x_3| < c_0\eta$, with $C_\wp, \wp \ge 0$ and $0 < c_0 \le 1/2$. Condition (Rec5) is $\ker H_\sigma = \mathbb{C}\Omega$. The quintuple $(\mathcal{H}, U, \Omega, \mathcal{D}_0, \phi)$ is the scalar reconstruction of Theorem YM3_I:AO. The first reconstruction constant at g can be taken to be $C'_g = C_\wp^g + \bar{c}_g$ for all Gibbs limits and components, with exponent 4 and margin 1/2, by Theorem YM3_I:AP. The centered components use $C_\wp^g$ by the centered estimate in the proof of Proposition YM3_I:111.1. Their reflection spaces are identified unitarily by the centering shift of Section YM3_I:107.

For a unit vector u put $d^u_\circ(z) = \mathrm{Re}(u\cdot z) - |\,\mathrm{Im}(z-(u\cdot z)u)|$. For a permutation ς, the tube $\mathsf{Tb}^{u,\varsigma}_n$ consists of the z with $d^u_\circ(z_{\varsigma(k+1)} - z_{\varsigma(k)}) > 0$ for $k < n$. Write $\mathsf{Tb}^{\mathrm{all}}_n$ for their union and $(\mathbb{R}^3)^n_{\neq}$ for the real configurations with distinct entries. Proposition YM3_I:108.3 gives the unique continuous kernel s_n on the real configuration set that integrates against the product of separated tests to give σ. Its holomorphic extension to $\mathsf{Tb}^{\mathrm{all}}_n$ is $\mathbf{S}_n$.

(6) *The trivial functional.* $\sigma_0(\varnothing) = 1$ and $\sigma_0(X) = 0$ for $|X| \geq 1$.

■

Lemma 18.165 (Polygons in the configurations and in the tubes)**.** Let $n \in \mathbb{N}$. Any two points of $(\mathbb{R}^3)^n_{\neq}$ are joined inside $(\mathbb{R}^3)^n_{\neq}$ by a polygon of two segments, and any two points of $\mathsf{Tb}^{\mathrm{all}}_n$ are joined inside $\mathsf{Tb}^{\mathrm{all}}_n$ by a polygon of four segments. So both sets are connected: neither is the union of two disjoint non-empty subsets that are open in it. ■

Proof. For $n = 1$ the two sets are $\mathbb{R}^3$ and $\mathbb{C}^3$. Let $n \geq 2$ and $x, y \in (\mathbb{R}^3)^n_{\neq}$. The finitely many lines $\mathbb{R}(x_i - x_l)$, $\mathbb{R}(y_i - y_l)$, $i \neq l$, meet the unit sphere in finitely many points; take a unit vector e outside them and put $w = (e, 2e, \dots, ne) \in (\mathbb{R}^3)^n_{\neq}$. For $p \in \{x, y\}$, $0 \leq t \leq 1$ and $i \neq l$, the difference of the entries i and l of $p + t(w-p)$ is $(1-t)(p_i - p_l) + t(i-l)e$; it is $p_i - p_l \neq 0$ at $t = 0$ and $(i-l)e \neq 0$ at $t = 1$, and if it vanished at some $t \in (0,1)$, e would be a real multiple of $p_i - p_l$. So the segments from x to w and from w to y lie in $(\mathbb{R}^3)^n_{\neq}$.

Each tube is convex since each margin is a linear real function minus a norm. Removing the imaginary part increases all the margins, so a point is joined inside its tube to its real part. Any real configuration of distinct points admits a direction outside the finitely many great circles perpendicular to the differences, so its projections can be strictly ordered. Conversely such an ordering requires distinct points. Thus the real points of the union are precisely $(\mathbb{R}^3)^n_{\neq}$. The two real segments with the segments to the real parts give the four-segment path and prove connectedness. □

Proposition 18.166 (Reconstruction data are fixed by their values in one ball)**.** Let σ and σ' be reconstruction data as in Definition 18.164(5), with the numbers $(C_\wp, \wp, c_0)$ and $(C'_\wp, \wp', c'_0)$ respectively, which need not be equal; (Rec5) is not assumed. Let $\mathsf{s}_n, \mathbf{S}_n$ and $\mathsf{s}'_n, \mathbf{S}'_n$ be their data kernels and the continuations of these (Definition 18.164(5)).

(a) *One order, one open set of configurations.* Let $n \in \mathbb{N}$ and let $W \subset (\mathbb{R}^3)^n_{\neq}$ be open and not empty. If $\sigma(X) = \sigma'(X)$ for every $X = (f_1, \dots, f_n) \in \mathfrak{S}_n(\mathbb{R}^3)$ with $\mathrm{supp}\, f_1 \times \cdots \times \mathrm{supp}\, f_n \subset W$, then $\mathbf{S}_n = \mathbf{S}'_n$ on $\mathsf{Tb}^{\mathrm{all}}_n$, $\mathsf{s}_n = \mathsf{s}'_n$ on $(\mathbb{R}^3)^n_{\neq}$, and $\sigma = \sigma'$ on $\mathfrak{S}_n(\mathbb{R}^3)$.

(b) *One ball, all orders.* Fix a nonempty open set $O \subset \mathbb{R}^3$, an open ball of arbitrary centre and radius being one example. Then $\sigma = \sigma'$ on $\mathfrak{S}(O)$ implies $\sigma = \sigma'$. So σ and σ' have one Hilbert space $\mathcal{H}(\sigma) = \mathcal{H}(\sigma')$, with the same classes and the same Ω, one Hamiltonian, one unitary group of the translations along the plane $\{x_3 = 0\}$, one joint spectral measure, and one quintuple $(\mathcal{H}, U, \Omega, \mathcal{D}_0, \phi)$ of Theorem YM3_I:AO, with one family of Wightman distributions; none of these objects reads the triple of numbers.

(c) *Which functionals are data.* Each of the following is reconstruction data, so that (a) and (b) hold for any two of them, whatever their labels, reference couplings, sequences, decompositions and settings are: every member of $A[b]$, $b > 0$; every component σ_ξ of every decomposition of one, with (Rec5); its centred component σ^{c}_ξ, with (Rec5); the limit of every convergent Gibbs sequence at any $0 < g \leq \gamma$ and every component of every decomposition of it, with the triple of Definition 18.164(5) at g, the components with (Rec5); the trivial functional σ_0, with every triple and with (Rec5); and every real dilate $\mathrm{dil}_s\varsigma$, $s > 0$, of a functional ς of this list, with first constant $C_\wp \max\{s^{\wp-4}, 2^\wp s^{-4}\}$ and unchanged $\wp, c_0$, and with (Rec5) if ς has it.

(d) *Three consequences.* Let $O \subset \mathbb{R}^3$ be open and not empty.

(d1) Let $(\Xi, \lambda, (\sigma_\xi))$ be a decomposition of a member of $A[b]$ or of the limit of a convergent Gibbs sequence at some $0 < g \le \gamma$. For $\xi \ne \xi'$ there is $X \in \mathfrak{S}(O)$ with $\sigma_\xi(X) \ne \sigma_{\xi'}(X)$, and $\xi \mapsto (\sigma_\xi(X))_{X\in\mathfrak{S}(O)}$ is a homeomorphism of Ξ onto its image in the product space $\mathbb{R}^{\mathfrak{S}(O)}$.

(d2) Let $\sigma \in A[b]$ and $\sigma' \in A[b']$, $b, b' > 0$; the limits of two convergent Gibbs sequences, at any two reference couplings, are such functionals, with b and b' limit points of the labels of the two sequences. If σ and σ' agree on $\mathfrak{S}(O)$, then $\sigma = \sigma'$; and for any decompositions $(\Xi, \lambda, (\sigma_\xi))$ of σ and $(\Xi', \lambda', (\sigma'_{\xi'}))$ of σ' there is exactly one map $h\colon \Xi \to \Xi'$ with $\sigma'_{h(\xi)} = \sigma_\xi$ for all ξ; it is a homeomorphism, and $h_*\lambda = \lambda'$. Under the absence of latent heat as in §12 also $b = b'$.

(d3) Reconstruction data σ with $\sigma(f, h) = 0$ for all $(f, h) \in \mathfrak{S}_2(O)$ are the trivial functional σ_0.

(e) *A normal family.* Let $C \ge 0$, $\wp \ge 0$, $n \in \mathbb{N}$, and let W be as in (a). Let $\sigma^{(j)}$ and $\sigma'^{(j)}$, $j \in \mathbb{N}$, be reconstruction data, each with the first two numbers C and $\wp$, the third numbers being free, and let $\mathsf{s}_n^{(j)}$, $\mathsf{s}_n'^{(j)}$ be their data kernels. If $\sigma^{(j)}(X) - \sigma'^{(j)}(X) \to 0$ as $j \to \infty$ for every $X = (f_i) \in \mathfrak{S}_n(\mathbb{R}^3)$ with $\prod_i \operatorname{supp} f_i \subset W$, then $\sup_{\mathcal{K}} |\mathsf{s}_n^{(j)} - \mathsf{s}_n'^{(j)}| \to 0$ for every compact $\mathcal{K} \subset (\mathbb{R}^3)^n_{\ne}$, and $\sigma^{(j)}(X) - \sigma'^{(j)}(X) \to 0$ for every $X \in \mathfrak{S}_n(\mathbb{R}^3)$. In the setting, at one reference coupling $0 < g \le \gamma$, the limits of all convergent Gibbs sequences at g and all components of all their decompositions are reconstruction data with the one triple of Definition 18.164(5) at g; and for every compact $J \subset (0, \infty)$ and every cover $W_J = ((z_i, g_i))_i$ of J with its number s_- (Definition 18.164), all members of A_J, all components of their decompositions and the centred components of these are reconstruction data with the one triple $(C^{\mathrm{R}}_{W_J}, 4, \frac{1}{2})$, where $C^{\mathrm{R}}_{W_J} = \max\{1, 16 s_-^{-4}\} \max_i C'_i$ and C'_i is the constant C'_{g_i} of Definition 18.164(5). So the convergence assertion of (e) holds for any two sequences whose members all lie in one of these two families.

■

Proof. Step 1: clause (a). Proposition YM3_I:108.3, whose one hypothesis is that the functional is data (Rec) with some numbers, gives $\sigma(X) = \int \mathsf{s}_n \prod_i f_i$ and $\sigma'(X) = \int \mathsf{s}'_n \prod_i f_i$ for $X = (f_i) \in \mathfrak{S}_n(\mathbb{R}^3)$, the integrals over the compact set $\prod_i \operatorname{supp} f_i \subset (\mathbb{R}^3)^n_{\ne}$. Let $x \in W$ and $\epsilon > 0$ with $\prod_i \bar{\mathbb{B}}(x_i, \epsilon) \subset W$; these balls are pairwise disjoint, as $W \subset (\mathbb{R}^3)^n_{\ne}$. For $f_i \ge 0$ of class C^1 with $\int f_i = 1$ and support in $\bar{\mathbb{B}}(x_i, \epsilon)$, the tuple (f_i) lies in $\mathfrak{S}_n(\mathbb{R}^3)$, with the product of its supports in W; so $\int (\mathsf{s}_n - \mathsf{s}'_n) \prod_i f_i = 0$, and as $\epsilon \to 0$ the left member tends to $(\mathsf{s}_n - \mathsf{s}'_n)(x)$, by continuity. So $\mathsf{s}_n = \mathsf{s}'_n$ on W. By Proposition YM3_I:108.3, $D = \mathbf{S}_n - \mathbf{S}'_n$ is holomorphic on $\mathsf{Tb}^{\mathrm{all}}_n$, an open set whose real points form $(\mathbb{R}^3)^n_{\ne}$, and $D = \mathsf{s}_n - \mathsf{s}'_n$ at these points. The set $O' = \{z \in \mathsf{Tb}^{\mathrm{all}}_n : \operatorname{Re} z \in W\}$ is open, it meets $\mathbb{R}^{3n}$, and $D = 0$ on $O' \cap \mathbb{R}^{3n} = W$; and $\mathsf{Tb}^{\mathrm{all}}_n$ is connected (Lemma 18.165). By the identity theorem, applied in each coordinate in a polydisc about a real point of W, $D = 0$ on $\mathsf{Tb}^{\mathrm{all}}_n$. So $\mathsf{s}_n = \mathsf{s}'_n$ on $(\mathbb{R}^3)^n_{\ne}$, and the integral representation gives $\sigma = \sigma'$ on $\mathfrak{S}_n(\mathbb{R}^3)$.

Step 2: clause (b). At $\varnothing$ both functionals are 1. Let $n \ge 1$ and $W_n = O^n \cap (\mathbb{R}^3)^n_{\ne}$, which is open, and not empty because O holds n different points. Let $X = (f_i) \in \mathfrak{S}_n(\mathbb{R}^3)$ with $\prod_i \operatorname{supp} f_i \subset W_n$. If an entry is 0, both values are 0, by multilinearity. Otherwise every support is not empty and is the image of the product under a projection, so it lies in O; then $X \in \mathfrak{S}_n(O)$, and the two values agree by hypothesis. Clause (a) at $W = W_n$ gives $\sigma = \sigma'$ on $\mathfrak{S}_n(\mathbb{R}^3)$. The objects named in (b) are formed from the functional alone: the Hilbert space, the classes and Ω from the form $\sigma(\theta \bar{F} \cdot F')$; the Hamiltonian, the translations along the plane and the joint spectral measure from the action of the translations on the classes, (Rec2) leaving one choice of them; the field $\phi(f)$, $f \in \mathcal{S}$, on $\mathcal{D}_\infty = \bigcap_k \operatorname{dom} H^k_\sigma$, which is one and the same operator whatever triple of numbers of the functional, and whatever integer above the second number of

that triple, its construction uses (Proposition YM3_I:109.1); with it the span $\mathcal{D}_0$ of Ω and of the vectors $\phi(f_1)\cdots\phi(f_n)\Omega$ (Proposition YM3_I:109.1), and the Wightman distributions, each the only tempered distribution that takes the value $\langle\Omega,\phi(f_1)\cdots\phi(f_n)\Omega\rangle$ at $f_1\otimes\cdots\otimes f_n$ (Proposition YM3_I:109.1); the translations $U(x)=\int e^{i(x^0E+\vec{x}\cdot q)}\,d\mathcal{P}(E,q)$, $x=(x^0,\vec{x})\in\mathbb{R}^{1+2}$, with the joint spectral measure $\mathcal{P}$ (Proposition YM3_I:109.1); and, for $\Lambda\in\mathcal{L}$, $U(\Lambda)$, the only unitary operator that fixes Ω, maps $\mathcal{D}_0$ onto itself and carries $\phi(f)$ to $\phi(f\circ\Lambda^{-1})$ on $\mathcal{D}_0$ (Proposition YM3_I:110.1). From these, with $U(a,\Lambda)=U(a)U(\Lambda)$, the quintuple of Theorem YM3_I:AO is made: under (Rec5) by Theorem YM3_I:AO, and without it by the closing paragraph of that theorem.

Step 3. Theorem YM3_I:AP gives reconstruction for the Gibbs limits at g and their components. The centering unitary preserves the one-dimensional zero-energy space of a component. To see that it is a self-centred limit, take the invariant-event conditioned states of Theorem YM3_I:AL. Invariant conditioning preserves the Gibbs equations, as in the proof of that theorem. Changing the centering law from the original to the conditioned law is the finite polynomial expressing self-centred moments in terms of the moments centered at the original law. It gives the centred component in the limit, at the same pairs.

We reduce arbitrary positive spacings to these frames. Write $a_j=L^{-k_j}r_j$, $1\le r_j<L$. For large j the label $a_j\beta_j/r_j$ belongs to the interval covered by W_J. Pick a pair (z_i,g_i) placing $L^{z_i}a_j\beta_j/r_j$ in $I(g_i)^\circ$. Put $K_j=k_j-z_i$ and $s_j=r_jL^{-z_i}$. Then $a_j=s_jL^{-K_j}$, $s_-\le s_j\le s_+$, and the pair (K_j,β_j) is a first-passage datum at g_i by Corollary YM3_I:74.2. Pass to a subsequence with fixed i and $s_j\to s\in[s_-,s_+]$. Relabel the bond configuration by dividing lengths by s_j. This leaves the Haar integrals, action and DLR equations unchanged. The observables at the two spacings are related by $\mathcal{O}_{sa}(f)=s^{-1}\mathcal{O}_a(f(s\,\cdot))$. The relabelled self-centred moments have a further limit τ by Theorem YM3_I:AP. The convergence persists for the tests $f_i(s_j\,\cdot)$, because their C^1 convergence takes place in fixed compact support neighborhoods with positive separation. The bounds of Proposition YM3_I:91.13 and the moment–cumulant formula bound the error by multilinear telescoping. Consequently the original limit is $\mathrm{dil}_s\tau$. Rescaling the translation vectors in the iterated plateaux gives the bijection of decompositions under this dilation.

For the reconstruction estimate, the map on tuple classes $[X]\mapsto[V_sX]$, $V_sX=s^{-|X|}X_{(s)}$, is unitary from the dilated Hilbert space to the original one since it preserves the reflection form and has an inverse. The generators are divided by s. In the insertion estimate at height η, the test becomes $s^{-1}h(s\,\cdot)$ of norm $s^{-4}\|h\|_1$. If $\eta\le s$ apply the estimate at η/s. If $\eta>s$, put $\eta'=\min(1,(1-c_0)\eta/s)\in[1/2,1]$ and partition the insertion by nonnegative smooth functions into slabs of half-width $c_0\eta'$ about heights y with $|y|\le c_0\eta/s$. Translate each piece to height zero. The exterior vectors shift in opposite directions and remain above η' since $\eta/s-|y|\ge\eta'$. Their norms after moving down by η' are bounded by the norms before the shifts after moving down by η/s, by the positive-time contraction. Summing the L^1 norms gives the original norm. The two constants are $C_\wp s^{\wp-4}$ and $C_\wp 2^\wp s^{-4}$. The unitary preserves (Rec5). Dilating the conditioned states proves membership of the centred components in $E[b]$ at the original label. The trivial functional is invariant under every isometry; for F in the span of the tuples supported in $\{x_3>0\}$, $\sigma_0(\theta\bar{F}\cdot F)=|c_\varnothing|^2\ge0$, $c_\varnothing$ being the coefficient of $\varnothing$ in F, so that $\mathcal{H}(\sigma_0)=\mathbb{C}\Omega$, every class $[X]$ with $|X|\ge1$ being 0; $H=0$, the translations act as 1, and the joint spectral measure is the point mass at $(0,0)$, which is carried by $\{E\ge|q|\}$; the left member of (Rec4) vanishes, because every tuple in $\theta\bar{F}\cdot(h)\cdot F'$ has the entry h; and $\ker H=\mathbb{C}\Omega$. The same dilation proof applies to the trivial data.

Step 4: clause (d). (d1): the components are reconstruction data, by (c). If $\xi\ne\xi'$, then $\sigma_\xi\ne\sigma_{\xi'}$, the map $\xi\mapsto\sigma_\xi$ being injective by the definition of the canonical decomposition; by (b) they differ at some $X\in\mathfrak{S}(O)$. Each coordinate $\xi\mapsto\sigma_\xi(X)$ is continuous by the definition of the canonical decomposition; so the map into the product space is continuous and injective, and, Ξ being compact and the product space a Hausdorff space, it is a homeomorphism onto its image. (d2): A convergent Gibbs sequence (K_j,β_j,ν_j) at a reference coupling g has its labels $a_{K_j}\beta_j$ in the compact interval

$I^{\mathrm{lab}}(g) \subset (0,\infty)$ by Proposition YM3_I:74.1; along a subsequence whose labels tend to a limit point b of them, the spacings a_{K_j} and the couplings β_j form a sequence of pairs $\mathfrak{q}$ with the label b, and the σ_{ν_j} tend there to the limit of the sequence, which so lies in $\mathsf{K}_{\mathfrak{q}} \subset A[b]$ (Definition 18.164). Now $\sigma = \sigma'$ by (b) and (c). The two triples decompose the same functional. For each finite list of tuples the plateaux give all mixed moments of their evaluation coordinates. These coordinates separate points on the compact union of the two images. Stone–Weierstrass thus gives equality of the pushforward measures, since coordinate polynomials are dense in the continuous functions on the union. Their supports are the two compact images, by full support of the component measures. Inverting the second evaluation map after the first yields the unique homeomorphism h and $h_*\lambda = \lambda'$. For label recovery take the cover in Step 3 with $g_i \le \gamma_W$. By Theorem YM3_I:AW, along one fixed positive test shape shrinking to zero the ratio of the frame two-point function to $\mathcal{K}_6$ tends to $c_2(b/s)^{-2}$, since the frame label is b/s. Simultaneous dilation of the tests preserves $\mathcal{K}_6$ and the shape parameter, and dilation of the functional multiplies the two-point coefficient by s^{-2}. The resulting coefficient is $c_2 b^{-2}$. Equality of the functionals therefore gives $b = b'$. (d3): σ_0 is reconstruction data, by (c). A pair of $\mathfrak{S}_2(\mathbb{R}^3)$ with the product of its supports in $O^2 \cap (\mathbb{R}^3)^2_{\neq}$ has an entry 0 or lies in $\mathfrak{S}_2(O)$, as in Step 2; so (a) at $n = 2$, read for σ and σ_0, gives $\sigma = 0$ on $\mathfrak{S}_2(\mathbb{R}^3)$. For a real $f \in C^1_c(\{x_3 > 0\})$ the pair $(\theta f, f)$ is separated, and $\|[(f)]\|^2 = \sigma(\theta f, f) = 0$. Let $n \ge 1$ and $X = (f_1, \dots, f_n) \in \mathfrak{S}_n(\mathbb{R}^3)$ with $\operatorname{supp} f_1 \subset \{x_3 < 0\}$ and $\operatorname{supp} f_i \subset \{x_3 > 0\}$ for $i \ge 2$. With $f = f_1 \circ \theta$ and $Y = (f_2, \dots, f_n)$, $X = \theta(f) \cdot Y$, so $\sigma(X) = \langle [(f)], [Y] \rangle$ and $|\sigma(X)| \le \|[(f)]\| \, \|[Y]\| = 0$ by the inequality of Schwarz for the positive form. Since the set $\{x \in (\mathbb{R}^3)^n_{\neq} : (x_1)_3 < 0, \text{ and } (x_i)_3 > 0 \text{ for } 2 \le i \le n\}$ is open and nonempty, and every tuple for which the product of its supports is contained in this set either has an entry equal to 0 or belongs to the kind just treated, (a), applied to σ and σ_0, yields $\sigma = \sigma_0$ on $\mathfrak{S}_n(\mathbb{R}^3)$ for every $n \ge 1$.

Step 5: clause (e), the normal family. Let D be a countable dense subset of the unit sphere. For $u \in \mathsf{D}$, a permutation ς and $m \in \mathbb{N}$ let $\mathcal{N}_{u,\varsigma,m}$ be the set of the $z \in (\mathbb{C}^3)^n$ with $d^u_\circ(z_{\varsigma(k+1)} - z_{\varsigma(k)}) > 2/m$ for $1 \le k < n$ (for $n = 1$, all of $\mathbb{C}^3$). Since $d^u_\circ$ is continuous, this set is open; it is contained in $\mathsf{Tb}^{u,\varsigma}_n$. Every point of $\mathsf{Tb}^{\mathrm{all}}_n$ lies in one of these sets, which form a countable family: for $n = 1$ each of them is $\mathbb{C}^3 = \mathsf{Tb}^{\mathrm{all}}_1$; for $n \ge 2$ and $z \in \mathsf{Tb}^{u_0,\varsigma}_n$, the displayed margin formula makes $u \mapsto \min_k d^u_\circ(z_{\varsigma(k+1)} - z_{\varsigma(k)})$ a continuous function on the sphere, and its value at u_0 is positive; therefore its value at some $u \in \mathsf{D}$ is larger than $2/m$, for some m. Put $D_j = \mathbf{S}^{(j)}_n - \mathbf{S}'^{(j)}_n$, a holomorphic function on $\mathsf{Tb}^{\mathrm{all}}_n$. By YM3_I:(2066) at $\eta = 1/m$, read with the numbers C and $\wp$, $|D_j| \le 2(Cm^{\wp})^n$ on $\mathcal{N}_{u,\varsigma,m}$ for every j. Number these sets $\mathcal{N}_1, \mathcal{N}_2, \dots$, and let $J_0 \subset \mathbb{N}$ be infinite. By the theorem of Montel (a sequence of holomorphic functions on an open subset of $\mathbb{C}^N$ with a common bound has a subsequence that converges uniformly on every compact subset) there are infinite sets $J_0 \supset J_1 \supset J_2 \supset \cdots$ such that $(D_j)_{j \in J_r}$ converges uniformly on the compact subsets of $\mathcal{N}_r$; let J_∞ hold the r-th member of J_r for every r. Along J_∞ the D_j converge uniformly on every closed ball that lies in one of the $\mathcal{N}_r$; every point of $\mathsf{Tb}^{\mathrm{all}}_n$ is the centre of such a ball, so the limit D is holomorphic on $\mathsf{Tb}^{\mathrm{all}}_n$ by locally uniform convergence, and the convergence is uniform on every compact subset of $\mathsf{Tb}^{\mathrm{all}}_n$, which finitely many such balls cover. For $X = (f_i) \in \mathfrak{S}_n(\mathbb{R}^3)$ with $\prod_i \operatorname{supp} f_i \subset W$, the uniform convergence on this compact set and the hypothesis give $\int D \prod_i f_i = \lim_{j \in J_\infty} (\sigma^{(j)}(X) - \sigma'^{(j)}(X)) = 0$; as in Step 1, $D = 0$ on W, and then on $\mathsf{Tb}^{\mathrm{all}}_n$. So every infinite J_0 holds an infinite J_∞ along which $\sup_{\mathcal{K}} |D_j| \to 0$ for every compact $\mathcal{K} \subset (\mathbb{R}^3)^n_{\neq}$, a compact subset of $\mathsf{Tb}^{\mathrm{all}}_n$; hence $\sup_{\mathcal{K}} |D_j| \to 0$ along $\mathbb{N}$, as otherwise some $\epsilon > 0$ and some infinite J_0 would have $\sup_{\mathcal{K}} |D_j| \ge \epsilon$ on J_0. At the real points $D_j = \mathsf{s}^{(j)}_n - \mathsf{s}'^{(j)}_n$, and $|\sigma^{(j)}(X) - \sigma'^{(j)}(X)| \le \sup_{\mathcal{K}} |D_j| \prod_i \|f_i\|_{L^1}$ with $\mathcal{K} = \prod_i \operatorname{supp} f_i$.

Step 6. At fixed g the constants of Theorem YM3_I:AP are uniform in the sequences and components. For compact J, Step 3 gives a dilation with $s \in [s_-, s_+]$ from one of the finitely many g_i. The centred components have frame bound $C^{g_i}_{\wp} \le C'_{g_i}$. For $\wp = 4$ the dilation bound is therefore at most $\max(1, 16 s_-^{-4}) \max_i C'_{g_i}$ for every member of the listed classes. $\square$

Lemma 18.167 (Choosing cutoffs on growing tori)**.** Fix $0 < g \le \gamma$ and let $\ell_k \in \mathfrak{L}$ tend to infinity. For each k, let $(K_i^k, \beta_i^k)_i$ be pairs in $\mathfrak{d}(g)$ with $K_i^k \to \infty$. Suppose that for each $n \ge 2$ and each separated C_c^1 tuple X in Q_{ℓ_k} the following limit exists.

$$B_n^{(k)}(X) = \lim_{i\to\infty} S^T_{n;K_i^k,\ell_k,\beta_i^k}(X^{\langle \ell_k\rangle}). \tag{18.xiii}$$

There are indices $i(k)$ with $K^k_{i(k)} \ge k$ for which

$$S^T_{n;K^k_{i(k)},\ell_k,\beta^k_{i(k)}}(X^{\langle \ell_k\rangle}) - B_n^{(k)}(X) \longrightarrow 0 \tag{18.xiv}$$

for every separated C_c^1 tuple X in $\mathbb{R}^3$, along the full sequence of k. If b_k is a prescribed limit point of $(a_{K_i^k}\beta_i^k)_i$, the indices can also satisfy $|a_{K^k_{i(k)}}\beta^k_{i(k)} - b_k| \le 1/k$.

Every infinite set of k contains a subsequence on which all $B_n^{(k)}(X)$ converge. The selected triples on any such subsequence realize the same limit along growing tori at g, which belongs to $\mathcal{K}(g)$. Each subsequential limit of the corresponding b_k is a label of that limit. ■

Proof. For each finite union D of closed cubes with rational vertices and edges parallel to the coordinate axes, take a countable dense subset of the C_c^1 functions supported in D, in the norm $\|\cdot\|_\sharp$. Such a subset exists since the function and its three first derivatives embed this space into $C(D)^4$, with an equivalent norm. Enumerate the tuples from these dense sets whose respective unions D are pairwise disjoint, over all orders $n \ge 2$. For each k, require that the error in eq. 18.xiv be at most $1/k$ on those of the first k enumerated tuples that have supports in Q_{ℓ_k}. The fixed-side convergence makes these finitely many inequalities and $K_i^k \ge k$ hold for all sufficiently large i. When a label is prescribed, choose such an i among the infinitely many indices whose labels lie within $1/k$ of b_k.

Any fixed separated tuple has its entries supported in pairwise disjoint unions D of the indicated kind. Approximate each entry in $\|\cdot\|_\sharp$ using the corresponding dense set. Proposition YM3_I:91.13 bounds the finite-cutoff forms uniformly on the product of these support classes for all sufficiently large k, since the unions have a common radius bound and a positive separation, and $\ell_k \to \infty$. The same bound passes to $B_n^{(k)}$. Telescoping the difference as one entry varies at a time then extends eq. 18.xiv from the enumerated tuples to the given tuple. Here every fixed enumerated tuple lies in Q_{ℓ_k} and among the first k entries for all sufficiently large k.

Eventually $\ell_k \in \mathfrak{L}(g)$, so the selected triples form a growing-torus sequence at g. Proposition YM3_I:92.1 gives the asserted subsequential compactness and bound for that sequence. Equation eq. 18.xiv transfers the conclusions to the inner limits. The error in the prescribed labels tends to zero, so a subsequence on which $b_k \to b$ makes the selected labels tend to b as well. □

Proposition 18.168 (Limit points of the torus limits: spacing first, then the volume)**.** Assume the setting. Let $0 < g \le \gamma$, $b \in I(g)$, and let $\ell_k \in \mathfrak{L}(g)$, $k \in \mathbb{N}$, be sides with $\ell_k \to \infty$.

(o) *The spacing first, on each torus.* For every k, $n \ge 2$ and $X \in \mathfrak{S}_n(Q_{\ell_k})$, $\mathsf{B}(\ell_k, b; X) = \lim_{K\to\infty} \mathsf{a}(K, \ell_k, L^K b; X)$ along the full sequence of the cutoffs, every pair $(K, L^K b)$ lying in $\mathfrak{d}_b \subset \mathfrak{d}(g)$; the same number is the limit of $\mathsf{a}(K_j, \ell_k, \beta_j; X)$ along all pairs (K_j, β_j) with $K_j \to \infty$ and $a_{K_j}\beta_j \to b$; and if X is of the type $(\mathsf{d}; R)$ and $\ell_k \ge 16n(R+1)$, then $|\mathsf{B}(\ell_k, b; X)| \le C_n^g(\mathsf{d}; R)\|X\|$.

(a) *Then the volume: limit points exist.* Every infinite set of indices holds indices $k_1 < k_2 < \cdots$ such that $\mathsf{B}(\ell_{k_i}, b; X)$ converges as $i \to \infty$ for all $n \ge 2$ and all $X \in \mathfrak{S}_n(\mathbb{R}^3)$; the family of the limits is a member of $\mathrm{SF}(b)$, taken along $(\ell_{k_i})_i$. In particular $\mathrm{SF}(b) \ne \varnothing$.

(b) *They are limits along growing tori.* Let $S \in \mathrm{SF}(b)$ be taken along sides ℓ'_k. There are cutoffs $K_k \ge k$ such that, for the k with $\ell'_k \in \mathfrak{L}(g)$, $(K_k, \ell'_k, L^{K_k} b)_k$ is a torus sequence at g over $\mathfrak{d}_b$ that defines S. So $S \in \mathrm{GT}_b \subset \mathrm{GT}(g)$, b is a label of S, and $S \in \mathcal{K}(g)$.

■

Proof. Step 1. Corollary YM3_I:74.2 gives the data $(K, L^K b) \in \mathfrak{d}(g)$. For X supported in Q_{ℓ_k}, periodization keeps the entries C^1 with disjoint supports and the same sharp norms: the quotient is isometric on the box and every test vanishes near its boundary. Theorem YM3_I:AS gives the limit along all cutoffs and YM3_I:(2216) gives the same limit along moving labels. A zero entry gives a zero cumulant. Proposition YM3_I:91.13 bounds the finite-cutoff cumulants at the stated side and test parameters, and the bound passes to the limit.

Step 2: clause (a). By Proposition YM3_I:91.13, the set of pairs $\mathfrak{d}(g)$ has the property (PB)$[\underline{C}^g; 2L^{m_{\mathfrak{L}}(g)}, 2\mathsf{l}(\cdot,\cdot)]$ on the tori; for $\ell \in \mathfrak{L}$ the condition $\ell \geq 2\mathsf{l}(n, R)$ says $\ell \geq 16n(R+1)$, and the sides of $\mathfrak{L}$ that are at least $2L^{m_{\mathfrak{L}}(g)}$ form $\mathfrak{L}(g)$. These are the bounds used in Lemma 18.167, applied with $\ell'_k = \ell_k$ and $(K_i^k, \beta_i^k) = (i, L^i b)$ for each k. Its inner limits eq. 18.xiii exist by (o) and equal $\mathsf{B}(\ell_k, b; X)$. The lemma gives, in every infinite set of indices, $k_1 < k_2 < \cdots$ along which $\mathsf{B}(\ell_{k_i}, b; X)$ converges for all $n \geq 2$ and $X \in \mathfrak{S}_n(\mathbb{R}^3)$; the limits form a member of $\mathrm{SF}(b)$, taken along $(\ell_{k_i})_i$ (Definition 18.164(2)).

Step 3: clause (b). Of its sides Lemma 18.167 asks only that they lie in $\mathfrak{L}$ and tend to infinity, as the sides ℓ'_k do; and at every side $\ell \in \mathfrak{L}$ and every $X \in \mathfrak{S}_n(Q_\ell)$, $n \geq 2$, the inner limit $\lim_i \mathsf{a}(i, \ell, L^i b; X)$ exists and is $\mathsf{B}(\ell, b; X)$ (Theorem YM3_I:AS, YM3_I:(2216)), the pairs $(i, L^i b)$ lying in $\mathfrak{d}(g)$ (Step 1). So Lemma 18.167, read as in Step 2 but for the whole sequence $(\ell'_k)_k$, gives indices $i(k)$ such that $K_k = i(k) \geq k$ for every k and $\mathsf{a}(K_k, \ell'_k, L^{K_k} b; X) - \mathsf{B}(\ell'_k, b; X) \to 0$ along the full sequence k, for all $n \geq 2$ and $X \in \mathfrak{S}_n(\mathbb{R}^3)$; so $\mathsf{a}(K_k, \ell'_k, L^{K_k} b; X) \to S_n(X)$. As $\mathfrak{L}(g)$ is a tail of $\mathfrak{L}$ and $\ell'_k \to \infty$, the k with $\ell'_k \in \mathfrak{L}(g)$ include every k from some index on. The triples $(K_k, \ell'_k, L^{K_k} b)$ of these k have their pairs in $\mathfrak{d}_b \subset \mathfrak{d}(g)$, $K_k \to \infty$ and sides $\ell'_k \to \infty$ in $\mathfrak{L}(g)$: they form a torus sequence at g over $\mathfrak{d}_b$ that defines S, and every member has the label $a_{K_k} L^{K_k} b = b$. So $S \in \mathrm{GT}_b \subset \mathrm{GT}(g)$, b is a label of S, and $S \in \mathcal{K}(g)$ by Proposition YM3_I:92.1. □

Proposition 18.169 (Spacing-first limits at every label, and what they have)**.** Assume the setting. Let $b > 0$ be real and let $\ell_k = 2L^{m_k} \in \mathfrak{L}$, $k \in \mathbb{N}$, be sides with $\ell_k \to \infty$. Let $z \geq 0$ be an integer with $L^z b \geq 2\gamma^{-2}$ and put $g_z = (L^z b/2)^{-1/2}$; then $0 < g_z \leq \gamma$ and $L^z b \in I(g_z)$. Put $C_n^{(z)}(\mathsf{d}; R) = L^{zn} C_n^{g_z}(L^z \mathsf{d}; L^z R)$ for $n \geq 2$ and $\mathsf{d}, R > 0$.

(o) For every k, $n \geq 2$ and $X \in \mathfrak{S}_n(Q_{\ell_k})$, $\mathsf{B}(\ell_k, b; X) = \lim_K \mathsf{a}(K, \ell_k, L^K b; X)$ exists along the full sequence of the cutoffs, and the same number is the limit along all pairs with $K_j \to \infty$ and $a_{K_j}\beta_j \to b$; and $\mathsf{B}(\ell_k, b; X) = L^{z'n}\mathsf{B}(L^{z'}\ell_k, L^{z'}b; X^{[z']})$ for every integer z' with $m_k + z' \geq 1$.

(a) *Extraction.* Every infinite set of indices holds $k_1 < k_2 < \cdots$ such that $\mathsf{B}(\ell_{k_i}, b; X)$ converges as $i \to \infty$ for all $n \geq 2$ and $X \in \mathfrak{S}_n(\mathbb{R}^3)$; the family of the limits lies in $\mathrm{SF}(b)$. So $\mathrm{SF}(b) \neq \varnothing$.

(b) *Dilations; growing tori.* $\mathrm{SF}(L^{z'}b) = \{\mathrm{dil}_{L^{z'}} S : S \in \mathrm{SF}(b)\}$ for every $z' \in \mathbb{Z}$. Every $S \in \mathrm{SF}(b)$ is $\mathrm{dil}_{L^{-z}} S'$ with $S' = \mathrm{dil}_{L^z} S \in \mathrm{SF}(L^z b) \subset \mathrm{GT}_{L^z b} \subset \mathrm{GT}(g_z)$, the label $L^z b$ being a label of S' at g_z. If $b \in I(g)$ for some $0 < g \leq \gamma$, then $\mathrm{SF}(b) \subset \mathrm{GT}_b \subset \mathrm{GT}(g)$.

(c) *What every $S \in \mathrm{SF}(b)$ has.*

(c1) Every S_n, and σ_S, is invariant under all translations τ_v, $v \in \mathbb{R}^3$, and under W_3.

(c2) σ_S is reflection positive at every coordinate plane $\{x_\mu = c\}$, $\mu \in \{1, 2, 3\}$, $c \in \mathbb{R}$, from both sides.

(c3) S is a family of real, symmetric, multilinear maps, and $|S_n(X)| \leq C_n^{(z)}(\mathsf{d}; R)\|X\|$ for all $n \geq 2$, $\mathsf{d}, R > 0$ and $X \in \mathfrak{S}_n(\mathbb{R}^3)$ of the type $(\mathsf{d}; R)$. If $b \in I(g)$, then also $|S_n(X)| \leq C_n^g(\mathsf{d}; R)\|X\|$ and $|S_n(X)| \leq C_n^{g,\infty}(\mathsf{d}; R)\|X\|$, with the table of Definition 18.164. None of these numbers reads a cutoff, a side, a sequence or a member of $\mathrm{SF}(b)$.

(c4) S and σ_S have off-diagonal distribution kernels: for every n there is exactly one distribution on $(\mathbb{R}^3)^n_{\neq}$ whose value at $f_1 \otimes \cdots \otimes f_n$ is $\sigma_S(f_1, \ldots, f_n)$ for every separated tuple of smooth functions, and the same for S_n, $n \geq 2$; these distributions are of order at most $4n + 1$ on compact sets.

(c5) σ_S satisfies the flat Schwartz-test growth estimate of Proposition YM3_I:93.4 with the constants $(k_{\mathrm{E}}, \mathsf{c}_{\mathrm{E}}, L^{z(1+k_{\mathrm{E}})}\mathsf{C}_{\mathrm{E}}^{\mathrm{c},g_z}, \varkappa_{\mathrm{E}})$, where $(k_{\mathrm{E}}, \mathsf{c}_{\mathrm{E}}, \mathsf{C}_{\mathrm{E}}^{\mathrm{c},g}, \varkappa_{\mathrm{E}})$ are the canonical growth constants at g of Definition 18.164; if $b \in I(g)$, with the canonical growth constants at g themselves.

(c6) $\mathcal{H}(S)$ is formed and separable; $\mathcal{T}_t = e^{-tH_S}$, $t \geq 0$, is a strongly continuous semigroup of self-adjoint contractions with $\ker \mathcal{T}_t = 0$, $H_S \geq 0$ and $H_S\Omega = 0$; $\mathcal{U}(v)[F] = [\tau_{(v,0)}F]$, $v \in \mathbb{R}^2$, is a strongly continuous unitary group $e^{iv_1P_1}e^{iv_2P_2}$ that commutes with $\mathcal{T}_t$ and fixes Ω; the joint spectral measure of (H_S, P_1, P_2) is carried by $[0,\infty)\times\mathbb{R}^2$; and every $w \in W_2$ acts by the unitary $\mathcal{U}(w)[F] = [wF]$, which fixes Ω, commutes with H_S, and maps the joint spectrum onto itself by $(E,q) \mapsto (E, wq)$.

(d) *The law of two points.* Let $\vartheta \in (0,1)$. If $b \in I(g)$ with $0 < g \leq \gamma_W$, then for every $S \in \mathrm{SF}(b)$, every $d \in (0, d_0(g,\vartheta)]$ and every pair (f,h) of the class of the law at the parameter ϑ and the size d, $S_2(f,h) = c_2 b^{-2} K_{\mathrm{free}}(f,h)(1+\eta)$ with $|\eta| \leq \bar{\varepsilon}_{g,\vartheta}(d) \leq \frac{1}{3}$. For every real $b > 0$, with an integer $z' \geq 0$ such that $L^{z'}b \geq 2\gamma_W^{-2}$ and with $g' = (L^{z'}b/2)^{-1/2} \leq \gamma_W$, the same holds for $0 < L^{z'}d \leq d_0(g',\vartheta)$, with $|\eta| \leq \bar{\varepsilon}_{g',\vartheta}(L^{z'}d) \leq \frac{1}{3}$. In both cases $b^{-2} = \lim_{t\to 0} S_2(f(\cdot/t), h(\cdot/t))/(c_2 K_{\mathrm{free}}(f,h))$ for every pair (f,h) of the class at the parameter ϑ and any size; so $\mathrm{SF}(b) \cap \mathrm{SF}(b') = \varnothing$ for $b \neq b'$.

■

Proof. Step 0. Such integers z exist because $L > 1$. With $x = L^z b$ and $g_z^{-2} = x/2$, we have $g_z \leq \gamma$ and $x/2 + \bar{B} < x$, since $\gamma^{-2} > \bar{B}$. The right end $L(x/2+\bar{B}) - 2\bar{B}$ is at least x, so $x \in I(g_z)$.

Step 1. Theorem YM3_I:AS and YM3_I:(2216) give the limits along fixed and moving labels on every side. For the dilation use YM3_I:(2215). Periodization commutes with dilation, since

$$\sum_{p \in L^z \ell\mathbb{Z}^3} f(L^{-z}(x+p)) = \sum_{q \in \ell\mathbb{Z}^3} f(L^{-z}x + q).$$

The formula for negative z' follows by inversion.

Step 2: clauses (a) and (b). Let $z' \in \mathbb{Z}$ and $S \in \mathrm{SF}(b)$, taken along (ℓ_k). For $Y \in \mathfrak{S}_n(\mathbb{R}^3)$ and all large k, (o) at $X = Y^{[-z']} = Y_{(L^{z'})}$ gives $\mathsf{B}(L^{z'}\ell_k, L^{z'}b; Y) = L^{-z'n}\mathsf{B}(\ell_k, b; Y_{(L^{z'})}) \to L^{-z'n}S_n(Y_{(L^{z'})}) = (\mathrm{dil}_{L^{z'}}S)_n(Y)$; so $\mathrm{dil}_{L^{z'}}S \in \mathrm{SF}(L^{z'}b)$, taken along the sides $L^{z'}\ell_k \in \mathfrak{L}$ of the large k. The other inclusion is the same statement at $(L^{z'}b, -z')$, as $\mathrm{dil}_{L^{-z'}}\mathrm{dil}_{L^{z'}}$ is the identity. At $z' = z$ the sides $L^z\ell_k$ lie in $\mathfrak{L}(g_z)$ from some index on, and Proposition 18.168, at the coupling g_z and the label $L^z b \in I(g_z)$, gives in every infinite set of indices a subsequence along which $\mathsf{B}(L^z\ell_k, L^z b; Y)$ converges at every Y; by (o) at $z' = z$, $\mathsf{B}(\ell_k, b; X) = L^{zn}\mathsf{B}(L^z\ell_k, L^z b; X^{[z]})$ converges at every X along it, which is (a). The same proposition gives $\mathrm{SF}(L^z b) \subset \mathrm{GT}_{L^z b} \subset \mathrm{GT}(g_z)$, with the label $L^z b$, and $\mathrm{SF}(b) \subset \mathrm{GT}_b$ when $b \in I(g)$.

Step 3. At $b \in I(g)$ the family S is a growing-torus limit by clause (b). Proposition YM3_I:92.3 gives the symmetries and Proposition YM3_I:92.4 the coordinate reflection positivity. Proposition YM3_I:92.1 gives the multilinear family and its bound C_n^g. The normalizer and growth bounds of Propositions YM3_I:89.4 and YM3_I:89.5 at the source-system constants in Definition 18.164 apply on each defining torus as soon as the side holds the tests and is large enough for their type. Passing to the limit gives the sharper table $C_n^{g,\infty}$. The moment–cumulant formula bounds each order of σ_S for fixed support separation. Proposition YM3_I:93.1 applies to this family and to S, and gives the unique off-diagonal kernels of order at most $4n+1$. For the global bound, use the factorial bound at $R = 1$ with $A(d) \leq A_{\mathrm{PL}} \max(1, d^{-4})$. Proposition YM3_I:93.4 at $a = 4$ gives exactly the canonical growth constants above. Finally apply Proposition YM3_I:94.1 to the reflection form in direction e_3 and to its tangential translations and W_2 symmetries.

Step 4: clause (c) at every label. Let $S \in \mathrm{SF}(b)$ and $S' = \mathrm{dil}_{L^z}S$; then $S = \mathrm{dil}_{L^{-z}}S'$, that is $S_n(X) = L^{zn}S'_n(X^{[z]})$ with $X^{[z]} = X_{(L^{-z})}$, and $\sigma_S = \mathrm{dil}_{L^{-z}}\sigma_{S'}$ (Definition 18.164(1)). By

(b) and Step 3 at $(g_z, L^z b)$, S' has (c1)–(c6) with the numbers at g_z. The map $X \mapsto X^{[z]}$ is a bijection of $\mathfrak{S}_n(O)$ onto $\mathfrak{S}_n(L^z O)$ for every open O; it carries the type $(\mathsf{d}; R)$ to the type $(L^z\mathsf{d}; L^z R)$; $\|f^{[z]}\|_\sharp = \max\{\|f\|_\infty, 40ML^{-z}\operatorname{Lip} f\} \le \|f\|_\sharp$, as $z \ge 0$; and $(\tau_v X)^{[z]} = \tau_{L^z v} X^{[z]}$, $(wX)^{[z]} = wX^{[z]}$ for $w \in W_3$, $(\theta_{\mu,c}X)^{[z]} = \theta_{\mu,L^z c}X^{[z]}$. (c1): $S_n(\tau_v X) = L^{zn}S'_n(\tau_{L^z v}X^{[z]}) = S_n(X)$, and the same for W_3 and for σ_S. (c2): for $F = \sum_i c_i X_i$ in the span of the tuples supported in $\{\epsilon(x_\mu - c) > 0\}$, $\sigma_S(\theta_{\mu,c}\bar F \cdot F) = \sum_{i,k} \bar c'_i c'_k \sigma_{S'}(\theta_{\mu,L^z c}X_i^{[z]} \cdot X_k^{[z]}) \ge 0$, where $c'_i = L^{z|X_i|}c_i$ and $\bar c'_i = L^{z|X_i|}\bar c_i$, as $L^{z|X_i|}$ is real, and where the tuples $X_i^{[z]}$ are supported in $\{\epsilon(x_\mu - L^z c) > 0\}$. (c3): $|S_n(X)| = L^{zn}|S'_n(X^{[z]})| \le L^{zn}C_n^{g_z}(L^z\mathsf{d}; L^z R)\|X^{[z]}\| \le C_n^{(z)}(\mathsf{d}; R)\|X\|$. (c4): with $F_z(y) = F(L^{-z}y)$, which is a test function on $(\mathbb{R}^3)^n_{\ne}$ when F is one, $F \mapsto L^{zn}T'(F_z)$ is a distribution of the same order for every distribution T' of $\sigma_{S'}$ or of S'_n, and at $F = \bigotimes_i f_i$ it takes the value $L^{zn}\sigma_{S'}(X^{[z]}) = \sigma_S(X)$, respectively $S_n(X)$; uniqueness passes in the same way at $-z$. (c5): the space $\mathcal{S}_{\ne}(\mathbb{R}^{3n})$ and the norms $|\cdot|_k$ are the Schwartz functions on $\mathbb{R}^{3n}$ whose derivatives of every order, the order 0 included, vanish at each point outside $(\mathbb{R}^3)^n_{\ne}$, and $|\varphi|_k = \sup\{(1+|x|^2)^{k/2}|\partial^\alpha\varphi(x)| : x \in \mathbb{R}^{3n},\ |\alpha| \le k\}$, α running over the multi-indices. With the Schwinger functions $\mathsf{S}_n^{\sigma_{S'}}$ of $\sigma_{S'}$ put $\mathsf{S}_n(\varphi) = L^{zn}\mathsf{S}_n^{\sigma_{S'}}(\varphi_z)$, $\varphi_z(y) = \varphi(L^{-z}y)$, for $\varphi \in \mathcal{S}_{\ne}(\mathbb{R}^{3n})$, a space that holds φ_z with φ; at the tensor of a separated tuple of smooth functions it is $\sigma_S(X)$; and $|\varphi_z|_k \le L^{zk}|\varphi|_k$, because $\partial^\alpha\varphi_z(y) = L^{-z|\alpha|}(\partial^\alpha\varphi)(L^{-z}y)$ with $L^{-z|\alpha|} \le 1$, and $1 + |y|^2 \le L^{2z}(1 + |L^{-z}y|^2)$, as $z \ge 0$; so $|\mathsf{S}_n(\varphi)| \le \mathsf{c}_{\mathrm{E}}(L^{z(1+k_{\mathrm{E}})}\mathsf{C}_{\mathrm{E}}^{\mathrm{c},g_z})^n(n!)^{\varkappa_{\mathrm{E}}}|\varphi|_{k_{\mathrm{E}}n}$. (c6): Use the reflection form under dilation at $s = L^{-z}$ as in the proof of Proposition 18.166: σ_S is reflection positive, $[F] \mapsto [V_s F]$, $V_s X = s^{-|X|}X_{(s)}$, extends to a unitary $\mathcal{V}\colon \mathcal{H}(S) \to \mathcal{H}(S')$ with $\mathcal{V}\Omega = \Omega$, $H_S = L^z\mathcal{V}^{-1}H_{S'}\mathcal{V}$, and $\mathcal{V}$ carries the translation by v along the plane to that by $L^z v$. The dilation commutes with every $w \in W_2$, so $\mathcal{V}$ carries $\mathcal{U}(w)$ to $\mathcal{U}(w)$. So all of (c6) passes from S' to S; the joint spectral measure of S is the image of that of S' under $(E, q) \mapsto (L^z E, L^z q)$, which keeps $[0,\infty) \times \mathbb{R}^2$ and commutes with W_2.

Step 5: clause (d). Let $b \in I(g)$, $0 < g \le \gamma_W$, and $S \in \mathrm{SF}(b)$. By (b), S is a continuum limit at g along growing tori with the label b, which is its one label by Theorem YM3_I:AW; Theorem YM3_I:AW is the law, and $\bar\varepsilon_{g,\vartheta} \le \frac{1}{3}$ on $(0, d_0(g,\vartheta)]$. For a real $b > 0$: $L^{z'}b \ge 2\gamma_W^{-2} \ge 2\gamma^{-2}$, so the window calculation of Step 0 gives $L^{z'}b \in I(g')$, and $g' \le \gamma_W$. By (b), $S' = \mathrm{dil}_{L^{z'}}S \in \mathrm{SF}(L^{z'}b)$. For a pair (f, h) of the class at $(d; \vartheta)$, the pair $(f(L^{-z'}\cdot), h(L^{-z'}\cdot))$ is of the class at $(L^{z'}d; \vartheta)$, with the same value of K_{free} by simultaneous dilation of the supports and the homogeneity of K_{free}; so $S_2(f,h) = L^{2z'}S'_2(f(L^{-z'}\cdot), h(L^{-z'}\cdot)) = L^{2z'}c_2(L^{z'}b)^{-2}K_{\mathrm{free}}(f,h)(1+\eta) = c_2 b^{-2}K_{\mathrm{free}}(f,h)(1+\eta)$, $|\eta| \le \bar\varepsilon_{g',\vartheta}(L^{z'}d)$. The limit: $(f(\cdot/t), h(\cdot/t))$ is of the class at the size td, with the same value of K_{free}, which is positive, f and h being ≥ 0 and not 0; the tolerance tends to 0 with the size. So S_2 determines b. □

Proposition 18.170 (A ceiling on the lowest mass at every label; the growth of the Källén–Lehmann measure)**.** Assume the setting, and let $b > 0$ be real.

(a) *Every component at every label.* Let $\sigma \in A[b]$ and let σ_ξ be a component of a decomposition of σ, with its Källén–Lehmann pair (κ_ξ, ρ_ξ), where κ_ξ is the constant part of the two-point kernel and ρ_ξ its Yukawa measure. Then $\ker H_{\sigma_\xi} = \mathbb{C}\Omega$; $\operatorname{spec} H_{\sigma_\xi}$ meets $(0, C_0/b]$; the connected function of two points of σ_ξ is $S_2^{\sigma_\xi}(f,h) = \iint f(x)h(y)\int \frac{e^{-m|x-y|}}{4\pi|x-y|}\,d\rho_\xi(m)\,dx\,dy$, ρ_ξ being the measure ψ of its kernel; and $\inf\operatorname{supp}\rho_\xi \le C_0/b$.

(b) *The growth of the measure.* Let ω be a member of $E[b]$, or a component of a decomposition of a member of $A[b]$, or, under the absence of latent heat, a member of $A[b]$, and let ψ_ω be the Yukawa measure of its connected two-point kernel, which equals the measure ρ of its Källén–Lehmann pair. Then

$$\psi_\omega([0,M]) \le \frac{e^5}{5^5}\,\frac{3\alpha}{\pi}\,b^{-2}M^5 \le 0.973\,b^{-2}M^5 \qquad \text{for } M \ge \frac{5}{k_0 b},$$

$$\psi_\omega([0,M]) \ge \frac{1}{21^5}\Big(\frac{3}{2\pi\alpha} - 4^5\,\frac{3\alpha}{\pi}\,e^{-63/4}\Big)\,b^{-2}M^5 \ge 4.7\cdot 10^{-9}\,b^{-2}M^5 \qquad \text{for } M \ge \frac{21}{k_0 b}.$$

As $21/k_0 = \frac{7}{2m_\circ}C_0$ and $\frac{7}{2m_\circ} = 1.3526\ldots$, both bounds hold for all $M \ge 1.36\,C_0/b$.

(c) *Below the ceiling: the local form.* Let $0 < g \le \gamma_W$ and $\vartheta \in (0,\vartheta_1]$; let σ be the limit of a convergent Gibbs sequence at g, and $(\Xi,\lambda,(\sigma_\xi))$ a decomposition of it. Then for every $\xi \in \Xi$, $\operatorname{spec} H_{\sigma_\xi}$ meets $(0, m_\circ/d_0(g,\vartheta)]$ and $\inf\operatorname{supp}\rho_\xi \le m_\circ/d_0(g,\vartheta)$; and $\operatorname{spec} H_\sigma$ meets $(0, m_\circ/d_0(g,\vartheta)]$. Here $m_\circ = 2.5874\ldots < 2.59$.

(d) *Limits along growing tori and spacing-first limits.* Let $0 < g \le \gamma_W$, $\vartheta \in (0,\vartheta_1]$ and $S \in \mathrm{GT}(g)$. Then σ_S is invariant under the translations and reflection positive at $\{x_3 = 0\}$, H_S is formed, and $\dim\ker H_S \ge 2$ or $\operatorname{spec} H_S$ meets $(0, m_\circ/d_0(g,\vartheta)]$; this holds in particular for every $S \in \mathrm{SF}(b)$ with $b \in I(g)$. For every real $b > 0$ and every $S \in \mathrm{SF}(b)$, $\dim\ker H_S \ge 2$ or $\operatorname{spec} H_S$ meets $(0, C_0/b]$.

■

Proof. Step 1. Dilation to a reference window. Put $G = \gamma_W^{-2}$ and $B = \bar{B}$. The interiors of $I(g_1)$ and $I(g_2)$ are $(G+B, \kappa_0 - 2B)$ and $(G+B+2B/L, \kappa_0)$. They cover $(\kappa_0/L, \kappa_0)$ because $G > L^2 B$ by YM3_I:(2346). The endpoint κ_0 belongs to the interior $(2G+B, 2LG+(L-2)B)$ of $I(g_3)$. Thus every $c > 0$ has a dilate $L^z c$ in one of the three open windows, with $L^z c \le \kappa_0$.

Suppose that $\sigma \in A[b]$ comes from spacings $a_j = t_j L^{-K_j}$, with $1 \le t_j < L$ and $K_j \to \infty$. Pass to a subsequence with $t_j \to t \in [1,L]$. Choose z, g_i so that $\widehat{b} = L^z b/t \in I(g_i)^\circ$ and $\widehat{b} \le \kappa_0$. Change length units by $s_j = t_j L^{-z}$, so the new spacing is $\widehat{a}_j = L^{-(K_j - z)}$ and its label tends to $\widehat{b}$. Corollary YM3_I:74.2 makes these pairs first-passage data for all large j. The change of units is a relabelling of the Wilson action and of the local Gibbs equations. The plaquette observable obeys $\mathcal{O}_{a_j}(f) = s_j^{-1}\mathcal{O}_{\widehat{a}_j}(f(s_j\,\cdot))$ on corresponding configurations, so the same dilation formula holds for their self-centred moments. The norm bounds of Proposition YM3_I:91.13, combined by the moment–cumulant formula, are uniform when a separated tuple is varied in sharp norm in a common compact set with a positive separation margin. For each fixed C_c^1 test, $f(s_j\,\cdot) \to f(s\,\cdot)$ in this norm with $s = tL^{-z} = b/\widehat{b}$. A multilinear telescope therefore gives a convergent Gibbs sequence in the new units with limit $\widehat{\sigma}$ and $\sigma = \mathrm{dil}_s\widehat{\sigma}$. Canonical decompositions are carried by the same dilation, since it preserves the barycentre and the iterated plateau identities of Theorem YM3_I:AL, with each translation parameter divided by s in the new units. Uniqueness of the canonical decomposition identifies the dilated components.

For any such functional σ' and its dilate, the map $[X] \mapsto s^{-|X|}[X_{(s)}]$ is an isometry from the reflection space of the dilate to that of σ' and has the inverse obtained using s^{-1}. It intertwines time u of the dilate with time u/s of σ'. Thus the Hamiltonian spectrum is multiplied by s^{-1}, with the zero space preserved. Changing variables in the connected two-point integral gives $s_{\mathrm{dil}_s\sigma'}(r) = s^{-8}s_{\sigma'}(r/s)$.

Step 2. Connected radial kernels. Theorem YM3_I:AP gives the components at a reference coupling their simple vacuum and clustering, and Proposition YM3_I:108.3 gives their radial two-point kernels. Proposition 13.25(a), (b) identifies the constant part as the large-distance limit and the remainder as the integral against a positive Yukawa measure. If the one-point constant of a component is c_ξ, clustering on a pair of nonnegative unit-mass tests moved far apart gives $\kappa_\xi = c_\xi^2$. Hence its connected kernel is

$$s_\xi(r) = \int_{[0,\infty)} \frac{e^{-mr}}{4\pi r}\,d\rho_\xi(m).$$

The same conclusions apply to a one-vacuum member, since it is its sole component. They pass through the dilation of Step 1 by changing m to m/s and multiplying the measure by s^{-7}. This also shows that the connected kernel is continuous and nonincreasing at every label.

Under absence of latent heat every component's one-point constant vanishes. Indeed, the component is a limit of periodic Gibbs laws centred at the defining laws of the same frame by

Theorems YM3_I:AL and YM3_I:AP. The one-point difference is bounded by a constant for the test times $a_j^{-4}J(\beta_j)$, as in §12. Since $a_j\beta_j \to b > 0$ and $\beta_j^4 J(\beta_j) \to 0$, that difference vanishes. At a reference window the full kernel has a positive Yukawa representation by Proposition 13.25. Its constant term is the large-time limit of the reflected pair of nonnegative unit-mass tests. In the canonical barycentre those pair values tend to zero componentwise and are dominated by their finite values at time zero, so its constant term is zero as well. The conclusion passes through dilation.

Step 3. From the two-point estimate to the growth law. At a reference window g let b' be the limit label. For a ball of radius d centred at y, use the bump $f(x) = (1 - |x-y|^2/d^2)_+^2$. It has mass $(32\pi/105)d^3$ and Lipschitz constant $8/(3\sqrt{3}d)$, so it meets the test conditions at $\vartheta_1 = 3\sqrt{3}/8$. Take two such bumps with centres $8d$ apart and normalize their masses to one. Their supports are at distance $6d$, and all pairwise point distances are in $[6d, 10d]$. For $d \le d_0(g, \vartheta_1)$, the component bound of Corollary YM3_I:127.11 gives a factor in $[2/3, 4/3]$ against the free kernel. The same bound holds for the full connected kernel under absence of latent heat, by averaging the component values in Step 2. Since the kernel is nonincreasing, the two estimates imply

$$s(6d) \ge \tfrac{2}{3}c_2(b')^{-2}(10d)^{-6}, \qquad s(10d) \le \tfrac{4}{3}c_2(b')^{-2}(6d)^{-6}.$$

Taking respectively $d = r/6$ and $d = r/10$ gives

$$\frac{2}{3\alpha}c_2(b')^{-2}r^{-6} \le s(r) \le \frac{4\alpha}{3}c_2(b')^{-2}r^{-6} \qquad (0 < r \le 6d_0(g, \vartheta_1)).$$

Step 1 carries this estimate to label b, with the same two coefficients, because the dilation factor is $s = b/\widehat{b} \ge b/\kappa_0$ and $d_0(g_i, \vartheta_1) \ge d^\star$. Thus it holds on $0 < r \le k_0 b$ for each ω in (b).

Let $G_\omega(r) = 4\pi r s_\omega(r)$ and $c_- = 3/(2\pi\alpha)$, $c_+ = 3\alpha/\pi$. The bounds just proved are $c_- b^{-2}r^{-5} \le G_\omega(r) \le c_+ b^{-2}r^{-5}$. Since $G_\omega(r) \ge e^{-Mr}\psi_\omega([0, M])$, take $r = 5/M$ for the upper bound in (b). For $0 < u < 1$ the mass above M satisfies

$$\int_{(M,\infty)} e^{-mr}\, d\psi_\omega(m) \le e^{-(1-u)Mr}G_\omega(ur).$$

Also $\psi_\omega([0, M]) \ge \int_{[0,M]} e^{-mr} d\psi_\omega(m)$. Subtract the tail bound and use the two inequalities for G_ω. Taking $u = 1/4$ and $r = 21/M$ gives $21^{-5}(c_- - 4^5 c_+ e^{-63/4})b^{-2}M^5$. The numerical upper and lower coefficients are respectively $0.9720447\ldots$ and $4.7129372\ldots\, 10^{-9}$. Finally $21/k_0 = 7C_0/(2m_\circ)$, as claimed.

Step 4. A low-energy spectral test. Take the same bump f of radius d about $2de_3$. For $\theta = \theta_{3,0}$ the pairs $(\theta f, f)$ and $(\theta f, \tau_{4de_3} f)$ have support distances $2d$ and $6d$, and point distances in $[2d, 6d]$ and $[6d, 10d]$. They satisfy the test conditions at all $0 < \vartheta \le \vartheta_1$. For $d = d_0(g, \vartheta)$ apply Corollary YM3_I:127.11 to each component. Writing $C_\xi(u) = S_2^{\sigma_\xi}(\theta f, \tau_{ue_3} f)$ gives

$$C_\xi(0) \le \tfrac{4}{3}c_2(b')^{-2}(2d)^{-6}(\textstyle\int f)^2, \qquad C_\xi(4d) \ge \tfrac{2}{3}c_2(b')^{-2}(10d)^{-6}(\textstyle\int f)^2 > 0.$$

Thus $C_\xi(4d) \ge C_\xi(0)/31250$. The reflection semigroup expresses $C_\xi(u)$ as the Laplace transform of the spectral measure of $[(f)] - \sigma_\xi((f))\Omega$. This vector is orthogonal to the simple vacuum, so its measure has no atom at zero. A nonzero positive measure supported on $(m_\circ/d, \infty)$ would have its transform at $4d$ strictly less than $e^{-4m_\circ}$ times its mass. The ratio just proved excludes this. The spectral measure therefore charges $(0, m_\circ/d]$. The Yukawa representation of Lemma 18.108(a), (b) for the vacuum-subtracted vector gives energies $\sqrt{m^2 + |q|^2} \ge m$, hence $\inf \operatorname{supp} \rho_\xi \le m_\circ/d$.

For the whole limit, put $C(u) = \sigma(\theta f, \tau_{ue_3} f)$. Its canonical decomposition gives $C(u) = \int [C_\xi(u) + \sigma_\xi((f))^2] d\lambda(\xi)$. Each $C_\xi(u)$ tends to zero and is bounded by $C_\xi(0)$. The latter has a finite integral by the same identity at zero. It follows that the Laplace transform for the positive-energy part of the vector $[(f)]$ is $C(u) - C(\infty) = \int C_\xi(u) d\lambda(\xi)$. The integral obeys the same positive lower ratio at $4d$, so that part of the measure charges $(0, m_\circ/d]$. This proves (c) and also yields the conclusions of (a) at every label after Step 1. In fact, at the reference window take $\vartheta = \vartheta_1$. The dilated ceiling is at most $s^{-1}m_\circ/d^\star \le C_0/b$ for both the Hamiltonian and the infimum of the mass support.

Step 5. Growing tori and spacing first. For $S \in \mathrm{GT}(g)$ use the centred reflection functional of Definition 13.4(5) and Theorem YM3_I:AW at its limit label. The same bump calculation applies to S_2, the Laplace transform of the spectral measure of $[(f)]$. The ratio forces positive measure on $[0, m_\circ/d]$. If its atom at zero is positive, the corresponding projection of $[(f)]$ is nonzero and orthogonal to the vacuum because $\sigma_S((f)) = 0$. The zero space then has dimension at least two. If the atom is zero, the positive spectrum meets $(0, m_\circ/d]$. Proposition 18.169(b) includes $\mathrm{SF}(b)$ in $\mathrm{GT}(g)$ when $b \in I(g)$. For general $b > 0$ choose z, g_i by Step 1 with $c = b$. The same proposition carries $S \in \mathrm{SF}(b)$ to $\mathrm{dil}_{L^z} S \in \mathrm{SF}(L^z b) \subset \mathrm{GT}(g_i)$. The unitary scaling in Step 1 preserves the zero-space dimension and returns the upper energy bound $L^z m_\circ/d^\star \le C_0/b$ to S. This proves (d). □

Proposition 18.171 (One limit at a label; one vacuum from ergodic states)**.** Assume the setting.

(a) *Ergodic states give one vacuum.* Let $0 < g \le \gamma$, and let $(K_j, \beta_j, \nu_j)_j$ be a convergent Gibbs sequence at g in which ν_j is ergodic for infinitely many j. Then its limit σ has $\lim_{|v|\to\infty} \sigma(X \cdot \tau_v X) = \sigma(X)^2$ for every $X \in \mathfrak{S}$, and every decomposition of σ has a space of one point: σ has one vacuum. If $a_{K_j}\beta_j \to b$, then $\sigma \in E[b]$, with the scalar Wightman reconstruction of Theorem YM3_I:AP and gap at most C_0/b by Proposition 18.170(a).

(b) *One limit at a label.* Let $0 < g \le \gamma$, and assume (H_g) of Definition 18.172(7): for every $n \ge 2$ and $X \in \mathfrak{S}_n(\mathbb{R}^3)$ there are $\epsilon_X(\ell) \to 0$ and $K_0(n, X)$ with $|\mathsf{a}(K, \ell, \beta; X) - \mathsf{a}(K, m, \beta; X)| \le \epsilon_X(\ell)$ for all $\ell \le m$ in $\mathfrak{L}(g)$ and all $(K, \beta) \in \mathfrak{d}(g)$ with $K \ge K_0(n, X)$. Then:

(b1) for every real $b > 0$, $n \ge 2$ and $X \in \mathfrak{S}_n(\mathbb{R}^3)$, $S_n^b(X) = \lim_{\ell \in \mathfrak{L}} \mathsf{B}(\ell, b; X)$ exists, and $\mathsf{a}(K_j, \ell_j, \beta_j; X) \to S_n^b(X)$ and $S_n^T[\nu_j](X) \to S_n^b(X)$, without passing to subsequences, along all pairs with $K_j \to \infty$ and $a_{K_j}\beta_j \to b$, all sides $\ell_j \to \infty$ of $\mathfrak{L}$ in any relation to K_j, and all states of tori ν_j at these pairs;

(b2) $b \mapsto S_n^b(X)$ is continuous on $(0, \infty)$, and $\mathsf{B}(\ell, b; X) \to S_n^b(X)$ uniformly for b in every compact $J \subset (0, \infty)$;

(b3) $S^{L^z b} = \mathrm{dil}_{L^z} S^b$ for every $z \in \mathbb{Z}$.

(c) *All real dilations.* If $(\mathrm{H}_{g^{(2)}})$ holds besides in a second setting, with a blocking factor L_2 such that $\log L / \log L_2$ is irrational and at a reference coupling $g^{(2)}$ of that setting, and the condition (Same) of Definition 18.172(6) holds, then $\mathrm{dil}_r S^b = S^{rb}$ for all real $r, b > 0$.

(d) *One vacuum at a label.* Under (H_g), let $b \in \Lambda(g)$ and let σ_b be the centred functional of S^b. Every state sequence at g with labels tending to b is a convergent Gibbs sequence at g with the limit σ_b. If in one such sequence ν_j is ergodic for infinitely many j, then σ_b has one vacuum, $\sigma_b \in E[b]$, and $\sigma_{L^z b} = \mathrm{dil}_{L^z} \sigma_b \in E[L^z b]$ for every $z \in \mathbb{Z}$.

■

Proof. Clause (a). The Gibbs-frame reconstruction of Theorem YM3_I:AP supplies the canonical decomposition. Under an ergodic law the invariant σ-algebra is trivial modulo null sets, so its L^2 has dimension one. The component count in Theorem YM3_I:AL is bounded by the lower limit of these dimensions along the frame. There is at least one component. Hence infinitely many ergodic indices give exactly one, and the clustering of that component is the clustering of σ. If the labels tend to b, the original sequence exhibits $\sigma \in A[b]$. It is then in $E[b]$, with the stated field and Hamiltonian by Theorem YM3_I:AP and the spectral bound of Proposition 18.170(a).

Clauses (b) and (c). The finite-size comparison and the reindexing in Proposition 18.173(b) apply to (H_g). They give the limit along every sequence of pairs and sides, its uniform convergence on compact sets of labels, and the integer dilation rule. The same proposition, with the second blocking factor and (Same), gives the real dilation rule in (c).

Clause (d). The pointwise limits of the cumulants in (b) give convergence of the self-centred moments by the finite moment–cumulant identities. The state sequence is a Gibbs sequence because the states of tori satisfy the Gibbs equations. If it has infinitely many ergodic indices, (a) shows

that its limit is in $E[b]$. Relabel the bonds of the sequence by the scale L^z. The observable identity in the proof of Proposition 18.166 carries the limit to $\mathrm{dil}_{L^z}\sigma_b \in A[L^z b]$ and gives a bijection of decompositions, so the new limit has one component as well. By (b3) it equals $\sigma_{L^z b}$. □

18.18. **One vacuum from ergodic states of tori; the cutoff removed first and the volume afterwards.** We use the limit classes and reconstruction of Definition 18.164. Proposition 18.173 states what the hypothesis $(\mathrm{H}^\circ[\mathfrak{d}(g), b])$ at a limit b of labels at g gives, and what (H_g) gives at all labels, together with the vacuum. Under $(\mathrm{H}^\circ[\mathfrak{d}(g), b])$ the limit spacing first S^b exists; the cumulants of all tori and of all states of tori whose pairs lie in $\mathfrak{d}(g)$ and whose labels tend to b tend to it along the full sequence, whatever the relation between cutoff and side; and S^b is the one limit at g of either kind with the label b. Under (H_g) the same holds at every reference coupling and at every label, $b \mapsto S^b$ is continuous and $\mathrm{dil}_{L^z} S^b = S^{L^z b}$; if moreover a second setting is given whose blocking factor L_2 makes $\log L/\log L_2$ irrational, with $(\mathrm{H}_{g_{(2)}})$ there at one of its reference couplings $g_{(2)}$ and with the condition (Same) on the states of tori of the two settings (Definition 18.172), then $\mathrm{dil}_r S^b = S^{rb}$ for every real $r > 0$. If in one state sequence at g with labels tending to b the states are ergodic, that is pure phases, at infinitely many indices, then the centred functional σ_b of S^b, which is the limit of every such state sequence, clusters with the rate $C^g(X,Y)/|v|$, every canonical decomposition of it has one point, and $\sigma_b \in E[b]$. This comes from a statement on every convergent Gibbs sequence at g whose states are ergodic at infinitely many indices: the iterated plateau of its limit is the limit of the means of products of conditional means given the translation-invariant events, under an ergodic law these conditional means are constants, so the limit clusters, and a functional that clusters has no decomposition with more than one point. Propositions 18.174 and 18.175 concern the order in which the cutoff is removed first, on tori of a fixed side, and the side grows afterwards. At a label $b \in I(g)$ every sequence (ℓ_k) of sides at g with $\ell_k \to \infty$ has a subsequence along which the torus limits $\mathsf{B}(\ell, b; \cdot)$ converge at every tuple, so that $\mathrm{SF}(b)$ is not empty; one choice of cutoffs, made once for the whole sequence of sides, gives one torus sequence at g whose convergent subsequences have exactly the limits of the corresponding subsequences of the torus limits; so every member of $\mathrm{SF}(b)$ is a continuum limit at g along growing tori with the label b, and the same holds when the label moves with the side, every limit point of the labels being a label of the limit.

Use the canonical Gibbs class $\mathcal{G}_{a,\beta}$ of §12.1 and the first-passage data $\mathfrak{d}(g)$ of Prop. YM3_I:74.1. A state of tori at a fixed pair (K, β) is a subsequential weak limit on the infinite lattice of the periodic lifts of the torus laws as the side tends to infinity in $\mathfrak{L}$. Such states exist by compactness of the configuration space. They satisfy the Gibbs equations: for a fixed finite set of bonds and continuous local test, the finite-volume Gibbs identity agrees with the infinite-lattice identity as soon as the support and the interaction neighbourhood embed in the torus. The local Gibbs kernel preserves continuity, so the identity passes to the weak limit and then extends to bounded Borel tests by a monotone class. Thus a sequence of these states is a Gibbs sequence. The cumulant of a fixed tuple is continuous in the law at a fixed pair because all entries are bounded continuous local observables. In particular the cumulant of a state of tori is a subsequential limit of the torus cumulants at that pair. Use $C^g(X,Y)$ and $r(X,Y)$ of the plateau bound in §12.1, following Prop. YM3_I:100.1.

Definition 18.172. *Ergodic states; conditional means; one choice of cutoffs; labels of a limit.*

(1) At spacing a_K, $\mathcal{I}$ is the Borel σ-algebra of sets fixed by all lattice translations. A translation-invariant law is ergodic when every such set has probability zero or one. Periodic Gibbs states are invariant under all translations by Prop. YM3_I:106.3. The ergodic members are exactly the extreme points, by Prop. YM3_I:106.1.

(2) For a Gibbs sequence (K_j, β_j, ω_j) and a separated tuple $X = (f_i)_i$, let

$$\Theta_j(X) = \prod_i [\mathcal{O}_{a_{K_j}}(f_i) - \omega_j(\mathcal{O}_{a_{K_j}}(f_i))], \qquad \Theta_j(\varnothing) = 1, \qquad \widehat{\Theta}_j(X) = E_{\omega_j}[\Theta_j(X) \mid \mathcal{I}].$$

These are bounded real functions, with $\Theta_j(X)$ local and $\omega_j(\Theta_j(X)) = \sigma_{\omega_j}(X)$. The conditional expectation and its products are defined up to null sets.

(3) Let $0 < g \le \gamma$, let $\ell_k \in \mathfrak{L}(g)$, $k \in \mathbb{N}$, be sides with $\ell_k \to \infty$, and let $b_k \in I(g)$, $k \in \mathbb{N}$. For $k \in \mathbb{N}$, $\mathfrak{F}_k$ is the finite set of the $\varphi^{k'}$ with $k' \le k$ all of whose entries have their supports in Q_{ℓ_k}, and $\kappa(k)$ is the least integer $K' \ge k$ such that $|\mathsf{a}(K, \ell_k, L^K b_k; \varphi) - \mathsf{B}(\ell_k, b_k; \varphi)| \le 1/k$ for all integers $K \ge K'$ and all $\varphi \in \mathfrak{F}_k$. It exists by Thm. YM3_I:AS: periodization of a tuple supported in $Q_{\ell_k} = (-\ell_k/4, \ell_k/4)^3$ gives a separated C^1 tuple on the torus. The enumeration $(\varphi^{k'})$ is the countable dense family of Lem. 18.167. The number $\kappa(k)$ depends on k, ℓ_k and b_k alone.

(4) A label of a member of $\mathrm{GT}(g)$, respectively $\mathrm{VF}(g)$, is a subsequential limit of $a_{K_j}\beta_j$ along a defining sequence of tori, respectively states of tori.

(5) For a compact nonempty $J \subset (0, \infty)$ set $K_J = \min\{K \ge 1 : L^K \min J > X_g\}$ and $Z_J = \{z \in \mathbb{Z} : L^z J \cap I^{\mathrm{lab}}(g) \ne \varnothing\}$, where $I^{\mathrm{lab}}(g)$ is the compact label interval from the bounds of Prop. YM3_I:74.1. It is finite. If $K \ge K_J$ and $b \in J$, the first-passage index for the bare coupling $L^K b$ is $K - z$ for a unique $z \in Z_J$. This follows from uniqueness of first passage and the fact that the new label is $L^z b$. In particular for each $b > 0$ some $L^z b$ lies in $\Lambda(g)$, by taking a subsequence with fixed z as $K \to \infty$.

(6) For settings with blocking factors L and L_2, (Same) means that for all sufficiently large bare couplings β, any state of tori ν in the first setting and any state of tori ν' in the second, both at β and with respective labels c, c', satisfy $\mathrm{dil}_{1/c} S^T[\nu] = \mathrm{dil}_{1/c'} S^T[\nu']$. The dilated cumulants are formed on all separated tuples in $\mathbb{R}^3$.

(7) For $m \ge \ell \ge \ell_0(X)$, where $\ell_0(X)$ is the least side with $\operatorname{supp} X \subset Q_\ell$, set $\Delta_X(K, \beta; \ell, m) = |\mathsf{a}(K, \ell, \beta; X) - \mathsf{a}(K, m, \beta; X)|$. Write $\mathfrak{p}_J = \{(K, \beta) : a_K \beta \in J\}$, $\mathfrak{p}_\infty = \mathbb{N} \times (0, \infty)$, and let $\Lambda(\mathfrak{p})$ be the positive limiting labels along pairs of $\mathfrak{p}$ with $K \to \infty$. Thus $\Lambda(g) = \Lambda(\mathfrak{d}(g))$. For a set of pairs $\mathfrak{p}$ put

$$\mathsf{e}_X(\ell; \mathfrak{p}) = \lim_{k \to \infty} \sup_{\substack{(K,\beta) \in \mathfrak{p},\ K \ge k \\ m \in \mathfrak{L},\ m \ge \ell}} \Delta_X(K, \beta; \ell, m),$$

$$\mathsf{e}_X(\ell; \mathfrak{p}, b) = \inf_{\eta > 0} \mathsf{e}_X(\ell; \mathfrak{p} \cap \mathfrak{p}_{[b-\eta, b+\eta]}),$$

with supremum of an empty family equal to zero. Use $S_n^b(X) = \lim_{\ell \to \infty} \mathsf{B}(\ell, b; X)$ whenever it exists along all sides. The finite-size hypotheses are as follows.

- (H_g) asks for $\Delta_X(K, \beta; \ell, m) \le \epsilon_X(\ell)$ for $\ell \le m$ in $\mathfrak{L}(g)$ and $(K, \beta) \in \mathfrak{d}(g)$ with $K \ge K_0(n, X)$.
- (H_*) asks for $\Delta_X(K, \beta; \ell, m) \le \epsilon_{X,J}(\ell)$ for every compact $J \subset (0, \infty)$, $\ell \le m$ in $\mathfrak{L}$ and $(K, \beta) \in \mathfrak{p}_J$ with $K \ge K_0(n, X, J)$.
- $(\mathrm{H}_g^\sharp)$ asks for $\Delta_X(K, \beta; \ell, m) \le \eta_n(\ell; \mathsf{d}, R)\|X\|$ for all $\ell \le m$ in $\mathfrak{L}(g)$, $(K, \beta) \in \mathfrak{d}(g)$ and tuples of type $(\mathsf{d}; R)$ in Q_ℓ. The bounds in these three hypotheses tend to zero as $\ell \to \infty$ and the cutoff thresholds are independent of ℓ, m.
- $(\mathrm{H}^\circ[\mathfrak{p}, b])$ means $\mathsf{e}_X(\ell; \mathfrak{p}, b) \to 0$; (H_g°) means $\mathsf{e}_X(\ell; \mathfrak{d}(g)) \to 0$; (H°) means $\mathsf{e}_X(\ell; \mathfrak{p}_J) \to 0$ for every compact $J \subset (0, \infty)$.

Each hypothesis concerns every separated tuple with $n \ge 2$ entries.

■

Proposition 18.173 (One limit at a label; one vacuum from ergodic states of tori)**.** Use Definition 18.164 and let $0 < g \le \gamma$. The cumulant families below are indexed by tuples with $n \ge 2$; the centred functionals are defined on all separated tuples.

(a) *One limit at the label b.* Let $b \in \Lambda(g)$ and assume $(\mathrm{H}^\circ[\mathfrak{d}(g), b])$. Under (H_g), in particular when (H_g) holds with the threshold $K_0(n, X) = 1$, so that $\Delta_X(K, \beta; \ell, m) \le \epsilon_X(\ell)$ is asked at all $\ell \le m$ in $\mathfrak{L}(g)$ and at all pairs of $\mathfrak{d}(g)$, this hypothesis holds at every $b \in \Lambda(g)$, with

$\mathsf{e}_X(\ell;\mathfrak{d}(g),b)\le\epsilon_X(\ell)$ for $\ell\in\mathfrak{L}(g)$, $\ell\ge\ell_0(X)$. Then for every $n\ge2$ and $X\in\mathfrak{S}_n(\mathbb{R}^3)$ the limit $S^b_n(X)=\lim_{\ell\in\mathfrak{L}}\mathsf{B}(\ell,b;X)$ exists, and $|\mathsf{B}(\ell,b;X)-S^b_n(X)|\le\mathsf{e}_X(\ell;\mathfrak{d}(g),b)$ for $\ell\in\mathfrak{L}$, $\ell\ge\ell_0(X)$. For all pairs $(K_j,\beta_j)\in\mathfrak{d}(g)$ with $K_j\to\infty$ and $a_{K_j}\beta_j\to b$, all sides $\ell_j\in\mathfrak{L}$ with $\ell_j\to\infty$, in whatever relation to the K_j, and all states of tori $\nu_j\in\mathcal{G}^{\mathrm{tor}}_{(K_j,\beta_j)}$, the numbers $\mathsf{a}(K_j,\ell_j,\beta_j;X)$ and $S^T_n[\nu_j](X)$ tend to $S^b_n(X)$ along the full sequence of indices; and along the same pairs $\lim_\ell\lim_j\mathsf{a}(K_j,\ell,\beta_j;X)=\lim_j\liminf_m\mathsf{a}(K_j,m,\beta_j;X)=\lim_j\limsup_m\mathsf{a}(K_j,m,\beta_j;X)=S^b_n(X)$, the limits in ℓ and m being taken in $\mathfrak{L}$. The family $S^b=(S^b_n)_{n\ge2}$ is a member of $\mathrm{GT}(g)$ and of $\mathrm{VF}(g)$ with the label b, and it is the only member of $\mathrm{GT}(g)$ and the only member of $\mathrm{VF}(g)$ that has b among its labels. Every state sequence at g whose labels tend to b is a convergent Gibbs sequence at g with the limit σ_b, where $\sigma_b(X)=\sum_\pi\prod_{I\in\pi}S^b_{|I|}(X_I)$, the sum over the partitions π of $\{1,\dots,|X|\}$ into blocks of at least two elements; so $\sigma_b(\varnothing)=1$ and $\sigma_b((f))=0$.

(b) *All couplings, all labels, all dilations.* Assume (H_g). Then $(\mathrm{H}_{g'})$ holds at every $0<g'\le\gamma$, so that (a) and (d) apply at every such g' and every $b\in\Lambda(g')$; and (H_*) holds with $\epsilon_{X,J}(\ell)=\max_{z\in Z_J}L^{zn}\epsilon_{X^{[z]}}(L^z\ell)$, a maximum in which a term with $L^z\ell\notin\mathfrak{L}(g)$ is read as $+\infty$, and $K_0(n,X,J)=\max\{K_J,\max_{z\in Z_J}(K_0(n,X^{[z]})+z)\}$, with Z_J and K_J of Definition 18.172(5). For every $n\ge2$ and $X\in\mathfrak{S}_n(\mathbb{R}^3)$: $S^b_n(X)$ exists at every $b>0$; for every compact $J\subset(0,\infty)$, all $b,b'\in J$ and all $\ell\in\mathfrak{L}$ with $\ell\ge\ell_0(X)$, $|\mathsf{B}(\ell,b;X)-S^b_n(X)|\le\epsilon_{X,J}(\ell)$ and $|S^b_n(X)-S^{b'}_n(X)|\le2\epsilon_{X,J}(\ell)+|\mathsf{B}(\ell,b;X)-\mathsf{B}(\ell,b';X)|$, so that $b\mapsto S^b_n(X)$ is continuous on $(0,\infty)$; $S^{L^zb}=\mathrm{dil}_{L^z}S^b$ for $b>0$ and $z\in\mathbb{Z}$; and for every $b>0$ the numbers $\mathsf{a}(K_j,\ell_j,\beta_j;X)$ and $S^T_n[\nu_j](X)$ tend to $S^b_n(X)$ along all pairs $(K_j,\beta_j)\in\mathfrak{p}_\infty$ with $K_j\to\infty$ and $a_{K_j}\beta_j\to b$, all sides $\ell_j\to\infty$ in $\mathfrak{L}$ and all $\nu_j\in\mathcal{G}^{\mathrm{tor}}_{(K_j,\beta_j)}$, no reference coupling entering. Let besides a second setting be given, with a blocking factor L_2 such that $\log L/\log L_2$ is irrational (the consecutive odd choices $L,L+2$ in the canonical construction have this property), let $(\mathrm{H}_{g_{(2)}})$ hold in it at one of its reference couplings $g_{(2)}$, and let (Same) hold. Then there is one family $\mathsf{u}=(\mathsf{u}_n)_{n\ge2}$ with $S^b=S^b_{(2)}=\mathrm{dil}_b\mathsf{u}$ for every $b>0$; so $\mathrm{dil}_rS^b=S^{rb}$ for every real $r>0$.

(c) *Ergodic states at infinitely many indices.* Let (K_j,β_j,ω_j) be a convergent Gibbs sequence at g with the limit σ, and let ω_j be ergodic for infinitely many j. Then $\lim_{|v|\to\infty}\sigma(X\cdot\tau_vY)=\sigma(X)\sigma(Y)$ for all $X,Y\in\mathfrak{S}$, and $|\sigma[X,Y;v]|\le C^g(X,Y)/|v|$ for $|v|\ge r(X,Y)$. Every decomposition $(\Xi,\lambda,(\sigma_\xi))$ of σ has a space $\Xi=\{\xi_0\}$ of one point, $\lambda=\delta_{\xi_0}$ and $\sigma_{\xi_0}=\sigma$; so σ has one vacuum, the Hamiltonian H_σ has the kernel $\mathbb{C}\Omega$, and the weak commutant $\mathcal{C}(\mathbb{R}^{1+2})$ of the fields of σ (the bounded operators weakly commuting with every smeared field on the common invariant polynomial domain) is $\mathbb{C}1$.

(d) *One vacuum at the label b.* Let b be as in (a), and let one state sequence (K_j,β_j,ν_j) at g with $a_{K_j}\beta_j\to b$ have ergodic states ν_j for infinitely many j. Then all that (c) says of σ holds for σ_b: it clusters, $|\sigma_b[X,Y;v]|\le C^g(X,Y)/|v|$ for $|v|\ge r(X,Y)$, every decomposition of σ_b has one point and its one component is σ_b, and $\ker H_{\sigma_b}=\mathbb{C}\Omega$. Moreover $\sigma_b\in E[b]$, so it has the scalar Wightman reconstruction with unique vacuum of Thm. YM3_I:AP and the spectral ceiling of Prop. 18.170(a), and every state sequence at g whose labels tend to b, with ergodic states or not, converges to this one functional with one vacuum. The hypothesis on the states holds, for instance, when for infinitely many j the set $\mathcal{G}_{a_{K_j},\beta_j}$ has exactly one member.

(e) *One vacuum at all labels.* For $b'>0$ such that $S^{b'}$ exists, let $\sigma_{b'}(X)=\sum_\pi\prod_{I\in\pi}S^{b'}_{|I|}(X_I)$ be its centred functional, the sum being as in (a). In the situation of (d), S^{L^zb} exists and $\sigma_{L^zb}=\mathrm{dil}_{L^z}\sigma_b\in E[L^zb]$ for every $z\in\mathbb{Z}$; and if $\mathrm{dil}_rS^b=S^{rb}$ for every real $r>0$, as under the hypotheses of (b) on a second setting, then $\sigma_{b'}\in E[b']$ for every $b'>0$.

■

Proof. Clause (a). Fix X. At fixed sides $m \geq \ell \geq \ell_0(X)$, pass to the limit along pairs in $\mathfrak{d}(g)$ with labels tending to b. Thm. YM3_I:AS and YM3_I:(2216) give

$$|\mathsf{B}(\ell, b; X) - \mathsf{B}(m, b; X)| \leq \mathsf{e}_X(\ell; \mathfrak{d}(g), b).$$

Indeed each fixed label neighbourhood and cutoff threshold in e_X contains the pairs eventually. Since the right side vanishes as $\ell \to \infty$, the side sequence is Cauchy. Sending $m \to \infty$ gives the claimed error for $S_n^b(X)$. Given $\epsilon > 0$, choose a side ℓ_* with $\mathsf{e}_X(\ell_*; \mathfrak{d}(g), b) < \epsilon$. The definition then supplies a label neighbourhood and a cutoff threshold on which $\Delta_X(K, \beta; \ell_*, m) < \epsilon$ for every $m \geq \ell_*$. Along the given pairs, fixed-side convergence gives $|\mathsf{a}(K_j, \ell_*, \beta_j; X) - \mathsf{B}(\ell_*, b; X)| < \epsilon$ for large j. The triangle inequality bounds all $|\mathsf{a}(K_j, m, \beta_j; X) - S_n^b(X)|$ by 3ϵ at once, for all $m \geq \ell_*$ and large j. This gives both the joint limit and the limits of the two side envelopes. It gives the same bound for the cumulants of every state of tori at these pairs by the fixed-pair subsequential characterization above. The spacing-first iterated limit follows from the fixed-side identity and the side limit.

Pairs with labels tending to b exist by $b \in \Lambda(g)$; choose any sides tending to infinity and any states of tori at these pairs. These realize S^b in both limit classes. If a convergent sequence has b among its labels, pass to a subsequence with labels tending to b to identify its limit as S^b. The partition formula for moments of the centred fields gives precisely σ_b because the first cumulants of centred fields vanish. Finally (H_g) bounds $\mathsf{e}_X(\ell; \mathfrak{d}(g), b)$ by $\epsilon_X(\ell)$ on admitted sides by its uniform cutoff threshold.

Clause (b). For $b \in J$ and $K \geq K_J$, use the $z \in Z_J$ of Definition 18.172(5). Relabel the same bond and plaquette graph by the dilation $x \mapsto L^z x$. The measure and bare coupling are unchanged, and each action insertion contributes the factor L^z, as in YM3_I:(2209). Consequently

$$\Delta_X(K, L^K b; \ell, m) = L^{zn} \Delta_{X^{[z]}}(K - z, L^K b; L^z \ell, L^z m), \qquad X^{[z]} = (f_i(L^{-z}\cdot))_i.$$

This holds for negative z by the inverse dilation whenever the new side is admitted. If a dilated side is too small the bound with $+\infty$ is automatic. Apply (H_g) to obtain the displayed $\epsilon_{X,J}$ and $K_0(n, X, J)$ of (H_*). The maximum over Z_J tends to zero since the set is finite. Applying (H_*) on the compact label interval of any first-passage family gives $(\mathrm{H}_{g'})$ at every g'.

Repeat the proof of (a) with the pairs of labels in a compact J. It yields the side convergence and the uniform error on J. The fixed-side limits are continuous in the label by Cor. YM3_I:117.1 and dilation; the uniform side error gives the displayed modulus of continuity and hence continuity of S^b. Each sequence of pairs with labels tending to $b > 0$ lies eventually in some compact J, so the same proof gives joint torus and state convergence with no first-passage restriction. For any $z \in \mathbb{Z}$, take the cutoff and side limits in the exact dilation identity. This gives $S^{L^z b} = \mathrm{dil}_{L^z} S^b$, and this last identity requires only the existence of S^b.

For the two settings, fix $b, b' > 0$. Irrationality makes $p \log L$ dense modulo $\log L_2$ even with p restricted to any tail of the positive integers. Choose $p_j, q_j \to \infty$ with $p_j \log L - q_j \log L_2 \to \log(b'/b)$. At the common bare coupling $\beta_j = bL^{p_j}$ choose arbitrary states of tori at cutoffs p_j and q_j in the two settings. Their labels are b and $b'_j = bL^{p_j} L_2^{-q_j} \to b'$. By (Same) their cumulants at spacing $1/\beta_j$ agree. The convergence just proved also holds at the moving tuples $Y(b_j'^{-1}\cdot)$. Indeed C_c^1 implies convergence in $\|\cdot\|_\sharp$ under the dilations approaching b'^{-1}, with the supports in fixed pairwise disjoint compact neighbourhoods. For a compact set of labels the cumulants of such tuples have one uniform bound by the product of their norms. To see this, map each pair to its first-passage index with the finite set Z_J, then use the table of Prop. YM3_I:91.13 on growing tori and its fixed-pair limit for states of tori. The transformed tuples have uniform positive separation and bounded support radii since the set of transformations is finite. Multilinearity bounds the change by a sum of n terms, each with one moving entry minus its limit, and gives the asserted moving-tuple convergence. Thus $\mathrm{dil}_{1/b} S^b = \mathrm{dil}_{1/b'} S^{b'}_{(2)}$. As b, b' were arbitrary, this is one family u and $\mathrm{dil}_r S^b = S^{rb}$ follows by

composition. The example of consecutive odd blocking factors uses the freedom to choose sufficiently large odd L in Prop. YM3_I:69.1; L and $L+2$ are coprime, so no positive powers are equal.

Clause (c). Restrict to the infinite subsequence of ergodic states, which has the same limit σ. A bounded real $\mathcal{I}$-measurable function is almost surely constant under an ergodic state because the probabilities of all its rational sublevel sets are zero or one. Therefore $\widehat{\Theta}_j(X) = \sigma_{\omega_j}(X)$ almost surely. Prop. YM3_I:100.2, using the bound system for the Gibbs class of Prop. YM3_I:106.3, identifies the two-tuple plateau with $\lim_j \omega_j(\widehat{\Theta}_j(X)\widehat{\Theta}_j(Y)) = \sigma(X)\sigma(Y)$. Thus σ clusters. A canonical decomposition exists by Thm. YM3_I:AP. In any such decomposition the first two plateau identities give

$$\int \sigma_\xi(X)\, d\lambda(\xi) = \sigma(X), \qquad \int \sigma_\xi(X)^2\, d\lambda(\xi) = \sigma(X)^2.$$

Each continuous function $\xi \mapsto \sigma_\xi(X)$ is therefore constant on the whole space, since λ has full support. This holds for every X, and the parametrization is injective, so the decomposition has one point. As σ is itself the one component, the rate is the component estimate of Thm. YM3_I:AP, equation YM3_I:(1996). The same theorem identifies its zero-energy space with the one-dimensional space of the decomposition.

For the weak commutant, use the scalar Wightman reconstruction of this component in Thm. YM3_I:AP. Let Q be a bounded operator in the weak commutant. Repeated weak commutation is valid for products P of smeared fields on the invariant polynomial domain, with P^* there the formal adjoint. With the inner product linear in its second entry, translation covariance gives for every Minkowski translation x

$$\langle Q^*\Omega, U(x)P\Omega\rangle = \langle \Omega, QU(x)P\Omega\rangle = \langle P^*\Omega, U(-x)Q\Omega\rangle.$$

The two Fourier transforms are finite spectral matrix-element measures on opposite closed cones by the spectrum condition. Their common support is the origin, so the function is constant. By the density of $P\Omega$, $Q^*\Omega$ is translation invariant and hence a scalar multiple of the unique vacuum. Apply the same argument to Q^* to see this for $Q\Omega$ too. For polynomial vectors $P\Omega, P'\Omega$ weak commutation now gives the scalar matrix element of Q from $Q\Omega$. Density yields $Q \in \mathbb{C}1$.

Clauses (d) and (e). By (a), the given state sequence converges to σ_b. Clause (c) gives its one vacuum, so this realization by lattice states with label tending to b puts σ_b in $E[b]$. If the Gibbs class is a singleton, its member is extreme and hence ergodic by Prop. YM3_I:106.1. All other sequences specified in (d) converge to the same functional by (a).

A real dilation $x \mapsto rx$ relabels bonds, keeps the Wilson Gibbs specification at the same β, and multiplies the spacing by r. Each centred action insertion transforms by r^{-1} with argument $f(r\cdot)$. It therefore carries limits at label b to limits at label rb and carries canonical decompositions with their same measures and parameter spaces, by the plateau identities and the rescaling of translations. The inverse dilation shows that it carries $E[b]$ onto $E[rb]$. The moment partition formula commutes with this operation because $\sum_{I\in\pi} |I| = |X|$. The integer dilation identity in (b) therefore proves the first statement of (e) using only existence of S^b. If the identity is available for every $r > 0$, the same argument gives the assertion at every label. □

Proposition 18.174 (The spacing removed first, then the volume: extraction)**.** Use the setting of Definition 18.164, let $0 < g \le \gamma$ and $b \in I(g)$, and let $\ell_k \in \mathfrak{L}(g)$, $k \in \mathbb{N}$, be sides with $\ell_k \to \infty$.

(o) *The cutoff first, on each torus.* For every k, every $n \ge 2$ and every $X \in \mathfrak{S}_n(Q_{\ell_k})$ the torus limit $\mathsf{B}(\ell_k, b; X) = \lim_{K\to\infty} \mathsf{a}(K, \ell_k, L^K b; X)$ exists along the full sequence of cutoffs, and it is the limit of $\mathsf{a}(K_i, \ell_k, \beta_i; X)$ along all pairs $(K_i, \beta_i) \in \mathfrak{p}_\infty$ with $K_i \to \infty$ and $a_{K_i}\beta_i \to b$; all the pairs $(K, L^K b)$, $K \in \mathbb{N}$, lie in $\mathfrak{d}_b \subset \mathfrak{d}(g)$. The map $\mathsf{B}(\ell_k, b; \cdot)$ is symmetric and multilinear on $\mathfrak{S}_n(Q_{\ell_k})$, and $|\mathsf{B}(\ell_k, b; X)| \le C_n^g(\mathsf{d}; R)\|X\|$ for every $X \in \mathfrak{S}_n(Q_{\ell_k})$ of the type $(\mathsf{d}; R)$ whenever $\ell_k \ge 16n(R+1)$, $C_n^g(\mathsf{d}; R)$ being the table at g of Prop. YM3_I:91.13. Every $X \in \mathfrak{S}_n(\mathbb{R}^3)$ lies in $\mathfrak{S}_n(Q_{\ell_k})$ for all large k.

(a) *Then the volume: extraction.* Every infinite set of indices contains indices $k_1 < k_2 < \cdots$ such that, for every $n \geq 2$ and every $X \in \mathfrak{S}_n(\mathbb{R}^3)$, the numbers $\mathsf{B}(\ell_{k_l}, b; X)$, formed for all large l, converge as $l \to \infty$. The family $S = (S_n)_{n\geq 2}$ of the limits is a member of $\mathrm{SF}(b)$, taken along $(\ell_{k_l})_l$, and of $\mathcal{K}(g)$. In particular $\mathrm{SF}(b)$ is not empty, and every sequence of sides at g that tends to infinity has a subsequence along which a member of $\mathrm{SF}(b)$ is taken.

(b) *A continuum limit along growing tori with the label b.* Let $k_1 < k_2 < \cdots$ be any indices as in (a), and S the family of the limits. There are cutoffs $K_l \geq k_l$ such that $(K_l, \ell_{k_l}, L^{K_l} b)_{l\in\mathbb{N}}$ is a torus sequence at g over $\mathfrak{d}_b$ that defines S, each of its members having the label $a_{K_l} L^{K_l} b = b$; so $S \in \mathrm{GT}_b \subset \mathrm{GT}(g)$, and b is a label of S. The cutoffs can be fixed before the indices k_l: for any cutoffs $K'_k \geq \kappa(k)$, $k \in \mathbb{N}$, with the numbers $\kappa(k)$ of Definition 18.172(3) at $b_k = b$, one may take $K_l = K'_{k_l}$.

■

Proof. For a fixed k, periodize each entry of X from the central cube Q_{ℓ_k} to T_{ℓ_k}. The entries remain C^1 and separated because the central cube embeds in the torus and the supports are compact in it. Thm. YM3_I:AS and YM3_I:(2216) give the limit $\mathsf{B}(\ell_k, b; X)$ both at fixed label and along convergent labels, for any sequence of cutoffs tending to infinity. Cor. YM3_I:74.2 gives $\mathfrak{d}_b \subset \mathfrak{d}(g)$. Thus the table of Prop. YM3_I:91.13 bounds the cutoff cumulants at all sides in the stated range and passes to their limits. Symmetry and multilinearity on separated supports also pass to the limit. Every fixed tuple eventually has support in Q_{ℓ_k}.

For any cutoffs $K'_k \geq \kappa(k)$, the cutoff error at every member of the countable family tends to zero, since a fixed member lies in $\mathfrak{F}_k$ for all sufficiently large k. The same holds at each tuple X. To see this, enclose the supports of its entries in pairwise disjoint finite unions of closed rational cubes as in Lem. 18.167, and approximate the entries in $\|\cdot\|_\sharp$ by the dense countable family on these sets. The table at g bounds both multilinear forms uniformly there, since the supports have one positive separation and one finite radius bound and the sides eventually exceed $16n(R+1)$. Telescoping the multilinear forms one entry at a time bounds the approximation error uniformly in all sufficiently large k. This proves the cutoff error tends to zero at X.

On any infinite set of indices the same table makes the cutoff cumulants bounded at every member of the countable family. Successive subsequences and the diagonal subsequence give their joint convergence on that family. The approximation argument just given shows convergence at all tuples. The triples $(K'_k, \ell_k, L^{K'_k} b)$ have cutoffs and sides tending to infinity and label exactly b. Hence along the selected indices their limit is in $\mathrm{GT}_b \subset \mathcal{K}(g)$, and the vanishing cutoff error gives the same limit for the torus limits. This proves (a) and nonemptiness of $\mathrm{SF}(b)$. On any already convergent subsequence of the torus limits, the same cutoff-error estimate identifies the limit for the triples with every such choice of K'_k, proving (b). □

Proposition 18.175 (The cutoff removed first on each torus: one torus sequence for all subsequences)**.** Use the setting of Definition 18.164, let $0 < g \leq \gamma$, let $\ell_k \in \mathfrak{L}(g)$, $k \in \mathbb{N}$, be sides with $\ell_k \to \infty$ and $b_k \in I(g)$, $k \in \mathbb{N}$, labels that may depend on k, and let $\kappa(k)$ be the numbers of Definition 18.172(3).

(a) *One choice of cutoffs.* For every choice of cutoffs $K_k \geq \kappa(k)$, every $n \geq 2$ and every $X \in \mathfrak{S}_n(\mathbb{R}^3)$, $\mathsf{a}(K_k, \ell_k, L^{K_k} b_k; X) - \mathsf{B}(\ell_k, b_k; X) \to 0$ as $k \to \infty$ along the full sequence of indices; the second term is formed for the k with $X \in \mathfrak{S}_n(Q_{\ell_k})$, which are all large k.

(b) *The same subsequences and the same limits.* For such cutoffs $\zeta_k = (K_k, \ell_k, L^{K_k} b_k)$ is a torus sequence at g whose member of index k has the label b_k. Indices $k_1 < k_2 < \cdots$ make $\mathsf{B}(\ell_{k_l}, b_{k_l}; X)$ converge for every $n \geq 2$ and $X \in \mathfrak{S}_n(\mathbb{R}^3)$ if and only if they make $\mathsf{a}(\zeta_{k_l}; X)$ converge for every $n \geq 2$ and $X \in \mathfrak{S}_n(\mathbb{R}^3)$, and then the two limits are equal. Every infinite set of indices contains such indices, and they can be taken such that $(b_{k_l})_l$ converges.

(c) *The limits and their labels.* Every limit S as in (b) is a member of $\mathrm{GT}(g) \subset \mathcal{K}(g)$, defined by the torus sequence $(\zeta_{k_l})_l$; every limit point of $(b_{k_l})_l$ lies in $[g^{-2} + \bar{B}, X_g - \bar{B}]$ and is a label of S.

(d) *One label.* Let $b \in I(g)$ and $b_k = b$ for every k. The members of $\mathrm{SF}(b)$ taken along subsequences of (ℓ_k) are exactly the limits of the convergent subsequences of (ζ_k), a torus sequence over $\mathfrak{d}_b$ all of whose members have the label b, each limit being the member taken along the corresponding sides; they lie in GT_b. And $\mathrm{SF}(b)$ is the set of the limits of the convergent torus sequences $(K_k, \ell_k, L^{K_k} b)_k$ over $\mathfrak{d}_b$, with sides $\ell_k \in \mathfrak{L}(g)$ tending to infinity, whose cutoffs satisfy $K_k \geq \kappa(k)$ for the numbers $\kappa(k)$ formed from their own sides at the label b.

■

Proof. The fixed-side convergence, the cutoff-error argument and the uniform table bound in the preceding proof apply with b_k at index k. In particular all pairs $(K, L^K b_k)$ are in $\mathfrak{d}(g)$, and the table does not depend on b_k. This proves (a). The difference tends to zero on every subsequence, so it identifies the convergent subsequences and their limits. The same countable diagonal extraction works in every infinite set of indices. On the selected subsequence, compactness of $[g^{-2} + \bar{B}, X_g - \bar{B}]$ allows a further subsequence on which the labels converge, proving (b).

The triples realizing the limit prove membership in $\mathrm{GT}(g) \subset \mathcal{K}(g)$. If their labels have a limit point, take a further subsequence tending to that point. It still realizes the same limit, and the limit point is thus a label of the limit by Definition 18.172(4). This proves (c). For fixed b, every realizing triple has exactly that label, so the same equivalence applies within GT_b. Every member of $\mathrm{SF}(b)$ is obtained this way by taking its own sides and choosing $K_k = \kappa(k)$. Conversely, any convergent sequence with cutoffs at least these thresholds has the same limit as the torus limits on its sides, by (a). This proves (d). □

18.19. **Disjoint events in closed cubes whose edges are half as long as those of a periodic cube, cylinders at a label, and a lattice gap carried to the volume-first limits.** Proposition 18.178 lives on one lattice, at every spacing $a > 0$ and every $\beta \geq 0$: for every integer $N \geq 3$, odd or even, and every closed cube with faces parallel to the coordinate planes and edges of length $Na/2$, wherever its faces lie, the eighth powers of the probabilities that periodic Gibbs states give to mutually exclusive events of the bonds of the cube add up to at most $e^{\delta(N^3)}$, $\delta(N^3)$ being the free energy excess of the periodic box N^3; the bound holds as well for boxes with three different sides and for non-negative functions whose sum is at most 1; the mean of every such function is at most $e^{\delta/8}$ times the eighth root of the mean, on the periodic box, of the product of its eight mirror copies; and the number of pairwise mutually singular periodic Gibbs states is at most the lower limit of $e^{\delta(N^3)}$ over all integers $N \geq 3$. Proposition 18.180 gives the cylinder limits at a label $\mathsf{b} \in I(g)$ and over cross-sections given by their lengths: the laws of the long boxes have one limit, the cylinder law; the limit points of the cylinder laws along growing cross-sections are periodic Gibbs states; their continuum limits are invariant under all Euclidean motions, positive under reflections, and mixtures of Wightman theories each of which has a single vacuum; and the upper limit m of the second level of the sector without flux bounds the semigroup at the mirror, with the constant 1, and is a gap in the spectrum of the generator of that semigroup, the vacuum being single, when it is positive. Proposition 18.189 concerns any volume-first limit S at a coupling $0 < g \leq \gamma$, any defining sequence of states $(K_j, \beta_j, \nu_j)_j$ and any canonical decomposition of σ_S. Let T_{ν_j} be the transfer operator of the reconstruction of ν_j at the plane $\{x_3 = \frac{1}{2} a_{K_j}\}$, restricted to the closed span of the classes of the polynomials in the plaquette variables, and let $e^{-m_{\mathrm{lat}}(\nu_j)}$ be its norm on the orthogonal complement of its invariant vectors there. If $m = \liminf_j m_{\mathrm{lat}}(\nu_j)/a_{K_j}$ is positive, then m is at most a number M_g^* that depends only on the radius, the constants and g; neither H_S nor the operator H of any component has spectrum in $(0, m)$; the energy-momentum spectrum of each component is contained

in $\{0\} \cup \{E > 0,\ E^2 - |q|^2 \geq m^2\}$; each component clusters at the rate m, with constants that do not depend on the component; and if the lattice vacua are simple along an infinite set of indices, then $\ker H_S = \mathbb{C}\Omega_S$ and the only component of σ_S is σ_S itself. Proposition 18.190 draws the same conclusions from the norms of the transfer operators on any closed invariant subspace that contains these classes, for instance on the gauge-invariant sector or on the whole space, and when the vacua are simple there it puts the energy-momentum spectrum of σ_S itself into that set.

The crossing operators in Lemma 18.177 handle site and bond walls in one formula. For Proposition 18.178, reflection positivity at coordinate planes is Proposition YM3_I:103.4. The finite-volume conditional densities and a surface bound give the passage from the state to the periodic pressure. The cylinder proof uses the ground state of a positive slice transfer operator and the Gibbs-limit reconstruction of Theorem YM3_I:AP. Propositions 18.189 and 18.190 use the site and bond reflection forms, the component two-point estimate of Corollary YM3_I:127.11, and the scalar reconstruction of Theorems YM3_I:AP and YM3_I:AO.

Definition 18.176 (Grids and slices; half-period boxes and their mirror copies)**.** Let $a > 0$ and $\beta \geq 0$. In this definition, in Lemma 18.177 and in the proof of Proposition 18.178 the sites of $a\mathbb{Z}^3$ are written ay with $y \in \mathbb{Z}^3$, and lengths along the axes are counted in units of a.

(1) A *factor* is either a *path* $[\alpha, \omega] \cap \mathbb{Z}$ with integers $\alpha < \omega$ or a *cycle* $\mathsf{C}_M = \mathbb{Z}/M\mathbb{Z}$ with $M \geq 3$. A *grid* is a product $\Lambda = \Lambda_1 \times \Lambda_2 \times \Lambda_3$ of three factors, and a *slice* a product of two. The bonds of a grid are the pairs $\{y, y + e_\mu\}$ of two of its points, no bond leaving the last point of a path upwards, and its plaquettes are the elementary squares $p_{\mu\nu}(y)$, $\mu < \nu$, whose four corners are points of the grid; the same words apply to a slice, and $|\mathsf{Bd}(\Sigma)|$ is the number of the bonds of a slice Σ, at most $2n_1n_2$ if its two factors have n_1 and n_2 points. For a bounded Borel function Ψ of the variables of the bonds of a grid Λ we put $Z_\Lambda[\Psi] = \int \Psi \exp[-\beta \sum_p a_p]\, dU$, the sum running over the plaquettes of Λ and the integral over the product of the Haar probability measures of its bonds. The grid of three cycles C_{N_μ} is the periodic box $\underline{N}$, and $Z_\Lambda[\Psi] = Z(\underline{N})\langle\Psi\rangle_{\underline{N}}$ where $Z(\underline{N}) = Z_\Lambda[1]$ and $\langle\cdot\rangle_{\underline{N}}$ is the normalized Wilson expectation.

(2) Let Σ be a slice and $\Lambda = \Lambda_1 \times \Sigma$ a grid, its first factor serving as the time. Let u_y be the field of the layer $y \in \Lambda_1$ and τ_y the field of the oriented bonds from that layer to $y+1$. Write $A^{(0)}(u)$ for the sum of the plaquette actions in the layer. For $b = \langle x, x'\rangle$ a positive bond in Σ, the plaquette crossing to the next layer contributes $1 - \frac{1}{2}\operatorname{tr}(u_b \tau_{x'} (u'_b)^{-1} \tau_x^{-1})$. Let $A_\times(u, \tau, u')$ be the sum of these terms. Then $\sum_p a_p = \sum_y A^{(0)}(u_y) + \sum_y A_\times(u_y, \tau_y, u_{y+1})$, with the second sum over the bonds of the first factor. $\mathcal{H}_\Sigma$ is the space of the square-integrable functions of the field u of one layer, with the Haar probability measure du; the *crossing operator* K_Σ of the slice is the integral operator on $\mathcal{H}_\Sigma$ with the kernel $K_\Sigma(u, u') = \int e^{-\beta A_\times(u,\tau,u')}\, d\tau$.

(3) Let $N \geq 3$ be an integer. A *half-period interval* of the length $N/2$ is an interval $J = [c^-, c^+]$ with $c^\pm \in \frac{1}{2}\mathbb{Z}$ and $c^+ - c^- = N/2$. Its *walls* are the numbers $c_j = c^- + jN/2$, $j \in \mathbb{Z}$; a wall is a *site wall* if it is an integer and a *bond wall* otherwise; and $J_j = [c_j, c_{j+1}]$, so that $J_0 = J$. If N is even, all walls are of the kind of c^-; if N is odd, the two kinds alternate. The maps ρ_j of $\mathbb{Z}$ onto itself are $\rho_j(y) = y + jN/2$ for even j and $\rho_j(y) = 2c^+ + (j-1)N/2 - y$ for odd j. Then ρ_j carries $J_0 \cap \mathbb{Z}$ onto $J_j \cap \mathbb{Z}$, $\rho_{j+2} = \rho_j + N$, and the reflection $\vartheta_i(y) = 2c_i - y$ in the wall c_i satisfies $\vartheta_i \circ \rho_k = \rho_{2i-1-k}$ for all $i, k \in \mathbb{Z}$. The set $J \cap \mathbb{Z}$ has $\lfloor c^+ \rfloor - \lceil c^- \rceil + 1 \geq 2$ points.

(4) A *half-period box* of the lengths $N_\mu/2$, $N_\mu \geq 3$ integers, is a product $C' = J^{(1)} \times J^{(2)} \times J^{(3)}$ of half-period intervals, $J^{(\mu)}$ of the length $N_\mu/2$ and placed on the axis μ. For $\mathbf{k} \in \mathbb{Z}^3$ the map $\rho_\mathbf{k} = \rho^{(1)}_{k_1} \times \rho^{(2)}_{k_2} \times \rho^{(3)}_{k_3}$, read as $ay \mapsto a\rho_\mathbf{k}(y)$, is an isometry of $a\mathbb{Z}^3$, a translation of the lattice composed with coordinate reflections, and $C'_\mathbf{k} = \rho_\mathbf{k} C'$. The bonds of a closed set are the bonds both ends of which lie in it. For a bounded Borel function F of the bonds of C', $F^{[\mathbf{k}]} = \rho_\mathbf{k} F$, where $(\rho F)(U) = F(\rho^{-1}U)$, is a function of the bonds of $C'_\mathbf{k}$. On a grid whose factor in the direction μ is the cycle of the length $m_\mu N_\mu/2$, m_μ even, the boxes $C'_\mathbf{k}$ with

$0 \le k_\mu < m_\mu$ fill one period, $F^{[\mathbf{k}]}$ is evaluated at the periodic extension of a configuration of the grid, and it depends on k_μ modulo m_μ alone, because $\rho_{j+2} = \rho_j + N_\mu$.

■

Lemma 18.177 (One direction: walls that are shared or crossed; the cycle and the path)**.** Let Σ be a slice and $\beta \ge 0$.

(a) K_Σ is continuous and symmetric, with values in $[e^{-2\beta|\mathsf{Bd}(\Sigma)|}, 1]$, and $\mathsf{K}_\Sigma \ge 0$.

(b) Let J be a half-period interval of the length $N/2$ on the first axis, $\Gamma \ge 0$ a bounded Borel function of the bonds of $(J \cap \mathbb{Z}) \times \Sigma$, and $\Gamma^{[j]} = (\rho_j \times \mathrm{id})\Gamma$. There is a positive operator Q of trace class on $\mathcal{H}_\Sigma$, formed from Γ, J, Σ and β, such that for every even integer $m \ge 2$

$$Z_{\mathsf{C}_{mN/2}\times\Sigma}\Big[\prod_{j=0}^{m-1}\Gamma^{[j]}\Big] = \operatorname{Tr}\mathsf{Q}^{m/2} \;\le\; \Big(Z_{\mathsf{C}_N\times\Sigma}\big[\Gamma^{[0]}\Gamma^{[1]}\big]\Big)^{m/2}.$$

(c) In (b), let $\mathsf{l}_m = [c_0, c_m] \cap \mathbb{Z}$ be the path from the wall $c_0 = c^-$ to the wall c_m. Then

$$Z_{\mathsf{l}_m\times\Sigma}\Big[\prod_{j=0}^{m-1}\Gamma^{[j]}\Big] \;\le\; e^{2\beta|\mathsf{Bd}(\Sigma)|\varsigma}\, Z_{\mathsf{C}_{mN/2}\times\Sigma}\Big[\prod_{j=0}^{m-1}\Gamma^{[j]}\Big],$$

with $\varsigma = 0$ if c^- is a site wall and $\varsigma = 1$ if it is a bond wall.

The same holds with the second or the third axis as the time. ■

Sketch. Step 1: the crossing operator. The substitution $\tau \mapsto \tau^{-1}$ keeps Haar measure, and $A_\times(u,\tau,u') = A_\times(u',\tau^{-1},u)$, because an element of SU(2) and its inverse have the same trace and the trace is cyclic; so K_Σ is symmetric. Each of the $|\mathsf{Bd}(\Sigma)|$ terms of $A_\times$ lies in $[0,2]$ and $d\tau$ is a probability measure, which gives the bounds; the integrand is continuous on a compact space. For the bond b from x to x' put $(u^\tau)_b = \tau_x^{-1} u_b \tau_{x'}$, and let $k_0(u,u') = \prod_b e^{-\beta(1-\frac12 \operatorname{tr} u_b u_b'^{-1})}$. Then $e^{-\beta A_\times(u,\tau,u')} = k_0(u^\tau, u')$; k_0 is positive as an integral operator. Indeed $\operatorname{tr}(gg'^{-1}) = \sum_{i,j} g_{ij}\overline{g'_{ij}}$ for $g, g' \in \mathrm{SU}(2)$. Expand each exponential of this trace in its power series and take the product over the bonds. The result is a uniformly absolutely convergent sum of kernels $d_\alpha \phi_\alpha(u)\overline{\phi_\alpha(u')}$, where $d_\alpha \ge 0$ and the ϕ_α are products of matrix entries. Integration against $\overline{\psi(u)}\psi(u')$ gives $\sum_\alpha d_\alpha |\langle \phi_\alpha, \psi\rangle|^2 \ge 0$ for bounded Borel ψ. The kernel is bounded, and such functions are dense in $\mathcal{H}_\Sigma$, so its integral operator K_0 is positive; and $k_0(u^\tau, u'^\tau) = k_0(u,u')$, while $u \mapsto u^\tau$ keeps Haar measure. With $(R_\tau\psi)(u) = \psi(u^\tau)$ and the orthogonal projection $\Pi_{\mathrm{g}} = \int R_\tau \, d\tau$ onto the gauge-invariant functions, K_0 commutes with every R_τ and $\mathsf{K}_\Sigma = \Pi_{\mathrm{g}}\mathsf{K}_0 = \Pi_{\mathrm{g}}\mathsf{K}_0\Pi_{\mathrm{g}} \ge 0$. The argument uses the same crossing action for a path or a periodic slice.

Step 2: the kernel of a cell. Let $y^- = \lceil c^- \rceil$ and $y^+ = \lfloor c^+ \rfloor$ be the first and the last point of $J \cap \mathbb{Z}$, and let $\varpi_y = 1$ for $y^- \le y \le y^+$, except that $\varpi_{y^\pm} = \frac12$ when $c^\pm$ is a site wall. Let $k_J(u,u')$ be the integral of

$$\Gamma \, \exp\Big[-\beta \sum_{y=y^-}^{y^+} \varpi_y A^{(0)}(u_y) - \beta \sum_{y=y^-}^{y^+-1} A_\times(u_y, \tau_y, u_{y+1})\Big]$$

over the fields u_y, $y^- < y < y^+$, and τ_y, $y^- \le y < y^+$, at $u_{y^-} = u$ and $u_{y^+} = u'$. It is a Borel function with $0 \le k_J \le \sup\Gamma$; its operator A is Hilbert–Schmidt, and A^* has the kernel $k_J(u',u)$. Let $\mathsf{B}^\pm$ be the identity if $c^\pm$ is a site wall and K_Σ if it is a bond wall; $\mathsf{B}^\pm \ge 0$ by (a).

Step 3: the cycle; (b). On $\mathsf{C}_{mN/2} \times \Sigma$ the walls $c_0, \dots, c_{m-1}$ cut the first factor into the images $J_j \cap \mathbb{Z}$, $0 \le j < m$, of $J \cap \mathbb{Z}$, and the cell j carries $\Gamma^{[j]}$. If j is odd, ρ_j puts the layers in the opposite order, and $\Gamma^{[j]}$ uses the field of the layer $\rho_j(y)$ in the role of u_y and, in the role of τ_y, the inverse of the field of the bonds going from the layer $\rho_j(y) - 1$ to the layer $\rho_j(y)$; after the change of variables $\tau \mapsto \tau^{-1}$, and with the symmetry of $A_\times$ from Step 1, the product of $\Gamma^{[j]}$ and the weight of the cell, integrated over the inner layers of the cell and over its fields τ, equals $k_J(u_{\rho_j(y^-)}, u_{\rho_j(y^+)})$; if j is

even, the same is true, a translation replacing the reversal. A layer on a site wall belongs to the two cells that meet there, each of which gives it one half of its action, and both functions may read its bonds; the bonds that cross a bond wall belong to no cell, and their integral gives the factor K_Σ. The walls c_j with odd j are the images of c^+ under ρ_{j-1} and ρ_j, those with even j the images of c^-. Integrating first inside the cells (Fubini's theorem), with $u_j^- = u_{\rho_j(y^-)}$ and $u_j^+ = u_{\rho_j(y^+)}$,

$$Z_{\mathsf{C}_{mN/2}\times\Sigma}\Big[\prod_{j=0}^{m-1}\Gamma^{[j]}\Big] = \int k_J(u_0^-,u_0^+)\,B^+(u_0^+,u_1^+)\,k_J(u_1^-,u_1^+)$$
$$\times\, B^-(u_1^-,u_2^-)\,k_J(u_2^-,u_2^+)\cdots k_J(u_{m-1}^-,u_{m-1}^+)\,B^-(u_{m-1}^-,u_0^-),$$

where $B^\pm$ stands for the kernel K_Σ at a bond wall and for the identification of its two arguments at a site wall, and the integral runs over the remaining fields. This is $\mathrm{Tr}\big((\mathsf{A}\mathsf{B}^+\mathsf{A}^*\mathsf{B}^-)^{m/2}\big)$, the trace of a product of integral operators being the cyclic integral of their kernels; by the cyclicity of the trace it equals $\mathrm{Tr}\,\mathsf{Q}^{m/2}$ with $\mathsf{G} = (\mathsf{B}^-)^{1/2}\mathsf{A}(\mathsf{B}^+)^{1/2}$ and $\mathsf{Q} = \mathsf{G}\mathsf{G}^* \geq 0$, an operator of trace class. With the eigenvalues $\mathsf{q}_i \geq 0$ of Q, $\sum_i \mathsf{q}_i^{m/2} \leq (\sum_i \mathsf{q}_i)^{m/2}$, and at $m = 2$ the number $\mathrm{Tr}\,\mathsf{Q}$ is $Z_{\mathsf{C}_N\times\Sigma}[\Gamma^{[0]}\Gamma^{[1]}]$. This is (b).

Step 4: the path; (c). The path l_m holds the cells $J_0 \cap \mathbb{Z}, \dots, J_{m-1} \cap \mathbb{Z}$ and differs from the cycle at the wall $c_0 \equiv c_m$ alone. If c^- is a bond wall, the path has the layers of the cycle and all its bonds except those that cross this wall, so its integral is that of the display of Step 3 without the factor $B^-(u_{m-1}^-,u_0^-) = K_\Sigma(u_{m-1}^-,u_0^-) \geq e^{-2\beta|\mathsf{Bd}(\Sigma)|}$, all factors being ≥ 0. If c^- is a site wall, the path has two end layers, with the fields u_0^- and u_{m-1}^-, each of which lies in one cell only, which gives it one half of its action, while the grid gives it the whole; with $\chi = e^{-\frac{\beta}{2}A^{(0)}}$, $0 < \chi \leq 1$, $\|\chi\| \leq 1$, and since B^- is then the identity, the integral over the path is $\langle \chi, (\mathsf{A}\mathsf{B}^+\mathsf{A}^*)^{m/2}\chi\rangle = \langle \chi, \mathsf{Q}^{m/2}\chi\rangle \leq \|\mathsf{Q}^{m/2}\| \leq \mathrm{Tr}\,\mathsf{Q}^{m/2}$. This is (c). □

Proposition 18.178 (Mutually exclusive events in a closed box with the edges $N_\mu a/2$, $N_\mu \geq 3$ integers of either parity, against the free energy excess of the periodic box $\underline{N}$)**.** Let $a > 0$ and $\beta \geq 0$, let $N_1, N_2, N_3 \geq 3$ be integers, $\underline{N} = (N_1, N_2, N_3)$, and let P be the limit of $|\underline{M}|^{-1}\log Z(\underline{M})$ as the least side of the periodic box grows. The existence and shape independence of P are proved below. The excess is $\delta(\underline{N}) = \log Z(\underline{N}) - |\underline{N}|P$, where $|\underline{N}| = N_1N_2N_3$, and $\delta(N^3)$ denotes the excess of the cube.

(a) For every $z \in \mathbb{R}^3$ there is a half-period box C' of the lengths $N_\mu/2$ whose bonds include the bonds of the closed box $C = \prod_\mu [z_\mu, z_\mu + N_\mu a/2]$.

(b) For every half-period box C' of the lengths $N_\mu/2$, every periodic Gibbs state ν at (a,β) and every bounded Borel function $F \geq 0$ of the bonds of C',

$$\nu(F)^8 \;\leq\; e^{\delta(\underline{N})}\Big\langle \prod_{\mathbf{k}\in\{0,1\}^3} F^{[\mathbf{k}]}\Big\rangle_{\underline{N}} \;\leq\; e^{\delta(\underline{N})}\,\langle F^8\rangle_{\underline{N}},$$

the functions $F^{[\mathbf{k}]}$ being evaluated on the periodic box $\underline{N}$ as in Definition 18.176(4).

(c) For every closed box C as in (a), every integer $r \geq 1$, any periodic Gibbs states $\nu_1, \dots, \nu_r$ at (a,β), equal or different, and any bounded Borel functions $F_1, \dots, F_r \geq 0$ of the bonds of C with $\sum_s F_s \leq 1$,

$$\sum_{s=1}^r \nu_s(F_s)^8 \;\leq\; e^{\delta(\underline{N})} = Z(\underline{N})\,e^{-|\underline{N}|P}.$$

In particular $\sum_s \nu_s(A_s)^8 \leq e^{\delta(\underline{N})}$ for pairwise disjoint Borel events $A_1, \dots, A_r$ of the bonds of C. For cubes: at a pair (a_K,β), whose label is $\mathsf{b} = a_K\beta$, for every integer $N \geq 3$ and every closed cube $\prod_\mu [z_\mu, z_\mu + q]$ with $q = Na_K/2$, all periodic Gibbs states $\nu_1, \dots, \nu_r$ and all pairwise disjoint Borel events $A_1, \dots, A_r$ of the bonds of that cube satisfy $\sum_s \nu_s(A_s)^8 \leq \exp\delta(N^3)$, where $\delta(N^3)$ belongs to the periodic box with $N = 2q/a_K$ sites along each axis.

(d) If $\nu_1, \dots, \nu_r$ are pairwise mutually singular periodic Gibbs states at (a, β), then $r \le \liminf_{N\to\infty} e^{\delta(N^3)}$, the lower limit being taken over all integers $N \ge 3$.

■

Sketch. Step 1: (a). Along one axis, in units of a, the integers of $[z, z+N/2]$ are $\lceil z\rceil, \dots, \lfloor z+N/2\rfloor$. If $N = 2n$ and $z \in \mathbb{Z}$, the interval $J = [z, z+n]$ holds them. If $N = 2n$ and $z \notin \mathbb{Z}$, then $\lfloor z+n\rfloor = \lceil z\rceil + n - 1$, and $J = [\lceil z\rceil - \frac12, \lceil z\rceil + n - \frac12]$ holds them. If $N = 2n+1$, then $z+n+\frac12 < \lceil z\rceil + n + 1$, and $J = [\lceil z\rceil, \lceil z\rceil + n + \frac12]$ holds them. Each of these intervals is a half-period interval of the length $N/2$. A bond lies in a closed box if and only if both its ends do; so every bond of C is a bond of the product C' of the three intervals.

Step 2: Schwarz's inequality at the walls. Let ν be a periodic Gibbs state. The planes $\{x_\mu = ac_j^{(\mu)}\}$ are lattice mirrors, through sites or through midpoints of bonds, and ν is reflection positive at each of them for the bounded Borel functions of finitely many bonds in one closed side (Proposition YM3_I: 103.4). For such a function $G \ge 0$ and the reflection θ in the plane, Schwarz's inequality for the positive form $(G_1, G_2) \mapsto \nu(\overline{\theta G_1}\, G_2)$, at $G_1 = 1$, gives $\nu(G)^2 \le \nu(\theta G \cdot G)$. Let G be the product of the $F^{[\mathbf{k}]}$ over a set of indices that is a product of sets of consecutive integers, with $\{0, \dots, \omega\}$ in the direction μ; it is a function of bonds in $\{x_\mu \le ac_{\omega+1}^{(\mu)}\}$. Since $\vartheta_{\omega+1} \circ \rho_k = \rho_{2\omega+1-k}$, and since the pull-back action on functions composes in the same order as the isometries, $\theta G \cdot G$, for the reflection in the plane $\{x_\mu = ac_{\omega+1}^{(\mu)}\}$, is the product over the same set with $\{0, \dots, 2\omega+1\}$ in the direction μ. Starting from $\{0\}$ and doubling r times in each of the three directions,

$$\nu(F)^{8^r} \;\le\; \nu(\Psi_r), \qquad \Psi_r = \prod_{\mathbf{k}\in\{0,\dots,2^r-1\}^3} F^{[\mathbf{k}]}.$$

Step 3: from the state to a grid of paths, and to the torus. Let $r \ge 1$, $M_\mu = 2^{r-1}N_\mu$, and let Λ be the grid of the three paths $[c_0^{(\mu)}, c_{2^r}^{(\mu)}] \cap \mathbb{Z}$. It has M_μ points in the direction μ if $c_0^{(\mu)}$ is a bond wall and $M_\mu + 1$ if it is a site wall, the two end walls being of one kind; Ψ_r is a function of the finite set B of the bonds of Λ; and we put $s = 1 + \max_\mu M_\mu$. The Gibbs conditional law $\gamma_B(\,\cdot \mid \omega)$ has density proportional to $\exp[-\beta \sum_{p: p\cap B\neq\varnothing} a_p(U_B\omega)]$ against Haar measure on the bonds of B. Here $p \cap B \neq \varnothing$ means that p uses a bond in B. Consequently $\nu(\Psi_r) = \nu(\gamma_B(\Psi_r|\cdot))$. Besides the plaquettes of Λ, the plaquettes that hold a bond of B are those that hold a bond of one of the six outermost layers of Λ and leave Λ across that layer: at most $12s^2$ of them, each with $0 \le a_p \le 2$. Hence $\gamma_B(\Psi_r|\omega) \le e^{24\beta s^2} Z_\Lambda[\Psi_r]/Z_\Lambda[1]$ for every configuration ω outside B. Lemma 18.177(c), applied in the first direction with Σ the slice formed by the two other paths and with $\Gamma = \prod_{k_2,k_3} F^{[(0,k_2,k_3)]}$, whose images are $\Gamma^{[j]} = \prod_{k_2,k_3} F^{[(j,k_2,k_3)]}$, lets us exchange the first path for the cycle C_{M_1} at the cost of a factor not exceeding $e^{2\beta|\mathsf{Bd}(\Sigma)|} \le e^{4\beta s^2}$; the second and then the third path are replaced in the same manner, the functions being considered on the periodic extension along the directions that have already been closed. If in a direction the grid has $M_\mu + 1$ points, removing its last layer in that direction removes at most $3s^2$ plaquettes, each with $e^{-\beta a_p} \ge e^{-2\beta}$, and bonds that are integrated with probability measures; the periodic box $\underline{M} = (M_1, M_2, M_3)$ has all bonds and plaquettes of the grid so reduced and others, each with $e^{-\beta a_p} \le 1$. So $Z_\Lambda[1] \ge e^{-18\beta s^2} Z(\underline{M})$. With $\mathcal{Z}(\underline{m}) = Z_{\prod_\mu \mathsf{C}_{m_\mu N_\mu/2}}[\prod_{0\le k_\mu < m_\mu} F^{[\mathbf{k}]}]$ for even $m_\mu \ge 2$,

$$\nu(F)^{8^r} \;\le\; e^{54\beta s^2}\, \mathcal{Z}(2^r, 2^r, 2^r)\,/\,Z(\underline{M}).$$

Step 4: on the tori. By Lemma 18.177(b) in the first direction, with the slice $\mathsf{C}_{m_2N_2/2} \times \mathsf{C}_{m_3N_3/2}$ and $\Gamma = \prod_{k_2<m_2,\, k_3<m_3} F^{[(0,k_2,k_3)]}$, $\mathcal{Z}(m_1, m_2, m_3) \le \mathcal{Z}(2, m_2, m_3)^{m_1/2}$; then in the second and in the third direction. So $\mathcal{Z}(2^r, 2^r, 2^r) \le \mathcal{Z}(2,2,2)^{8^{r-1}}$, and $\mathcal{Z}(2,2,2) = Z(\underline{N})\langle \prod_{\mathbf{k}\in\{0,1\}^3} F^{[\mathbf{k}]}\rangle_{\underline{N}}$.

Step 5: the limit; (b). Taking the root of the order 8^{r-1} gives

$$\nu(F)^8 \le e^{54\beta s^2/8^{r-1}}\, \mathcal{Z}(2,2,2)\, Z(\underline{M})^{-1/8^{r-1}}.$$

Here $s \le 2^r \max_\mu N_\mu$, so that $54\beta s^2/8^{r-1} \le 432\,\beta \max_\mu N_\mu^2\, 2^{-r} \to 0$; and $|\underline{M}| = 8^{r-1}|\underline{N}|$.

For the pressure limit, fix an integer $n \ge 3$ and partition each axis of an open rectangular grid of side lengths M_μ into intervals of n sites and a possible shorter terminal interval. Deleting plaquettes crossing the resulting cuts factors its partition function into those of the smaller open grids. There are at most $2|\underline{M}|/n$ deleted plaquettes per axis, since a cut meets at most two crossing plaquettes per site in its cross-section and there are at most M_μ/n cuts along axis μ. As $0 \le a_p \le 2$, the deletion changes the logarithm per site by at most $12\beta/n$. For fixed n the fraction of sites in blocks with a short side goes to zero as $\min_\mu M_\mu$ grows. The normalized logarithms of all the block partition functions lie in $[-6\beta, 0]$, since the number of plaquettes is at most three per site. Thus the upper and lower limits of the normalized open-grid logarithm differ by at most $12\beta/n$. This difference vanishes as $n \to \infty$. Closing the grid removes no old plaquette and adds at most $2|\underline{M}| \sum_\mu M_\mu^{-1}$ plaquettes across the periodic seams. The normalized change tends to zero by the same comparison of weights. This proves $\log Z(\underline{M})/|\underline{M}| \to P$ along every sequence with least side tending to infinity. Therefore $Z(\underline{M})^{-1/8^{r-1}} \to e^{-|\underline{N}|P}$, and the first inequality of (b) follows. The second is Hölder's inequality with eight factors: on the periodic box $\underline{N}$ the map $\rho_{\mathbf{k}}$ acts in each direction as $y_\mu \mapsto \pm y_\mu + \text{const}$ modulo N_μ, which keeps the action and the Haar measures, so that $\langle (F^{[\mathbf{k}]})^8 \rangle_{\underline{N}} = \langle F^8 \rangle_{\underline{N}}$.

Step 6: (c). By (a), the F_s are functions of the bonds of C'. All $F_s^{[\mathbf{k}]}$ are ≥ 0, and $1 \ge \prod_{\mathbf{k}} \sum_s F_s^{[\mathbf{k}]} \ge \sum_s \prod_{\mathbf{k}} F_s^{[\mathbf{k}]}$, the terms with one and the same s in every factor being a part of the expansion of the product. So (b), summed over s, gives (c). For the cube, $N_\mu = N$ and $C = \prod_\mu [z_\mu, z_\mu + q]$, and the excess is that of the cube N^3 at (a_K, β).

Step 7: (d). Pairwise mutually singular laws have pairwise disjoint Borel sets E_s with $\nu_s(E_s) = 1$. Let $\epsilon > 0$ and $\bar\nu = \frac{1}{r}\sum_s \nu_s$. The events of finitely many bonds form an algebra that generates the Borel sets, so there are events A'_s of one finite set of bonds with $\bar\nu(A'_s \triangle E_s) < \epsilon$; as $\nu_s \le r\bar\nu$, the events $A_s = A'_s \setminus \bigcup_{s' \ne s} A'_{s'}$ are pairwise disjoint and $\nu_s(A_s) \ge 1 - r\epsilon - (r-1)r\epsilon \ge 1 - r^2\epsilon$. For every large N some closed cube $\prod_\mu [z_\mu, z_\mu + Na/2]$ holds that finite set of bonds, and (c) gives $r(1 - r^2\epsilon)^8 \le e^{\delta(N^3)}$. Let $N \to \infty$ along a sequence that realises the lower limit, and then $\epsilon \to 0$. □

Definition 18.179 (Cylinder data and the space at the mirror)**.** Use the construction constants, the first-passage set $\mathfrak{d}(g)$ and the interval $I(g)$ of §YM3_I:74 and Corollary YM3_I:74.2, with $L \ge 13$ odd and $0 < g \le \gamma$. Write $a_K = L^{-K}$. On a lattice of spacing a let t_n be the translation by nae_3, and let Θ_c be reflection sending layer j to layer $c - j$, for $c \in \mathbb{Z}$. On functions the actions are pull-backs by the inverse isometries. In particular Θ_0 is the site mirror at 0 and Θ_1 the bond mirror at $a/2$. The lattice observable is $\mathcal{O}_a(f) = a^{-1} \sum_p f(x(p)) a_p$ with the plaquette barycentre $x(p)$.

For a periodic slice $\Sigma = \mathsf{C}_{N_1} \times \mathsf{C}_{N_2}$ let W be multiplication by $e^{-\beta A^{(0)}/2}$ on the one-layer space of Definition 18.176. The slice transfer is $\mathsf{T}_\Sigma = \mathsf{W}\mathsf{K}_\Sigma\mathsf{W}$. For $\mu = 1, 2$, flip the sign of every positively oriented μ-bond crossing a fixed periodic seam in direction μ. This gives two commuting unitary involutions on that space. The sector without flux is their common fixed subspace. Let λ_0 be the largest eigenvalue of T_Σ and let λ_1^{00} be the second eigenvalue in this subspace, counted with multiplicity and taken to be 0 if there is no second positive eigenvalue. Put

$$y(\Sigma) = \lambda_1^{00}/\lambda_0, \qquad E_1(\Sigma; a, \beta) = -a^{-1} \log y(\Sigma), \qquad E^K(\underline{\ell}) = E_1(\underline{\ell}/a_K; a_K, L^K \mathsf{b}).$$

Here $-\log 0 = \infty$ and $e^{-\infty \cdot 0} = 1$. The cylinder law μ_Σ is the limit of the periodic laws over Σ as the number of time layers goes to infinity. Its existence, and the ground-state facts used in the level definition, are proved below. A state through cylinders consists of a limit $\nu = \lim_k \mu_{\Sigma_k}$ with $\min \Sigma_k \to \infty$, together with the sequence of cross-sections, and its number is $m_\nu = \limsup_k E_1(\Sigma_k; a, \beta)$.

Use the centered functions and Gibbs limits of Definition 18.205. For a functional σ from Theorem YM3_I:AP, or one of its canonical components, $\mathcal{D}$ is the linear span of separated tuples

supported in $\{x_3 > 0\}$, including $\varnothing$. The reflection Hilbert space $\mathcal{H}(\sigma)$ is the completion of this space modulo the null space of the positive form $\langle X, Y\rangle_\sigma = \sigma(\Theta_0 X \cdot Y)$ on real tuples, extended sesquilinearly to their complex linear span. Write $\Omega_\sigma = [\varnothing]$ and let $H_\sigma \geq 0$ be the generator of the strongly continuous semigroup of time translations, $e^{-tH_\sigma}[F] = [\tau_{te_3}F]$. ■

Proposition 18.180 (Cylinder laws at a label: the time first, then the cross-section, then the cutoff)**.** Use Definition 18.179. Let $0 < g \leq \gamma$ and $\mathsf{b} \in I(g)$, and put $\beta_K = L^K\mathsf{b}$ for $K \in \mathbb{N}$. For $K \in \mathbb{N}$, a pair of lengths $\underline{\ell} = (\ell_1, \ell_2)$ such that ℓ_1/a_K and ℓ_2/a_K are integers ≥ 3, and $t \in a_K\mathbb{N}$ with $t \geq 3a_K$, let $\mu_{K,\underline{\ell},t}$ be the Wilson measure, as a law, of the periodic box with t/a_K layers along e_3 over the cross-section $\underline{\ell}/a_K$ at (a_K, β_K), and let $E^K(\underline{\ell})$ be the second level of the sector without flux at the cutoff K along the label b .

(1) As $t \to \infty$ the laws $\mu_{K,\underline{\ell},t}$ have exactly one weak limit point, the cylinder law $\mu^{\mathrm{cyl}}_{K,\underline{\ell}} = \mu_{\underline{\ell}/a_K}$ at (a_K, β_K); it is invariant under every t_n and every Θ_c, $n, c \in \mathbb{Z}$.

(2) Let $\underline{\ell}^{(k)}$, $k \in \mathbb{N}$, be such pairs at one cutoff K, with $\min \underline{\ell}^{(k)} \to \infty$. Then $(\mu^{\mathrm{cyl}}_{K,\underline{\ell}^{(k)}})_k$ has weak limit points. Each of them, ν, is a periodic Gibbs state at (a_K, β_K), invariant under $a_K\mathbb{Z}^3$ and under every Θ_c; with a subsequence of the $\underline{\ell}^{(k)}$ along which the cylinder laws converge to it, ν is a state through cylinders at (a_K, β_K), whose number is $m_\nu = \limsup E^K(\underline{\ell}^{(k)})$ along that subsequence; and along it $\mu^{\mathrm{cyl}}_{K,\underline{\ell}^{(k)}}(\mathcal{O}_{a_K}(f)) \to \nu(\mathcal{O}_{a_K}(f))$ and $\sigma_{\mu^{\mathrm{cyl}}_{K,\underline{\ell}^{(k)}}}(X) \to \sigma_\nu(X)$ for every bounded function f with compact support and every tuple $X = (f_1, \dots, f_n)$ of such functions; here, for a law μ on the configurations of $a_K\mathbb{Z}^3$ and such a tuple, $\sigma_\mu(X)$ is the mean under μ of $\prod_{i=1}^n(\mathcal{O}_{a_K}(f_i) - \mu(\mathcal{O}_{a_K}(f_i)))$, also the expression used on separated tuples in Definition 18.205.

(3) Let $K_j \to \infty$, and for every j let ν_j be a law as in (2) at the cutoff K_j, together with its subsequence of cross-sections. Then $(K_j, \beta_{K_j}, \nu_j)_j$ is, at the label b, a sequence through cylinders at g , hence a Gibbs sequence at g; there is a subsequence of $(\sigma_{\nu_j})_j$ that converges at each separated tuple; and whenever σ is the limit of such a subsequence and $(\mathsf{X}, \lambda, (\sigma_\xi)_{\xi\in\mathsf{X}})$ is a canonical decomposition of σ, one has $\sigma = \int \sigma_\xi\, \lambda(d\xi)$, the functional σ and each σ_ξ are reflection positive at every mirror and invariant under $\mathbb{R}^3 \rtimes \mathrm{O}(3)$, and each σ_ξ is the functional of a Wightman theory on $\mathbb{R}^{1+2}$, with a single Hermitian scalar field and a unique vacuum, and obeys (E0′)–(E4).

(4) Let $m = \limsup_j m_{\nu_j} \in [0, \infty]$, the upper limits being taken along the subsequences of cross-sections of (2) and along the subsequence of j that defines σ. Then for all $F = \sum_i \zeta_i X_i \in \mathcal{D}$ and all real $t \geq 0$, with $\varphi_F(t) = \sum_{i,k} \bar{\zeta}_i\zeta_k\, \sigma(\Theta_0 X_i \cdot \tau_{te_3}X_k)$,

$$0 \;\leq\; \varphi_F(t) - |\sigma(F)|^2 \;\leq\; e^{-mt}[\varphi_F(0) - |\sigma(F)|^2];$$

for every j the same holds with σ_{ν_j} and m_{ν_j} in the places of σ and m, at the times $t = na_{K_j}$, $n \in \mathbb{N}_0$, whenever the supports of F lie in $\{x_3 > \frac{1}{2}a_{K_j}\}$. If $m > 0$, then $\ker H_\sigma = \mathbb{C}\Omega_\sigma$ and $\operatorname{spec} H_\sigma \subset \{0\} \cup [m, \infty)$ (with $\mathcal{H}(\sigma) = \mathbb{C}\Omega_\sigma$ if $m = \infty$), every canonical decomposition of σ has a single point, and σ, undecomposed, is the functional of a Wightman theory with a unique vacuum.

(5) Let $K \in \mathbb{N}$ and $\beta > 0$. Item (2) holds at the pair (a_K, β), with the cylinder laws $\mu_{\underline{\ell}/a_K}$ and the levels $E_1(\underline{\ell}/a_K; a_K, \beta)$, both formed at (a_K, β), in the places of $\mu^{\mathrm{cyl}}_{K,\underline{\ell}}$ and of $E^K(\underline{\ell})$. Further, let $(K_j, \beta_j) \in \mathfrak{d}(g)$ with $K_j \to \infty$, and for every j let ν_j be a law as in (2) at the pair (a_{K_j}, β_j), in the sense just given, together with its subsequence of cross-sections. Then $(K_j, \beta_j, \nu_j)_j$ is a sequence through cylinders at g , and so a Gibbs sequence at g; and what (3) asserts of the subsequences of $(\sigma_{\nu_j})_j$, of their limits and of the canonical decompositions of these limits, as well as all of (4), holds for this sequence in the place of $(K_j, \beta_{K_j}, \nu_j)_j$.

■

Sketch of proof. The ground state and the cylinder. The slice transfer has a bounded continuous strictly positive kernel and is a positive Hilbert–Schmidt operator by Lemma 18.177(a). Its top eigenvalue λ_0 is positive. A real maximizer of its Rayleigh quotient can be replaced by its absolute value, which is still a maximizer. Applying the positive kernel shows that this nonnegative eigenfunction is strictly positive almost everywhere. If the top eigenvalue had multiplicity larger than one, a real eigenfunction orthogonal to this positive vector would change sign on sets of positive measure. Taking its absolute value would strictly increase its Rayleigh quotient, by strict positivity of the kernel, a contradiction. Let v_0 be the positive normalized top eigenfunction. Simultaneous seam flips on two layers preserve each crossing plaquette, which contains either none or two of the flipped bonds. The flips also preserve the plaquettes in a layer, and their substitutions preserve Haar measure. Thus they commute with T_Σ. Positivity and simplicity give v_0 in their common fixed space. In particular $y(\Sigma) < 1$.

For a bounded function A of bonds between layers α and $\alpha + d$ inclusive, take $d \geq 1$ by including an extra layer if necessary. Let $\mathsf{B}[A]$ be the operator from the layer at $\alpha + d$ to that at α with kernel given by integrating the slab weight times A over the interior layers and all its vertical bonds. The endpoint layer actions have weight $1/2$, all other actions weight 1. Then $\mathsf{B}[1] = \mathsf{T}_\Sigma^d$. On a time circle of N layers, integrating the other bonds gives the expectation

$$\frac{\operatorname{Tr}(\mathsf{B}[A]\mathsf{T}_\Sigma^{N-d})}{\operatorname{Tr}\mathsf{T}_\Sigma^N}.$$

Indeed, each shared endpoint layer supplies one half of its action to each adjacent factor, and each time bond is integrated once. The expression is valid for $N \geq d + 2$. If $\{\lambda_j\}$ are the eigenvalues of T_Σ outside its top eigenspace, their ratios to λ_0 are nonnegative, have supremum $q < 1$, and have summable squares. Thus $\lambda_0^{-k}\mathsf{T}_\Sigma^k \to |v_0\rangle\langle v_0|$ in trace norm, with error at most $q^{k-2}\sum_j(\lambda_j/\lambda_0)^2$ for $k \geq 2$. The limit of the expectation is $\lambda_0^{-d}\langle v_0, \mathsf{B}[A]v_0\rangle$. The product configuration space of the cylinder is compact and metrisable. Continuous local functions determine the weak limit, so this proves existence and uniqueness in (1). Each finite-period law is invariant under every time translation and time reflection, and the invariance passes to the limit.

The cross-section limit. Embed the cylinder laws and the periodic laws as periodic configurations on the full lattice in the periodic directions. Weak limit points of the cylinders exist by compactness of the full product space. For any convergent subsequence of cylinders, choose for its kth member a time period at least $\min \Sigma_k$ for which the weak distance from the cylinder is at most $1/k$. This is possible by (1), and the resulting periodic boxes converge to the same ν with all periods tending to infinity. Translation and reflection invariance pass to the limit. For any fixed finite bond set B, the Wilson conditional density on B uses only the finite set of plaquettes incident to B. For continuous local tests it gives continuous local functions of the exterior bonds. Those Gibbs identities are exact once the finite test and the incident plaquettes embed without identifications into the periodic box. Passing to the weak limit proves the same identities for ν. Continuous local tests determine measures, so these are the DLR identities. This proves that ν is a periodic Gibbs state. The stated observable and tuple moments are polynomials in expectations of continuous local functions and hence converge. This proves (2), and works at every (a, β) in (5).

Reflected correlation on a cylinder. Take a bounded polynomial A in plaquette actions supported in layers $\alpha, \dots, \alpha+d$ with $\alpha \geq 1$. Reflecting the slab and conjugating A replaces $\mathsf{B}[A]$ by $\mathsf{B}[A]^*$. Each plaquette action is unchanged under the seam flips, so $\mathsf{B}[A]$ commutes with them. Consequently $u = \lambda_0^{-d}\mathsf{B}[A]v_0$ belongs to the sector without flux. The two slabs in $\overline{\Theta_0 A}\,\mathsf{t}_n A$ are separated by $2\alpha + n$ steps. With $R = \lambda_0^{-1}\mathsf{T}_\Sigma$ and $u_\perp = u - \langle v_0, u\rangle v_0$, the same slab integration gives

$$\mu_\Sigma(\overline{\Theta_0 A}\,\mathsf{t}_n A) - |\mu_\Sigma(A)|^2 = \langle u_\perp, R^{2\alpha+n}u_\perp\rangle.$$

The spectrum of R on the sector without flux orthogonal to v_0 is contained in $[0, y(\Sigma)]$. The last expression is nonnegative, and its value at $n + n'$ is at most its value at n times $y(\Sigma)^{n'}$. For a state

through cylinders, use a subsequence with $E_1(\Sigma_k; a, \beta) \to m_\nu$. All fixed supports embed in those cross-sections for large k. Weak convergence passes the inequality to ν, with $y(\Sigma_k)^{n'} \to e^{-m_\nu n' a}$.

The cutoff limit. Corollary YM3_I:74.2 gives the first-passage condition $(K, L^K \mathsf{b}) \in \mathfrak{d}(g)$ for $\mathsf{b} \in I(g)$. Since every ν_j is periodic Gibbs, Theorem YM3_I:AP gives the subsequence and the conclusions of (3). For $F = \sum_i \zeta_i X_i \in \mathcal{D}$ at fixed j, take $A = \sum_i \zeta_i (X_i)^{\nu_j}_{a_{K_j}}$ using the products of centered plaquette observables in Definition 18.205. If all the test supports lie strictly above $a_{K_j}/2$, all plaquettes involved have their bonds in layers ≥ 1. By the covariance of $\mathcal{O}_a(f)$ under translations and reflection, the last cylinder inequality, passed to ν_j, is exactly (4) at lattice times. To pass to σ, use a further subsequence with $m_{\nu_j} \to m$. For each $t = pL^{-k}$, $p, k \in \mathbb{N}_0$, the lattice times equal t for all large j, and the reflected tuples are fixed separated tuples. Thus (4) passes to the limit at these times. Strong continuity of e^{-tH_σ} extends it to every $t \geq 0$.

A positive rate. Suppose $m > 0$. Letting $t \to \infty$ in (4) gives $\|P_{\ker H_\sigma}[F]\|^2 = |\sigma(F)|^2$, with $\sigma(F) = \langle \Omega_\sigma, [F] \rangle$. The classes of $\mathcal{D}$ are dense, so this proves $\ker H_\sigma = \mathbb{C}\Omega_\sigma$. After removing that component the spectral measure of each $[F]$ is positive. If it put positive mass in $(0, m')$ for some $m' < m$, its Laplace transform would be bounded below by that mass times $e^{-m't}$, contradicting (4) as $t \to \infty$. Density of the classes proves the claimed spectral inclusion, also for $m = \infty$ by taking all finite m'.

In the canonical decomposition, the reflected correlation is the integral of those of the components. In each component the projection onto zero energy is its vacuum projection by Theorem YM3_I:AP. The integrands at $t \geq 0$ are bounded by their integrable values at 0. Passing to $t = \infty$ under this integral yields $\int |\sigma_\xi(F)|^2 \, d\lambda = |\sigma(F)|^2$. Since $\int \sigma_\xi(F) \, d\lambda = \sigma(F)$, every such variance vanishes. The canonical component maps are continuous and the canonical measure has full support (Theorem YM3_I:AL), so $\sigma_\xi = \sigma$ on all tuples supported in $\{x_3 > 0\}$ for every ξ. Translation invariance extends this to all separated tuples. Injectivity of the component map gives a one-point decomposition. The reconstruction statement now follows from (3). The argument uses $\mathsf{b} \in I(g)$ only to guarantee the first-passage data and identify the fixed label. It proves all of (5) with arbitrary data in $\mathfrak{d}(g)$. □

Definition 18.181 (The transfer operator of a periodic Gibbs state at a plane of bond midpoints; sectors; the lattice gap; lattice functions; two families of numbers)**.** Let $a > 0$ and $\beta \geq 0$, and let ν be a periodic Gibbs state at (a, β).

(1) *The reconstruction at the plane* $\{x_3 = \frac{1}{2}a\}$. Let $\mathcal{F}^+$ consist of bounded Borel functions of finitely many bonds with both endpoints in layers ≥ 1. Write $\mathcal{H}_\nu$ for the completion of the quotient by the null space of $\langle F, G \rangle_\nu = \nu(\overline{\Theta_1 F} G)$ on $\mathcal{F}^+$. Positivity follows from Proposition YM3_I:103.4. Put $\Omega_\nu = [1]$. The transfer T_ν on this space has $T_\nu[F] = [\mathsf{t}_1 F]$, $0 \leq T_\nu \leq 1$ and $T_\nu \Omega_\nu = \Omega_\nu$. In particular

$$\langle [F], T_\nu^k [G] \rangle = \nu(\overline{\Theta_1 F} \, \mathsf{t}_k G), \qquad k \geq 0.$$

For these assertions, reflection conjugates translations to their inverses, and translation invariance gives $\langle \mathsf{t}_i F, \mathsf{t}_j G \rangle_\nu = \langle F, \mathsf{t}_{i+j} G \rangle_\nu$ for $i, j \geq 0$. For fixed F put $b_n = \|\mathsf{t}_n F\|_\nu$. By Cauchy–Schwarz $b_n^2 \leq b_{n-1} b_{n+1}$ for $n \geq 1$, and by invariance $b_n \leq \|F\|_{L^2(\nu)}$. If $b_0 = 0$ this forces $b_1 = 0$. If $b_1 > b_0 > 0$, the successive ratios are nondecreasing, contradicting boundedness. Thus $b_1 \leq b_0$, and the shift descends to a contraction on the quotient. The same pairing identity makes it symmetric. The relation $\Theta_2 \mathsf{t}_1 F = \Theta_1 F$ and reflection positivity at the site mirror $x_3 = a$ give $\langle F, \mathsf{t}_1 F \rangle_\nu \geq 0$. This proves positivity of the contraction, and its remaining properties follow by iteration and the constant function.

(2) *Sectors; the lattice gap.* $\mathcal{A}_a^+$ is the set of the polynomials with complex coefficients in the functions a_p of the plaquettes p contained in $\{x_3 \geq \frac{1}{2}a\}$; then $\mathcal{A}_a^+ \subset \mathcal{F}^+$ and $\mathsf{t}_1 \mathcal{A}_a^+ \subset \mathcal{A}_a^+$. A *sector* of ν is a closed subspace $\mathcal{K} \subset \mathcal{H}_\nu$ with $T_\nu \mathcal{K} \subset \mathcal{K}$ that contains $[A]$ for every $A \in \mathcal{A}_a^+$. The *action sector* $\mathcal{H}_\nu^{\mathrm{act}}$, the closure of $\{[A] : A \in \mathcal{A}_a^+\}$, is the least sector; the *gauge-invariant*

sector, the closure of the classes of the $F \in \mathcal{F}^+$ with $F(U^u) = F(U)$ for every configuration U and every gauge transformation u of $a\mathbb{Z}^3$, is a sector: it holds the classes of $\mathcal{A}_a^+$, the plaquette functions a_p being unchanged by gauge transformations by cancellation of site gauge factors around the plaquette, and the bounded operator T_ν maps it into itself, because $\mathsf{t}_{-1}(U^u) = (\mathsf{t}_{-1}U)^{u'}$ with the gauge transformation $u'(x) = u(x + ae_3)$, so that $\mathsf{t}_1 F$ is gauge invariant whenever F is; $\mathcal{H}_\nu$ is a sector too. For a sector $\mathcal{K}$ let $\mathcal{K}^0 = \{\psi \in \mathcal{K} : T_\nu\psi = \psi\}$, a closed subspace that holds Ω_ν, and $\mathcal{K}^1 = \mathcal{K} \ominus \mathcal{K}^0$; T_ν maps $\mathcal{K}^1$ into itself, and

$$q_{\mathcal{K}}(\nu) = \|T_\nu|_{\mathcal{K}^1}\| \in [0,1] \quad (q_{\mathcal{K}}(\nu) = 0 \text{ if } \mathcal{K}^1 = \{0\}), \qquad m_{\mathcal{K}}(\nu) = -\log q_{\mathcal{K}}(\nu) \in [0,\infty].$$

We put $q_{\mathrm{lat}}(\nu) = q_{\mathcal{H}_\nu^{\mathrm{act}}}(\nu)$, and the *lattice gap* of ν is $m_{\mathrm{lat}}(\nu) = -\log q_{\mathrm{lat}}(\nu)$. The vacuum of ν is *simple in* $\mathcal{K}$ if $\mathcal{K}^0 = \mathbb{C}\Omega_\nu$.

(3) *Lattice functions.* For an open set $O \subset \mathbb{R}^3$ and an integer $n \geq 0$, $\mathfrak{S}_n(O)$ is the set of the separated tuples in O with n entries; for $X = (f_1, \dots, f_n) \in \mathfrak{S}_n(O)$ we write $|X| = n$, and for $J \subset \{1, \dots, n\}$ we write X_J for the tuple of the entries f_i with $i \in J$, in increasing order of i; and $\mathbb{C}\mathfrak{S}(O)$ is the complex vector space with the basis $\mathfrak{S}(O)$, whose elements are the finite sums $\sum_i \zeta_i X_i$ with $\zeta_i \in \mathbb{C}$ and $X_i \in \mathfrak{S}(O)$. For $X = (f_1, \dots, f_n) \in \mathfrak{S}(\mathbb{R}^3)$ let $X_a^\nu = \prod_{i=1}^n (\mathcal{O}_a(f_i) - \nu(\mathcal{O}_a(f_i)))$ and $\varnothing_a^\nu = 1$, so that $\sigma_\nu(X) = \nu(X_a^\nu)$ as in Definition 18.205. For $F = \sum_i \zeta_i X_i \in \mathbb{C}\mathfrak{S}(\mathbb{R}^3)$ let $F_a^\nu = \sum_i \zeta_i (X_i)_a^\nu$ and $\sigma_\nu(F) = \sum_i \zeta_i \sigma_\nu(X_i)$. If $F \in \mathcal{D}$ and $t \geq 0$ is real, the entries of every $\Theta_0 X_i$ have their supports in $\{x_3 < 0\}$ and those of every $\tau_{te_3} X_k$ in $\{x_3 > 0\}$, so that the tuples $\Theta_0 X_i \cdot \tau_{te_3} X_k$ are separated, and for these F and t alone we put $\varphi_F^{\sigma_\nu}(t) = \sum_{i,k} \bar{\zeta}_i \zeta_k \, \sigma_\nu(\Theta_0 X_i \cdot \tau_{te_3} X_k)$. For $F \in \mathcal{D}$ let $\varepsilon(F) \in (0,\infty]$ be the least value of x_3 on the union of the supports of the entries of the X_i, and $\varepsilon(F) = +\infty$ if that union is empty.

(4) *Volume-first limits.* In the setting of Definition 18.179 let $0 < g \leq \gamma$, let S be a volume-first limit at g and $(K_j, \beta_j, \nu_j)_j$ a defining sequence of states of S as in Definition 18.205, $a_j = a_{K_j}$, and let σ_S be the centred functional of S. Its space at the mirror, the classes, the vacuum and the operator of Definition 18.179 are written $\mathcal{H}(S)$, $[F]$, Ω_S and H_S; P_0 is the projection onto $\ker H_S$, and $\varphi_F(t) = \langle [F], e^{-tH_S}[F]\rangle = \varphi_F^{\sigma_S}(t)$ for $F \in \mathcal{D}$ and real $t \geq 0$, where φ_F^σ is formed, at these F and t, for any functional σ on separated tuples by the formula of (3). For a component σ_ξ of a canonical decomposition $(\mathsf{X}, \lambda, (\sigma_\xi)_{\xi \in \mathsf{X}})$ of σ_S the same objects are $\mathcal{H}(\sigma_\xi)$, $[F]_\xi$, Ω_{σ_ξ}, H_{σ_ξ} and $\varphi_F^\xi = \varphi_F^{\sigma_\xi}$. The momenta $P_{1,\sigma}$, $P_{2,\sigma}$, the joint projection-valued measure $\mathcal{P}_\sigma$ of $H_\sigma, P_{1,\sigma}, P_{2,\sigma}$ and the joint spectrum $\operatorname{supp}\mathcal{P}_\sigma \subset \mathbb{R} \times \mathbb{R}^2$ are the generators and joint spectral measure of the strongly commuting time and transverse translations from Theorem YM3_I:AO; for $\sigma = \sigma_S$ we write $P_{1,S}$, $P_{2,S}$, $\mathcal{P}_S$. For real $m > 0$ let $\mathsf{H}_m = \{(0,0)\} \cup \{(E,q) \in \mathbb{R} \times \mathbb{R}^2 : \ E > 0, \ E^2 - |q|^2 \geq m^2\}$.

(5) *The numbers of the ceiling.* γ_W is the ceiling and $\mathsf{d}_0(g', \mathfrak{u})$ the threshold of YM3_I:(2346) and YM3_I:(2350), respectively, and $\mathfrak{u}_1 = 3\sqrt{3}/8$. For $0 < g' \leq \gamma_W$ put $\mathsf{M}_{g'} = \log(93312)/(5\,\mathsf{d}_0(g', \mathfrak{u}_1))$, where $93312 = 2 \cdot 6^6$; further $\mathsf{M}_W = \max\{\mathsf{M}_{\gamma_W}, \mathsf{M}_{\gamma_W/\sqrt{2}}\}$, $\kappa_0 = L(\gamma_W^{-2} + \bar{B})$ with the number $\bar{B} = B_\sharp L/(L-1)$ of §YM3_I:74, and $M_g^* = \kappa_0 \, g^2 \, \mathsf{M}_W$ for $0 < g \leq \gamma$. These numbers are formed from the radius, the constants and g alone.

(6) *The numbers of clustering.* For $X = (f_1, \dots, f_n) \in \mathfrak{S}(\mathbb{R}^3)$ let $\mathfrak{r}(X)$ be the least $r \geq 0$ such that the supports of all its entries lie in the closed ball of the radius r about 0, with $\mathfrak{r}(\varnothing) = 0$; let $\mathsf{d}_X = \min\{\mathsf{d}(X), 1\}$ and $R_X = \max\{R(X), 1\}$, with $\mathsf{d}(X)$ the least distance between two distinct supports (infinite for a one-entry tuple) and $R(X)$ the largest of the least enclosing-ball radii of its supports. With the canonical bound table $C_k^g(\mathsf{d}; R)$, $k \geq 2$, of YM3_I:(1850) and the one-point constant $\bar{\mathfrak{r}}(\mathsf{C}^g) = \bar{c}_g$ of Theorem YM3_I:AP, put $\mathfrak{a}_1(\mathsf{d}; R) = \frac{4\pi}{3} R^3 \, \bar{\mathfrak{r}}(\mathsf{C}^g)$, $\mathfrak{a}_k(\mathsf{d}; R) = C_k^g(\mathsf{d}; R)$ for $k \geq 2$, $\mathfrak{A}_k(\mathsf{d}; R) = \sum_{\pi \in \mathrm{Part}(k)} \prod_{J \in \pi} \mathfrak{a}_{|J|}(\mathsf{d}; R)$, the sum running over the set $\mathrm{Part}(k)$ of the partitions of $\{1, \dots, k\}$ into non-empty blocks,

and, with $\|f\|_\sharp = \max\{\|f\|_\infty, 40M \operatorname{Lip} f\}$,

$$\mathfrak{n}_g(X) = \mathfrak{A}_{2n}(\mathsf{d}_X; R_X)^{1/2} \prod_{i=1}^{n} \|f_i\|_\sharp \quad (\mathfrak{n}_g(\varnothing) = 1),$$
$$\mathfrak{r}(X,Y) = 2\max\{\mathfrak{r}(X), \mathfrak{r}(Y)\} + 1,$$
$$\mathfrak{C}_g(X,Y) = \mathfrak{n}_g(X)\,\mathfrak{n}_g(Y)\, e^{M_g^*\,\mathfrak{r}(X,Y)}.$$

These numbers are formed from the radius, the constants, g and the tuples alone.

■

Lemma 18.182 (One lattice: the gap in a sector bounds the decay of reflected correlations)**.** Let $a > 0$, $\beta \geq 0$, ν a periodic Gibbs state at (a, β), $\mathcal{K}$ a sector of ν, $q = q_{\mathcal{K}}(\nu)$ with $q^0 = 1$, and let Π_ν be the orthogonal projection of $\mathcal{H}_\nu$ onto $\ker(1 - T_\nu)$.

(a) For $A, A' \in \mathcal{F}^+$ and every integer $n \geq -1$, $\nu(\overline{\Theta_0 A}\, \mathsf{t}_n A') = \langle [A], T_\nu^{n+1}[A'] \rangle$.

(b) Let $A \in \mathcal{F}^+$ with $[A] \in \mathcal{K}$, $\Phi_A(n) = \nu(\overline{\Theta_0 A}\, \mathsf{t}_n A)$, and $c_A = \|P_{\mathcal{K}^0}[A]\|^2$ with the orthogonal projection $P_{\mathcal{K}^0}$ onto $\mathcal{K}^0$. For all integers $n, k \geq 0$, $0 \leq \Phi_A(n) - \Phi_A(n+k) \leq q^n(\Phi_A(0) - \Phi_A(k))$ and $0 \leq \Phi_A(n) - c_A \leq q^n(\Phi_A(0) - c_A)$.

(c) If the vacuum of ν is simple in $\mathcal{K}$, then $c_A = |\nu(A)|^2$.

(d) $\mathcal{K}^0 = \Pi_\nu \mathcal{K}$ and $\mathcal{K}^1 = \mathcal{K} \cap (1 - \Pi_\nu)\mathcal{H}_\nu$. Hence $q_{\mathcal{K}}(\nu) \leq q_{\mathcal{K}'}(\nu)$ for sectors $\mathcal{K} \subset \mathcal{K}'$; $m_{\mathrm{lat}}(\nu) \geq m_{\mathcal{K}}(\nu)$ for every sector; a vacuum that is simple in $\mathcal{K}'$ is simple in $\mathcal{K}$; and if $\ker(1 - T_\nu) = \mathbb{C}\Omega_\nu$, the vacuum is simple in every sector.

■

Sketch. (a) From the lattice actions of Definition 18.179, $\Theta_1 U = \mathsf{t}_1 \Theta_0 U = \Theta_0 \mathsf{t}_{-1} U$, hence $\Theta_1 A = \mathsf{t}_1(\Theta_0 A)$ for every function A; the actions of isometries on functions are multiplicative and commute with complex conjugation. So $\overline{\Theta_1 A}\, \mathsf{t}_{n+1} A' = \mathsf{t}_1\big[\overline{\Theta_0 A}\, \mathsf{t}_n A'\big]$, and ν is invariant under t_1; the transfer pairing of Definition 18.181(1) at $k = n + 1 \geq 0$ gives (a).

(b) Put $\psi = [A] = \psi^0 + \psi^1$ with $\psi^0 = P_{\mathcal{K}^0}\psi$ and $\psi^1 \in \mathcal{K}^1$. Then $T_\nu^l \psi^0 = \psi^0$ and $T_\nu^l \psi^1 \in \mathcal{K}^1 \perp \mathcal{K}^0$, so that by (a) $\Phi_A(n) = c_A + \langle \psi^1, T_\nu^{n+1} \psi^1 \rangle = c_A + \int_{[0,q]} \lambda^{n+1}\, d\mu(\lambda)$, with the spectral measure μ at ψ^1 of the restriction of T_ν to $\mathcal{K}^1$, which is carried by $[0, q]$. On $[0, q]$, $0 \leq \lambda^{n+1} \leq q^n \lambda$ and $0 \leq \lambda^{n+1}(1 - \lambda^k) \leq q^n \lambda (1 - \lambda^k)$; integrating gives both inequalities.

(c) Then $P_{\mathcal{K}^0}\psi = \langle \Omega_\nu, \psi \rangle \Omega_\nu$ and $\langle \Omega_\nu, [A] \rangle = \nu(A)$.

(d) By the spectral theorem and $0 \leq T_\nu \leq 1$, $T_\nu^n \to \Pi_\nu$ strongly; $\mathcal{K}$ is closed and invariant, so $\Pi_\nu \mathcal{K} \subset \mathcal{K} \cap \ker(1 - T_\nu) = \mathcal{K}^0$, and Π_ν is the identity on $\mathcal{K}^0$. For $\psi \in \mathcal{K}^1$, $\Pi_\nu \psi \in \mathcal{K}^0$ is orthogonal to ψ, so $\|\Pi_\nu \psi\|^2 = \langle \psi, \Pi_\nu \psi \rangle = 0$; conversely a vector of $\mathcal{K}$ with $\Pi_\nu \psi = 0$ is orthogonal to $\ker(1 - T_\nu) \supset \mathcal{K}^0$. The rest follows, as $\mathcal{H}_\nu^{\mathrm{act}}$ is contained in every sector and $\Omega_\nu \in \mathcal{K}^0$. □

Lemma 18.183 (Lattice functions of separated tuples)**.** Let $a > 0$, and let ν be a law on the configurations of $a\mathbb{Z}^3$ that is invariant under all isometries of $a\mathbb{Z}^3$; every periodic Gibbs state is such a law (Proposition YM3_I:103.4).

(a) $F \mapsto F_a^\nu$ is linear; X_a^ν is a real polynomial in the a_p with $x(p)$ in the union of the supports of the entries of X; $X_a^\nu Y_a^\nu = (X \cdot Y)_a^\nu$ whenever $X \cdot Y$ is defined; and $\mathsf{r}(X_a^\nu) = (\mathsf{r}X)_a^\nu$ for every isometry r of $a\mathbb{Z}^3$, in particular $\Theta_0(X_a^\nu) = (\Theta_0 X)_a^\nu$ and $\mathsf{t}_n(X_a^\nu) = (\tau_{nae_3} X)_a^\nu$.

(b) If $F \in \mathcal{D}$ and $a \leq \varepsilon(F)$, then $F_a^\nu \in \mathcal{A}_a^+$.

(c) For $F = \sum_i \zeta_i X_i$ and $F' = \sum_k \zeta'_k X'_k$ in $\mathcal{D}$ and every integer $n \geq 0$, $\nu(\overline{\Theta_0 F_a^\nu}\, \mathsf{t}_n F_a'^\nu) = \sum_{i,k} \bar{\zeta}_i \zeta'_k\, \sigma_\nu(\Theta_0 X_i \cdot \tau_{nae_3} X'_k)$, and $\nu(F_a^\nu) = \sigma_\nu(F)$; at $F' = F$ the first number is $\varphi_F^{\sigma_\nu}(na)$.

■

Sketch. (a) $\mathcal{O}_a(f)$ is a finite real combination of the a_p with $f(x(p)) \neq 0$, and $\nu(\mathcal{O}_a(f))$ is real. An isometry carries a_p to $a_{\mathsf{r}p}$ and $x(p)$ to $\mathsf{r}x(p)$, so that $\mathsf{r}\mathcal{O}_a(f) = \mathcal{O}_a(\mathsf{r}f)$, and $\nu(\mathcal{O}_a(\mathsf{r}f)) = \nu(\mathsf{r}\mathcal{O}_a(f)) = \nu(\mathcal{O}_a(f))$ by the invariance; the action of r on functions is multiplicative. The other assertions are

read off the products. (b) For a plaquette p with $x(p)$ in a support of an entry, $x(p)_3 \geq \varepsilon(F) \geq a$, and every point of p has $x_3 \geq x(p)_3 - \frac{1}{2}a \geq \frac{1}{2}a$; by (a), F_a^ν is a polynomial in such a_p. (c) The supports of $\Theta_0 X_i$ lie in $\{x_3 < 0\}$ and those of $\tau_{nae_3} X'_k$ in $\{x_3 > 0\}$, so that the concatenations are defined; the X_a^ν are real; (a) turns the product into $\sum_{i,k} \bar{\zeta}_i \zeta'_k (\Theta_0 X_i \cdot \tau_{nae_3} X'_k)_a^\nu$, whose mean is the asserted sum. □

Lemma 18.184 (One self-adjoint operator: three forms of a gap)**.** Let $H \geq 0$ be a self-adjoint operator with the spectral measure $\mathbf{E}$, $P_0 = \mathbf{E}(\{0\})$, $\mathcal{D}_0$ a dense subset of the space, and $m > 0$ real. The following say the same: (i) $\mathbf{E}((0,m)) = 0$, that is, $\operatorname{spec} H \subset \{0\} \cup [m, \infty)$; (ii) $\langle \psi, (e^{-tH} - P_0)\psi \rangle \leq e^{-mt} \langle \psi, (1 - P_0)\psi \rangle$ for all $\psi \in \mathcal{D}_0$ and $t \geq 0$; (iii) $\langle \psi, (e^{-tH} - e^{-(t+s)H})\psi \rangle \leq e^{-mt} \langle \psi, (1 - e^{-sH})\psi \rangle$ for all $\psi \in \mathcal{D}_0$ and $s, t \geq 0$. If they hold, (ii) and (iii) hold for all vectors, and $\|e^{-tH} - P_0\| \leq e^{-mt}$ for $t \geq 0$. ■

Sketch. Let μ_ψ be the spectral measure of H at ψ. (i) implies (iii) for every ψ: the left member is $\int e^{-tE}(1 - e^{-sE})\, d\mu_\psi(E)$, whose integrand vanishes at $E = 0$ and is at most $e^{-mt}(1 - e^{-sE})$ on $[m, \infty)$, and $\int_{[m,\infty)} (1 - e^{-sE})\, d\mu_\psi = \langle \psi, (1 - e^{-sH})\psi \rangle$. (iii) implies (ii): as $s \to \infty$, $e^{-sE} \to \mathbf{1}_{\{0\}}(E)$ boundedly, so $e^{-sH} \to P_0$ and $e^{-(t+s)H} \to P_0$ strongly. (ii) implies (i): both members of (ii) are continuous in ψ, so (ii) holds for all ψ; for $0 < m' < m$ and ψ in the range of $\mathbf{E}((0,m'])$ the left member is at least $e^{-m't}\|\psi\|^2$ and the right one is $e^{-mt}\|\psi\|^2$; at $t = 1$ this forces $\psi = 0$; so $\mathbf{E}((0,m']) = 0$ for every $m' < m$, and $\mathbf{E}((0,m)) = 0$. Under (i), $e^{-tH} - P_0 = \int_{[m,\infty)} e^{-tE}\, d\mathbf{E}(E)$. □

Lemma 18.185 (The spectral measures of a limit and of its components)**.** In the setting of Definition 18.179 let $0 < g \leq \gamma$, let S be a volume-first limit at g, $\sigma = \sigma_S$ its centred functional, so that $H_\sigma = H_S$ (Definition 18.181(4)), and $(\mathsf{X}, \lambda, (\sigma_\xi)_{\xi \in \mathsf{X}})$ a canonical decomposition of σ. For $F \in \mathcal{D}$ let μ_F and μ_F^ξ be the spectral measures of H_σ at $[F]$ and of H_{σ_ξ} at $[F]_\xi$, finite positive Borel measures on $[0, \infty)$.

(a) For every continuous real function h on $[0, \infty)$ with a finite limit at ∞, the function $\xi \mapsto \int h\, d\mu_F^\xi$ is continuous on X, and $\int_{\mathsf{X}} (\int h\, d\mu_F^\xi) \lambda(d\xi) = \int h\, d\mu_F$.

(b) For every relatively open set $G \subset [0, \infty)$: $\mu_F(G) = 0$ if and only if $\mu_F^\xi(G) = 0$ for every $\xi \in \mathsf{X}$.

(c) For every real $m > 0$: $\operatorname{spec} H_\sigma \subset \{0\} \cup [m, \infty)$ if and only if $\operatorname{spec} H_{\sigma_\xi} \subset \{0\} \cup [m, \infty)$ for every $\xi \in \mathsf{X}$.

■

Sketch. Step 1: Laplace transforms. A defining sequence of states of S as in Definition 18.205 is a convergent Gibbs sequence at g whose limit is σ; so the spaces at the mirror and the semigroups of σ and of every σ_ξ exist by Theorem YM3_I:AP; $\int e^{-tE}\, d\mu_F(E) = \varphi_F^\sigma(t)$ and $\int e^{-tE}\, d\mu_F^\xi(E) = \varphi_F^{\sigma_\xi}(t)$. The latter is a finite combination of the numbers $\sigma_\xi(\Theta_0 X_i \cdot \tau_{te_3} X_k)$, continuous in ξ, and $\int \varphi_F^{\sigma_\xi}(t)\, \lambda(d\xi) = \varphi_F^\sigma(t)$ by the canonical decomposition of Theorem YM3_I:AL. So (a) holds for the functions $e_t(E) = e^{-tE}$, $t \geq 0$.

Step 2: (a). On the compactification $[0, \infty]$, with $e_t(\infty) = 0$ for $t > 0$ and $e_0 = 1$, the real span of the e_t is an algebra that holds the constants and separates the points; by the theorem of Stone and Weierstrass it is dense in the continuous functions. The masses $\mu_F^\xi([0,\infty)) = \varphi_F^{\sigma_\xi}(0)$ are bounded, a continuous function on the compact space X; uniform approximation of h gives (a).

Step 3: (b). Let $h_n(E) = \min\{1, n \operatorname{dist}(E, [0,\infty) \setminus G)\} \cdot \max\{0, \min\{1, n + 1 - E\}\}$ (the first factor being 1 if $G = [0, \infty)$): continuous, vanishing for $E \geq n + 1$, and increasing to $\mathbf{1}_G$. The functions $I_n(\xi) = \int h_n\, d\mu_F^\xi \geq 0$ are continuous by (a). If $\mu_F(G) = 0$, then $\int I_n\, d\lambda = 0$ by (a); a point with $I_n > 0$ would have a neighbourhood of positive measure; so $I_n = 0$ everywhere, and $\mu_F^\xi(G) = \lim_n I_n(\xi) = 0$ by monotone convergence. The converse is read in the same way.

Step 4: (c). Take $G=(0,m)$. The spectrum of H_σ misses $(0,m)$ if and only if $\mu_F((0,m))=0$ for every $F\in\mathcal{D}$, the classes being dense; the same holds in every $\mathcal{H}(\sigma_\xi)$; and (b) applies F by F. □

Lemma 18.186 (A dilation acts on the space at the mirror as a unitary)**.** Let $s>0$, and let σ be a symmetric functional on separated tuples over $\mathbb{R}^3$ such that σ and $\sigma'=\mathsf{dil}_s\sigma$, defined by $\sigma'(X)=s^{-|X|}\sigma(X_{(s)})$ with $X_{(s)}=(f_1(s\,\cdot),\dots,f_n(s\,\cdot))$ for $X=(f_1,\dots,f_n)$ are invariant under translations, reflection positive at $(e_3,0)$, and have the Hilbert spaces and translation semigroups of Definition 18.179. Put $W_0X=s^{-|X|}X_{(s)}$ for separated tuples X, extended linearly. Then there is exactly one unitary operator $W:\mathcal{H}(\sigma')\to\mathcal{H}(\sigma)$ with $W[F]_{\sigma'}=[W_0F]_\sigma$ for all $F\in\mathcal{D}$; moreover $W\Omega_{\sigma'}=\Omega_\sigma$ and $H_\sigma=s\,WH_{\sigma'}W^{-1}$. In particular $\operatorname{spec}H_\sigma=s\cdot\operatorname{spec}H_{\sigma'}$ and $\ker H_\sigma=W\ker H_{\sigma'}$. ■

Sketch. The map $X\mapsto X_{(s)}$ is a bijection of $\mathfrak{S}_n(\mathbb{R}^3)$ onto itself with $\operatorname{supp}X_{(s)}=s^{-1}\operatorname{supp}X$, so that it maps $\mathfrak{S}_n(\{x_3>0\})$ onto itself; $(X\cdot Y)_{(s)}=X_{(s)}\cdot Y_{(s)}$ and $(\tau_vX)_{(s)}=\tau_{v/s}X_{(s)}$; and $(\Theta_0X)_{(s)}=\Theta_0(X_{(s)})$, as Θ_0 is linear. So W_0 is a linear bijection of $\mathcal{D}$, $W_0\varnothing=\varnothing$, $W_0\tau_{te_3}F=\tau_{(t/s)e_3}W_0F$, and

$$\langle W_0F,W_0F'\rangle_\sigma=\sum_{i,k}\bar\zeta_i\zeta'_k\,s^{-|\Theta_0X_i\cdot X'_k|}\,\sigma\big((\Theta_0X_i\cdot X'_k)_{(s)}\big)=\langle F,F'\rangle_{\sigma'}.$$

Hence $[F]_{\sigma'}\mapsto[W_0F]_\sigma$ is well defined and isometric on a dense subspace, with a dense range, and it extends to a unitary W; on the classes $We^{-tH_{\sigma'}}=e^{-(t/s)H_\sigma}W$, so everywhere. The operator $s^{-1}W^{-1}H_\sigma W$ is self-adjoint and ≥0, and its semigroup is $e^{-tH_{\sigma'}}$; by the uniqueness of the generator it is $H_{\sigma'}$. □

Lemma 18.187 (A ceiling in every component at couplings up to γ_W)**.** In the setting of Definition 18.179 let $0<g'\le\gamma_W$, let S' be a volume-first limit at g' and $\sigma=\sigma_{S'}$ its centred functional, and let $(\mathsf{X},\lambda,(\sigma_\xi)_{\xi\in\mathsf{X}})$ be a canonical decomposition of σ. Then $\operatorname{spec}H_{\sigma_\xi}\cap(0,\mathsf{M}_{g'}]\ne\emptyset$ for every $\xi\in\mathsf{X}$, and $\operatorname{spec}H_\sigma\cap(0,\mathsf{M}_{g'}]\ne\emptyset$. ■

Sketch. Step 1: a bump. Let $\mathsf{d}=\mathsf{d}_0(g',\mathfrak{u}_1)$, $f_0(x)=(1-|x|^2/\mathsf{d}^2)^2$ for $|x|\le\mathsf{d}$ and $f_0(x)=0$ otherwise, and $f=\tau_{\frac32\mathsf{d}e_3}f_0$. Then f_0 is of class C^1, $f_0\ge0$, $\|f_0\|_\infty=1$, its support is the closed ball of the radius d about 0, $\int f_0=\frac{32\pi}{105}\mathsf{d}^3\ge\mathfrak{u}_1\mathsf{d}^3$, and $\sup|\nabla f_0|=\frac{4}{\mathsf{d}}\cdot\frac{1}{\sqrt3}\cdot\frac23=\frac{1}{\mathfrak{u}_1\mathsf{d}}$, attained at $|x|^2=\mathsf{d}^2/3$; the support of f lies in $\{x_3\ge\frac12\mathsf{d}\}$, so $(f)\in\mathfrak{S}_1(\{x_3>0\})$.

Step 2: test pairs. For $0\le t\le5\mathsf{d}$ the supports of Θ_0f and of $\tau_{te_3}f$ are the closed balls of the radius d about $-\frac32\mathsf{d}e_3$ and $(\frac32\mathsf{d}+t)e_3$, at the distance $\mathsf{d}+t\in[\mathsf{d},6\mathsf{d}]$. With Step 1, $(\Theta_0f,\tau_{te_3}f)$ meets the support, integral and Lipschitz conditions for the C^1 test pairs in Theorem YM3_I:C, at scale d and shape parameter $\mathfrak{u}_1$.

Step 3: the law in the component. Theorem YM3_I:AP gives a converging Gibbs frame for the defining sequence of S'. Fix ξ and put $D(t)=S_2^{\sigma_\xi}(\Theta_0f,\tau_{te_3}f)$ and $\mathcal{K}(t)=\mathcal{K}_{\text{free}}(\Theta_0f,\tau_{te_3}f)$, with the kernel of YM3_I:(2240). Corollary YM3_I:127.11 gives the common label b and $D(t)=\mathsf{c}_2\mathsf{b}^{-2}\mathcal{K}(t)(1+\eta_t)$ with $|\eta_t|\le\bar\varepsilon_{g',\mathfrak{u}_1}(\mathsf{d})\le1/3$ for $0\le t\le5\mathsf{d}$. In particular $D(0)>0$. In $\mathcal{K}(t)=\iint(\Theta_0f)(x)\,f(y)\,|x-y-te_3|^{-6}\,dx\,dy$ the integrand vanishes unless $|x-y|\ge\mathsf{d}$, and then $|x-y-te_3|\le|x-y|(1+t/\mathsf{d})$; as $f\ge0$, $\mathcal{K}(5\mathsf{d})\ge6^{-6}\mathcal{K}(0)$. So $D(5\mathsf{d})/D(0)\ge\frac{2/3}{4/3}\,6^{-6}=1/93312$.

Step 4: in the space at the mirror. By the two-point cumulant identity and the isometry invariance of σ_ξ from Theorem YM3_I:AP, $D(t)=\varphi^{\sigma_\xi}_{(f)}(t)-\sigma_\xi(f)^2$; as $\ker H_{\sigma_\xi}=\mathbb{C}\Omega_{\sigma_\xi}$ by Theorem YM3_I:AP and $\langle\Omega_{\sigma_\xi},[(f)]_\xi\rangle=\sigma_\xi(f)$, this is $\langle[(f)]_\xi,(e^{-tH_{\sigma_\xi}}-P_{0,\xi})[(f)]_\xi\rangle$, $P_{0,\xi}$ the projection onto the kernel.

Step 5: the ceiling. Suppose that the spectrum of H_{σ_ξ} misses $(0,\mathsf{M}_{g'}]$. It is closed, so it misses $(0,\mathsf{M}_{g'}+\epsilon)$ for some $\epsilon>0$, and Lemma 18.184 gives $D(5\mathsf{d})\le e^{-5(\mathsf{M}_{g'}+\epsilon)\mathsf{d}}D(0)<D(0)/93312$, against Step 3. For σ: if its spectrum missed $(0,\mathsf{M}_{g'}]$, it would lie in $\{0\}\cup[\mathsf{M}_{g'}+\epsilon,\infty)$ for some $\epsilon>0$, and by Lemma 18.185(c), applied to S', so would the spectrum of every component, X being non-empty. □

Lemma 18.188 (A ceiling at every coupling for volume-first limits)**.** In the setting of Definition 18.179 let $0 < g \le \gamma$, let S be a volume-first limit at g, $(K_j, \beta_j, \nu_j)_j$ a defining sequence of states of S, and $(\mathsf{X}, \lambda, (\sigma_\xi)_{\xi\in\mathsf{X}})$ a canonical decomposition of σ_S.

(a) The labels $a_{K_j}\beta_j$ have limit points; every limit point b satisfies $\mathsf{b} \ge g^{-2} + B_\sharp \frac{L-2}{L-1} \ge g^{-2}$; and for every limit point b and every $\xi \in \mathsf{X}$, $\operatorname{spec} H_{\sigma_\xi} \cap (0, \kappa_0 \mathsf{M}_W/\mathsf{b}] \neq \emptyset$.
(b) For every $\xi \in \mathsf{X}$, $\operatorname{spec} H_{\sigma_\xi} \cap (0, M_g^*] \neq \emptyset$.
(c) $\operatorname{spec} H_S \cap (0, M_g^*] \neq \emptyset$, and $\operatorname{spec} H_S \cap (0, \kappa_0 \mathsf{M}_W/\mathsf{b}] \neq \emptyset$ for every limit point b of the labels.

■

Sketch. Step 1: the labels. By Corollary YM3_I:74.2 and YM3_I:(1854), the labels at first-passage data lie in the compact interval $I^{\mathrm{lab}}(g)$. Each limit point satisfies $g^{-2} + B_\sharp(L-2)/(L-1) \le \mathsf{b} \le L(g^{-2} + \bar{B})$. Fix one such b.

Step 2: two reference couplings. Put $x_W = \gamma_W^{-2}$, so $x_W > L^2\bar{B}$ and $\gamma_W \le \gamma$ by YM3_I:(2346). From §YM3_I:74, the interior $\mathcal{I}(g')$ of $I(g')$ is $(g'^{-2} + \bar{B}, L(g'^{-2} + \bar{B}) - 2\bar{B})$. For $g_1 = \gamma_W$ and $g_2 = \gamma_W/\sqrt{2}$ the two intervals are $(x_W + \bar{B}, Lx_W + (L-2)\bar{B})$ and $(2x_W + \bar{B}, 2Lx_W + (L-2)\bar{B})$. They overlap because $2x_W + \bar{B} < Lx_W + (L-2)\bar{B}$. Their union is $(\mathsf{x}_-, \mathsf{x}_+)$ with $\mathsf{x}_- = x_W + \bar{B}$ and $\mathsf{x}_+ = 2Lx_W + (L-2)\bar{B}$. Since $\mathsf{x}_+ - L\mathsf{x}_- = Lx_W - 2\bar{B} > 0$, the union contains $(\mathsf{x}_-, L\mathsf{x}_-]$. Here $\kappa_0 = L\mathsf{x}_-$.

Step 3: the integer. Let $z \in \mathbb{Z}$ be the least integer with $L^z\mathsf{b} > \mathsf{x}_-$; then $L^{z-1}\mathsf{b} \le \mathsf{x}_-$, so $\mathsf{x}_- < L^z\mathsf{b} \le L\mathsf{x}_- < \mathsf{x}_+$, and $L^z\mathsf{b} \in \mathcal{I}(g_i)$ for $i = 1$ or $i = 2$; fix such an i. Put $s = L^z$; then $s \le L\mathsf{x}_-/\mathsf{b} = \kappa_0/\mathsf{b} \le \kappa_0 g^2$, by Step 1. The coupling g_i satisfies $g_i \le \gamma_W \le \gamma$.

Step 4: the dilated limit. Along a subsequence with labels tending to b, the dilated labels $L^z a_{K_j}\beta_j$ eventually lie in $I(g_i)$ because their limit lies in its interior. Corollary YM3_I:74.2 gives first-passage data $(K_j - z, \beta_j)$ at g_i for all large j. The dilation $x \mapsto sx$ sends the bare lattice, plaquettes, Haar variables and Gibbs kernels to those data at unchanged bare coupling. It sends a volume-first state to a volume-first state, since it sends each approximating torus of side $2L^k$ to a torus of side $2L^{k+z}$. The lattice action observable transforms with a factor s^{-1} and test function $f(s\,\cdot)$, directly from its barycentre sum. Centering has the same factor. Thus the dilated sequence gives the volume-first limit $S^{[z]}$ at g_i with centered functional $\sigma_{S^{[z]}} = \mathsf{dil}_s\sigma_S$. Proposition YM3_I:101.1 gives its canonical decomposition on the same probability space with components $\mathsf{dil}_s\sigma_\xi$.

Step 5: the ceiling at g_i, and back. Lemma 18.187 gives $\operatorname{spec} H_{\mathsf{dil}_s\sigma_\xi} \cap (0, \mathsf{M}_{g_i}] \neq \emptyset$ for every ξ. Theorem YM3_I:AP gives the isometry invariance, reflection positivity and reconstruction for both sets of components. Lemma 18.186 therefore gives $\operatorname{spec} H_{\sigma_\xi} = s \operatorname{spec} H_{\mathsf{dil}_s\sigma_\xi}$. Since $s\,\mathsf{M}_{g_i} \le \kappa_0\mathsf{M}_W/\mathsf{b} \le M_g^*$, this proves (a) and (b).

Step 6: (c). If the spectrum of H_S missed $(0, M]$, with $M = M_g^*$ or $M = \kappa_0\mathsf{M}_W/\mathsf{b}$, it would lie in $\{0\} \cup [M + \epsilon, \infty)$ for some $\epsilon > 0$, the spectrum being closed; by Lemma 18.185(c), applied to S and to the decomposition $(\mathsf{X}, \lambda, (\sigma_\xi)_{\xi\in\mathsf{X}})$, so would the spectrum of every component, against (a) or (b). □

Proposition 18.189 (Transfer operators whose lattice gap stays bounded below in physical units: the spectral gap of H_S and of the components, the hyperboloid, and clustering)**.** In the setting of Definition 18.179 let $0 < g \le \gamma$, let S be a volume-first limit at g, let $(K_j, \beta_j, \nu_j)_j$ be any defining sequence of states of S, $a_j = a_{K_j}$, and let $(\mathsf{X}, \lambda, (\sigma_\xi)_{\xi\in\mathsf{X}})$ be any canonical decomposition of σ_S. With the lattice gaps of Definition 18.181(2), suppose that

$$m = \liminf_{j\to\infty} \frac{m_{\mathrm{lat}}(\nu_j)}{a_j} > 0.$$

The spaces $(\mathcal{H}^{\mathrm{act}}_{\nu_j})^0$ and the labels $a_j\beta_j$ are arbitrary. Then $m \le M_g^* < \infty$, and the following hold.

(a) $\operatorname{spec} H_S \subset \{0\} \cup [m, \infty)$; equivalently, $\langle [F], e^{-tH_S}[F]\rangle - \|P_0[F]\|^2 \le e^{-mt}(\|[F]\|^2 - \|P_0[F]\|^2)$ for all $F \in \mathcal{D}$ and all real $t \ge 0$.

(b) For every $\xi \in \mathsf{X}$: $\operatorname{spec} H_{\sigma_\xi} \subset \{0\} \cup [m, \infty)$, and $\varphi^\xi_F(t) - |\sigma_\xi(F)|^2 \le e^{-mt}(\varphi^\xi_F(0) - |\sigma_\xi(F)|^2)$ for all $F \in \mathcal{D}$ and $t \ge 0$.

(c) For every $\xi \in \mathsf{X}$ the joint spectrum of $(H_{\sigma_\xi}, P_{1,\sigma_\xi}, P_{2,\sigma_\xi})$ lies in $\mathsf{H}_m = \{(0,0)\} \cup \{(E,q) : E > 0,\ E^2 - |q|^2 \ge m^2\}$.

(d) For every $\xi \in \mathsf{X}$, all $X \in \mathfrak{S}_n(\mathbb{R}^3)$, $Y \in \mathfrak{S}_{n'}(\mathbb{R}^3)$ and all $v \in \mathbb{R}^3$ with $|v| \ge \mathfrak{r}(X,Y)$, the tuple $X \cdot \tau_v Y$ is defined and

$$|\sigma_\xi(X \cdot \tau_v Y) - \sigma_\xi(X)\,\sigma_\xi(Y)| \ \le\ \mathfrak{n}_g(X)\,\mathfrak{n}_g(Y)\,e^{-m(|v|-\mathfrak{r}(X,Y))} \ \le\ \mathfrak{C}_g(X,Y)\,e^{-m|v|},$$

with the numbers of Definition 18.181(6); $\mathfrak{C}_g(X,Y)$ is formed from the radius, the constants, g, X and Y alone, and it depends neither on the component, nor on the canonical decomposition, nor on the volume-first limit at g, nor on its defining sequence.

(e) If moreover the set of the indices j at which the vacuum of ν_j is simple in the action sector is infinite, then $\ker H_S = \mathbb{C}\Omega_S$, every canonical decomposition of σ_S has a single point, whose component is σ_S itself, (b)–(d) hold with σ_S in the place of σ_ξ, and $\varphi_F(t) - |\sigma_S(F)|^2 \le e^{-mt}(\varphi_F(0) - |\sigma_S(F)|^2)$ for all $F \in \mathcal{D}$ and $t \ge 0$.

(f) (a)–(d) hold also with the upper limit of $m_{\mathrm{lat}}(\nu_j)/a_j$ in the place of m, whenever that upper limit is positive; it is then at most M^*_g.

■

Sketch. Step 1: one lattice at a time. Fix $F = \sum_i \zeta_i X_i \in \mathcal{D}$ and a real m' with $0 < m' < m$. For all large j, $a_j \le \varepsilon(F)$, because $K_j \to \infty$, and $m_{\mathrm{lat}}(\nu_j) \ge m' a_j$, by the definition of the lower limit. For such j the state ν_j is a periodic Gibbs state; put $A_j = F^{\nu_j}_{a_j}$, which lies in $\mathcal{A}^+_{a_j}$ by Lemma 18.183(b), $\Phi_j(n) = \nu_j(\overline{\Theta_0 A_j}\,\mathfrak{t}_n A_j)$, and $c_j = \|P_{(\mathcal{H}^{\mathrm{act}}_{\nu_j})^0}[A_j]\|^2$. By Lemma 18.183(c), $\Phi_j(n) = \varphi_F^{\sigma_{\nu_j}}(na_j)$, and by Lemma 18.182(b), as $q_{\mathrm{lat}}(\nu_j)^n \le e^{-m'na_j}$, for all integers $n, k \ge 0$

$$0 \le \Phi_j(n) - \Phi_j(n+k) \le e^{-m'na_j}\big(\Phi_j(0) - \Phi_j(k)\big), \qquad 0 \le \Phi_j(n) - c_j \le e^{-m'na_j}\big(\Phi_j(0) - c_j\big).$$

Step 2: times of the form $pL^{-k'}$. Let $t = pL^{-k'}$ and $s = p'L^{-k'}$ with integers $p, p', k' \ge 0$. For j with $K_j \ge k'$, $n_j = t/a_j$ and $k_j = s/a_j$ are integers, and $\Phi_j(n_j)$, $\Phi_j(n_j + k_j)$, $\Phi_j(0)$, $\Phi_j(k_j)$ are the values of $\varphi_F^{\sigma_{\nu_j}}$ at t, $t+s$, 0, s, finite combinations of the values of σ_{ν_j} at tuples that do not depend on j. Since $\sigma_{\nu_j} \to \sigma_S$ at every separated tuple, letting $j \to \infty$ in the first inequality of Step 1 gives

$$\varphi_F(t) - \varphi_F(t+s) \ \le\ e^{-m't}\big(\varphi_F(0) - \varphi_F(s)\big).$$

Step 3: all real times. $\varphi_F(t) = \langle [F], e^{-tH_S}[F]\rangle$ is continuous in t, the semigroup being strongly continuous; the numbers $pL^{-k'}$ are dense in $[0,\infty)$, and any two of them have a common denominator. So the inequality of Step 2 holds for all real $s, t \ge 0$; the classes $[F]$, $F \in \mathcal{D}$, are dense in $\mathcal{H}(S)$, and Lemma 18.184, (iii) implying (i), gives $\operatorname{spec} H_S \subset \{0\} \cup [m', \infty)$.

Step 4: the ceiling; (a). If $m > M^*_g$, a real m' with $M^*_g < m' < m$ gives, by Step 3, a spectrum of H_S that misses $(0, M^*_g]$, against Lemma 18.188(c). So $m \le M^*_g < \infty$. A point of $\operatorname{spec} H_S$ in $(0,m)$ would lie in $(0,m')$ for some $m' < m$; so $\operatorname{spec} H_S \subset \{0\} \cup [m,\infty)$, and Lemma 18.184 gives the display of (a).

Step 5: (b). The defining sequence is a convergent Gibbs sequence at g with the limit σ_S; Lemma 18.185(c) gives $\operatorname{spec} H_{\sigma_\xi} \subset \{0\} \cup [m,\infty)$ for every ξ. As $\ker H_{\sigma_\xi} = \mathbb{C}\Omega_{\sigma_\xi}$ by Theorem YM3_I:AP, the projection onto the kernel is $\psi \mapsto \langle \Omega_{\sigma_\xi}, \psi\rangle \Omega_{\sigma_\xi}$, and $\langle \Omega_{\sigma_\xi}, [F]_\xi\rangle = \sigma_\xi(\Theta_0 \varnothing \cdot F) = \sigma_\xi(F)$; Lemma 18.184, (i) implying (ii), is the display.

Step 6: (c), the hyperboloid. Fix ξ and write $\mathcal{P} = \mathcal{P}_{\sigma_\xi}$. By Theorems YM3_I:AP and YM3_I:AO, the component has a unitary representation U of the proper orthochronous Poincaré group. Its translation spectral measure E is supported in the closed forward cone, and is the image of $\mathcal{P}$ under $(E,q) \mapsto (E,-q)$ when translations are written with Minkowski pairing $x \cdot p = x^0 p^0 - \vec{x} \cdot \vec{p}$. (1) For $\Lambda \in \mathcal{L}$, $\mathsf{E}_\Lambda(\Delta) = U(0,\Lambda)^{-1}\mathsf{E}(\Lambda\Delta)U(0,\Lambda)$ is a projection-valued measure

with $\int e^{ix\cdot p}\,d\mathsf{E}_\Lambda(p) = U(0,\Lambda)^{-1}U(\Lambda x,1)U(0,\Lambda) = U(x,1)$, because Λ keeps the Minkowski product and $(0,\Lambda^{-1})(\Lambda x,1)(0,\Lambda) = (x,1)$; by the uniqueness, $\mathsf{E}_\Lambda = \mathsf{E}$, so $\mathsf{E}(\Lambda\Delta) = 0$ if and only if $\mathsf{E}(\Delta) = 0$. (2) Let $\Delta_0 = \{p : 0 < p^0 < m\}$, an open set. Since $H_{\sigma_\xi} = \int E\,d\mathcal{P}(E,q)$, the image of $\mathcal{P}$ under $(E,q)\mapsto E$ is the spectral measure of H_{σ_ξ}, which vanishes on $(0,m)$ by (b); so $\mathsf{E}(\Delta_0) = \mathcal{P}(\{0 < E < m\}) = 0$. (3) For a unit vector $\mathsf{n}\in\mathbb{R}^2$ and $\eta\in\mathbb{R}$ the boost $\Lambda_{\mathsf{n},\eta}$, $p^0\mapsto p^0\cosh\eta - (\mathsf{n}\cdot\vec p)\sinh\eta$, $\vec p\mapsto \vec p + [(\cosh\eta - 1)(\mathsf{n}\cdot\vec p) - p^0\sinh\eta]\,\mathsf{n}$, keeps $p\cdot p$ and is joined to 1 by $\eta'\mapsto\Lambda_{\mathsf{n},\eta'}$, so it lies in $\mathcal{L}$. Let $p = (E,\vec q)\in\overline{V_+}$, $p\neq 0$, $p\cdot p < m^2$; then $E > 0$. If $\vec q = 0$, $p\in\Delta_0$. If $\vec q\neq 0$ and $\mathsf{n} = \vec q/|\vec q|$, then $(\Lambda_{\mathsf{n},\eta}p)^0 = E\cosh\eta - |\vec q|\sinh\eta$, which equals $(E^2 - |\vec q|^2)^{1/2}\in(0,m)$ at $\tanh\eta = |\vec q|/E$ if $E > |\vec q|$, and equals $Ee^{-\eta}\in(0,m)$ for large η if $E = |\vec q|$. So the open sets $\Lambda^{-1}\Delta_0$, $\Lambda\in\mathcal{L}$, cover the set of these p; by Lindelöf's theorem countably many of them do; each has measure 0 by (1) and (2). (4) Hence E is carried by $\{0\}\cup\{p : p^0 > 0,\ p\cdot p\geq m^2\}$, a closed set that the map $(E,q)\mapsto(E,-q)$ carries onto H_m; so $\mathcal{P}$ is carried by the closed set H_m, and $\operatorname{supp}\mathcal{P}\subset\mathsf{H}_m$.

Step 7: (d), clustering. When $n = 0$ or $n' = 0$, one of the two tuples is empty, and $\sigma_\xi(\varnothing) = 1$, every component being a functional on separated tuples; then the left member of (d) vanishes, and the middle member, which is ≥ 0, does not exceed the right one, as $e^{-m(|v|-\mathfrak{r}(X,Y))} = e^{m\mathfrak{r}(X,Y)}e^{-m|v|}$ and $m\leq M_g^*$. Otherwise let $\mathfrak{r} = \max\{\mathfrak{r}(X),\mathfrak{r}(Y)\}$ and $|v|\geq 2\mathfrak{r}+1$; the supports of X and of $\tau_v Y$ lie in the closed balls of the radius $\mathfrak{r}$ about 0 and v, so $X\cdot\tau_v Y$ is defined. Choose $\mathsf{R}\in\mathrm{SO}(3)$ with $\mathsf{R}v = |v|e_3$, and put $\mathsf{A} = \Theta_0\tau_{-(\mathfrak{r}+\frac12)e_3}\mathsf{R}X$, $\mathsf{B} = \tau_{(\mathfrak{r}+\frac12)e_3}\mathsf{R}Y$, both with supports in $\{x_3\geq\frac12\}$, and $t = |v| - 2\mathfrak{r} - 1\geq 0$. By the invariance of σ_ξ under the isometries of $\mathbb{R}^3$ by Theorem YM3_I:AP, $\langle[\mathsf{A}]_\xi, e^{-tH_{\sigma_\xi}}[\mathsf{B}]_\xi\rangle = \sigma_\xi(\tau_{-(\mathfrak{r}+\frac12)e_3}\mathsf{R}X\cdot\tau_{(t+\mathfrak{r}+\frac12)e_3}\mathsf{R}Y) = \sigma_\xi(X\cdot\tau_v Y)$, $\langle[\mathsf{A}]_\xi,\Omega_{\sigma_\xi}\rangle = \sigma_\xi(X)$ and $\langle\Omega_{\sigma_\xi},[\mathsf{B}]_\xi\rangle = \sigma_\xi(Y)$. So, with the projection $P_{0,\xi}$ onto $\ker H_{\sigma_\xi} = \mathbb{C}\Omega_{\sigma_\xi}$, the left member of (d) is $|\langle[\mathsf{A}]_\xi,(e^{-tH_{\sigma_\xi}} - P_{0,\xi})[\mathsf{B}]_\xi\rangle|\leq e^{-mt}\|[\mathsf{A}]_\xi\|\,\|[\mathsf{B}]_\xi\|$, by (b) and Lemma 18.184. Further $\|[\mathsf{A}]_\xi\|^2 = \sigma_\xi(Z)$ with $Z = \Theta_0\mathsf{A}\cdot\mathsf{A}$, a tuple of $2n$ isometric images of the entries of X: two entries of the same half lie at a distance $\geq\mathsf{d}(X)$, two of different halves lie in $\{x_3\leq-\frac12\}$ and in $\{x_3\geq\frac12\}$, so Z and all its subtuples are of the type $(\mathsf{d}_X;R_X)$, and isometries keep $\|\cdot\|_\sharp$. Expanding $\sigma_\xi(Z)$ as the sum over all partitions of the products of the connected functions $S^{\sigma_\xi}_{|J|}(Z_J)$, and bounding $|S^{\sigma_\xi}_k(Z_J)|\leq C^g_k(\mathsf{d}_X;R_X)\prod\|z_i\|_\sharp$ for $k\geq 2$ and $|S^{\sigma_\xi}_1(z)| = |\mathfrak{c}_\xi\int z|\leq\bar{\mathfrak{c}}(\mathsf{C}^g)\frac{4\pi}{3}R_X^3\|z\|_\infty$ by Theorem YM3_I:AP and Proposition YM3_I:91.13 (higher cumulants are unchanged by centering and pass to the limit from the conditioned Gibbs states), we obtain $\|[\mathsf{A}]_\xi\|\leq\mathfrak{n}_g(X)$, and in the same way $\|[\mathsf{B}]_\xi\|\leq\mathfrak{n}_g(Y)$. As $e^{-mt} = e^{-m(|v|-\mathfrak{r}(X,Y))}$ and $m\leq M_g^*$, the two inequalities of (d) follow.

Step 8: (e). Let J be the infinite set of the j at which the vacuum of ν_j is simple in the action sector. Fix $F\in\mathcal{D}$, $m' < m$ and $t = pL^{-k'} > 0$. For large $j\in\mathsf{J}$, Step 1 gives $0\leq\Phi_j(n_j) - c_j\leq e^{-m't}\Phi_j(0)$, and (a) at m' gives $0\leq\varphi_F(t) - \|P_0[F]\|^2\leq e^{-m't}\varphi_F(0)$; with $\Phi_j(n_j)\to\varphi_F(t)$ and $\Phi_j(0)\to\varphi_F(0)$, $\limsup_{\mathsf{J}\ni j\to\infty}|c_j - \|P_0[F]\|^2|\leq 2e^{-m't}\varphi_F(0)$, and $t\to\infty$ gives $c_j\to\|P_0[F]\|^2$ along J. By Lemma 18.182(c) and Lemma 18.183(c), $c_j = |\nu_j(A_j)|^2 = |\sigma_{\nu_j}(F)|^2\to|\sigma_S(F)|^2 = |\langle\Omega_S,[F]\rangle|^2$. So the projection P_0 and the projection onto $\mathbb{C}\Omega_S$, which lies below it as $H_S\Omega_S = 0$, agree in norm on a dense set of vectors; their difference is a projection that vanishes there, so $\ker H_S = \mathbb{C}\Omega_S$. Theorem YM3_I:AP identifies $\ker H_S$ with $L^2(\mathsf{X},\lambda)$. Since λ has full support on the compact Hausdorff canonical space, one-dimensionality of this space forces $\mathsf{X} = \{\xi_0\}$. The decomposition then gives $\sigma_S = \sigma_{\xi_0}$. Then (b)–(d) for that component are (b)–(d) for σ_S, and the last display is (b) for it.

Step 9: (f). If the upper limit is positive, a subsequence along which $m_{\mathrm{lat}}(\nu_j)/a_j$ tends to it is again a defining sequence of states of S, with the same σ_S and the same decompositions; along it the lower limit is the upper limit of the whole sequence, and (a)–(d) apply. □

Proposition 18.190 (The reduction with the transfer operators on any sector)**.** In the setting of Proposition 18.189, let $\mathcal{K}_j$ be a sector of ν_j for every j (Definition 18.181(2)), for instance the

gauge-invariant sector or the whole space $\mathcal{H}_{\nu_j}$, and suppose that

$$m_{\mathcal{K}} = \liminf_{j\to\infty} \frac{m_{\mathcal{K}_j}(\nu_j)}{a_j} > 0.$$

Then $m_{\mathcal{K}} \le M_g^*$; $\operatorname{spec} H_S \subset \{0\} \cup [m_{\mathcal{K}}, \infty)$, and the inequality of Proposition 18.189(a) remains true when $m_{\mathcal{K}}$ replaces m; for every canonical decomposition of σ_S and every component σ_ξ, $\operatorname{spec} H_{\sigma_\xi} \subset \{0\} \cup [m_{\mathcal{K}}, \infty)$, the inequality of Proposition 18.189(b) remains true when $m_{\mathcal{K}}$ replaces m, the joint spectrum of $(H_{\sigma_\xi}, P_{1,\sigma_\xi}, P_{2,\sigma_\xi})$ is contained in $\mathsf{H}_{m_{\mathcal{K}}} = \{(0,0)\} \cup \{(E,q) : E > 0,\ E^2 - |q|^2 \ge m_{\mathcal{K}}^2\}$, and

$$|\sigma_\xi(X \cdot \tau_v Y) - \sigma_\xi(X)\,\sigma_\xi(Y)| \ \le\ \mathfrak{C}_g(X,Y)\, e^{-m_{\mathcal{K}}|v|} \qquad (X, Y \in \mathfrak{S}(\mathbb{R}^3),\ |v| \ge \mathfrak{r}(X,Y)),$$

with the number $\mathfrak{C}_g(X,Y)$ of Definition 18.181(6), which does not depend on ξ. If moreover the set of the indices j at which the vacuum of ν_j is simple in $\mathcal{K}_j$ is infinite, then $\ker H_S = \mathbb{C}\Omega_S$, σ_S is the only component of its canonical decompositions, and the joint spectrum of $(H_S, P_{1,S}, P_{2,S})$ lies in $\mathsf{H}_{m_{\mathcal{K}}}$. ■

Sketch. By Lemma 18.182(d), $m_{\mathrm{lat}}(\nu_j) \ge m_{\mathcal{K}_j}(\nu_j)$ for every j, so the number m of Proposition 18.189 satisfies $m \ge m_{\mathcal{K}} > 0$, and that proposition applies. Its conclusions at m give those at $m_{\mathcal{K}}$: $\{0\} \cup [m, \infty) \subset \{0\} \cup [m_{\mathcal{K}}, \infty)$; $e^{-mt} \le e^{-m_{\mathcal{K}} t}$ for $t \ge 0$, while the brackets on the right of the inequalities of Proposition 18.189(a), (b) are ≥ 0, each being $\|\psi\|^2 - \|P\psi\|^2$ for a vector ψ and an orthogonal projection P; $e^{-m|v|} \le e^{-m_{\mathcal{K}}|v|}$; $\mathsf{H}_m \subset \mathsf{H}_{m_{\mathcal{K}}}$, which with Proposition 18.189(c) places the joint spectrum of every component in $\mathsf{H}_{m_{\mathcal{K}}}$; and $m_{\mathcal{K}} \le m \le M_g^*$. By Lemma 18.182(d) again, a vacuum that is simple in $\mathcal{K}_j$ is simple in the action sector, which is contained in $\mathcal{K}_j$; so Proposition 18.189(e) gives $\ker H_S = \mathbb{C}\Omega_S$ and makes σ_S the one component of every canonical decomposition, and Proposition 18.189(c), read for this component, places the joint spectrum of $(H_S, P_{1,S}, P_{2,S})$ in $\mathsf{H}_m \subset \mathsf{H}_{m_{\mathcal{K}}}$. □

18.20. **Clustering in space from the Poincaré constant of the lattice Langevin generator.** At a fixed cutoff, the Poincaré constant $\mathsf{c_P}$ for the gauge-invariant functions gives a bound on the spatial correlations of functions of the bonds. Proposition 18.194 gives a decay length $e\sqrt{6\mathsf{b}\mathsf{c_P}} + a$, where a is the lattice spacing and $\mathsf{b} = a\beta$. The proof uses a weighted identity for the Poisson equation and iterates a conditional expectation estimate across successive shells. For $\beta \ge 25$ a single plaquette gives the floor $\mathsf{c_P} \ge a^2/(48\mathsf{b})$, which bounds the decay length by $\sqrt{185\mathsf{b}\mathsf{c_P}}$.

At a reference coupling, site reflection positivity and the truncated-function bounds of Proposition YM3_I:91.13 allow the prefactor for the smeared action density to be chosen independently of the cutoff and side. The resulting bounds pass first to torus-limit states and then to volume-first limits whenever the corresponding lower limits of $\mathsf{b}\mathsf{c_P}$ are finite (Proposition 18.196). Under a uniform bound on $\mathsf{c_P}$ on one torus, the limiting block observables decorrelate in space and have exponential bounds on their Langevin time correlations (Remark 18.197).

Let $L \ge 3$ be odd, $K, m \in \mathbb{N}$, $\ell = 2L^m$ and $\beta > 0$. Set $a = a_K = L^{-K}$, $\mathsf{b} = a\beta$ and $\Lambda_d = L^{-d}\mathbb{Z}^3/\ell\mathbb{Z}^3$ for $0 \le d \le K$. A configuration in Ω_K assigns an SU(2) matrix to each positive bond and its inverse to the reversed bond. Write $a_p = 1 - \frac{1}{2}\operatorname{tr} U(\partial p)$, $A_K = \sum_p a_p$ and $\mu_K = Z_K^{-1} e^{-\beta A_K}\, dU$ for product Haar dU. The block variables $\pi_d U = \mathcal{M}^{K-d} U$ use the map in Definition 2.7(3) and Proposition YM3_I:4.5. Site gauges act by left multiplication at the initial endpoint and right inverse multiplication at the final endpoint. Write Π for their normalized Haar average.

For $I = (b, i)$, $i = 1, 2, 3$, let ∂_I differentiate the link $U(b)$ by left multiplication by $e^{it\varsigma_i}$, with the Pauli matrices ς_i. The generator and energy are

$$\mathcal{L}_K = -a^{-1} \sum_I \partial_I^* \partial_I, \qquad \mathcal{E}_K(F,G) = a^{-1} \sum_I (\partial_I F, \partial_I G).$$

Here the adjoint, inner product and norm are in $L^2(\mu_K)$. The square field is $\Gamma_K(F,G) = a^{-1}\sum_I \partial_I F\,\partial_I G$. Observables in this subsection are real-valued. Means, variances, covariances and conditional expectations are taken with respect to μ_K. We write $J=(b',j)$ for a second derivative index.

Definition 18.191 (Carriers, distances, neighbours, Poincaré constants, site mirrors)**.** (1) *Carriers.* For a set $\mathcal{Y}$ of bonds, $\mathcal{F}_{\mathcal{Y}}$ is the σ-algebra generated by the maps $U\mapsto U(b)$, $b\in\mathcal{Y}$, and $\mathcal{Y}^c$ is the set of the bonds outside $\mathcal{Y}$. A Borel function on Ω_K is carried by $\mathcal{Y}$ if it is $\mathcal{F}_{\mathcal{Y}}$-measurable, that is, if its value depends on the values of the field at the bonds of $\mathcal{Y}$ alone; an element of $L^2(\mu_K)$ is carried by $\mathcal{Y}$ if one of its representatives is.

(2) *Distances.* $x_b\in T_\ell$ is the midpoint of the bond b, and $|x-y|$ is the Euclidean distance of T_ℓ, the least Euclidean distance of two lifts. For a non-empty set $\mathcal{Y}$ of bonds, $d_{\mathcal{Y}}(b)=\min_{b'\in\mathcal{Y}}|x_b-x_{b'}|$, and $\mathcal{Y}^{[t]}=\{b:\ d_{\mathcal{Y}}(b)\ge t\}$ for $t\ge 0$; for two non-empty sets, $\operatorname{dist}(\mathcal{Y},\mathcal{Y}')=\min\{|x_b-x_{b'}|:\ b\in\mathcal{Y},\ b'\in\mathcal{Y}'\}$.

(3) *Neighbours.* Two bonds $b\neq b'$ are neighbours, $b\sim b'$, if one plaquette has both among its four bonds; sums over $b\sim b'$ run over ordered pairs. For a set $\mathcal{Y}$ of bonds, $\partial^{\mathrm{in}}\mathcal{Y}$ is the set of the bonds of $\mathcal{Y}$ that have a neighbour outside $\mathcal{Y}$.

(4) *Poincaré constants.* $\mathsf{c}_{\mathrm{P}}=\mathsf{c}_{\mathrm{P}}(K,\ell,\beta)$ is the least number C with $\operatorname{Var}(F)\le C\,\mathcal{E}_K(F)$ for every real gauge-invariant $F\in C^\infty(\Omega_K)$, and $\mathsf{c}_{\mathrm{P}}^{\mathrm{all}}=\mathsf{c}_{\mathrm{P}}^{\mathrm{all}}(K,\ell,\beta)$ is the least number C with the same inequality for every real $F\in C^\infty(\Omega_K)$. Then $0<\mathsf{c}_{\mathrm{P}}\le\mathsf{c}_{\mathrm{P}}^{\mathrm{all}}<\infty$: the elliptic operator $-\mathcal{L}_K$, symmetric for μ_K, has a discrete spectrum on the compact connected manifold Ω_K, its kernel consists of the constants, and non-constant smooth gauge-invariant functions exist. Of the size of these constants nothing is assumed. For a fixed side ℓ and a sequence β_K, a uniform C_{P} is a positive number that bounds $\mathsf{c}_{\mathrm{P}}(K,\ell,\beta_K)$ for all large K.

(5) *Site mirrors.* Let $\mu\in\{1,2,3\}$ and $z\in a\mathbb{Z}$. The reflection $\mathsf{r}_z\colon x\mapsto x-2(x_\mu-z)e_\mu$ of $\mathbb{R}^3$ induces a map of T_ℓ, again written r_z, that maps sites to sites and bonds to bonds of either orientation; it acts on fields by $(\mathsf{r}_zU)(b)=U(\mathsf{r}_zb)$, on functions on Ω_K by $(\theta_zF)(U)=F(\mathsf{r}_zU)$, and on functions on $\mathbb{R}^3$ by $\mathsf{r}_zf=f\circ\mathsf{r}_z$. As ℓ/a is even, $z+\frac{\ell}{2}\in a\mathbb{Z}$. Σ_z is the set of the bonds with both end points in $\{x_\mu=z\}\cup\{x_\mu=z+\frac{\ell}{2}\}$, and H_z^+ (H_z^-) is the set of the bonds with an end point in the open slab $\{z<x_\mu<z+\frac{\ell}{2}\}$ ($\{z-\frac{\ell}{2}<x_\mu<z\}$), the coordinate being taken modulo ℓ.

■

Lemma 18.192 (Commutators, neighbours, and two identities for the generator)**.** Let $L\ge 3$ be odd, $K,m\in\mathbb{N}$ and $\beta>0$. For $I=(b,i)$ let $\partial_I^*=-\partial_I+\beta(\partial_IA_K)$; then $(\partial_IF,G)=(F,\partial_I^*G)$ for $F,G\in C^1(\Omega_K)$, and $\mathcal{L}_K=-a^{-1}\sum_I\partial_I^*\partial_I$ on $C^2(\Omega_K)$.

(a) $[\partial_b^i,\partial_{b'}^j]=0$ for $b\neq b'$, and $[\partial_b^i,\partial_b^j]=2\sum_k\epsilon_{ijk}\partial_b^k$. Every bond has exactly twelve neighbours, and $|x_b-x_{b'}|\le a$ if $b\sim b'$. If $b\neq b'$ and $b\not\sim b'$, then $\partial_b^i\partial_{b'}^jA_K=0$; if $b\sim b'$, then $|\sum_{i,j}y_iy'_j\,\partial_b^i\partial_{b'}^jA_K(U)|\le|y|\,|y'|$ for all $U\in\Omega_K$ and $y,y'\in\mathbb{R}^3$.

(b) *The square.* Let $f\in C^\infty(\Omega_K)$ be real and λ a real function on the bonds; put $\mathsf{v}_I=\partial_If$, $\delta_\lambda f=\sum_I\lambda_b\,\partial_I^*\mathsf{v}_I$ and, for $I=(b,i)$ and $J=(b',j)$, $\mathsf{q}_{IJ}(f)=\|\partial_J\mathsf{v}_I\|^2+\beta\,\langle\mathsf{v}_I\,(\partial_I\partial_JA_K)\,\mathsf{v}_J\rangle$. Then $\|\delta_\lambda f\|^2=\sum_{I,J}\lambda_b\lambda_{b'}\,\mathsf{q}_{IJ}(f)$.

(c) *The identity with the generator.* For f and λ as in (b),

$$a\sum_I\lambda_b^2\,(\mathsf{v}_I,\partial_I\mathcal{L}_Kf)=-\|\delta_\lambda f\|^2-\frac12\sum_{I,J:\ b\neq b'}(\lambda_b-\lambda_{b'})^2\,\mathsf{q}_{IJ}(f);$$

hence, with $\|\mathsf{v}_b\|^2=\sum_i\|\mathsf{v}_{(b,i)}\|^2$,

$$\|\delta_\lambda f\|^2+a\sum_I\lambda_b^2\,(\mathsf{v}_I,\partial_I\mathcal{L}_Kf)\le\frac{\beta}{2}\sum_{b\sim b'}(\lambda_b-\lambda_{b'})^2\,\|\mathsf{v}_b\|\,\|\mathsf{v}_{b'}\|.$$

■

Proof. Each ∂_I is skew-adjoint for product Haar measure by left invariance. Differentiating the density $e^{-\beta A_K}$ gives $\partial_I^* = -\partial_I + \beta \partial_I A_K$ in $L^2(\mu_K)$. The generator identity follows from its definition.

(a) Derivatives at different bonds act on different factors of Ω_K. At one bond, $\partial_b^i \partial_b^j F(U)$ is the mixed derivative at $s = t = 0$ of F at the field with $e^{it\varsigma_j} e^{is\varsigma_i} U(b)$ at b, and the commutator of two derivatives along left multiplication is the derivative along left multiplication by the one-parameter group of $-[i\varsigma_i, i\varsigma_j] = [\varsigma_i, \varsigma_j] = 2i \sum_k \epsilon_{ijk} \varsigma_k$; below only the antisymmetry of ϵ_{ijk} in its three indices is used. A bond lies in exactly four plaquettes, two different plaquettes have at most one bond in common, and $\ell/a \geq 18$; so the twelve further bonds of these four plaquettes are distinct, and two distinct bonds lie in at most one common plaquette. Two parallel sides of a plaquette have midpoints at the distance a, two adjacent sides at the distance $a/\sqrt{2}$. As a_p depends on the four bonds of p alone, $\partial_b^i \partial_{b'}^j A_K$ with $b \neq b'$ vanishes unless one plaquette p holds both bonds, and then it is $\partial_b^i \partial_{b'}^j a_p$. The left multiplication of $U(b)$ by $e^{is\, y\cdot\varsigma}$ inserts $e^{is\, y\cdot\varsigma}$ in front of $U(b)$ in $\partial U(p)$, or $e^{-is\, y\cdot\varsigma}$ behind $U(b)^{-1}$; by the cyclicity of the trace, $\frac{1}{2}\mathrm{tr}\, \partial U(p)$ at the field varied at b and at b' is $\frac{1}{2}\mathrm{tr}(e^{\pm is\, y\cdot\varsigma} V_1 e^{\pm it\, y'\cdot\varsigma} V_2)$ with $V_1, V_2 \in \mathrm{SU}(2)$ that do not depend on s, t, so that $\sum_{i,j} y_i y'_j\, \partial_b^i \partial_{b'}^j a_p = \pm\frac{1}{2}\mathrm{tr}((y\cdot\varsigma) V_1 (y'\cdot\varsigma) V_2)$. For unit vectors y, y' the matrix in this trace is unitary, and the trace of a unitary 2×2 matrix has modulus at most 2.

(b) $\|\delta_\lambda f\|^2 = \sum_{I,J} \lambda_b \lambda_{b'} (\mathsf{v}_I, \partial_I \partial_J^* \mathsf{v}_J)$, and on smooth functions $\partial_I \partial_J^* = \partial_J^* \partial_I - [\partial_I, \partial_J] + \beta(\partial_I \partial_J A_K)$. For $b \neq b'$ the commutator vanishes and $\partial_I \mathsf{v}_J = \partial_J \mathsf{v}_I$, so that $(\mathsf{v}_I, \partial_I \partial_J^* \mathsf{v}_J) = \mathsf{q}_{IJ}(f)$. At one bond, with the indices i, j, k, (a) gives $\partial_i \mathsf{v}_j = \partial_j \mathsf{v}_i + 2\sum_k \epsilon_{ijk} \mathsf{v}_k$; summed over i and j, the term $2\sum \epsilon_{ijk} (\partial_j \mathsf{v}_i, \mathsf{v}_k)$ that this produces in $(\partial_j \mathsf{v}_i, \partial_i \mathsf{v}_j)$ and the term $-2\sum \epsilon_{ijk} (\mathsf{v}_i, \partial_k \mathsf{v}_j)$ of the commutator cancel after the cyclic renaming $(i, j, k) \to (k, i, j)$ of the second, and what remains is $\sum_{i,j} \mathsf{q}_{(b,i)(b,j)}(f)$.

(c) By the form of $\mathcal{L}_K$, $a\, \partial_I \mathcal{L}_K f = -\sum_J \partial_I \partial_J^* \mathsf{v}_J$, so that the left member of the identity is $-\sum_{I,J} \lambda_b^2 (\mathsf{v}_I, \partial_I \partial_J^* \mathsf{v}_J)$, which by the proof of (b) is $-\sum_{I,J} \lambda_b^2 \mathsf{q}_{IJ}(f)$, the terms with $b = b'$ being summed over i, j first. For $b = b'$, $\lambda_b^2 = \lambda_b \lambda_{b'}$; for $b \neq b'$, $\mathsf{q}_{IJ} = \mathsf{q}_{JI}$, so that λ_b^2 may be replaced by $\frac{1}{2}(\lambda_b^2 + \lambda_{b'}^2) = \lambda_b \lambda_{b'} + \frac{1}{2}(\lambda_b - \lambda_{b'})^2$; together with (b) this is the identity. For the inequality, discard the nonnegative terms $\|\partial_J \mathsf{v}_I\|^2$. By (a), the remaining terms with $b \neq b'$ and $b \not\sim b'$ vanish, and for $b \sim b'$, at every field, $|\sum_{i,j} \mathsf{v}_{(b,i)} (\partial_b^i \partial_{b'}^j A_K) \mathsf{v}_{(b',j)}| \leq |\mathsf{v}_b|\, |\mathsf{v}_{b'}|$ with $|\mathsf{v}_b|^2 = \sum_i \mathsf{v}_{(b,i)}^2$, a product whose mean is at most $\|\mathsf{v}_b\|\, \|\mathsf{v}_{b'}\|$. □

Lemma 18.193 (The Markov property of Wilson's measure)**.** Let $L \geq 3$ be odd, $K, m \in \mathbb{N}$ and $\beta > 0$.

(a) Let $\mathcal{Y}$ be a set of bonds and $F \in L^2(\mu_K)$ carried by $\mathcal{Y}^c$. Then $E[F|\mathcal{F}_\mathcal{Y}]$ is carried by $\partial^{\mathrm{in}}\mathcal{Y}$, and it is gauge invariant if F is.

(b) Let μ be a direction and $z \in a\mathbb{Z}$. The bonds form the disjoint union of Σ_z, H_z^+ and H_z^-; no plaquette has a bond in H_z^+ and a bond in H_z^-; r_z fixes every bond of Σ_z, and for each $b \in H_z^-$ exactly one of $\mathsf{r}_z b$ and its reverse lies in H_z^+; the map that takes b to this bond is a bijection of H_z^- onto H_z^+. If $F \in L^2(\mu_K)$ is carried by $H_z^- \cup \Sigma_z$ and $G \in L^2(\mu_K)$ by $H_z^+ \cup \Sigma_z$, then $(F, G) = (E[F|\mathcal{F}_{\Sigma_z}], E[G|\mathcal{F}_{\Sigma_z}])$; and $E[\theta_z F|\mathcal{F}_{\Sigma_z}] = E[F|\mathcal{F}_{\Sigma_z}]$ for every $F \in L^2(\mu_K)$. Consequently $(F, F') \mapsto \mathrm{Cov}(F, \theta_z F') = \mathrm{Cov}(E[F|\mathcal{F}_{\Sigma_z}], E[F'|\mathcal{F}_{\Sigma_z}])$ is a symmetric non-negative bilinear form on the elements of $L^2(\mu_K)$ carried by $H_z^- \cup \Sigma_z$, and likewise on those carried by $H_z^+ \cup \Sigma_z$; $\mathrm{Cov}(F, \theta_z F) = \mathrm{Var}(E[F|\mathcal{F}_{\Sigma_z}]) \geq 0$; and $|\mathrm{Cov}(F, G)|^2 \leq \mathrm{Cov}(F, \theta_z F)\, \mathrm{Cov}(G, \theta_z G)$ for F carried by $H_z^- \cup \Sigma_z$ and G carried by $H_z^+ \cup \Sigma_z$.

■

Proof. (a) A plaquette with a bond outside $\mathcal{Y}$ has each of its four bonds outside $\mathcal{Y}$ or in $\partial^{\mathrm{in}}\mathcal{Y}$. Write $A_K = A' + A''$, where A' is the sum of the a_p over these plaquettes and A'', the sum over the others,

is carried by $\mathcal{Y}$. As dU is a product of Haar measures, for bounded F carried by $\mathcal{Y}^c$

$$E[F|\mathcal{F}_{\mathcal{Y}}] = \frac{\int F\, e^{-\beta A'}\, dU_{\mathcal{Y}^c}}{\int e^{-\beta A'}\, dU_{\mathcal{Y}^c}},$$

the integrals being taken over the variables of the bonds outside $\mathcal{Y}$; the quotient depends on the field only through its values at the bonds of $\partial^{\mathrm{in}}\mathcal{Y}$. A gauge transformation multiplies every variable $U(b)$, $b \notin \mathcal{Y}$, from the left and from the right by elements that do not depend on the field, which preserves the Haar measure, and A' is gauge invariant; so the quotient is gauge invariant if F is. The bounded functions are dense in $L^2(\mu_K)$, and a conditional mean is a contraction.

(b) The μ-th coordinates of the end points of a bond, and of the corners of a plaquette, form one element or two consecutive elements of $a\mathbb{Z}$ modulo ℓ; as z and $z+\frac{\ell}{2}$ lie in $a\mathbb{Z}$, a bond lies in exactly one of the three sets, and no plaquette has a bond in each of the two slabs. The reflection fixes every point of the two planes, hence every bond of Σ_z, and it exchanges the two open slabs; it carries bonds to bonds and commutes with their reversal, the positively oriented bonds along e_μ going to negatively oriented ones and the other positively oriented bonds to positively oriented ones; as $\mathsf{r}_z^{-1} = \mathsf{r}_z$, this gives the bijection of H_z^- onto H_z^+. So $A_K = A_\Sigma + A_+ + A_-$, where $A_\pm$ is the sum of the a_p over the plaquettes with a bond in $H_z^\pm$, a function of the variables of $H_z^\pm \cup \Sigma_z$, and A_Σ is carried by Σ_z; under μ_K the variables of H_z^+ and those of H_z^- are therefore independent given $\mathcal{F}_{\Sigma_z}$, which is the first identity. For bounded Ψ carried by Σ_z we have $\theta_z\Psi = \Psi$, and μ_K is invariant under r_z, which permutes unoriented bonds and plaquettes. Product Haar measure is invariant under permutations and inversion of link variables, and the trace of each plaquette is unchanged by orientation reversal. Hence $\langle(\theta_z F)\Psi\rangle = \langle\theta_z(F\Psi)\rangle = \langle F\Psi\rangle$, which is the second identity. For the rest: as $(\mathsf{r}_z U)(b) = U(\mathsf{r}_z b)$ and $U(\bar b) = U(b)^{-1}$, $\theta_z F'$ is carried by $H_z^+ \cup \Sigma_z$ if F' is carried by $H_z^- \cup \Sigma_z$, and $\langle\theta_z F'\rangle = \langle F'\rangle$; the last inequality is Schwarz's inequality for $\mathrm{Cov}(F,G) = \mathrm{Cov}(E[F|\mathcal{F}_{\Sigma_z}], E[G|\mathcal{F}_{\Sigma_z}])$. □

Proposition 18.194 (Clustering at the length $\sqrt{\mathsf{bc_P}}$ on every torus and at every cutoff)**.** Let $L \geq 3$ be odd, $K, m \in \mathbb{N}$ and $\beta > 0$; $a = a_K$, $\mathsf{b} = a\beta$ and $\mathsf{c_P} = \mathsf{c_P}(K,\ell,\beta)$.

(a) *An inequality of Caccioppoli type for the Poisson equation.* Let $F \in C^\infty(\Omega_K)$ be real and carried by a non-empty set $\mathcal{Y}$ of bonds, gauge invariant or not, and let $u \in C^\infty(\Omega_K)$ be the solution of $-\mathcal{L}_K u = F - \langle F\rangle$ with $\langle u\rangle = 0$, which exists and is unique. Let $w_0 \geq 0$, $w > 0$ and $\mathrm{Sh} = \{b :\ w_0 - a < d_{\mathcal{Y}}(b) < w_0 + w + a\}$. Then

$$\big\|E[F\,|\,\mathcal{F}_{\mathcal{Y}^{[w_0+w]}}] - \langle F\rangle\big\|^2 \leq \frac{6\,\mathsf{b}}{w^2}\, a^{-1} \sum_{b\in\mathrm{Sh}} \sum_{k=1}^{3} \|\partial_b^k u\|^2.$$

(b) *The conditional mean at the distance w.* Let $F \in L^2(\mu_K)$ be gauge invariant and carried by $\mathcal{Y}$, and let $w > 0$. Then $\|E[F|\mathcal{F}_{\mathcal{Y}^{[w]}}] - \langle F\rangle\| \leq (6\,\mathsf{bc_P})^{1/2} w^{-1} \mathrm{Var}(F)^{1/2}$; equivalently, $|\mathrm{Cov}(F,G)| \leq (6\,\mathsf{bc_P})^{1/2} w^{-1} (\mathrm{Var}F\,\mathrm{Var}G)^{1/2}$ for every $G \in L^2(\mu_K)$ carried by $\mathcal{Y}^{[w]}$. In particular, every such pair F, G with $\mathrm{Var}F, \mathrm{Var}G > 0$ and the correlation coefficient $\mathrm{corr}(F,G)$ gives the floor $\mathsf{c_P} \geq \mathrm{corr}(F,G)^2 w^2/(6\,\mathsf{b})$.

(c) *Clustering.* Let $F, G \in L^2(\mu_K)$ be carried by $\mathcal{Y}$ and by $\mathcal{Y}'$, with $r = \mathrm{dist}(\mathcal{Y},\mathcal{Y}') > 0$, and let one of the two be gauge invariant. Then

$$|\mathrm{Cov}(F,G)| \leq e\,(\mathrm{Var}F\,\mathrm{Var}G)^{1/2} \exp\Big(-\frac{r}{e\sqrt{6\,\mathsf{bc_P}} + a}\Big), \qquad e\sqrt{6} = 6.658\ldots$$

(d) *Functions without gauge invariance.* (b) holds for every $F \in L^2(\mu_K)$ carried by $\mathcal{Y}$, and (c) for every pair F, G, with $\mathsf{c_P^{all}}$ in the place of $\mathsf{c_P}$.

(e) *Block fields.* Let $0 \leq d \leq K$ and let $\mathcal{Q}$ be a non-empty set of positively oriented bonds of Λ_d. Let $\mathcal{Y}_{\mathcal{Q}}$ be the set of the bonds of Λ_K with both end points in $B^{K-d}(c_-) \cup B^{K-d}(c_+)$ for some $c \in \mathcal{Q}$, where $B^{K-d}(y) = y + a\{-q,\ldots,q\}^3$ in T_ℓ is the block about $y \in \Lambda_d$, with $q = (L^{K-d}-1)/2$, and let $\Delta(\mathcal{Q}) \subset T_\ell$ be the union of the closed cubes $\{x :\ |x-y|_\infty \leq \frac{1}{2}a_d\}$

over the end points y of the bonds of $\mathcal{Q}$. Every bounded Borel function φ on Ω_d that depends on $(V(c))_{c\in\mathcal{Q}}$ alone gives a bounded Borel function $\varphi\circ\pi_d$ on Ω_K, carried by $\mathcal{Y}_\mathcal{Q}$ and gauge invariant if φ is; and the midpoints of the bonds of $\mathcal{Y}_\mathcal{Q}$ lie in $\Delta(\mathcal{Q})$. Hence, if $0\le d'\le K$ and $\mathcal{Q}'$, ψ are of the same kind at the depth d', if φ or ψ is gauge invariant, and if $r_\mathcal{Q}=\operatorname{dist}(\mathcal{Y}_\mathcal{Q},\mathcal{Y}_{\mathcal{Q}'})$,

$$|\operatorname{Cov}(\varphi\circ\pi_d,\psi\circ\pi_{d'})|\le e\,\|\varphi\|_\infty\|\psi\|_\infty\exp\Bigl(-\frac{r_\mathcal{Q}}{e\sqrt{6\,\mathsf{bc}_\mathrm{P}}+a}\Bigr),\qquad r_\mathcal{Q}\ge\operatorname{dist}(\Delta(\mathcal{Q}),\Delta(\mathcal{Q}')),$$

the distance of two subsets of T_ℓ being the infimum of the Euclidean distances of their points; at $r_\mathcal{Q}=0$ the bound is Schwarz's inequality.

■

Proof. Step 1: the Poisson equation. The vector fields ∂_b^k span the tangent space of Ω_K at every point, and the coefficients $\partial_b^k A_K$ are smooth; so $\mathcal{L}_K$ is an elliptic operator with smooth coefficients on the compact connected manifold Ω_K, symmetric for μ_K, whose density for the Haar measure is smooth and positive: $(G,\mathcal{L}_K F)=-\mathcal{E}_K(F,G)$ for $F\in C^2$, $G\in C^1$. By the theory of such operators (Fredholm alternative and elliptic regularity), $\mathcal{L}_K$ maps $C^\infty(\Omega_K)$ onto the smooth functions that are orthogonal in $L^2(\mu_K)$ to its kernel; a smooth h with $\mathcal{L}_K h=0$ has $\mathcal{E}_K(h)=0$, hence $\partial_b^k h=0$ for all b,k, and it is constant, as Ω_K is connected. So for real smooth F there is exactly one real $u\in C^\infty(\Omega_K)$ with $\langle u\rangle=0$ and $-\mathcal{L}_K u=F-\langle F\rangle$. If F is gauge invariant, so is u: the gauges preserve μ_K and the energy because the sum of squares on each bond is bi-invariant. They therefore commute with $\mathcal{L}_K$, so that $U\mapsto u(U^v)$ solves the same problem for every $v\in\mathcal{G}_K$. Then $\mathcal{E}_K(u)=(u,F-\langle F\rangle)\le\|u\|\operatorname{Var}(F)^{1/2}$ and $\|u\|^2=\operatorname{Var}(u)\le\mathsf{c}_\mathrm{P}\,\mathcal{E}_K(u)$, whence $\mathcal{E}_K(u)\le\mathsf{c}_\mathrm{P}\operatorname{Var}(F)$; without gauge invariance the same holds with $\mathsf{c}_\mathrm{P}^{\mathrm{all}}$.

Step 2: clause (a). Put $\lambda_b=\min\{1,(d_\mathcal{Y}(b)-w_0)_+/w\}$. Then $\lambda=0$ on $\mathcal{Y}$ and $\lambda=1$ on $\mathcal{Y}^{[w_0+w]}$; for $b\sim b'$, $|d_\mathcal{Y}(b)-d_\mathcal{Y}(b')|\le|x_b-x_{b'}|\le a$ (Lemma 18.192(a)), so that $(\lambda_b-\lambda_{b'})^2\le a^2/w^2$, and $\lambda_b\ne\lambda_{b'}$ only if the interval between $d_\mathcal{Y}(b)$ and $d_\mathcal{Y}(b')$ meets (w_0,w_0+w), which puts both bonds in Sh. We apply Lemma 18.192(c) at $f=u$, with $\mathsf{v}_I=\partial_I u$. Its second term on the left is $-a\sum_I\lambda_b^2(\mathsf{v}_I,\partial_I F)=0$, because $\partial_I F=0$ for $b\notin\mathcal{Y}$ and $\lambda_b=0$ for $b\in\mathcal{Y}$. With $\|\mathsf{v}_b\|\,\|\mathsf{v}_{b'}\|\le\frac12(\|\mathsf{v}_b\|^2+\|\mathsf{v}_{b'}\|^2)$ and the twelve neighbours of every bond,

$$\|\delta_\lambda u\|^2\le\frac{\beta}{2}\cdot\frac{a^2}{w^2}\sum_{b\sim b',\ b,b'\in\mathrm{Sh}}\|\mathsf{v}_b\|\,\|\mathsf{v}_{b'}\|\le\frac{6\,\beta a^2}{w^2}\sum_{b\in\mathrm{Sh}}\|\mathsf{v}_b\|^2.$$

Let $F'=a^{-1}\delta_\lambda u$; as $\beta=\mathsf{b}/a$, $\|F'\|^2\le 6\,\mathsf{b}w^{-2}a^{-1}\sum_{b\in\mathrm{Sh}}\|\mathsf{v}_b\|^2$. For a real smooth Ψ carried by $\mathcal{Y}^{[w_0+w]}$, $\partial_I\Psi=0$ unless $\lambda_b=1$; so the integration by parts of Lemma 18.192 gives $(F',\Psi)=a^{-1}\sum_I\lambda_b(\partial_I u,\partial_I\Psi)=\mathcal{E}_K(u,\Psi)=(F-\langle F\rangle,\Psi)$. The real smooth functions carried by a set of bonds are dense in the elements of $L^2(\mu_K)$ carried by it: the density of μ_K for the Haar measure lies between two positive numbers, the continuous functions are dense in L^2 of the Haar measure of a product of copies of SU(2), and convolution with a smooth approximate identity on that finite product approximates continuous functions uniformly by smooth functions of the same variables. Hence $E[F|\mathcal{F}_{\mathcal{Y}^{[w_0+w]}}]-\langle F\rangle=E[F'|\mathcal{F}_{\mathcal{Y}^{[w_0+w]}}]$, whose norm is at most $\|F'\|$.

Step 3: clause (b). For smooth gauge-invariant F, (a) at $w_0=0$ and Step 1 give the first inequality, as $a^{-1}\sum_{b\in\mathrm{Sh}}\sum_k\|\partial_b^k u\|^2\le\mathcal{E}_K(u)\le\mathsf{c}_\mathrm{P}\operatorname{Var}(F)$. A gauge-invariant $F\in L^2(\mu_K)$ carried by $\mathcal{Y}$ is the limit in $L^2(\mu_K)$ of the functions ΠF_n, where the F_n are real smooth functions carried by $\mathcal{Y}$ that converge to F (Step 2): Π is the orthogonal projection onto the gauge-invariant functions by Haar invariance and the invariance of μ_K, and ΠF_n is smooth and carried by $\mathcal{Y}$, since a gauge transformation acts on every bond variable separately. Both members of the inequality are continuous on $L^2(\mu_K)$. The second form is Schwarz's inequality for $\operatorname{Cov}(F,G)=(E[F|\mathcal{F}_{\mathcal{Y}^{[w]}}]-\langle F\rangle,G-\langle G\rangle)$, and it gives back the first at $G=E[F|\mathcal{F}_{\mathcal{Y}^{[w]}}]$; the floor of c_P is the second form solved for c_P.

Step 4: clause (c). Let F be gauge invariant (otherwise exchange F and G), let $w = e\sqrt{6\,\mathsf{bc_P}}$, let $\mathcal{T}_0$ be the set of all bonds and $\mathcal{T}_k = \mathcal{Y}^{[k(w+a)]}$ for $k \geq 1$, and $F_k = E[F|\mathcal{F}_{\mathcal{T}_k}] - \langle F\rangle$, so that $F_0 = F - \langle F\rangle$; let $\mathcal{Y}_0 = \mathcal{Y}$ and $\mathcal{Y}_k = \partial^{\mathrm{in}}\mathcal{T}_k$ for $k \geq 1$. For $k \geq 1$ the set $\mathcal{T}_k$ does not meet $\mathcal{Y}$, so that by Lemma 18.193(a) F_k is gauge invariant and carried by $\mathcal{Y}_k$; if $\mathcal{Y}_k$ is empty, $F_k = 0$. A bond $b' \in \mathcal{Y}_k$, $k \geq 1$, has a neighbour outside $\mathcal{T}_k$, so that $d_{\mathcal{Y}}(b') < k(w+a) + a$; hence every $b \in \mathcal{T}_{k+1}$ has $|x_b - x_{b'}| \geq d_{\mathcal{Y}}(b) - d_{\mathcal{Y}}(b') > w$, that is, $\mathcal{T}_{k+1} \subset \mathcal{Y}_k^{[w]}$, and this holds also at $k = 0$. As $\mathcal{F}_{\mathcal{T}_{k+1}} \subset \mathcal{F}_{\mathcal{T}_k}$ and $\langle F_k\rangle = 0$, $F_{k+1} = E[F_k|\mathcal{F}_{\mathcal{T}_{k+1}}]$, and (b) at the carrier $\mathcal{Y}_k$ and the distance w gives

$$\|F_{k+1}\| \leq \big\|E[F_k|\mathcal{F}_{\mathcal{Y}_k^{[w]}}]\big\| \leq (6\,\mathsf{bc_P})^{1/2} w^{-1}\|F_k\| = e^{-1}\|F_k\|.$$

Let $k = \lfloor r/(w+a)\rfloor$. Every bond of $\mathcal{Y}'$ lies in $\mathcal{T}_k$, so that G is $\mathcal{F}_{\mathcal{T}_k}$-measurable and $\mathrm{Cov}(F,G) = (F_k, G - \langle G\rangle)$; thus $|\mathrm{Cov}(F,G)| \leq e^{-k}(\mathrm{Var}F\,\mathrm{Var}G)^{1/2}$, and $e^{-k} < e\cdot e^{-r/(w+a)}$.

Step 5: clause (d). The same steps, without the projection Π and with $\mathsf{c}_{\mathrm{P}}^{\mathrm{all}}$ (Step 1); the functions F_k need not be gauge invariant.

Step 6: clause (e). The one-step locality of Proposition YM3_I:4.5 and nesting of the blocks imply that the value $(\pi_d U)(c) = \mathcal{M}^{K-d}(U)(c)$ at a bond c of Λ_d is a function of the values of U at the bonds of Λ_K with both end points in $B^{K-d}(c_-) \cup B^{K-d}(c_+)$ alone; so $\varphi\circ\pi_d$ is carried by $\mathcal{Y}_{\mathcal{Q}}$. The averaging map is Borel by Proposition YM3_I:4.5, so $\varphi\circ\pi_d$ is Borel. For a gauge transformation u of Λ_K with the restriction $u|$ to the sites of Λ_d, the iterated map is covariant, $\mathcal{M}^{K-d}(U^u) = (\mathcal{M}^{K-d}U)^{u|}$ (Proposition YM3_I:4.5); so $\varphi\circ\pi_d$ is gauge invariant if φ is. The block $B^{K-d}(y)$ lies in the closed cube of side a_d centred at y by the formula for $B^{K-d}(y)$. The cubes of the two end points of c form a box containing the midpoints of all bonds with both end points in $B^{K-d}(c_-) \cup B^{K-d}(c_+)$. Thus the distance between the midpoint carriers is at least the distance between $\Delta(\mathcal{Q})$ and $\Delta(\mathcal{Q}')$. Apply (c) with $\mathrm{Var}(\varphi\circ\pi_d) \leq \|\varphi\|_\infty^2$ and the corresponding bound for $\psi\circ\pi_d$. At distance zero, the bound follows from Cauchy–Schwarz. □

Definition 18.195 (The smeared action density at a reference coupling)**.** (1) *The setting at g.* Fix the construction constants, in particular odd $L \geq 13$, $B_\sharp \geq 0$ and $0 < \gamma \leq \frac{1}{2}$. For $0 < g \leq \gamma$, $\mathfrak{d}(g)$ is the canonical first-passage family at g (Corollary YM3_I:74.2 and YM3_I:(1843)), and $\mathfrak{L}(g)$ is the tail of the sides specified in YM3_I:(1528). At a first-passage datum, the initial inverse coupling satisfies $\beta > X_g = L(g^{-2} + B_\sharp) \geq 52$. We use the configuration space Ω_K and Wilson law μ_K on T_ℓ defined above.

(2) *Tuples.* Lip_c is the set of the real Lipschitz functions on $\mathbb{R}^3$ with compact support; $\|f\|_\sharp = \max\{\|f\|_\infty, 40M\,\mathrm{Lip}f\}$, with the construction cube size M. The periodisation is $f^{\langle\ell\rangle}([x]) = \sum_{v\in\ell\mathbb{Z}^3} f(x+v)$. The observable with weight h is $\mathcal{O}(h) = a^{-1}\sum_p h(x(p))\,a_p$, where $x(p)$ is the barycentre of p (YM3_I:(1739)). A tuple is a finite sequence $X = (f_1,\dots,f_n)$ of elements of Lip_c with $n \geq 1$, with $|X| = n$ and $\|X\|_\sharp = \prod_i \|f_i\|_\sharp$; its sub-tuples are the $X_J = (f_i)_{i\in J}$, $\emptyset \neq J \subset \{1,\dots,n\}$; the empty sequence $\emptyset$ is not a tuple, and it occurs only in the places that name it; $X\cdot Y$ is the concatenation; $\tau_v X = (f_i(\cdot - v))_i$ for $v \in \mathbb{R}^3$; and $\mathsf{r}_z X = (f_i\circ\mathsf{r}_z)_i$. The tuple lies in the ball $\mathbb{B}(x_X, R)$ at the separation $\mathsf{d} > 0$ if the supports of its entries lie in the closed ball $\mathbb{B}(x_X,R)$ of $\mathbb{R}^3$ and any two of them are at a distance $\geq \mathsf{d}$; it is of the type $(\mathsf{d}; R)$ if the support of each entry lies in some ball of radius R and any two of them are at a distance $\geq \mathsf{d}$ (Proposition YM3_I:91.13).

(3) *Moments and cumulants.* $A_X = \prod_i(\mathcal{O}(f_i^{\langle\ell\rangle}) - \langle\mathcal{O}(f_i^{\langle\ell\rangle})\rangle)$, and $\sigma(X) = \sigma_{K,\ell,\beta}(X) = \langle A_X\rangle$; so $\sigma(X\cdot Y) = \langle A_X A_Y\rangle$ and $\mathrm{Cov}(A_X, A_Y) = \sigma(X\cdot Y) - \sigma(X)\,\sigma(Y)$. $S^T_{n;K,\ell,\beta}(X)$ is the joint cumulant of the $\mathcal{O}(f_i^{\langle\ell\rangle})$ under μ_K. For a law ν on the infinite lattice $\mathbb{L}_K = a_K\mathbb{Z}^3$, $S_n^T[\nu]$ and σ_ν are its cumulants and its centred functional. For a side ℓ, $\tilde\mu_{K,\ell,\beta}$ is the law on $\mathbb{L}_K$ that μ_K on T_ℓ induces when every field is extended periodically to the bonds of $\mathbb{L}_K$, that is, the push-forward $(\mathsf{per}_\ell)_*\mu_{K,\ell,\beta}$ by the map per_ℓ of periodic extension. $\mathcal{G}^{\mathrm{tor}}_{K,\beta}$ is the set of the infinite-volume limit states of the tori: the laws on $\mathbb{L}_K$ reached as weak limits,

along subsequences, by the Wilson measures on $\mathbb{L}_K$ with the periods $2L^j\mathbb{Z}^3$, $j\in\mathbb{N}$; and a sequence of sides for $\nu\in\mathcal{G}^{\mathrm{tor}}_{K,\beta}$ is a sequence $\ell_i\to\infty$ in $\{2L^j:\ j\in\mathbb{N}\}$ with $\tilde\mu_{K,\ell_i,\beta}\to\nu$ weakly (Proposition YM3_I:91.2). A volume-first limit at g is a family $S=(S_n)_{n\ge2}$ with $S_n(X)=\lim_j S_n^T[\nu_j](X)$ for every separated n-tuple X over $\mathbb{R}^3$, along a defining sequence of states (K_j,β_j,ν_j) with $(K_j,\beta_j)\in\mathfrak{d}(g)$, $\nu_j\in\mathcal{G}^{\mathrm{tor}}_{K_j,\beta_j}$ and $K_j\to\infty$; the entries of a separated tuple are real functions of class C^1 with compact and pairwise disjoint supports. For such a limit the centred functional is $\sigma_S(X)=\sum_{\pi\in\mathrm{Part}_{\ge2}(|X|)}\prod_{J\in\pi}S_{|J|}(X_J)$, with $\sigma_S(\emptyset)=1$. This follows from the moment–cumulant formula because a centred variable has zero first cumulant.

(4) *Numbers.* $C^g_n(\mathsf{d};R)$, $n\ge2$, is the bound table in YM3_I:(1850), and $\mathsf{T}_k(\mathsf{d};R)=\sum_{\pi\in\mathrm{Part}_{\ge2}(k)}\prod_{J\in\pi}C^g_{|J|}(\mathsf{d};R)$ for $k\ge2$, the sum running over the partitions of $\{1,\dots,k\}$ into blocks of at least two elements. For tuples X, Y that lie in $\mathbb{B}(x_X,R)$ and in $\mathbb{B}(x_Y,R)$, $R\ge1$, at the separation d, with $n=\max\{|X|,|Y|\}$, let

$$\mathsf{T}_X=\mathsf{T}_{2|X|}(\min\{\mathsf{d},2\};R)\,\|X\|_\sharp^2,\qquad C(X,Y)=\max\{1,\mathsf{T}_X\}^{1/2}\max\{1,\mathsf{T}_Y\}^{1/2},\qquad r_0=2\sqrt3\,(|x_X-x_Y|+2R+6),$$

$$\mathsf{N}_K(X)=1+2\sum_{i=1}^{|X|}\log^+\!\big(12\,\|f_i\|_\infty(2R{+}1)^3\big)+8\,|X|\,K\log L,\qquad \mathsf{N}_K(X,Y)=\max\{\mathsf{N}_K(X),\mathsf{N}_K(Y)\},$$

$$\alpha_{\mathrm{P}}=(185\,\mathsf{b}\mathsf{c}_{\mathrm{P}})^{-1/2},\qquad \alpha_{\mathrm{eff}}=\alpha_{\mathrm{P}}-\frac{\mathsf{N}_K(X,Y)}{\frac{\ell}{2}-2R-4},$$

with $\mathsf{b}=a_K\beta$, $\mathsf{c}_{\mathrm{P}}=\mathsf{c}_{\mathrm{P}}(K,\ell,\beta)$, and $\log^+t=\log t$ for $t\ge1$, $\log^+t=0$ for $0\le t<1$. For the truncated functions let $\mathsf{t}(Z)=\mathsf{T}_{|Z|}(\mathsf{d};R)\,\|Z\|_\sharp$ for a sub-tuple Z of X or of Y with $|Z|\ge2$, $\mathsf{t}(Z)=0$ for $|Z|=1$, $\mathsf{t}(\emptyset)=1$, and

$$\bar C(X,Y)=\max_{X',Y'\neq\emptyset}C(X',Y'),$$
$$\mathsf{p}(X,Y)=1+\max_{X',Y'}\mathsf{t}(X')\,\mathsf{t}(Y')+\bar C(X,Y),$$
$$C'(X,Y)=\bar C(X,Y)\sum_{\pi\in\mathrm{Part}(N)}(|\pi|-1)!\,|\pi|\,\mathsf{p}(X,Y)^{|\pi|-1},$$

the maxima being taken over the sub-tuples X' of X and Y' of Y, and in the second also with $\emptyset$ in the place of X', of Y' or of both, $N=|X|+|Y|$, and $\mathrm{Part}(N)$ being the set of the partitions of $\{1,\dots,N\}$. The numbers $C(X,Y)$, $\bar C(X,Y)$, $\mathsf{p}(X,Y)$ and $C'(X,Y)$ are formed from the constants of the main text, g, d, R and the norms of the entries; they depend neither on K, ℓ, β nor on a position or a state (Proposition YM3_I:91.13).

(5) *Mirrors of a tuple.* For a direction μ and a tuple X in $\mathbb{B}(x_X,R)$ let $\xi=(x_X)_\mu$, let z_1 be the least element of $a\mathbb{Z}$ with $z_1\ge\xi+R+1$ and z_2 the largest element of $a\mathbb{Z}$ with $z_2\le\xi+\frac{\ell}{4}$, and let $\mathsf{h}_X(z)=\mathrm{Cov}(A_X,\theta_zA_X)$ for $z\in a\mathbb{Z}$.

■

Proposition 18.196. *From a finite Poincaré constant to exponential clustering in space.*

(a) *A floor.* Let $L\ge3$ be odd, $K,m\in\mathbb{N}$ and $\beta>0$. The mean $x=\langle a_p\rangle$ is the same for all plaquettes p, and

$$\mathsf{c}_{\mathrm{P}}\ge\frac{a^2}{16\,\mathsf{b}}\cdot\frac{1-x}{2-x}.$$

If $\beta\ge25$, then $x\le0.4157$ and $\mathsf{c}_{\mathrm{P}}\ge a^2/(48\,\mathsf{b})$.

(b) *Functions of $L^2(\mu_K)$ and block fields at $\beta\ge25$.* Let besides $\beta\ge25$. Then $e\sqrt{6\,\mathsf{b}\mathsf{c}_{\mathrm{P}}}+a\le\sqrt{185\,\mathsf{b}\mathsf{c}_{\mathrm{P}}}$; for F, G, r as in Proposition 18.194(c), and for $\varphi\circ\pi_d$, $\psi\circ\pi_{d'}$, $r_{\mathcal{Q}}$ as in

Proposition 18.194(e),

$$|\mathrm{Cov}(F,G)| \le e\,(\mathrm{Var}F\,\mathrm{Var}G)^{1/2}e^{-r/\sqrt{185\,\mathsf{bc}_{\mathrm{P}}}}, \qquad |\mathrm{Cov}(\varphi\circ\pi_d,\psi\circ\pi_{d'})| \le e\,\|\varphi\|_\infty\|\psi\|_\infty\,e^{-r_{\mathfrak{Q}}/\sqrt{185\,\mathsf{bc}_{\mathrm{P}}}};$$

the numbers e and 185 depend on nothing. This holds in particular at every $(K,\beta)\in\mathfrak{d}(g)$, $0<g\le\gamma$, on every torus.

In (c)–(g), $0<g\le\gamma$, and the objects and numbers are those of Definition 18.195; X and Y are tuples that lie in $\mathbb{B}(x_X,R)$ and in $\mathbb{B}(x_Y,R)$, $R\ge 1$, at the separation $\mathsf{d}>0$, and $n=\max\{|X|,|Y|\}$. Clauses (c)–(g) use the uniform cumulant bounds of Proposition YM3_I:91.13, which follow from the construction and stability theorems (Theorems YM3_I:D and YM3_I:AJ).

(c) *One tuple and its mirror images.* Let $(K,\beta)\in\mathfrak{d}(g)$, $\ell\in\mathfrak{L}(g)$ with $\ell\ge 32|X|(R+1)$, and let μ be a direction. For $z\in a\mathbb{Z}$ with $z_1\le z\le z_2$,

$$0\le \mathsf{h}_X(z)=\sigma(X\cdot\mathsf{r}_zX)-\sigma(X)^2\le\max\{1,\mathsf{T}_X\}\,\exp\Big(-2(z-z_1)\Big[\alpha_{\mathrm{P}}-\frac{\mathsf{N}_K(X)}{\frac{\ell}{2}-2R-4}\Big]\Big).$$

(d) *Two tuples on one torus.* Let $(K,\beta)\in\mathfrak{d}(g)$, $\ell\in\mathfrak{L}(g)$ with $\ell\ge 32n(R+1)$, and $v\in\mathbb{R}^3$ with $r_0\le|v|\le\frac{\ell}{4}$. If $\alpha_{\mathrm{eff}}\ge 0$, then

$$\big|\sigma(X\cdot\tau_vY)-\sigma(X)\,\sigma(\tau_vY)\big|\le C(X,Y)\,e^{-\alpha_{\mathrm{eff}}|v|/(2\sqrt{3})}.$$

On the tori with $\ell\ge 4R+8+4\,\mathsf{N}_K(X,Y)\sqrt{185\,\mathsf{bc}_{\mathrm{P}}}$, a side that grows linearly in $K\sqrt{\mathsf{bc}_{\mathrm{P}}}$, we have $\alpha_{\mathrm{eff}}\ge\frac12\alpha_{\mathrm{P}}$, and the right member is at most $C(X,Y)\exp(-|v|/(4\sqrt3\sqrt{185\,\mathsf{bc}_{\mathrm{P}}}))$.

(e) *The states of the tori.* Let $(K,\beta)\in\mathfrak{d}(g)$, $\nu\in\mathcal{G}^{\mathrm{tor}}_{K,\beta}$, let (ℓ_i) be a sequence of sides for ν, and $\mathsf{c}^\sharp=\liminf_i\mathsf{c}_{\mathrm{P}}(K,\ell_i,\beta)$. Then $\mathsf{c}^\sharp\ge a^2/(48\,\mathsf{b})$, and if $\mathsf{c}^\sharp<\infty$, then for every $v\in\mathbb{R}^3$ with $|v|\ge r_0$

$$\big|\sigma_\nu(X\cdot\tau_vY)-\sigma_\nu(X)\,\sigma_\nu(\tau_vY)\big|\le C(X,Y)\exp\Big(-\frac{|v|}{2\sqrt3\,\sqrt{185\,\mathsf{bc}^\sharp}}\Big).$$

No condition on a side enters, and the bound depends on K and β through $\mathsf{bc}^\sharp$ alone.

(f) *Volume-first limits.* Let S be a volume-first limit at g with a defining sequence of states (K_j,β_j,ν_j); for each j let a sequence of sides for ν_j be given, let $\mathsf{c}^\sharp_j$ be the lower limit of $\mathsf{c}_{\mathrm{P}}(K_j,\ell,\beta_j)$ along it, and let $\mathsf{c}^*=\liminf_j a_{K_j}\beta_j\,\mathsf{c}^\sharp_j$. Let X and Y be separated tuples. If $\mathsf{c}^*<\infty$, then for every v with $|v|\ge r_0$ the tuple $X\cdot\tau_vY$ is separated, and

$$\big|\sigma_S(X\cdot\tau_vY)-\sigma_S(X)\,\sigma_S(\tau_vY)\big|\le C(X,Y)\exp\Big(-\frac{|v|}{2\sqrt3\,\sqrt{185\,\mathsf{c}^*}}\Big),$$

the right member being read as 0 if $\mathsf{c}^*=0$. Thus a volume-first limit clusters exponentially, with the constants $C(X,Y)$ and r_0 of one torus, as soon as it has a defining sequence and sequences of sides along which bc_{P} stays bounded in this sense, the volume being removed first and the cutoff second.

(g) *Truncated functions.* Let $N=|X|+|Y|$. Under the hypotheses of (d), of (e) and of (f), respectively, $|S^T_{N;K,\ell,\beta}(X\cdot\tau_vY)|$, $|S^T_N[\nu](X\cdot\tau_vY)|$ and $|S_N(X\cdot\tau_vY)|$ are at most $C'(X,Y)$ times the exponential of (d), of (e) and of (f).

■

Proof. Step 1: clause (a). The translations of Λ_K and the permutations of the three axes map plaquettes onto plaquettes, act transitively on them, and preserve dU and A_K (a permutation that reverses the orientation of a plaquette replaces $\partial U(p)$ by a conjugate of its inverse, which has the same trace); so all the a_p have one law under μ_K. Fix a plaquette p and one of its bonds b, and write $y_i=\partial^i_b a_p$. At the field with $e^{is\,y'\cdot\varsigma}U(b)$ at b, the holonomy of p carries the factor $e^{is\,y'\cdot\varsigma}$ in front of $U(b)$, or the factor $e^{-is\,y'\cdot\varsigma}$ behind $U(b)^{-1}$; under the trace a cyclic permutation

moves this factor to the first place, so that $\frac12\mathrm{tr}\,\partial U(p)$ is there $\frac12\mathrm{tr}(e^{\pm is\,y'\cdot\varsigma}W)$, where W, the product of the four factors of $\partial U(p)$ at U in a cyclic order, does not depend on s and is conjugate to $\partial U(p)$; thus $W=w_0\mathbf{1}+i\sum_k w_k\varsigma_k\in\mathrm{SU}(2)$ with $w_0=1-a_p$ and $w_0^2+|w|^2=1$. Hence $y_i=\pm w_i$, so that $|y|^2=1-w_0^2=a_p(2-a_p)$; $\sum_i(\partial_b^i)^2a_p=3w_0$; $\partial_b^j\partial_b^ia_p=w_0\delta_{ij}\mp\sum_k\epsilon_{ijk}w_k$, so that $\sum_{i,j}(\partial_b^j\partial_b^ia_p)^2=3w_0^2+2|w|^2\le3$; and the symmetric part of the matrix $(\partial_b^i\partial_b^ja_{p'})_{ij}$ is $(1-a_{p'})\mathbf{1}$ for each of the four plaquettes p' that hold b. Let $\eta=\langle a_p(2-a_p)\rangle$, the same for all plaquettes, and $\mathsf{z}=\sum_i(\partial_b^i)^*y_i$. Then $\langle\mathsf{z}\rangle=0$ and $\mathsf{z}=-3w_0+\beta\sum_{p'\ni b}\sum_i(\partial_b^ia_{p'})\,y_i$, so that Schwarz's inequality gives $3(1-x)=3\langle w_0\rangle\le4\beta\eta$. Next, $\eta=\langle\sum_i y_i\,\partial_b^ia_p\rangle=(a_p,\mathsf{z})=\mathrm{Cov}(a_p,\mathsf{z})\le\mathrm{Var}(a_p)^{1/2}\|\mathsf{z}\|$, and Lemma 18.192(b) at $f=a_p$ and $\lambda=\mathbf{1}_{\{b\}}$, with the facts above, gives $\|\mathsf{z}\|^2\le3+4\beta\eta$. As a_p is a smooth gauge-invariant function with $\mathcal{E}_K(a_p)=4a^{-1}\eta$, each of the four bonds of p contributing $a^{-1}\eta$, and as $\tau\mapsto\tau/(3+4\tau)$ increases,

$$\mathsf{c_P}\ge\frac{\mathrm{Var}(a_p)}{\mathcal{E}_K(a_p)}\ge\frac{a\,\eta}{4(3+4\beta\eta)}=\frac{a}{4\beta}\cdot\frac{\beta\eta}{3+4\beta\eta}\ge\frac{a}{4\beta}\cdot\frac{\frac34(1-x)}{3+3(1-x)}=\frac{a^2}{16\,\mathsf{b}}\cdot\frac{1-x}{2-x}.$$

For the bound of x, let $N_K=3(\ell/a)^3$ be the number of the plaquettes, which is the number of the bonds, and $Z(\beta')=\int e^{-\beta' A_K}dU$. The mean $\langle A_K\rangle_{\beta'}$ under $Z(\beta')^{-1}e^{-\beta' A_K}dU$ does not increase in β', its derivative being $-\mathrm{Var}_{\beta'}(A_K)$, and $Z(0)=1$; so $-\log Z(\beta)=\int_0^\beta\langle A_K\rangle_{\beta'}d\beta'\ge\beta N_Kx$. Let $\angle V\in[0,\pi]$ be the angle of $V\in\mathrm{SU}(2)$, $\frac12\mathrm{tr}\,V=\cos\angle V$, which is the distance of V from $\mathbf{1}$ for the bi-invariant metric of the unit sphere $\mathrm{SU}(2)\subset\mathbb{R}^4$; it is subadditive and invariant under inversion, and its law under the Haar measure has the density $\frac2\pi\sin^2$. Where $\angle U(b)\le\delta$ at every bond, $\angle\partial U(p)\le4\delta$ and $a_p\le8\delta^2$; this set has the Haar measure q^{N_K}, $q=\frac1\pi(\delta-\frac12\sin2\delta)\ge\frac{2\delta^3}{3\pi}(1-\frac{\delta^2}{5})$ for $0<\delta\le1$. So $-\log Z(\beta)\le N_K(8\beta\delta^2-\log q)$, and at $\delta^2=3/(16\beta)$

$$x\le\frac1\beta\Big[\frac32+\log\frac{3\pi}{2}+\frac32\log\frac{16\beta}{3}-\log\Big(1-\frac{3}{80\beta}\Big)\Big],$$

a function that decreases on $\beta\ge1$ and has the value $0.41563\ldots$ at $\beta=25$. Then $\frac{1-x}{2-x}\ge\frac13$.

Step 2: clause (b). By (a), $a\le\sqrt{48\,\mathsf{bc_P}}$, so that $e\sqrt{6\,\mathsf{bc_P}}+a\le(e\sqrt6+\sqrt{48})\sqrt{\mathsf{bc_P}}$, and $(e\sqrt6+\sqrt{48})^2=184.59\ldots<185$; then Proposition 18.194(c), (e). At $(K,\beta)\in\mathfrak{d}(g)$, $\beta>52$ (Definition 18.195(1)).

Step 3: the observables on the torus. Let $(K,\beta)\in\mathfrak{d}(g)$ and $\ell\in\mathfrak{L}(g)$, and let $f\in\mathrm{Lip}_c$ have its support in a ball $\mathbb{B}(x,R)$ with $2R+2a<\frac\ell2$. (i) A point of T_ℓ has at most one lift in $\mathbb{B}(x,R)$, so $|f^{\langle\ell\rangle}|\le\|f\|_\infty$. The barycentres of the plaquettes of one orientation are the image in T_ℓ of a translate of $a\mathbb{Z}^3$, of which a ball of radius R holds at most $(2R/a+1)^3$ points; so at most $3(2R/a+1)^3$ plaquettes have $f^{\langle\ell\rangle}(x(p))\ne0$, and the end points of their bonds lie within the distance $a/\sqrt2$ of their barycentres. As $0\le a_p\le2$ and $a\le1$, $\mathcal{O}(f^{\langle\ell\rangle})$ is a smooth gauge-invariant function, carried by the bonds with both end points in the image of $\mathbb{B}(x,R+a)$, and $\sup|\mathcal{O}(f^{\langle\ell\rangle})|\le6\,\|f\|_\infty(2R+1)^3a^{-4}$. For a tuple X in $\mathbb{B}(x_X,R)$, therefore, A_X is smooth, gauge invariant and carried by the bonds with both end points in the image of $\mathbb{B}(x_X,R+a)$, and $e\,\mathrm{Var}(A_X)\le e\sup|A_X|^2\le e^{\mathsf{N}_K(X)}$, since a centred observable is at most twice the supremum of the observable and $a^{-1}=L^K$. (ii) Let $\mathsf{r}\in\mathsf{Iso}(\mathbb{L}_K)$, the group of the maps $x\mapsto\mathsf{r}^\circ x+v$ with a signed permutation r° of the coordinates and $v\in a\mathbb{Z}^3$, and let r_ℓ be the map that it induces on T_ℓ; the group holds the translations by the vectors of $a\mathbb{Z}^3$, the permutations of the axes and the reflections r_z, $z\in a\mathbb{Z}$, in every direction. Periodisation commutes with r: $(f\circ\mathsf{r}^{-1})^{\langle\ell\rangle}=f^{\langle\ell\rangle}\circ\mathsf{r}_\ell^{-1}$. The isometry sends plaquette barycentres to plaquette barycentres, and relabelling the plaquettes in the sum gives $\mathcal{O}((f\circ\mathsf{r}^{-1})^{\langle\ell\rangle})(\mathsf{r}_\ell U)=\mathcal{O}(f^{\langle\ell\rangle})(U)$. It also preserves A_K and the product Haar measure, hence μ_K. Besides, $\|f\circ\mathsf{r}^{-1}\|_\sharp=\|f\|_\sharp$ for $f\in\mathrm{Lip}_c$: r preserves the Euclidean distance of $\mathbb{R}^3$, so that composing with r^{-1} changes neither the supremum nor the Lipschitz constant. For the tuple $\mathsf{r}X=(f_i\circ\mathsf{r}^{-1})_i$ it follows that $A_{\mathsf{r}X}(\mathsf{r}_\ell U)=A_X(U)$ and $\sigma(\mathsf{r}X)=\sigma(X)$. At $\mathsf{r}=\mathsf{r}_z$ this is $\theta_zA_X=A_{\mathsf{r}_zX}$, so that $\mathsf{h}_X(z)=\sigma(X\cdot\mathsf{r}_zX)-\sigma(X)^2$. (iii) Let Z be

a tuple of $k \geq 2$ entries of the type $(\mathsf{d}'; R)$ whose supports lie in one ball $\mathbb{B}(y, \rho)$ with $\rho + a < \frac{\ell}{4}$, and let $\ell \geq 16k(R+1)$. Then $|\sigma(Z)| \leq \mathsf{T}_k(\mathsf{d}'; R)\, \|Z\|_\sharp$. Indeed, for $w \in a\mathbb{Z}^3$ with $|y-w|_\infty \leq \frac{a}{2}$ the tuple $\tau_{-w}Z$ has, by (ii), the same σ and the same norms, and its supports lie in $\mathbb{B}(y-w,\rho) \subset (-\frac{\ell}{4}, \frac{\ell}{4})^3$; by the moment–cumulant formula, $\sigma(Z) = \sum_{\pi \in \mathrm{Part}_{\geq 2}(k)} \prod_{J \in \pi} S^T_{|J|;K,\ell,\beta}(Z_J)$, and Proposition YM3_I: 91.13 bounds every factor by $C^g_{|J|}(\mathsf{d}'; R) \prod_{f \in Z_J} \|f\|_\sharp$, as $\ell \geq 16|J|(R+1)$.

Step 4: the near mirror. Let X, μ, ξ and z_1 be as in (c). The supports of the entries of $\mathsf{r}_{z_1}X$ lie in $\mathbb{B}(\mathsf{r}_{z_1}x_X, R)$, whose points have their μ-th coordinate $\geq 2z_1 - \xi - R \geq \xi + R + 2$, while those of X have it $\leq \xi + R$. So the $2|X|$ entries of $X \cdot \mathsf{r}_{z_1}X$ are of the type $(\min\{\mathsf{d}, 2\}; R)$, and their supports lie in the ball of radius $R + z_1 - \xi < 2R + 1 + a$ about $x_X + (z_1 - \xi)e_\mu$. As $\frac{\ell}{4} \geq 8|X|(R+1)$, Step 3(iii) applies with $k = 2|X|$ and gives $\sigma(X \cdot \mathsf{r}_{z_1}X) \leq \mathsf{T}_X$; hence $\mathsf{h}_X(z_1) \leq \mathsf{T}_X$ by Step 3(ii).

Step 5: the sign and the convexity. By Step 3(i), the end points of the bonds that carry A_X have their μ-th coordinate in $[\xi - R - a, \xi + R + a]$ modulo ℓ. For $z \in a\mathbb{Z}$ with $\xi + R + a < z < \xi + \frac{\ell}{2} - R - a$, A_X is therefore carried by H^-_z, and Lemma 18.193(b) gives $\mathsf{h}_X(z) = \mathrm{Var}(E[A_X|\mathcal{F}_{\Sigma_z}]) \geq 0$. Let now $\xi + R + 2a < z < \xi + \frac{\ell}{2} - R - 2a$, $z' = z - a$ and $X' = \tau_{-2ae_\mu}X$; then A_X and $A_{X'}$ are carried by $H^-_{z'}$. For $t, t' \in a\mathbb{Z}$ with $t + t' \in 2a\mathbb{Z}$, the point $z' - \frac{t+t'}{2}$ lies in $a\mathbb{Z}$ and $\tau_{-te_\mu} \circ \mathsf{r}_{z'} \circ \tau_{t'e_\mu} = \mathsf{r}_{z'-(t+t')/2}$, so that Step 3(ii) gives $\mathrm{Cov}(A_{\tau_{te_\mu}X}, \theta_{z'}A_{\tau_{t'e_\mu}X}) = \mathsf{h}_X(z' - \frac{t+t'}{2})$. At $(t,t') = (0,0)$, $(0,-2a)$ and $(-2a,-2a)$ these numbers are $\mathsf{h}_X(z-a)$, $\mathsf{h}_X(z)$ and $\mathsf{h}_X(z+a)$, and Schwarz's inequality for the non-negative form of Lemma 18.193(b) at the mirror z' gives $\mathsf{h}_X(z)^2 \leq \mathsf{h}_X(z-a)\,\mathsf{h}_X(z+a)$. A finite sequence $h_k \geq 0$, $k_1 \leq k \leq k_2$, with $h_k^2 \leq h_{k-1}h_{k+1}$ for $k_1 < k < k_2$ satisfies $h_k \leq h_{k_1}^{1-t}h_{k_2}^t$, $t = \frac{k-k_1}{k_2-k_1}$: if one inner member vanishes, the inequality, applied step by step, makes all inner members vanish; otherwise all members are positive, since an end member that vanished would make its inner neighbour vanish, and $\log h_k$ is convex in k.

Step 6: the far mirror; clause (c). As $a \leq \frac{1}{13}$ and $\frac{\ell}{4} \geq 8(R+1)$, the points z_1 and z_2 satisfy $\xi + R + a < z < \xi + \frac{\ell}{2} - R - a$, and every point z of $a\mathbb{Z}$ strictly between them satisfies $\xi + R + 2a < z < \xi + \frac{\ell}{2} - R - 2a$; so Step 5 applies on $a\mathbb{Z} \cap [z_1, z_2]$. The function $\theta_{z_2}A_X = A_{\mathsf{r}_{z_2}X}$ is carried by bonds whose end points, and so whose midpoints, have their μ-th coordinate in $[2z_2 - \xi - R - a, 2z_2 - \xi + R + a]$. As $\frac{\ell}{2} - 2a < 2(z_2 - \xi) \leq \frac{\ell}{2}$, and as the Euclidean distance of T_ℓ is at least the distance of the μ-th coordinates on the circle $\mathbb{R}/\ell\mathbb{Z}$, the carriers of A_X and of $\theta_{z_2}A_X$ are at a distance $r_2 \geq 2(z_2 - \xi) - 2R - 2a > 0$. Both functions are gauge invariant, so (b), Step 3(i) and Step 5 give $\mathsf{h}_X(z_2) \leq e\,\mathrm{Var}(A_X)\, e^{-\alpha_{\mathrm{P}} r_2} \leq e^{\mathsf{N}_K(X) - \alpha_{\mathrm{P}} r_2}$. For $z \in a\mathbb{Z} \cap [z_1, z_2]$ and $t = \frac{z - z_1}{z_2 - z_1}$, Steps 4 and 5 give

$$\mathsf{h}_X(z) \leq \mathsf{h}_X(z_1)^{1-t}\, \mathsf{h}_X(z_2)^t \leq \max\{1, \mathsf{T}_X\}\, \exp(t\, \mathsf{N}_K(X) - t\, \alpha_{\mathrm{P}} r_2).$$

Since $z_1 \geq \xi + R + 1$, $r_2 \geq 2(z_2 - z_1) + 2 - 2a$, so that $t\, r_2 \geq 2(z - z_1)$; since $z_2 - z_1 > \frac{\ell}{4} - R - 1 - 2a \geq \frac{\ell}{4} - R - 2$, $t \leq (z - z_1)/(\frac{\ell}{4} - R - 2)$. This is (c).

Step 7: clause (d). Choose a direction μ with $|v_\mu| \geq |v|/\sqrt{3}$, and let $\xi_1 = (x_X)_\mu$, $\xi_2 = (x_Y + v)_\mu$ and $\mathsf{s} = |\xi_2 - \xi_1|$; then $\frac{|v|}{\sqrt{3}} - |x_X - x_Y| \leq \mathsf{s} \leq |v| + |x_X - x_Y|$. The reflection $\rho\colon x_\mu \mapsto -x_\mu$ lies in $\mathsf{Iso}(\mathbb{L}_K)$, and by Step 3(ii) it leaves the left member of (d) unchanged when it is applied to X, to Y and to v; so we may take $\xi_2 > \xi_1$. As $|v| \geq r_0$, $|x_X - x_Y| + 2R + 4 \leq \frac{r_0}{2\sqrt{3}} \leq \frac{|v|}{2\sqrt{3}}$; hence $\mathsf{s} \geq 4R + 12$ and $\mathsf{s} - 2R - 4 \geq \frac{|v|}{2\sqrt{3}}$, and, as $|v| \leq \frac{\ell}{4}$, $\mathsf{s} \leq \frac{\ell}{4} + \frac{\ell}{8\sqrt{3}} < \frac{\ell}{2} - 2a$. Let $z \in a\mathbb{Z}$ with $|z - \frac{\xi_1 + \xi_2}{2}| \leq \frac{a}{2}$. Then $\xi_1 + R + 1 \leq z \leq \xi_1 + \frac{\ell}{4}$, so that $z_1 \leq z \leq z_2$ for the mirrors of X in the direction μ, and $z - z_1 \geq \frac{\mathsf{s}}{2} - \frac{a}{2} - R - 1 - a \geq \frac{\mathsf{s}}{2} - R - 2$. The reflection ρ carries $\tau_v Y$ to a tuple $\rho\tau_v Y$ in a ball whose centre has the μ-th coordinate $-\xi_2$, the mirror z to $-z$, and θ_z to θ_{-z}; for $\rho\tau_v Y$ and $-z$ the same bounds hold. So A_X is carried by H^-_z and $A_{\tau_v Y}$ by H^+_z (Step 5), and Lemma 18.193(b), Step 3(ii) and (c), applied to X and to $\rho\tau_v Y$, give

$$|\mathrm{Cov}(A_X, A_{\tau_v Y})|^2 \leq \mathsf{h}_X(z)\, \mathsf{h}_{\rho\tau_v Y}(-z) \leq \max\{1, \mathsf{T}_X\} \max\{1, \mathsf{T}_Y\}\, e^{-2\alpha_{\mathrm{eff}}(\mathsf{s} - 2R - 4)},$$

where $\alpha_{\mathrm{eff}} \geq 0$ is used, and where $\mathsf{T}_{\rho\tau_v Y} = \mathsf{T}_Y$ and $\mathsf{N}_K(\rho\tau_v Y) = \mathsf{N}_K(Y)$, the isometries of $\mathbb{R}^3$ preserving the type of a tuple and the norms of its entries. As $\mathrm{Cov}(A_X, A_{\tau_v Y}) = \sigma(X \cdot \tau_v Y) - \sigma(X)\sigma(\tau_v Y)$ and $\mathsf{s} - 2R - 4 \geq \frac{|v|}{2\sqrt{3}}$, this is (d). If $\ell \geq 4R + 8 + 4\,\mathsf{N}_K(X,Y)\sqrt{185\,\mathsf{bc}_{\mathrm{P}}}$, then $\mathsf{N}_K(X,Y)/(\frac{\ell}{2} - 2R - 4) \leq \frac{1}{2}\alpha_{\mathrm{P}}$.

Step 8: clause (e). By Proposition YM3_I:91.2, $\ell_i \to \infty$, $\ell_i \in \{2L^j : j \in \mathbb{N}\}$ and $\tilde{\mu}_{K,\ell_i,\beta} \to \nu$ weakly. As $\beta > 52$, (a) gives $\mathsf{c}_{\mathrm{P}}(K, \ell_i, \beta) \geq a^2/(48\,\mathsf{b})$ for every i, hence the floor of $\mathsf{c}^\sharp$. Let $\mathsf{c}^\sharp < \infty$, take a subsequence along which $\mathsf{c}_{\mathrm{P}}(K, \ell_i, \beta) \to \mathsf{c}^\sharp$, and fix v with $|v| \geq r_0$. For all large i of the subsequence, $\ell_i \in \mathfrak{L}(g)$, $\ell_i \geq 32n(R+1)$ and $|v| \leq \frac{\ell_i}{4}$; and the number α_{eff} formed at ℓ_i tends to $(185\,\mathsf{bc}^\sharp)^{-1/2} > 0$, since $\mathsf{N}_K(X,Y)$ does not depend on the side. So (d) holds at these ℓ_i. By YM3_I:(1824), $\sigma_\nu(Z) = \lim_i \sigma_{K,\ell_i,\beta}(Z)$ for the tuples $Z = X \cdot \tau_v Y$, X and $\tau_v Y$, whose entries are bounded real functions with compact supports; the bound passes to the limit.

Step 9: clause (f). By the definition of a volume-first limit, $(K_j, \beta_j) \in \mathfrak{d}(g)$ and $\nu_j \in \mathcal{G}^{\mathrm{tor}}_{K_j,\beta_j}$; so (e) holds at every j, with $\mathsf{b}_j\mathsf{c}^\sharp_j$, $\mathsf{b}_j = a_{K_j}\beta_j$, in the place of $\mathsf{bc}^\sharp$, and with one constant $C(X,Y)$ for all j (Proposition YM3_I:91.13). For a law ν and a tuple Z of k entries, $\sigma_\nu(Z) = \sum_{\pi \in \mathrm{Part}_{\geq 2}(k)} \prod_{J \in \pi} S^T_{|J|}[\nu](Z_J)$. Sub-tuples of separated tuples are separated, so the defining convergence of cumulants gives $\sigma_S(Z) = \lim_j \sigma_{\nu_j}(Z)$ for every separated tuple Z. For $|v| \geq r_0$ the balls $\mathbb{B}(x_X, R)$ and $\mathbb{B}(x_Y + v, R)$ are disjoint, as $|x_X - x_Y - v| \geq r_0 - |x_X - x_Y| > 2R$, so that $X \cdot \tau_v Y$ is separated. Along a subsequence with $\mathsf{b}_j\mathsf{c}^\sharp_j \to \mathsf{c}^*$ the bounds of (e) tend to the bound of (f).

Step 10: clause (g). Let I and J index the entries of X and of $\tau_v Y$ in $X \cdot \tau_v Y$. For $B \subset \mathsf{I} \sqcup \mathsf{J}$ let m_B be the centred moment of the sub-tuple Z_B of $X \cdot \tau_v Y$ with the entries indexed by B, that is $\sigma(Z_B)$, $\sigma_\nu(Z_B)$ or $\sigma_S(Z_B)$, with $m_\emptyset = 1$, and let $\tilde{m}_B = m_{B\cap\mathsf{I}}\, m_{B\cap\mathsf{J}}$. A cumulant of order $N \geq 2$ does not change when constants are added to the variables, and it is a polynomial in the moments. Expanding the logarithm of the generating function shows that the truncated function of (g) is $\sum_{\pi \in \mathrm{Part}(N)} (-1)^{|\pi|-1}(|\pi|-1)! \prod_{B\in\pi} m_B$, on the torus and at ν, and, by passage to the limit as in Step 9, for S. The same polynomial in the $\tilde{m}_B$ vanishes by a formal factorization. In the commutative algebra with $z_i^2 = 0$, put $z_B = \prod_{i \in B} z_i$. The moment series $\sum_B \tilde{m}_B z_B$ factors as

$$\Big(\sum_{C \subset \mathsf{I}} m_C z_C\Big)\Big(\sum_{D \subset \mathsf{J}} m_D z_D\Big).$$

Its formal logarithm is the sum of the logarithms of the factors. Each summand uses only one of the two nonempty index sets, so the coefficient of $z_{\mathsf{I}\sqcup\mathsf{J}}$ is zero. Hence the truncated function equals $\sum_\pi (-1)^{|\pi|-1}(|\pi|-1)!\,[\prod_{B\in\pi} m_B - \prod_{B\in\pi}\tilde{m}_B]$, and $|\prod_{B\in\pi} m_B - \prod_{B\in\pi}\tilde{m}_B| \leq \mathsf{p}(X,Y)^{|\pi|-1}\sum_{B\in\pi}|m_B - \tilde{m}_B|$ as soon as all $|m_B|$ and $|\tilde{m}_B|$ are at most $\mathsf{p}(X,Y)$. Here $m_B - \tilde{m}_B = 0$ unless B meets both I and J, and then it is the left member of (d), (e) or (f) for a pair of non-empty sub-tuples X', Y'; these lie in the same balls, and $\mathsf{N}_K(X',Y') \leq \mathsf{N}_K(X,Y)$, so that the bound holds with $C(X',Y') \leq \bar{C}(X,Y)$ and the exponential of (d), (e) or (f). For $B \subset \mathsf{I}$, $|m_B| \leq \mathsf{t}(X_B)$ by Step 3(iii), the sub-tuple lying in one ball of radius R and $\ell \geq 16|B|(R+1)$, and by passage to the limit at ν and for S; likewise for $B \subset \mathsf{J}$; and for B that meets both, $|m_B| \leq |\tilde{m}_B| + |m_B - \tilde{m}_B| \leq \mathsf{t}(X')\,\mathsf{t}(Y') + C(X',Y')$, the exponential being at most 1. So all $|m_B|, |\tilde{m}_B| \leq \mathsf{p}(X,Y)$, and the sum over π gives the factor $C'(X,Y)$. □

Remark 18.197 (The limit laws of the block fields under a uniform Poincaré constant). Fix a side $\ell = 2L^m$ and a label b in the fixed-torus setting (E), with $\mathsf{b} \geq \gamma^{-2}$ and $MR(\mathsf{b}) \leq L^m$ (YM3_I:(2201)). Set $\beta_K = L^K\mathsf{b}$ and assume a uniform C_{P}. For $d \geq 0$, let φ, ψ be bounded Borel functions on Ω_d with bond carriers $\mathcal{Q}, \mathcal{Q}'$ as in Proposition 18.194(e), and suppose at least one is gauge invariant. The limiting law μ_d satisfies

$$|\,\mathrm{Cov}_{\mu_d}(\varphi,\psi)| \leq e\,\|\varphi\|_\infty\|\psi\|_\infty \exp\Big(-\frac{\mathrm{dist}(\Delta(\mathcal{Q}),\Delta(\mathcal{Q}'))}{e\sqrt{6\mathsf{b}C_{\mathrm{P}}}}\Big).$$

Indeed, Proposition 18.194(e) gives this estimate at cutoff K with an additional a_K in the denominator. Corollary 2.8(c) gives total-variation convergence of the block laws, so the three bounded Borel expectations converge.

For the time estimate let $P_t^K = e^{t\mathcal{L}_K}$. The smooth elliptic generator on the compact configuration space gives a reversible diffusion with invariant law μ_K. Gauge invariance of μ_K and the energy implies that P_t^K preserves gauge-invariant functions. For a centred gauge-invariant function H, smoothing at $t > 0$ and the Poincaré inequality give

$$\frac{d}{dt}\|P_t^K H\|^2 = -2\mathcal{E}_K(P_t^K H) \le -\frac{2}{C_{\mathrm{P}}}\|P_t^K H\|^2.$$

Strong continuity at $t = 0$ and integration give $\|P_t^K H\| \le e^{-t/C_{\mathrm{P}}}\|H\|$ for all large K. Use the time convention of the generator $\frac{1}{2}\mathcal{L}_K$. Stationarity, reversibility and Cauchy–Schwarz bound the absolute covariance between $\varphi(\pi_d U_0)$ and $\psi(\pi_d U_{t/2})$ by

$$e^{-t/(2C_{\mathrm{P}})}\big(\mathrm{Var}_{\mu_d^K}(\varphi)\,\mathrm{Var}_{\mu_d^K}(\psi)\big)^{1/2}.$$

Here U_t denotes the stationary diffusion for $\mathcal{L}_K$. The estimate passes to each subsequential two-time law of these bounded observations, with μ_d in place of μ_d^K. Such subsequences exist at every fixed t by compactness of the range closures of the two observations. In particular the two-time covariance of a nonconstant bounded gauge-invariant observable with itself has this exponential decay, and the mean square change is at least twice its limiting variance times $1 - e^{-t/(2C_{\mathrm{P}})}$.

18.21. **A slab with an infinite section, all the cubes at all labels, and a coupling that varies with the place.** The constructions use the Wilson law and the sourced frames of Definitions 13.1 and 13.2. Further notation is given in Definitions 18.198, 18.200 and 18.202. Proposition 18.199 concerns the slab $\mathbb{R}^2 \times (\mathbb{R}/l\mathbb{Z})$ whose thickness l is a side admitted at the reference coupling. At a fixed cutoff the Wilson measures of the periodic boxes $\Lambda \times \Lambda \times l$ are first taken to infinite section, $\Lambda \to \infty$; then the cutoff is removed along first-passage data. Along a subsequence the connected functions of the action density converge on the slab; the limit is invariant under the translations of the slab and reflection positive at the mirrors of all three coordinate directions; and when the supports lie in balls of a radius R, pairwise at a distance $\ge \mathsf{d}$, it obeys one bound of the shape of the growth bound of the main text, a number of d times the n-th power of a number of R times $(n!)^{5+\mathsf{p}}$ times the product of the norms $\|\cdot\|_\sharp$ of the n test functions; its two numbers are formed from the numbers of item (6) of Definition 18.198, and they depend neither on the cutoff nor on the section, the thickness or the state. The reconstruction in the periodic direction gives exactly one self-adjoint generator and an antiunitary involution that reverses it; the kernels of the limit at sharp heights are holomorphic in all the heights and of slow growth; and they define a state on an algebra of fields smeared in time which satisfies the condition of Kubo, Martin and Schwinger at the inverse temperature l, at imaginary and at real times. Proposition 18.201 bounds the limit cumulants $S_n^{(\ell,\mathsf{b})}$ on every periodic cube T_ℓ, $\ell = 2L^m$, $m \in \mathbb{Z}$, at every label $\mathsf{b} > 0$, by $\mathsf{b}^{-n}\mathsf{A}(\mathsf{d}/\mathsf{b})\hat{\mathsf{B}}(R/\mathsf{b})^n(n!)^{\varkappa_\star}\prod_q \max\{\sup|f_q|, \mathsf{b}\,\mathrm{Lip} f_q\}$, with two functions of d/b and of R/b alone and the exponent $\varkappa_\star$ of the main text; on the cubes that are small against the label the base is one number, and it tends to 0 like $(\ell/\mathsf{b})^{1/2}$ up to a power of a logarithm. Corollary YM3_I:119.2 supplies the full cutoff limit on each cube. Proposition 18.201 supplies the bound uniformly in ℓ/b. Proposition 18.203 concerns one torus on which the plaquette p carries the coupling $a_K^{-1}(\mathsf{b} + h(x(p)))$, with a real Lipschitz function h in the real source ball $\|h\|_\flat < 2\varrho$ of Theorem YM3_I:AD: the connected functions of the action density converge along all the cutoffs; for $\|h\|_\flat < r_1$ the limit is the series $\sum_k \frac{(-1)^k}{k!} S_{n+k}^{(\ell,\mathsf{b})}(\underline{f}, h, \dots, h)$, obtained by Taylor expansion at zero source; and at a constant h the limit is the limit cumulant at the label $\mathsf{b} + h$. Its new ingredient is a floor for the partition function at all the real sources of the class, uniform in the cutoff, drawn from the history without large fields.

Definition 18.198 (The slab; boxes over it; observables and tuples on it)**.** Fix a frame of Definition 13.1 with radius parameter ϱ, so its source ball has radius 2ϱ. Write $a_K = L^{-K}$, $\mathbb{L}_K = a_K\mathbb{Z}^3$ and $\mathfrak{L} = \{2L^m : m \geq 1\}$. A law is a Borel probability measure on the product of the bond configuration spaces. As in Definition 13.1, set $C_g = C_{\mathrm{st}} + \frac{9}{2}\log X_g$. For a Euclidean closed ball write $\mathbb{B}(y,r)$, and for compactly supported Lipschitz functions v_q put $\mathbb{D}_\varrho(\underline{v}) = \{z : \sum_q |z_q|\,\|v_q\|_\sharp < \varrho\}$, with $\|v_q\|_\sharp = \max\{\|v_q\|_\infty, 40M\,\mathrm{Lip}\,v_q\}$.

Let $0 < g \leq \gamma$, and let $l = 2L^{m_l} \in \mathfrak{L}(g)$ be a side admitted at g. The slab is $\mathbb{E} := \mathbb{R}^3/\mathbb{Z}le_3 = \mathbb{R}^2 \times (\mathbb{R}/l\mathbb{Z})$, with the projection $\mathrm{pr}\colon \mathbb{R}^3 \to \mathbb{E}$ and the quotient distance $|x-y|$; balls are closed.

(1) *Boxes.* For $K \in \mathbb{N}$, $\beta > 0$ and a side $\Lambda \in \mathfrak{L}$ with $\Lambda \geq l$ let $\Gamma_\Lambda := \Lambda\mathbb{Z} \times \Lambda\mathbb{Z} \times l\mathbb{Z}$. The law $\mu_{\Gamma_\Lambda,\beta}$ is the Wilson law on the corresponding rectangular quotient, periodically lifted to $\mathbb{L}_K$. For an unbounded set $\mathfrak{l}_0 \subset \mathfrak{L}$, $\mathcal{G}^{\mathrm{box}}_{K,\beta}(\mathfrak{l}_0)$ is the set of the weak limit points of $\mu_{\Gamma_\Lambda,\beta}$ as $\Lambda \to \infty$ in $\mathfrak{l}_0$. It is not empty, because the space of the configurations is compact and metrisable as a countable product of compact metrisable spaces and so the laws on it form a weakly compact set. Each of its members is carried by the closed set $\mathcal{V}^{\mathrm{sl}} := \{U : \tau_{le_3}U = U\}$.

(2) *The sequence.* (K_j, β_j), $j \in \mathbb{N}$, are first-passage data at g with $K_j \to \infty$ and labels $b_j = a_{K_j}\beta_j \to b$, and $\nu_j \in \mathcal{G}^{\mathrm{box}}_{K_j,\beta_j}(\mathfrak{L}(g))$.

(3) *Observables.* For a bounded function f on $\mathbb{E}$ with compact support, $\mathcal{O}^{\mathrm{sl}}_K(f)(U) := a_K^{-1}\sum_p f(\mathrm{pr}\,x(p))\,a_p(U)$ on $\mathcal{V}^{\mathrm{sl}}$, the sum running over one plaquette of every class modulo $\mathbb{Z}le_3$. For a bounded function $\tilde f$ on $\mathbb{R}^3$ with compact support, $\tilde f^{\langle l\rangle}(\mathrm{pr}\,x) := \sum_{k\in\mathbb{Z}} \tilde f(x + kle_3)$; then $\mathcal{O}_K(\tilde f) = \mathcal{O}^{\mathrm{sl}}_K(\tilde f^{\langle l\rangle})$ on $\mathcal{V}^{\mathrm{sl}}$. For a law ν carried by $\mathcal{V}^{\mathrm{sl}}$, $S^T_n[\nu](f_1,\dots,f_n)$ is the joint cumulant of $\mathcal{O}^{\mathrm{sl}}_K(f_1),\dots,\mathcal{O}^{\mathrm{sl}}_K(f_n)$ under ν, and $\sigma_\nu(X) := \nu(\prod_q(\mathcal{O}^{\mathrm{sl}}_K(f_q) - \nu(\mathcal{O}^{\mathrm{sl}}_K(f_q))))$ for $X = (f_1,\dots,f_n)$; by the moment–cumulant identity YM3_I:(1741), since centring removes the singleton blocks, $\sigma_\nu(X) = \sum_{\pi\in\mathrm{Part}_{\geq 2}(\{1,\dots,n\})}\prod_{J\in\pi} S^T_{|J|}[\nu](X_J)$.

(4) *Tuples.* For an open set $O \subset \mathbb{E}$, $\mathfrak{S}_n(O)$ is the set of the n-tuples of real functions of class $C^1_c(\mathbb{E})$ with pairwise disjoint supports in O; $\mathfrak{S}(O) = \bigcup_{n\geq 0}\mathfrak{S}_n(O)$, the empty tuple $\varnothing$ included; $\mathbb{C}\mathfrak{S}(O)$ is the set of the finite complex combinations, and $\bar F$ conjugates the coefficients, $X \cdot X'$ concatenates tuples when their joint supports are separated, X_J selects the indices in J, and a map r acts by $rX = (f_q \circ r^{-1})_q$, extended to combinations. A tuple is of the type $(\mathsf{d}; R)$ if its supports lie pairwise at the distance $\geq \mathsf{d}$ and each in a ball of radius R; $\|\cdot\|_\sharp$ is formed with the distance of $\mathbb{E}$, and $\|X\|_\sharp = \prod_q \|f_q\|_\sharp$. A family $S = (S_n)_{n\geq 2}$ of maps on the tuples has the centred functional $\sigma_S(X) := \sum_{\pi\in\mathrm{Part}_{\geq 2}}\prod_{J\in\pi} S_{|J|}(X_J)$, $\sigma_S(\varnothing) = 1$, extended linearly to combinations.

(5) *Maps.* τ_v, $v \in \mathbb{R}^3$, are the translations. For $\mu \in \{1,2,3\}$ and $c \in \mathbb{R}$, $\theta_{e_\mu,c}$ is the reflection of $\mathbb{R}^3$ that sends the coordinate x_μ to $2c - x_\mu$ and keeps the two others. When $c \in \frac{a_K}{2}\mathbb{Z}$, the plane $\Sigma(e_\mu, c) = \{x_\mu = c\}$ is a lattice mirror of $\mathbb{L}_K$, $\theta_{e_\mu,c}$ is its reflection and $\mathbb{H}^\pm(e_\mu, c) = \{\pm(x_\mu - c) \geq 0\}$ are its closed sides, and $\theta_{e_\mu,c}$ is an isometry of $\mathbb{L}_K$ because $2c$ is a lattice coordinate. The linear part of $\theta_{e_\mu,c}$ maps $\mathbb{Z}le_3$ onto itself, so $\theta_{e_\mu,c}$ induces a map of $\mathbb{E}$; for $\mu = 1,2$ this induced map bears the same name, and r_c stands both for $\theta_{e_3,c}$ and for the map $x_3 \mapsto 2c - x_3$ that it induces on $\mathbb{E}$. W_2 is the group of the eight signed permutations of (e_1, e_2), acting on the first two coordinates; $\mathsf{E}_2 := \mathbb{R}^2 \rtimes W_2$, acting on the first two coordinates.

(6) *Numbers.* Let C_Q, p and U be the constants of Proposition YM3_I:91.12 at g. Put $A^{\mathrm{per}}(\mathsf{d}) = 1 + \mathsf{U}(1,\mathsf{d})$. Use for C^{sl}_B the constant YM3_I:(1848) with $e^{2C_{\mathrm{S}}+C_g}C_Q$ in place of C_Q; $B^{\mathrm{sl}}(R) := C^{\mathrm{sl}}_B(R+1)^3$; and for $n \geq 2$, $\mathsf{d}, R > 0$,

$$C^{\mathrm{sl}}_n(\mathsf{d};R) := A^{\mathrm{per}}(\mathsf{d})\big[(1+40M)\,B^{\mathrm{sl}}(2R+1)\big]^n (n!)^{5+\mathsf{p}}, \qquad C^{\sigma}_n(\mathsf{d};R) := \sum_{\pi\in\mathrm{Part}_{\geq 2}(\{1,\dots,n\})}\prod_{J\in\pi} C^{\mathrm{sl}}_{|J|}(\mathsf{d};R).$$

■

Proposition 18.199 (The slab $\mathbb{R}^2\times(\mathbb{R}/l\mathbb{Z})$: limits with the section first, mirrors in three directions, a self-adjoint generator, a state at the inverse temperature l)**.** Let the data be as in Definition 18.198.

(a) Domination. Let $K\in\mathbb{N}$, $\beta>0$, $\mathfrak{l}_0\subset\mathfrak{L}$ unbounded, $\nu\in\mathcal{G}^{\mathrm{box}}_{K,\beta}(\mathfrak{l}_0)$, let (i,o) be a board of $\mathbb{L}_K$ of the side $\mathsf{l}=a_i$, $i\le K$ and $o\in a_K\mathbb{Z}^3$, with the cells and copies of Lemma 18.239, and let $\ell'\in\mathfrak{L}$ with $2\mathsf{l}\le\ell'\le l$. For every finite set $\mathsf{S}\subset\mathbb{Z}^3$ whose members are pairwise incongruent modulo $(l/\mathsf{l})\mathbb{Z}e_3$ and all continuous functions $F_{\mathbf{k}}$ of the bonds of the cells $\square_{\mathbf{k}}$, $\mathbf{k}\in\mathsf{S}$,

$$\Big|\nu\Big(\prod_{\mathbf{k}\in\mathsf{S}}F_{\mathbf{k}}\Big)\Big|\le\prod_{\mathbf{k}\in\mathsf{S}}q_{\mathsf{l}}^{\mathrm{sl}}\,\|F_{\mathbf{k}}\|_{\mathrm{ch},\ell'},\qquad q_{\mathsf{l}}^{\mathrm{sl}}:=e^{\mathsf{l}^3(p_{\ell'}-p_\infty)},\quad p_\infty:=\inf_{\ell\in\mathfrak{L}}p_\ell,$$

where $p_\ell=\ell^{-3}\log Z_{K,\ell,\beta}$ and the reflected-product seminorm at side ℓ' is that of Lemma 18.239. If (K,β) is a first-passage datum at g and $\ell'\in\mathfrak{L}(g)$, then $q_{\mathsf{l}}^{\mathrm{sl}}\le e^{\mathsf{l}^3(2C_{\mathrm{S}}+C_g)}$.

(b) Symmetries and mirrors of the box limits. Every $\nu\in\mathcal{G}^{\mathrm{box}}_{K,\beta}(\mathfrak{l}_0)$ is invariant under the translations by $a_K\mathbb{Z}^3$, under W_2 and under the reflections $\theta_{e_\mu,c}$, $\mu=1,2,3$, $c\in\frac{a_K}{2}\mathbb{Z}$. It is reflection positive at every lattice mirror $\Sigma(e_\mu,c)$, $\mu\in\{1,2\}$, $c\in\frac{a_K}{2}\mathbb{Z}$, on bounded local functions of bonds with both endpoints in the closed positive half-space; and $\nu(\overline{\theta_{e_3,c}F}\,F)\ge0$ for every $c\in\frac{a_K}{2}\mathbb{Z}$ and every continuous function F of finitely many bonds in $\{c\le x_3\le c+\frac{l}{2}\}$.

(c) Bounds. Let (K,β) be a first-passage datum at g and $\nu\in\mathcal{G}^{\mathrm{box}}_{K,\beta}(\mathfrak{L}(g))$. For $n\ge2$, $\mathsf{d},R>0$ and real Lipschitz functions $f_1,\dots,f_n$ on $\mathbb{E}$ of the type $(\mathsf{d};R)$,

$$|S_n^T[\nu](f_1,\dots,f_n)|\le C_n^{\mathrm{sl}}(\mathsf{d};R)\prod_q\|f_q\|_\sharp,\qquad|\sigma_\nu(f_1,\dots,f_n)|\le C_n^{\sigma}(\mathsf{d};R)\prod_q\|f_q\|_\sharp.$$

Both bounds remain true when ν is replaced by the measure $\mu_{\Gamma_\Lambda,\beta}$ of a finite box, for every $\Lambda\in\mathfrak{L}(g)$ with $\Lambda\ge l$ that is larger than d plus the Euclidean diameter of the set $\{(x_1,x_2):x\in\bigcup_q\mathrm{supp}f_q\}\subset\mathbb{R}^2$. The two numbers are built from g, the radius ϱ and the constants; they depend neither on K, β, l, Λ, ν nor on the positions of the supports, and they do not increase in d.

(d) Limits with the section first. There is a subsequence of (j) along which $S_n^T[\nu_j](X)$ converges for every $n\ge2$ and every $X\in\mathfrak{S}_n(\mathbb{E})$. Every limit S, taken along a subsequence on which all these numbers converge, is real, symmetric and multilinear; it obeys the two bounds of (c); and it is invariant under all the translations of $\mathbb{E}$, under W_2 and under every r_c, $c\in\mathbb{R}$. If $X^{(j)}\to X$ member by member in $\|\cdot\|_\sharp$, the supports lying in one compact set and, at each j, pairwise at the distance $\ge\mathsf{d}>0$, then $\sigma_{\nu_j}(X^{(j)})\to\sigma_S(X)$ along the subsequence.

(e) Mirrors of the limit in the three directions. For every such S, every real c and every $F\in\mathbb{C}\mathfrak{S}(H_+)$, $\sigma_S(\theta\bar F\cdot F)\ge0$ for $(\theta,H_+)=(\theta_{e_\mu,c},\{x_\mu>c\})$, $\mu=1,2$, and for $(\theta,H_+)=(\mathsf{r}_c,\{c<x_3<c+\frac{l}{2}\})$.

(f) The generator and the involution. For an open interval $I\subset(0,\frac{l}{2})$ put $\mathcal{D}_I:=\mathbb{C}\mathfrak{S}(\{x_3\in I\})$, and $\mathcal{D}:=\mathcal{D}_{(0,l/2)}$. The form $\langle F,G\rangle:=\sigma_S(\mathsf{r}_0\bar F\cdot G)$ is positive on $\mathcal{D}$; it gives a Hilbert space $\mathcal{H}^{\mathrm{sl}}$, classes $[F]$ and $\Omega^{\mathrm{sl}}:=[\varnothing]$. For $0<\mathsf{a}<\mathsf{a}'<\frac{l}{2}$ and $F\in\mathcal{D}_{(\mathsf{a},\mathsf{a}')}$ there is exactly one finite positive Borel measure ρ_F on $\mathbb{R}$ with $\sigma_S(\mathsf{r}_0\bar F\cdot\tau_{re_3}F)=\int e^{-r\lambda}\,d\rho_F(\lambda)$ for $-2\mathsf{a}<r<l-2\mathsf{a}'$. There is exactly one self-adjoint operator H_3 in $\mathcal{H}^{\mathrm{sl}}$ such that $[F]\in\mathrm{Dom}(e^{-r\mathsf{H}_3})$ and $e^{-r\mathsf{H}_3}[F]=[\tau_{re_3}F]$ for all such a,a',F and all $-\mathsf{a}<r<\frac{l}{2}-\mathsf{a}'$. Then $\mathsf{H}_3\Omega^{\mathrm{sl}}=0$; $z\mapsto e^{-z\mathsf{H}_3}[F]$ is holomorphic on $-\mathsf{a}<\mathrm{Re}\,z<\frac{l}{2}-\mathsf{a}'$; and ρ_F is the spectral measure of H_3 in $[F]$. There is exactly one antiunitary operator J^{sl} with $J^{\mathrm{sl}}[F]=[\mathsf{r}_{l/4}\overline{F}]$; $(J^{\mathrm{sl}})^2=1$, $J^{\mathrm{sl}}\Omega^{\mathrm{sl}}=\Omega^{\mathrm{sl}}$ and $J^{\mathrm{sl}}\mathsf{H}_3J^{\mathrm{sl}}=-\mathsf{H}_3$, so that $J^{\mathrm{sl}}e^{-s\mathsf{H}_3}J^{\mathrm{sl}}=e^{s\mathsf{H}_3}$ and the spectrum of H_3 is symmetric about 0. The group E_2 acts by unitary operators $[F]\mapsto[\mathsf{g}F]$ that fix Ω^{sl}, commute with $e^{it\mathsf{H}_3}$ and with J^{sl}, and are strongly continuous on the translations.

(g) Kernels at sharp heights. For $\chi\in C^1_c(\mathbb{R})$ and $h\in C^1_c(\mathbb{R}^2)$ put $(\chi\otimes h)(\mathrm{pr}\,x):=h(x_1,x_2)\sum_{k\in\mathbb{Z}}\chi(x_3+kl)$; let $\mathcal{U}_n:=\{s\in\mathbb{R}^n:s_k-s_{k'}\notin l\mathbb{Z}\text{ for }k\ne k'\}$ and $\mathrm{gap}(s):=$

$\min_{k\neq k'}\operatorname{dist}(s_k-s_{k'},l\mathbb{Z})$. For every $n\geq 1$ and $h=(h_1,\dots,h_n)\in C^1_c(\mathbb{R}^2)^n$ there is exactly one continuous function $\mathfrak{K}_n(\cdot;h)$ on $\mathcal{U}_n$ with

$$\sigma_S(\chi_1\otimes h_1,\dots,\chi_n\otimes h_n)=\int\prod_k\chi_k(s_k)\,\mathfrak{K}_n(s;h)\,ds$$

whenever $\prod_k\operatorname{supp}\chi_k\subset\mathcal{U}_n$ and each $\operatorname{supp}\chi_k$ lies in an interval shorter than l. It is the restriction of a function holomorphic on $\mathcal{U}_n+i\mathbb{R}^n$; it is multilinear in h, symmetric under the common permutations of the pairs (z_k,h_k), of the period l in each z_k, invariant under $z\mapsto z+c\mathbf{1}$ $(c\in\mathbb{C})$, under $z\mapsto -z$ and under $h\mapsto \mathsf{g}h$, $\mathsf{g}\in\mathsf{E}_2$, and real at real points; $\mathfrak{K}_1=0$. If $n\geq 2$ and every $\operatorname{supp}h_k$ lies in a disc of radius R, then

$$|\mathfrak{K}_n(z;h)|\leq \mathsf{c}_n(R,l)\,\min\{1,\operatorname{gap}(\operatorname{Re}z)\}^{-\varkappa_{\mathrm{w}}n}\prod_k\|h_k\|_\sharp,\qquad \varkappa_{\mathrm{w}}:=\tfrac{21}{2}+\mathsf{p},$$

with a number $\mathsf{c}_n(R,l)$ built from n, R, l, g, the radius ϱ and the constants. Continued complex-multilinearly in h, with $\mathfrak{K}_0:=1$, the kernel

$$((z,h),(z',h'))\mapsto \mathfrak{K}_{n+n'}(-\bar z_n,\dots,-\bar z_1,z'_1,\dots,z'_{n'};\bar h_n,\dots,\bar h_1,h'_1,\dots,h'_{n'})$$

is of positive type on the set of the pairs (z,h), $n\geq 0$, $0<\operatorname{Re}z_1<\dots<\operatorname{Re}z_n<\frac{l}{2}$, $h\in C^1_c(\mathbb{R}^2;\mathbb{C})^n$.

(h) The state and the condition at the inverse temperature l. Let $\mathscr{G}$ be the space of the entire functions ϕ with $\sup_{|\operatorname{Im}t|\leq c}(1+|t|)^N|\phi(t)|<\infty$ for all $c,N\geq 0$; $\phi^*(t):=\overline{\phi(\bar t)}$ and $(\alpha_c\phi)(t):=\phi(t-c)$, $c\in\mathbb{C}$. Let $\mathfrak{A}^{\mathrm{sl}}$ be the tensor algebra over $\mathscr{G}\otimes C^1_c(\mathbb{R}^2;\mathbb{C})$ with the generators $\Phi(\phi,h)$, the involution $\Phi(\phi,h)^*:=\Phi(\phi^*,\bar h)$, the automorphisms $\alpha_c\Phi(\phi,h):=\Phi(\alpha_c\phi,h)$, which are $*$-automorphisms for real c, and $\mathsf{g}\Phi(\phi,h):=\Phi(\phi,\mathsf{g}h)$, $\mathsf{g}\in\mathsf{E}_2$. Put $\mathfrak{R}_n(t;h):=\mathfrak{K}_n(-it;h)$ for $\operatorname{Im}t_1<\dots<\operatorname{Im}t_n<\operatorname{Im}t_1+l$. Then

$$\omega^{\mathrm{sl}}(\Phi(\phi_1,h_1)\cdots\Phi(\phi_n,h_n)):=\int_{\mathbb{R}^n}\prod_k\phi_k(t_k+is_k)\,\mathfrak{R}_n(t+is;h)\,dt\qquad(s_1<\dots<s_n<s_1+l),\qquad\omega^{\mathrm{sl}}(1):=1,$$

does not depend on s and defines a state on $\mathfrak{A}^{\mathrm{sl}}$, invariant under α_t, $t\in\mathbb{R}$, and under E_2. For $A,B\in\mathfrak{A}^{\mathrm{sl}}$ the function $c\mapsto\omega^{\mathrm{sl}}(A\,\alpha_c(B))$ is entire and bounded on every strip $|\operatorname{Im}c|\leq c_1$, and

$$\omega^{\mathrm{sl}}(A\,\alpha_{t+il}(B))=\omega^{\mathrm{sl}}(\alpha_t(B)\,A)\qquad(t\in\mathbb{R}).$$

The connected functions are the truncated functions of ω^{sl} at imaginary times: $S_n(\chi_1\otimes h_1,\dots,\chi_n\otimes h_n)=\int\prod_k\chi_k(s_k)\,\mathfrak{R}^T_n(is;h)\,ds$ when $\operatorname{supp}\chi_1,\dots,\operatorname{supp}\chi_n$ follow one another in an interval shorter than l, $\mathfrak{R}^T_n$ being formed from the $\mathfrak{R}_m$ by the formula that expresses cumulants through moments. There is a linear map $\Psi^{\mathrm{sl}}\colon\mathfrak{A}^{\mathrm{sl}}\to\mathcal{H}^{\mathrm{sl}}$ with $\Psi^{\mathrm{sl}}(1)=\Omega^{\mathrm{sl}}$, $\omega^{\mathrm{sl}}(B^*A)=\langle\Psi^{\mathrm{sl}}(B),\Psi^{\mathrm{sl}}(A)\rangle$, $e^{it\mathsf{H}_3}\Psi^{\mathrm{sl}}(A)=\Psi^{\mathrm{sl}}(\alpha_tA)$, $[\mathsf{g}\cdot]\Psi^{\mathrm{sl}}(A)=\Psi^{\mathrm{sl}}(\mathsf{g}A)$ for the unitary operators of (f), and $J^{\mathrm{sl}}e^{-\frac{l}{2}\mathsf{H}_3}\Psi^{\mathrm{sl}}(A)=\Psi^{\mathrm{sl}}(A^*)$. So the closure of $\Psi^{\mathrm{sl}}(\mathfrak{A}^{\mathrm{sl}})$, with Ψ^{sl} and Ω^{sl}, is the space of the state, H_3 implements α_t on it, and the last relation is the modular relation with the modular operator $e^{-l\mathsf{H}_3}$.

(i) Real times. Let $\mathfrak{A}^{\mathrm{sl}}_{\mathcal{S}}\supset\mathfrak{A}^{\mathrm{sl}}$ be the tensor algebra over $\mathcal{S}(\mathbb{R})\otimes C^1_c(\mathbb{R}^2;\mathbb{C})$, with the same involution, the α_t for real t and E_2. For $n\geq 1$, h, $G\in\mathcal{S}(\mathbb{R}^n)$ and $s^*\in\mathbb{R}^n$ with $s^*_1<\dots<s^*_n$ the limit

$$\mathfrak{R}^0_n(G;h):=\lim_{\varepsilon\downarrow 0}\int G(t)\,\mathfrak{R}_n(t+i\varepsilon s^*;h)\,dt$$

exists and does not depend on s^*; $\mathfrak{R}^0_n(\cdot;h)$ is a tempered distribution of an order $\leq\lceil\varkappa_{\mathrm{w}}n\rceil+1$. The functional $\tilde\omega^{\mathrm{sl}}(\Phi(\phi_1,h_1)\cdots\Phi(\phi_n,h_n)):=\mathfrak{R}^0_n(\phi_1\otimes\cdots\otimes\phi_n;h)$ is a state on $\mathfrak{A}^{\mathrm{sl}}_{\mathcal{S}}$ that extends ω^{sl} and is invariant under α_t and E_2; and for $A,B\in\mathfrak{A}^{\mathrm{sl}}_{\mathcal{S}}$ there is a function, continuous and bounded on $0\leq\operatorname{Im}c\leq l$ and holomorphic inside, equal to $\tilde\omega^{\mathrm{sl}}(A\,\alpha_t(B))$ at $c=t$ and to $\tilde\omega^{\mathrm{sl}}(\alpha_t(B)\,A)$ at $c=t+il$. The map Ψ^{sl} extends to $\mathfrak{A}^{\mathrm{sl}}_{\mathcal{S}}$ with all the rules of (h); in particular $\Psi^{\mathrm{sl}}(A)\in\operatorname{Dom}(e^{-\frac{l}{2}\mathsf{H}_3})$. ■

Sketch. Step 1: the rectangular comparison (a). If the cell indices are distinct modulo $(l/\mathsf{l})\mathbb{Z}e_3$, they are also distinct on every sufficiently large rectangular box. By Lemma 18.239(a), (b), the box expectation of their product is bounded by the product of the cubic seminorms times one factor $e^{\mathsf{l}^3(p_{\ell'}-p_\Lambda)}$ per cell. Since $p_\Lambda \geq p_\infty$, this bound is uniform over the defining sequence. The products are continuous local functions, so it passes to ν. The same comparison applies on each finite box whose cell indices are already distinct.

Step 2: the number at g. The source stability and vacuum-energy comparison at first passage give $p_{\ell'} - p_\infty \leq 2C_{\mathrm{S}} + C_g$, as in Lemma 18.239(d), with the frame constants of Definition 13.1.

Step 3: the symmetries and mirrors (b). The finite box is invariant under translations by $a_K\mathbb{Z}^3$, under W_2, and under the listed reflections. Each operation permutes its oriented bonds and preserves the plaquette actions and product Haar measure, so the invariances pass to weak limits. The finite-box reflection form at each of the listed double mirrors is positive by Proposition YM3_I:91.7. For $\mu = 1, 2$, any finite set of half-space bonds lies in the positive half-box for sufficiently large Λ. For $\mu = 3$ the two mirrors stay a distance $l/2$ apart. This gives positivity of the limiting form on continuous local functions, and hence on bounded Borel local functions by the L^2 approximation argument of Lemma 18.242. This argument uses only that the defining sides diverge in $\mathfrak{L}$.

Step 4: the bounds (c). For ν apply Proposition 18.244(a), (c), (d), using the same datum, thickness and constants. To see that the same proof applies on a finite box, lift each entry as in (a). The horizontal projections of the lifted supports equal those of the original supports. Thus the support separation modulo Γ_Λ is at least d if $\Lambda > \mathsf{d}$ plus the horizontal diameter in (c). On the fine mesh split the lifts into pieces as in the proof of Proposition 18.244(d). The pieces keep that separation. Place each tuple of pieces on the side-one board and move its occupied cells into period representatives by translations in Γ_Λ. The periods are even integer multiples of the cell side. Translation by a period preserves the observables and the cell seminorms, and different representative cells are incongruent. Apply the finite-box comparison from Step 1 to the product of exponentials in the occupied cells. The graded normalizer from Proposition YM3_I:91.12, with the reference side $\ell_g = \min \mathfrak{L}(g) \leq l$, transfers with base $e^{2C_{\mathrm{S}}+C_g} C_Q (2\eta)^{-\mathsf{p}}$ as in the slab argument, where η is the radius of the pieces. Its mixed derivative uses the same distance bound and YM3_I:(1845). The graded cumulant estimate YM3_I:(1842), the sum over pieces, and the coarse-mesh plaquette count thus have the same constants. The moment estimate follows by the partition formula of Definition 18.198(3). Monotonicity in d follows from YM3_I:(1785).

Step 5: the limits (d). $C^1_c(\mathbb{E})$ contains a countable set $\mathcal{Q}$ such that for every $f \in C^1_c(\mathbb{E})$ and $\varepsilon > 0$ some $f' \in \mathcal{Q}$ has $\|f - f'\|_\sharp < \varepsilon$ and its support in the ε-neighbourhood of $\mathrm{supp} f$ (C^1 of a compact box is separable; cut-offs with rational data). By (c) and a diagonal choice there is a subsequence along which $S^T_n[\nu_j](X')$ converges at every separated tuple X' with members in $\mathcal{Q}$. For X of the type $(\mathsf{d}; R)$ and X' with members in $\mathcal{Q}$, $\|f_i - f'_i\|_\sharp < \varepsilon < \min\{\frac{\mathsf{d}}{4}, 1\}$ and $\mathrm{supp} f'_i$ in the ε-neighbourhood of $\mathrm{supp} f_i$, the tuples of the telescope between X and X' are of the type $(\frac{\mathsf{d}}{2}; R+1)$, and by multilinearity and (c), $|S^T_n[\nu_j](X) - S^T_n[\nu_j](X')| \leq n\,\varepsilon\, C^{\mathsf{sl}}_n(\frac{\mathsf{d}}{2}; R+1) \prod_i (\|f_i\|_\sharp + 1)$ for all j; so $(S^T_n[\nu_j](X))_j$ is a Cauchy sequence. For the continuity in the last sentence of (d) let k be the compact set: if $\liminf_j \mathrm{dist}(\mathrm{supp} f^{(j)}_k, \mathrm{supp} f_m) < \mathsf{d}$ for some $k \neq m$, there are $\epsilon > 0$ and, along a subsequence, $y_j \in \mathrm{supp} f^{(j)}_k$ and $x_j \in \mathrm{supp} f_m$ with $|y_j - x_j| \leq \mathsf{d} - \epsilon$, $x_j \to x$; a point x' with $f_m(x') \neq 0$ and $|x' - x| < \frac{\epsilon}{4}$ lies in $\mathrm{supp} f^{(j)}_m$ for large j by the uniform convergence, so $|y_j - x'| \geq \mathsf{d}$, while $|y_j - x'| < \mathsf{d}$: a contradiction. Hence for large j all the tuples of the telescope between $X^{(j)}$ and X are of the type $(\frac{\mathsf{d}}{2}; R')$, R' the radius of a ball that contains k, and (c) gives $\sigma_{\nu_j}(X^{(j)}) - \sigma_{\nu_j}(X) \to 0$. Reality, symmetry, multilinearity and the bounds hold at every j, cumulants being multilinear and symmetric, and pass to the limit. For a translation τ_v or a mirror r_c take $v_j \in a_{K_j}\mathbb{Z}^3$, $v_j \to v$, and $c_j \in \frac{1}{2}a_{K_j}\mathbb{Z}$, $c_j \to c$; by (b) and the relabelling of the plaquette sums under the isometries,

$S_n^T[\nu_j](\tau_{v_j}X) = S_n^T[\nu_j](X)$ and the same for θ_{e_3,c_j}; as ∇f is uniformly continuous, $\tau_{v_j}X \to \tau_v X$ in the sense of the continuity just shown. The invariance under W_2 holds at every j.

Step 6: the mirrors of S (e). Let $F = \sum_\alpha c_\alpha X_\alpha$, the supports in H_+ at the distance $\geq 3\epsilon > 0$ from its boundary; let n_0 be the normal (e_μ or e_3) and c_j lattice offsets with $c_j \to c$, $\theta^{(j)}$ the reflection at c_j, and $F_j := \sum_\alpha c_\alpha X_\alpha^{\nu_j}$ the combination of the centred products under ν_j. A plaquette whose barycentre lies in a support has its corners within a_{K_j} of it; so for large j, F_j is a continuous function of finitely many bonds of the closed half space at c_j, respectively of $\{c_j \leq x_3 \leq c_j + \frac{l}{2}\}$. By (b), ν_j is invariant under $\theta^{(j)}$, so $\theta^{(j)}(X^{\nu_j}) = (\theta^{(j)}X)^{\nu_j}$, and $0 \leq \nu_j(\overline{\theta^{(j)}F_j}\, F_j) = \sum_{\alpha,\alpha'} \bar{c}_\alpha c_{\alpha'} \sigma_{\nu_j}(\theta^{(j)}X_\alpha \cdot X_{\alpha'})$. As $\theta^{(j)} = \tau_{v_j}\theta$ with $v_j \to 0$, the continuity of (d) gives $\sigma_S(\theta\bar{F} \cdot F) \geq 0$.

Step 7: one box in the direction e_3. Fix j and $\Lambda \in \mathfrak{L}(g)$, $\Lambda \geq l$; write $a = a_{K_j}$, $\beta = \beta_j$, $N := l/a = 2L^{m_l+K_j}$, $N' := \frac{N}{2}$, $\mu_\Lambda := \mu_{\Gamma_\Lambda,\beta}$, and Z for its partition function. On the horizontal layer Hilbert space use the positive crossing operator K of Proposition YM3_I:85.1 and the slab operators $\mathfrak{S}[\Phi]$, $\mathfrak{Y}[\Phi] = \mathsf{K}^{1/2}\mathfrak{S}[\Phi]\mathsf{K}^{1/2}$ of YM3_I:(1744). Let M_1 be the multiplication by $e^{-\beta A_\Sigma}$ on the space of one layer, and $\hat{\mathsf{T}} := \mathsf{K}^{1/2}\mathsf{M}_1\mathsf{K}^{1/2} \geq 0$. Splitting the outer layers off the weight preceding YM3_I:(1744) and integrating gives $\mathfrak{S}[\Phi^{1,0}] = \mathsf{M}_1\mathsf{K}\,\mathfrak{S}[\Phi]$ and $\mathfrak{S}[\Phi^{0,1}] = \mathfrak{S}[\Phi]\,\mathsf{K}\mathsf{M}_1$, where $\Phi^{x',x}$ is Φ evaluated on the layers $x+1,\dots,x+\mathsf{v}$ of a slab of $\mathsf{v}+x+x'$ layers; hence $\mathfrak{Y}[\Phi^{x',x}] = \hat{\mathsf{T}}^{x'}\mathfrak{Y}[\Phi]\hat{\mathsf{T}}^{x}$, and $\mathfrak{Y}[1_2] = \hat{\mathsf{T}}^2$ for the function 1 on two layers. By YM3_I:(1744), $\hat{\mathsf{T}}^2 = \mathfrak{Y}[1_2]$ is Hilbert–Schmidt, so $\hat{\mathsf{T}}$ is compact: $\hat{\mathsf{T}} = \sum_i t_i |e_i\rangle\langle e_i|$ with an orthonormal basis (e_i) and $t_i \geq 0$. Put $\hat{\mathsf{T}}^\zeta := \sum_{t_i>0} t_i^\zeta |e_i\rangle\langle e_i|$ for $\operatorname{Re}\zeta > 0$ and for $\zeta \in i\mathbb{R}$; $\|\hat{\mathsf{T}}^\zeta\| \leq \|\hat{\mathsf{T}}\|^{\operatorname{Re}\zeta}$, $\zeta \mapsto \hat{\mathsf{T}}^\zeta$ is holomorphic in the operator norm on $\operatorname{Re}\zeta > 0$, and every $\mathfrak{Y}[\Phi]$ vanishes on $\ker\hat{\mathsf{T}}$ and maps into its orthogonal complement, as $\hat{\mathsf{T}}\psi = 0$ forces $\mathsf{K}^{1/2}\psi = 0$. Take an integer $r \geq 2$ and integers $\mathsf{v}_1,\dots,\mathsf{v}_r \geq 2$. For bounded Borel functions $\Psi^1,\dots,\Psi^r$ on slab spaces of $\mathsf{v}_1,\dots,\mathsf{v}_r$ layers, the function $\zeta \mapsto \operatorname{Tr}(\mathfrak{Y}[\Psi^r]\hat{\mathsf{T}}^{\zeta_r}\cdots\mathfrak{Y}[\Psi^1]\hat{\mathsf{T}}^{\zeta_1})$ is holomorphic on $\{\operatorname{Re}\zeta_k > 0\}$, two of its factors being Hilbert–Schmidt operators; at integers $\zeta_k \geq 0$ with $\sum_k(\mathsf{v}_k+\zeta_k) = N$ it is the integral against the Wilson weight of the box of the product of the functions placed upwards, with the gaps ζ_k, around the periodic direction by Proposition YM3_I:85.2 and the padding identity for $\Phi^{x',x}$. Let $0 < \mathsf{a} < \mathsf{a}' < \frac{l}{2}$, $F = \sum_\alpha c_\alpha X_\alpha \in \mathcal{D}_{(\mathsf{a},\mathsf{a}')}$, and $F_\Lambda := \sum_\alpha c_\alpha X_\alpha^{\mu_\Lambda}$. With $x := \lfloor \mathsf{a}/a \rfloor - 2$, $x' := \lfloor (\frac{l}{2} - \mathsf{a}')/a \rfloor - 2$ and $\mathsf{v} := N' - x - x'$, for large j the function F_Λ is a function Ψ on the slab space of v layers placed on the layers $x+1,\dots,x+\mathsf{v}$; put $\mathsf{Y}_\Lambda := \mathfrak{Y}[\Psi]$. The reflection $\theta^{(j)} := \theta_{e_3,a/2} = \tau_{ae_3}\mathsf{r}_0$, the translation of layer indices, the adjoint identity YM3_I:(1745), and the two-slab trace formula give, for integers $k_1, k_2 \in [-x, x']$ and $k = k_1 + k_2$,

$$Z\,\mu_\Lambda\big(\overline{\theta^{(j)}\tau_{k_1ae_3}F_\Lambda}\,\tau_{k_2ae_3}F_\Lambda\big) = \operatorname{Tr}\big(\hat{\mathsf{T}}^{x'-k_2}\mathsf{Y}_\Lambda\hat{\mathsf{T}}^{x+k_2}\hat{\mathsf{T}}^{x+k_1}\mathsf{Y}_\Lambda^*\hat{\mathsf{T}}^{x'-k_1}\big) = \sum_{t_i,t_{i'}>0} t_i^{2x'-k}\,t_{i'}^{2x+k}\,|\langle e_i, \mathsf{Y}_\Lambda e_{i'}\rangle|^2.$$

By the invariance of μ_Λ under $a\mathbb{Z}^3$ and $\theta^{(j)}$, and $\mathsf{r}_0\tau_v = \tau_{-v}\mathsf{r}_0$ for $v \parallel e_3$, the left member is $Z\sigma_{\mu_\Lambda}(\mathsf{r}_0\bar{F} \cdot \tau_{(k-1)ae_3}F)$. So, with the finite positive measure $\rho_{\Lambda,j} := Z^{-1}\sum t_i^{2x'}t_{i'}^{2x}|\langle e_i, \mathsf{Y}_\Lambda e_{i'}\rangle|^2\,\delta_{\lambda_{ii'}}$, $\lambda_{ii'} := a^{-1}\log(t_i/t_{i'})$,

$$\sigma_{\mu_\Lambda}(\mathsf{r}_0\bar{F} \cdot \tau_{(k-1)ae_3}F) = \int e^{-ka\lambda}\,d\rho_{\Lambda,j}(\lambda) \qquad (k \in \mathbb{Z},\ -2x \leq k \leq 2x').$$

Step 8: the measures ρ_F. Let $-2\mathsf{a} < r_- < 0 < r_+ < l - 2\mathsf{a}'$. For $r \in [r_-, r_+]$ the tuples $\mathsf{r}_0X_\alpha \cdot \tau_{re_3}X_{\alpha'}$ are of one type; by (c) the left members of the last display are bounded by a number C_F for all large Λ, j and all k with $(k-1)a \in [r_-, r_+]$. With $k_\pm$ the extreme such k, the measures $(e^{-k_-a\lambda} + e^{-k_+a\lambda})\,d\rho_{\Lambda,j}$ have masses $\leq 2C_F$. Helly's selection theorem, applied first to the limit $\Lambda \to \infty$ taken along the sequence defining ν_j and next to the limit $j \to \infty$ taken along the subsequence of S, provides a further subsequence that converges vaguely. When $(k^{(j)}-1)a \to r \in (r_-, r_+)$, the functions $e^{-k^{(j)}a\lambda}/(e^{-k_-a\lambda} + e^{-k_+a\lambda})$ tend to $e^{-r\lambda}/(e^{-r_-\lambda} + e^{-r_+\lambda})$ uniformly on $\mathbb{R}$, and this limit is continuous and vanishes at $\pm\infty$; by weak convergence at fixed j and by (d), the left members

tend to $\sigma_S(\mathsf{r}_0\bar F\cdot\tau_{re_3}F)$. So the formula of (f) holds with $\rho_F:=(e^{-r_-\lambda}+e^{-r_+\lambda})^{-1}d(\lim)$. If two finite positive measures have equal integrals of $e^{-r\lambda}$ on an interval, both members are holomorphic in a strip over it, and the Fourier transforms of $e^{-r_0\lambda}\,d\rho$ and $e^{-r_0\lambda}\,d\rho'$ agree; so the measure, with mass $\sigma_S(\mathsf{r}_0\bar F\cdot F)$, is independent of the subsequences. Exhausting the full open interval by nested intervals containing zero gives the same measure throughout.

Step 9: the generator and the involution (f). By (e) at $c=0$ the form is positive; $\mathcal{H}^{\mathrm{sl}}$ is the completion of the quotient by the null vectors, and $D_I:=\{[F]:F\in\mathcal{D}_I\}$, $D:=\bigcup_I D_I$, is dense. Fix $I=(\mathsf{a},\mathsf{a}')$ and put $\mathrm{St}_I:=\{z:-\mathsf{a}<\operatorname{Re}z<\frac{l}{2}-\mathsf{a}'\}$. For $F,G\in\mathcal{D}_I$ and real r,r' in St_I, the invariance under translations and $\tau_{-re_3}\mathsf{r}_0=\mathsf{r}_0\tau_{re_3}$ give $\langle\tau_{r'e_3}G,\tau_{re_3}F\rangle=\sigma_S(\mathsf{r}_0\bar G\cdot\tau_{(r+r')e_3}F)$; so by Step 8, $\|\sum_a c_a[\tau_{ra e_3}F]\|^2=\int|\sum_a c_a e^{-r_a\lambda}|^2d\rho_F$. Hence $\mathsf{S}(r)[F]:=[\tau_{re_3}F]$ is well defined and linear on D_I, and there is a linear isometry I_F of the closed span of the functions $e^{-r\,\cdot}$ in $L^2(\rho_F)$ into $\mathcal{H}^{\mathrm{sl}}$ with $\mathsf{I}_F(e^{-r\,\cdot})=\mathsf{S}(r)[F]$. For $z\in\mathrm{St}_I$, $e^{-z\,\cdot}$ lies in that span (a function orthogonal to all $e^{-r\,\cdot}$ gives a holomorphic function that vanishes on an interval) and depends holomorphically on z; $\mathsf{S}(z)[F]:=\mathsf{I}_F(e^{-z\,\cdot})$ is the holomorphic continuation of $r\mapsto\mathsf{S}(r)[F]$, linear on D_I, and unchanged when I is enlarged. For $\psi,\psi'\in D_I$ the function $\mathsf{h}(z',z):=\langle\mathsf{S}(\bar z')\psi',\mathsf{S}(z)\psi\rangle$ is holomorphic on St_I^2 and at real points depends on $z+z'$ alone; so $(\partial_z-\partial_{z'})\mathsf{h}=0$, h is constant on the segments $(z'+c,z-c)$, and $\langle\mathsf{S}(it)\psi',\mathsf{S}(it)\psi\rangle=\langle\psi',\psi\rangle$: $\mathsf{U}_t:=\mathsf{S}(it)$ extends to an isometry. For small real r the real translation law gives $\mathsf{S}(u)\mathsf{S}(r)\psi=\mathsf{S}(u+r)\psi$ for real u near zero, using an interval containing both supports. Continue in u to it to obtain $\mathsf{U}_t\mathsf{S}(r)\psi=\mathsf{S}(r+it)\psi$. Both sides then continue holomorphically in r to $z\in\mathrm{St}_I$; at $z=it'$ this gives $\mathsf{U}_t\mathsf{U}_{t'}=\mathsf{U}_{t+t'}$ on D; with $\mathsf{U}_0=1$ and the continuity on D, (U_t) is a strongly continuous unitary group, and by Stone's theorem $\mathsf{U}_t=e^{-it\mathsf{H}_3}$ with a self-adjoint H_3. If a self-adjoint A, a vector ψ and a function Ξ holomorphic on an open strip $\{r_1<\operatorname{Re}z<r_2\}\ni 0$ satisfy $\Xi(it)=e^{-it\mathsf{A}}\psi$, then for the spectral projection P_m of $[-m,m]$ the entire function $\langle e^{-\bar z\mathsf{A}}\chi,\psi\rangle$ and $\langle\chi,\Xi(z)\rangle$, $\chi\in\mathsf{P}_m\mathcal{H}^{\mathrm{sl}}$, agree on $i\mathbb{R}$, so $\mathsf{P}_m\Xi(r)=e^{-r\mathsf{A}}\mathsf{P}_m\psi$; letting $m\to\infty$, $\psi\in\mathrm{Dom}(e^{-r\mathsf{A}})$ and $e^{-r\mathsf{A}}\psi=\Xi(r)$ for real r of the strip. With $\Xi=\mathsf{S}(\cdot)[F]$ this gives the domain and the action of $e^{-r\mathsf{H}_3}$, the holomorphy, and, near $r=0$, that ρ_F is the spectral measure in $[F]$; a second self-adjoint operator with the property has the same unitary group on D, so H_3 is unique; $\tau_v\varnothing=\varnothing$ gives $\mathsf{H}_3\Omega^{\mathrm{sl}}=0$. For J^{sl}: $\mathsf{r}_{l/4}$ keeps $\{0<x_3<\frac{l}{2}\}$, $\mathsf{r}_{l/4}\mathsf{r}_0\mathsf{r}_{l/4}=\mathsf{r}_0$ on $\mathbb{E}$ (because $x_3\mapsto l-x_3$ is $x_3\mapsto-x_3$ modulo l), and $\mathsf{r}_{l/4}\tau_{re_3}=\tau_{-re_3}\mathsf{r}_{l/4}$; by the invariance of σ_S under $\mathsf{r}_{l/4}$ and r_0 and its symmetry, $\langle\overline{\mathsf{r}_{l/4}F},\overline{\mathsf{r}_{l/4}G}\rangle=\langle G,F\rangle$. So $J^{\mathrm{sl}}[F]:=[\overline{\mathsf{r}_{l/4}F}]$ is well defined and antiunitary, $(J^{\mathrm{sl}})^2=1$, $J^{\mathrm{sl}}\Omega^{\mathrm{sl}}=\Omega^{\mathrm{sl}}$, and $J^{\mathrm{sl}}\mathsf{S}(r)=\mathsf{S}(-r)J^{\mathrm{sl}}$ on D_I; the functions $z\mapsto J^{\mathrm{sl}}\mathsf{S}(\bar z)\psi$ and $z\mapsto\mathsf{S}(-z)J^{\mathrm{sl}}\psi$ are holomorphic and agree at real z, so $J^{\mathrm{sl}}e^{it\mathsf{H}_3}=e^{it\mathsf{H}_3}J^{\mathrm{sl}}$, and as J^{sl} is antiunitary, $J^{\mathrm{sl}}\mathsf{H}_3J^{\mathrm{sl}}=-\mathsf{H}_3$; the functional calculus gives the rest. An element of E_2 commutes with r_0, $\mathsf{r}_{l/4}$ and τ_{re_3}, keeps $\{0<x_3<\frac{l}{2}\}$ and leaves σ_S invariant (d); so $[F]\mapsto[\mathsf{g}F]$ is unitary, fixes Ω^{sl}, commutes with J^{sl} and with $\mathsf{S}(r)$, and by holomorphy with U_t; the continuity on the translations follows from the continuity of (d).

Step 10: all the heights at once. Let $n\ge 2$, $s^0\in\mathcal{U}_n$, $R>0$, $\epsilon:=\min\{1,\mathrm{gap}(s^0)/32nL\}$, and $f_k\in C^1_c(\mathbb{E})$ with $\mathrm{supp}f_k\subset\mathrm{pr}(\bar B^{(2)}_{R,k}\times[s^0_k-\epsilon,s^0_k+\epsilon])$, each $\bar B^{(2)}_{R,k}$ a closed disc of radius R. Let $\delta_{\mathrm{a}}=l/p$ be the power of L in $(\frac{\mathrm{gap}(s^0)}{2L},\frac{\mathrm{gap}(s^0)}{2}]$; then $p=2L^{r_{\mathrm{a}}}$ with an integer $r_{\mathrm{a}}\ge 1$. The offsets $c\in[0,\delta_{\mathrm{a}})$ at which some s^0_k is nearer than $\delta_{\mathrm{a}}/4n$ to $c+\delta_{\mathrm{a}}\mathbb{Z}$ fill a set of measure $\le\frac12\delta_{\mathrm{a}}$; fix c outside it. The arcs $(c+(m-1)\delta_{\mathrm{a}},c+m\delta_{\mathrm{a}})$, $m\in\mathbb{Z}/p$, then hold the heights s^0_k in different arcs m_k, each at the distance $>4\epsilon$ from the points of $c+\delta_{\mathrm{a}}\mathbb{Z}$. Let j be so large that $\nu_{\mathrm{a}}:=\delta_{\mathrm{a}}/a\in\mathbb{N}$ and $a\le\frac{\epsilon}{8}$, and choose $c_j\in a(\mathbb{Z}+\frac12)$ with $|c_j-c|\le a$. On a box as in Step 7 the walls are the planes $x_3=c_j+m\delta_{\mathrm{a}}$, $m\in\mathbb{Z}$, which lie in $a(\mathbb{Z}+\frac12)$ as $\delta_{\mathrm{a}}=\nu_{\mathrm{a}}a$; two consecutive walls enclose ν_{a} layers, and those enclosed by $c_j+(m-1)\delta_{\mathrm{a}}$ and $c_j+m\delta_{\mathrm{a}}$ form the slab that stands for the arc m on the box. A plaquette whose barycentre lies in $\mathrm{supp}f_k$ has its corners at heights within a of $[s^0_k-\epsilon,s^0_k+\epsilon]$, hence no nearer than $3\epsilon-3a$ to any wall; so the centred entries A_k are functions Ψ^k placed inside the arc m_k with a margin of $x_{\mathrm{a}}:=\lfloor 3\epsilon/a\rfloor-4$ layers. For $|\operatorname{Re}w_k|<x_{\mathrm{a}}a$ put $\mathsf{A}_{m_k}(w):=\hat{\mathsf{T}}^{x_{\mathrm{a}}-w_k/a}\mathfrak{Y}[\Psi^k]\hat{\mathsf{T}}^{x_{\mathrm{a}}+w_k/a}$, $\mathsf{A}_m(w):=\hat{\mathsf{T}}^{\nu_{\mathrm{a}}}$

on the arcs without an entry, and $\mathsf{G}_\Lambda(w) := Z^{-1}\mathrm{Tr}(\mathsf{A}_p(w)\cdots\mathsf{A}_1(w))$. After neighbouring powers of $\hat{\mathsf{T}}$ are multiplied, $Z\mathsf{G}_\Lambda$ is the trace function of Step 7 at the gaps $\mathsf{g}_k + (w_k - w_{k-1})/a$, the entries being numbered upwards, $m_1 < \cdots < m_n$ in $\{1,\dots,p\}$, a renumbering of the pairs (f_k, w_k) that leaves G_Λ unchanged, $k-1$ being read modulo n, and g_k being the number of layers between the entries $k-1$ and k around the circle; so it is holomorphic, it does not depend on the arcs, and $\mathsf{G}_\Lambda(u) = \sigma_{\mu_\Lambda}(\tau_{u_1 e_3} f_1, \dots, \tau_{u_n e_3} f_n)$ at $u \in (a\mathbb{Z})^n$. By Hölder's inequality for traces, Lemma YM3_I: 86.1 with $2k = p$, $|\mathsf{G}_\Lambda(w)| \le Z^{-1}\prod_m \|\mathsf{A}_m(w)\|_p$. As $\mathsf{A}_{m_k}(u+iy) = \hat{\mathsf{T}}^{-iy/a}\mathsf{A}_{m_k}(u)\hat{\mathsf{T}}^{iy/a}$ and $\mathsf{A}_{m_k}(u)$ lives on the orthogonal complement of $\ker\hat{\mathsf{T}}$, $\|\mathsf{A}_m(w)\|_p = \|\mathsf{A}_m(\mathrm{Re}\, w)\|_p$. At $u \in a\mathbb{Z}$, $|u| \le \epsilon + a$, the number $\|\mathsf{A}_{m_k}(u)\|_p^p = \mathrm{Tr}(\mathsf{A}_{m_k}^*\mathsf{A}_{m_k})^{p/2}$ is, by the trace formula at p slabs of ν_{a} layers and the alternating adjoint rule YM3_I:(1745), Z times the box mean of the product of the p images of $\tau_{ue_3}\mathsf{A}_k$ under the elements of the group generated by the reflections $\theta_{e_3, c_j + m\delta_{\mathrm{a}}}$ in the walls, that carry the arc m_k to the arcs m. These reflections are isometries of $\mathbb{L}_K$ whose linear part keeps Γ_Λ, so μ_Λ is invariant under them as in Step 3; and the support of $\tau_{ue_3} f_k$ keeps the distance $\ge 2\epsilon - 2a \ge \epsilon$ from the walls, so that its images lie in different arcs, pairwise at the distance $\ge 2\epsilon$. Thus $\|\mathsf{A}_{m_k}(u)\|_p^p$ equals $Z\sigma_{\mu_\Lambda}$ of a tuple of the type $(2\epsilon; R+l)$, at most $ZC_p^\sigma(2\epsilon; R+l)\|f_k\|_\sharp^p$ by (c) for $\Lambda > 2\epsilon + 2R$, since the reflections act on the third coordinate alone, so that all p images have their first two coordinates in $\bar{B}^{(2)}_{R,k}$; and $\|\hat{\mathsf{T}}^{\nu_{\mathrm{a}}}\|_p^p = \mathrm{Tr}\,\hat{\mathsf{T}}^N = Z$. Hence $|\mathsf{G}_\Lambda(w)| \le \mathsf{C}^{\mathrm{An}}\prod_k \|f_k\|_\sharp$, $\mathsf{C}^{\mathrm{An}} := C_p^\sigma(2\epsilon; R+l)^{n/p}$, when $\mathrm{Re}\, w \in (a\mathbb{Z})^n$ and $|\mathrm{Re}\, w_k| \le \epsilon + a$; by the three lines theorem, in one variable after the other, the bound holds on the whole tube $|\mathrm{Re}\, w_k| \le a\lceil \epsilon/a\rceil$. By Montel's theorem, as $\Lambda \to \infty$ along the sequence that defines ν_j and then as $j \to \infty$ along the subsequence of S, the G_Λ converge locally uniformly on $\{|\mathrm{Re}\, w_k| < \epsilon\}$ along subsequences; at real points the limit is $\sigma_S(\tau_{u_1 e_3} f_1, \dots, \tau_{u_n e_3} f_n)$ by weak convergence and by (d), so it is one holomorphic function $\mathsf{G}[\underline{f}]$, with $|\mathsf{G}[\underline{f}]| \le \mathsf{C}^{\mathrm{An}}\prod_k \|f_k\|_\sharp$. Let now $\underline{f}^\alpha$ be finitely many tuples of $n_\alpha \ge 0$ entries, the k-th with its support in $\mathrm{pr}(\bar{B}^{(2)}_{R,\alpha,k} \times [s_k^{0,\alpha} - \epsilon, s_k^{0,\alpha} + \epsilon])$, $\bar{B}^{(2)}_{R,\alpha,k}$ a closed disc of radius R, where $0 < s_1^{0,\alpha} < \cdots < s_{n_\alpha}^{0,\alpha} < \frac{l}{2}$ and ϵ is at most the number ϵ formed as at the head of this step from every joint height $(-s^{0,\alpha,\mathrm{rev}}, s^{0,\alpha'})$ with at least two entries, where rev reverses the order, and let $|\mathrm{Re}\, w_k^\alpha| < \epsilon$. The same construction on the half box, the slab of the layers $1,\dots,N'$ of Step 7, places the centred entries of $\underline{f}^\alpha$ there upwards as functions $\Psi^1,\dots,\Psi^n$, $n := n_\alpha$; with g_0^α the number of the layers of the half box below Ψ^1, g_k^α the number between Ψ^k and Ψ^{k+1} and g_n^α the number above Ψ^n, so that these numbers and the numbers of layers of the Ψ^k add up to N', with $\mathsf{B}_\alpha(w) := \hat{\mathsf{T}}^{\mathsf{g}_n^\alpha - w_n/a}\mathfrak{Y}[\Psi^n]\hat{\mathsf{T}}^{\mathsf{g}_{n-1}^\alpha + (w_n - w_{n-1})/a}\cdots\mathfrak{Y}[\Psi^1]\hat{\mathsf{T}}^{\mathsf{g}_0^\alpha + w_1/a}$, and with $\mathsf{B}_\alpha := \hat{\mathsf{T}}^{N'}$ if $n_\alpha = 0$, it gives $Z^{-1}\mathrm{Tr}(\mathsf{B}_\alpha(w)^*\mathsf{B}_{\alpha'}(w')) = \mathsf{G}_\Lambda[\theta^{(j)}\underline{f}^{\alpha,\mathrm{rev}} \cdot \underline{f}^{\alpha'}](-\overline{w^{\mathrm{rev}}}, w')$, where G_Λ and G are 1 at the empty joint tuple and 0 at a joint tuple of one entry: $\mathrm{Tr}\,\hat{\mathsf{T}}^N = Z$, and at one entry Ψ, of v layers, the powers of $\hat{\mathsf{T}}$ join by cyclicity into $\mathrm{Tr}(\hat{\mathsf{T}}^{N-\mathsf{v}}\mathfrak{Y}[\Psi])$ or its conjugate, free of w, which the trace formula of Step 7 with the two slab functions Ψ and 1_2, as $\hat{\mathsf{T}}^2 = \mathfrak{Y}[1_2]$, makes Z times the mean under μ_Λ of a centred entry, that is 0; hence $\sum_{\alpha,\alpha'}\bar{c}_\alpha c_{\alpha'}\mathsf{G}[\mathsf{r}_0\underline{f}^{\alpha,\mathrm{rev}} \cdot \underline{f}^{\alpha'}](-\overline{w^{\alpha,\mathrm{rev}}}, w^{\alpha'})$ is a limit of the numbers $Z^{-1}\|\sum_\alpha c_\alpha \mathsf{B}_\alpha(w^\alpha)\|_2^2 \ge 0$. For the reflected entries the lattice mirror approaches r_0 in the sharp norm after acting on the test functions, with supports in a common compact set. The same trace estimates are uniform for those entries on a slightly smaller tube. On real shifts the limits are therefore identified by (d), and the identity theorem identifies the corresponding holomorphic limits.

Step 11: kernels at sharp heights (g). Fix an even $\chi_0 \in C_c^\infty((-1,1))$ equal to 1 on $[-\frac{1}{2}, \frac{1}{2}]$, and for a width $0 < \varpi \le 1$ put $\mathsf{E}_\varpi(s) := \chi_0(s/\varpi)\frac{s|s|}{4}$. As the third derivative of $\frac{s|s|}{4}$ is the Dirac measure, $\mathsf{E}_\varpi''' = \delta + \mathsf{e}_\varpi$ with a smooth e_ϖ supported in $\frac{\varpi}{2} \le |s| \le \varpi$; $\|\mathsf{E}_\varpi \otimes h\|_\sharp \le (1 + 40Mc_0)\|h\|_\sharp$ and $\|\mathsf{e}_\varpi \otimes h\|_\sharp \le (1+40M)c_0\varpi^{-2}\|h\|_\sharp$ with a numeral c_0 that depends on χ_0. Near $s^0 \in \mathcal{U}_n$ let $\varpi := \epsilon$ of Step 10, and for $\mathsf{a} \subset \{1,\dots,n\}$ let $\underline{f}^{\mathsf{a}}$ have the entries $\tau_{s_k^0 e_3}(\mathsf{E}_\varpi \otimes h_k)$ for $k \in \mathsf{a}$ and $\tau_{s_k^0 e_3}(\mathsf{e}_\varpi \otimes h_k)$ otherwise; put $\mathfrak{K}_n(s^0 + w; h) := (-1)^n\sum_{\mathsf{a}}\prod_{k\in\mathsf{a}}\partial_{w_k}^3\mathsf{G}[\underline{f}^{\mathsf{a}}](w)$. Writing $\chi_k = \chi_k''' * \mathsf{E}_\varpi - \chi_k * \mathsf{e}_\varpi$ as

Riemann integrals of translates that converge in C^1, using the multilinearity and the continuity of σ_S at separated supports (d), and integrating by parts three times in each s_k, $k \in \mathsf{a}$, gives the integral formula of (g) for $\chi_k \in C_c^\infty((s_k^0-\epsilon, s_k^0+\epsilon))$, and by mollification for $\chi_k \in C_c^1$. A continuous kernel is determined by these integrals; so the local functions agree on overlaps at real points, hence as holomorphic functions on the tubes over the convex components of $\mathcal{U}_n$, and they glue to $\mathfrak{K}_n$; a partition of unity gives the general χ_k; $\mathfrak{K}_1 = 0$ since σ_S vanishes at one entry. Cauchy's estimate on polydiscs of radius $\epsilon/2$ bounds $\partial_{w_k}^3$ by $3!\,(2/\epsilon)^3$ times the supremum, so $|\mathfrak{K}_n(z;h)| \le (c_E\epsilon^{-3})^n \mathsf{C}^{\mathrm{An}} \prod_k \|h_k\|_\sharp$ with $c_E := (48+c_0)(1+40M)(1+c_0)$. The rules hold at real points by (d) and by the period l of $\chi \otimes h$ in x_3, and pass to the tubes by holomorphy; for complex c, $c \mapsto \mathfrak{K}_n(z+c\mathbf{1};h)$ is entire and constant on $\mathbb{R}$. To obtain positive type, take a smooth nonnegative χ of integral 1 supported in $(-1,1)$, and put $\chi^{(\varpi)} := \varpi^{-1}\chi(\cdot/\varpi)$. At finitely many tuples of increasing real heights in the positive half-circle, apply the last part of Step 10 to the entries $\tau_{s_k e_3}(\chi^{(\varpi)} \otimes h_k)$ for sufficiently small ϖ. For real shifts the resulting matrix entries are the integrals of $\mathfrak{K}$ against the products of the mollifiers in the height variables, by the kernel formula. The same identity holds for complex shifts by holomorphy: the real parts of the joint heights stay in a compact subset of $\mathcal{U}_{n+n'}$, so the kernel bound on each smaller tube allows integration of the holomorphic kernels. As $\varpi \downarrow 0$ the integrals converge to the sharp kernel entries by continuity. The matrices are positive semidefinite before the limit and hence after it. For complex h use sesquilinearity in the two tuples and the same trace Gram form. The growth: by the display of U in YM3_I: (1785) at $R=1$, with $\delta_e := \kappa - \kappa_{\mathcal{D}}$ and $\log_L^+ y \le y \le \max\{1, y^3\}$, $A^{\mathrm{per}}(\mathsf{d}) \le A_\star \max\{1, \mathsf{d}^{-3}\}$, $A_\star := 1 + 27 C_{\mathrm{S}} S(\kappa)[32(C''_\Sigma(\delta_e) + (5\sqrt{3}M)^3) + 4C'_\Sigma(\delta_e,4)(2\sqrt{3})^3]$; in C_p^σ there are at most p^p partitions, each with at most $\frac{p}{2}$ blocks and $\prod_J |J|! \le p^p$; so $\mathsf{C}^{\mathrm{An}} \le (A^{\mathrm{per}}(2\epsilon)^{1/2}\,\mathsf{b}'\,p^{6+\mathsf{p}})^n$ with $\mathsf{b}' := (1+40M)B^{\mathrm{sl}}(2R+2l+1)$. As $p < 2Ll/\mathrm{gap}(s^0)$ and $\epsilon = \min\{1, \mathrm{gap}(s^0)/32nL\}$, the powers of $\min\{1,\mathrm{gap}\}^{-1}$ add up to $3+\frac{3}{2}+6+\mathsf{p} = \varkappa_{\mathrm{w}}$ per point.

Step 12: the state (h). On the convex component $\mathsf{O}_n := \{s : s_1 < \cdots < s_n < s_1 + l\}$ of $\mathcal{U}_n$ the kernel is bounded in t for s in a compact set, and $\prod_k |\phi_k(t_k + is_k)| \le C_N \prod_k (1+|t_k|)^{-N}$; the integral that defines ω^{sl} converges, its integrand is holomorphic in $t+is$, and by Cauchy's theorem in one variable after the other, the vertical sides of long rectangles contributing $O(|t_k|^{-N})$, it does not change along segments of O_n parallel to the axes: it does not depend on s. Positivity: in $\omega^{\mathrm{sl}}(A^*A)$, $A = \sum_\alpha c_\alpha \Phi(\phi_1^\alpha, h_1^\alpha)\cdots\Phi(\phi_{n_\alpha}^\alpha, h_{n_\alpha}^\alpha)$, take for the term (α,α') the heights $(-s_n,\dots,-s_1,s'_1,\dots,s'_{n'})$ with $0 < s_1 < \cdots < s_n < \frac{l}{2}$ and the same for s'; as $\phi^*(t-is) = \overline{\phi(t+is)}$, the term is the double integral of $\overline{\prod_k \phi_k^\alpha(t_k+is_k)}\prod_k \phi_k^{\alpha'}(t'_k+is'_k)$ against the kernel of positive type of (g) at $(s-it, h^\alpha)$ and $(s'-it', h^{\alpha'})$, a limit of Riemann sums each of which is ≥ 0. The invariance under α_{t_0} follows by a shift of the variables and the invariance of $\mathfrak{K}_n$ under $z \mapsto z + c\mathbf{1}$; under E_2 by (g). The condition at l: for $A = \Phi(\phi_1,h_1)\cdots\Phi(\phi_m,h_m)$ and $B = \Phi(\phi_{m+1},h_{m+1})\cdots\Phi(\phi_n,h_n)$, $\omega^{\mathrm{sl}}(A\alpha_c(B)) = \int \prod_{k\le m}\phi_k(t_k+is_k)\prod_{k>m}\phi_k(t_k+is_k-c)\,\mathfrak{R}_n(t+is;h)\,dt$ is entire in c and bounded on strips (shift t_k by $\mathrm{Re}\,c$ for $k>m$); at $c = t_0 + il$ put $s'_k := s_k - l$ for $k > m$, so that $s'_{m+1} < \cdots < s'_n < s_1 < \cdots < s_m < s'_{m+1} + l$; the period l and the symmetry of the kernel turn the integral into $\omega^{\mathrm{sl}}(\alpha_{t_0}(B)A)$. The truncated functions: σ_S is the centred functional of S and vanishes at one entry, so the inversion of the moment-cumulant formula gives S_n in terms of σ_S, whose kernels are the $\mathfrak{K}_m(s;h) = \mathfrak{R}_m(is;h)$ on O_m. The vectors: for (s,h) at increasing heights in $(0,\frac{l}{2})$ the classes $[(\tau_{s_k e_3}(\chi^{(\varpi)}\otimes h_k))_k]$ form a Cauchy family as $\varpi \to 0$, by (g), with a limit $\Psi_n(s;h)$; form the Hilbert space of formal kernel vectors using the positive-type kernel in (g). Their real-height vectors have the inner products of the sharp vectors just constructed. The span of the real-height vectors is dense in the kernel space. Indeed, an orthogonal vector gives a scalar holomorphic function in each tuple's complex heights that vanishes at all real heights and hence throughout its tube. Holomorphy follows first for finite sums of kernel vectors and then by the locally bounded diagonal of the kernel. Thus the isometry at real heights extends to this whole space

with image in $\mathcal{H}^{\mathrm{sl}}$, defining $\Psi_n(z;h)$ with the stated inner products. Weak holomorphy and the same local norm bound give Hilbert-space holomorphy; $e^{-it\mathsf{H}_3}\Psi_n(z;h)=\Psi_n(z+it\mathbf{1};h)$ by Step 9 and holomorphy, and $J^{\mathrm{sl}}\Psi_n(z;h)=\Psi_n(\frac{l}{2}\mathbf{1}-\bar{z}^{\mathrm{rev}};\bar{h}^{\mathrm{rev}})$. For $\mathsf{g}\in\mathsf{E}_2$, $[\mathsf{g}\cdot]\Psi_n(z;h)=\Psi_n(z;\mathsf{g}h_1,\dots,\mathsf{g}h_n)$: g acts on the first two coordinates, so it commutes with τ_{se_3} and $\mathsf{g}(\chi\otimes h_k)=\chi\otimes\mathsf{g}h_k$; the unitary operator $[\mathsf{g}\cdot]$ of (f) thus maps $[(\tau_{s_ke_3}(\chi^{(\varpi)}\otimes h_k))_k]$ to $[(\tau_{s_ke_3}(\chi^{(\varpi)}\otimes \mathsf{g}h_k))_k]$, and the identity passes to the limit $\varpi\to 0$, then to complex z, both sides being holomorphic, and to complex h, both sides being multilinear. With $\Psi_0:=\Omega^{\mathrm{sl}}=[\varnothing]$, put $\Psi^{\mathrm{sl}}(1):=\Omega^{\mathrm{sl}}$. Then $\Psi^{\mathrm{sl}}(\Phi(\phi_1,h_1)\cdots\Phi(\phi_n,h_n)):=\int\prod_k\phi_k(t_k+is_k)\,\Psi_n(s-it;h)\,dt$, $0<s_1<\cdots<s_n<\frac{l}{2}$, is a norm-convergent integral independent of s; $\langle\Psi^{\mathrm{sl}}(B),\Psi^{\mathrm{sl}}(A)\rangle=\omega^{\mathrm{sl}}(B^*A)$ is the computation of positivity; $\Psi^{\mathrm{sl}}(\alpha_{t_0}A)=e^{it_0\mathsf{H}_3}\Psi^{\mathrm{sl}}(A)$ by the shift; $[\mathsf{g}\cdot]\Psi^{\mathrm{sl}}(A)=\Psi^{\mathrm{sl}}(\mathsf{g}A)$, as $[\mathsf{g}\cdot]$, being bounded, may be taken inside the integral, which converges in norm, and $\mathsf{g}\Phi(\phi,h)=\Phi(\phi,\mathsf{g}h)$; the function $c\mapsto\Psi^{\mathrm{sl}}(\alpha_cA)$ is entire, and the lemma on domains of Step 9, applied to $\Xi(z):=\Psi^{\mathrm{sl}}(\alpha_{iz}A)$, gives $e^{-r\mathsf{H}_3}\Psi^{\mathrm{sl}}(A)=\Psi^{\mathrm{sl}}(\alpha_{ir}A)$ for all real r; at $r=\frac{l}{2}$ the formula for J^{sl} and $\phi^*(t+i(\frac{l}{2}-s))=\overline{\phi(t+i(s-\frac{l}{2}))}$ give $J^{\mathrm{sl}}e^{-\frac{l}{2}\mathsf{H}_3}\Psi^{\mathrm{sl}}(A)=\Psi^{\mathrm{sl}}(A^*)$. The closed span of the range of Ψ^{sl} reduces H_3 by real translation covariance. The span of the algebra vectors is a core for $e^{-l\mathsf{H}_3/2}$ on this subspace. To see this, convolve the real unitary group with Gaussian kernels to get $e^{-\delta\mathsf{H}_3^2}$, $\delta>0$. Applied to an algebra vector, each such convolution is a graph-norm limit of linear combinations of translates of that vector. For fixed $\delta>0$ the convolution maps the Hilbert space boundedly into the graph domain, by the spectral theorem, and as $\delta\downarrow 0$ it converges there on the domain. The algebra vectors are dense, so their graph closure is the full domain. The operator $e^{-l\mathsf{H}_3/2}$ has dense range in this subspace by the spectral theorem. The modular identity on the core therefore implies that J^{sl} leaves the subspace invariant. Consequently the closure of the conjugate-linear map $\Psi^{\mathrm{sl}}(A)\mapsto\Psi^{\mathrm{sl}}(A^*)$ has square modulus $e^{-l\mathsf{H}_3}$.

Step 13: real times (i). For $G\in\mathcal{S}(\mathbb{R}^n)$ and $s\in\mathsf{O}_n$ put $\Phi_G(s):=\int G(t)\,\mathfrak{R}_n(t+is;h)\,dt$; by (g), $|\Phi_G(s)|\le 2^n\mathsf{c}_n(R,l)\min\{1,\mathrm{gap}(s)\}^{-\varkappa_{\mathrm{w}}n}\|G\|_{L^1}\prod_k\|h_k\|_\sharp$. At $s=\varepsilon s^*$ with $0<\varepsilon\le\varepsilon_0$, $\varepsilon_0(s_n^*-s_1^*)\le\frac{l}{2}$ and $\varepsilon_0\mathsf{g}_*\le 1$, g_* the least difference of consecutive s_k^*, one has $\mathrm{gap}(\varepsilon s^*)=\varepsilon\mathsf{g}_*$; as $\partial_\varepsilon\mathfrak{R}_n(t+i\varepsilon s^*)=i(s^*\cdot\nabla_t)\mathfrak{R}_n(t+i\varepsilon s^*)$, integration by parts gives $\partial_\varepsilon^\mu\Phi_G(\varepsilon s^*)=(-i)^\mu\Phi_{(s^*\cdot\nabla)^\mu G}(\varepsilon s^*)$, of modulus at most a constant times $\varepsilon^{-\varkappa_{\mathrm{w}}n}\|(s^*\cdot\nabla)^\mu G\|_{L^1}$. Taylor's formula at ε_0 to the order $\mathsf{N}:=\lceil\varkappa_{\mathrm{w}}n\rceil+1$ has a remainder with an integrable bound, because $\mathsf{N}-1-\varkappa_{\mathrm{w}}n\ge 0$; so the limit as $\varepsilon\downarrow 0$ exists and is bounded by a constant times $\sum_{|\alpha|\le\mathsf{N}}\|\partial^\alpha G\|_{L^1}$, uniformly in $\varepsilon\in(0,\varepsilon_0]$. Along the segment between two directions s^* and s^{**}, the Taylor bounds are uniform because the consecutive gaps have a positive minimum there. The parameter derivative is $-i\varepsilon\Phi_{((s^{**}-s^*)\cdot\nabla)G}$ at the interpolated direction. Apply the uniform Taylor bound to this new test function and integrate along the segment. The difference is $O(\varepsilon)$, so the limit is independent of the direction. For $\phi_k\in\mathscr{G}$ the functions $\prod_k\phi_k(t_k+i\varepsilon s_k^*)$ converge to $\prod_k\phi_k(t_k)$ in these norms, so $\tilde{\omega}^{\mathrm{sl}}=\omega^{\mathrm{sl}}$ on $\mathfrak{A}^{\mathrm{sl}}$. The space $\mathscr{G}$ is dense in $\mathcal{S}(\mathbb{R})$: the Fourier transform of a smooth function of compact support lies in $\mathscr{G}$, and these transforms are dense; positivity and invariance pass to $\mathfrak{A}^{\mathrm{sl}}_{\mathcal{S}}$ by the bound just shown. The strip: for $A,B\in\mathfrak{A}^{\mathrm{sl}}$ the entire function $c\mapsto\omega^{\mathrm{sl}}(A\alpha_c(B))$, bounded on $0\le\mathrm{Im}\,c\le l$, is bounded on the two edges by $\omega^{\mathrm{sl}}(AA^*)^{1/2}\omega^{\mathrm{sl}}(B^*B)^{1/2}$ and $\omega^{\mathrm{sl}}(BB^*)^{1/2}\omega^{\mathrm{sl}}(A^*A)^{1/2}$ (Schwarz' inequality for the state and the condition at l), so by the three lines theorem on the whole strip by the larger of the two; for $A,B\in\mathfrak{A}^{\mathrm{sl}}_{\mathcal{S}}$, approximated by members of $\mathfrak{A}^{\mathrm{sl}}$, these functions converge uniformly on the closed strip, and the limit has the stated boundary values. Finally $\|\Psi^{\mathrm{sl}}(A_m)-\Psi^{\mathrm{sl}}(A_{m'})\|^2=\omega^{\mathrm{sl}}((A_m-A_{m'})^*(A_m-A_{m'}))\to 0$ defines Ψ^{sl} on $\mathfrak{A}^{\mathrm{sl}}_{\mathcal{S}}$; $e^{-\frac{l}{2}\mathsf{H}_3}$ is closed, and $e^{-\frac{l}{2}\mathsf{H}_3}\Psi^{\mathrm{sl}}(A_m)=J^{\mathrm{sl}}\Psi^{\mathrm{sl}}(A_m^*)$ converges, so $\Psi^{\mathrm{sl}}(A)\in\mathrm{Dom}(e^{-\frac{l}{2}\mathsf{H}_3})$ and the last rule of (h) holds on $\mathfrak{A}^{\mathrm{sl}}_{\mathcal{S}}$. □

Definition 18.200 (Numbers for all the cubes)**.** Use the constants of Theorem YM3_I:AD, with the source radius ϱ and the threshold γ fixed in the preceding definition. Set $g_1=\gamma_W$, where YM3_I:(2345) and YM3_I:(2346) define $\hat{\gamma}_W\in(0,\gamma/2]$ and

$$\gamma_W^{-2}=L^2\big(\bar{B}+\max\{\hat{\gamma}_W^{-2},\gamma^{-4},e^{C_{\mathrm{s}}}\}\big).$$

In particular $g_1 \le \gamma$, $g_1^{-2} \ge 16L^2$ and $g_1^{-2} > L^2\bar B$. Let $\mathsf{b}_- = g_1^{-2} + B_\sharp - L^{-1}\bar B$ and $\mathsf{b}_+ = L(g_1^{-2} + \bar B)$ be the endpoints of the outer label interval in YM3_I:(1535), and put $\kappa_1 = \mathsf{b}_+ \max\{1, 40M/\mathsf{b}_-\}$. For a reference coupling g, the least allowed side is

$$\ell_{\mathrm G}(g) = 2LM \max\{R(L(g^{-2}+\bar B)), L^{\lceil \log_L C_{\mathrm s}\rceil}\}, \qquad \rho_1 = \ell_{\mathrm G}(g_1)/\mathsf{b}_-,$$

by YM3_I:(1491). Here $R(u)$ is the least power L^v, $v \ge 0$, at least $(\log u)^{\mathsf r}$ (Section YM3_I:74). Use $\mathsf U$ from YM3_I:(1785), $\delta_e = \kappa - \kappa_{\mathcal D}$, and $\mathsf p$, $\varkappa_\star = 5 + \mathsf p$ and $B_{[g]}(R)$ from YM3_I:(1799)–(1803), with the constants $\rho_* = 2\varrho$, $C_e = C_{\mathrm S}$, $\kappa_e = \kappa$, $E_+ = C_{\mathrm S}$ and $C_{\mathrm{low}} = C_{\mathrm S}(1 + \log g^{-2})$ from Sections YM3_I:88 and YM3_I:89. Set $\mathrm{norm}_{\mathsf b}(f) = \max\{\sup|f|, \mathsf b\,\mathrm{Lip} f\}$.

(1) *The two functions of the big cubes.* $\mathsf A(x) := 1 + \mathsf U(1, \frac12 \mathsf b_- x)$ and $\mathsf B(y) := \kappa_1 B_{[g_1]}(2\mathsf b_+ y)$ for $x, y > 0$.

(2) *The ladder.* $y_0 := g_1^{-2}$, $y_{k+1} := Ly_k + (L-3)\bar B$, $g^{(k)} := y_k^{-1/2}$, $Y_k := Ly_k + (L-2)\bar B$, $t_k := 1 + \log y_k$, i_k the least integer $i \ge 0$ with $L^{3i} \ge t_k$, and

$$2\varrho_k := \min\{\sigma^{\mathrm S}(y_k - \bar B),\ \sigma_{\mathrm L}^{\mathrm S}\, y_k^{1/2} (\log y_k)^{-\mathfrak p_0}\},$$

with the positive constants $\sigma^{\mathrm S}$ and $\sigma_{\mathrm L}^{\mathrm S}$ of YM3_I:(1715)–(1716) and YM3_I:(1717). The inner first-passage interval of Corollary YM3_I:74.2 is $I(g^{(k)}) = (y_k + \bar B, Y_k]$, and $Y_k = y_{k+1} + \bar B$.

(3) *Constants.* $\mathsf u_0 := y_0 + \bar B + 1$; for $\lambda \ge \mathsf u_0$, $\Psi_{\mathrm s}(\lambda) := 2LM \max\{R(L(\lambda + \bar B)), L^{\lceil \log_L C_{\mathrm s}\rceil}\}$;

$$\mathsf c_Q := \exp\Big[C_{\mathrm S} S(\kappa)\Big\{\tfrac{27}{26} + 27[32(C''_\Sigma(\delta_e) + \log_L 5) + 4C'_\Sigma(\delta_e, 4)]\Big\}\Big], \qquad \mathsf k_1 := 27 \cdot 417\, M\, e^{5+\mathsf p}(2e\, 3^{\mathsf p} e^{2C_{\mathrm S}} \mathsf c_Q + 1),$$

$$\mathsf c_\varrho := \frac{2}{\sigma^{\mathrm S}} + \frac{1}{\sigma_{\mathrm L}^{\mathrm S}}, \qquad \mathsf c_\Psi := 2LM \max\{L(1 + \log(2L^2))^{\mathsf r}, L^{\lceil \log_L C_{\mathrm s}\rceil}\}, \qquad \mathsf c_\ell(\bar\rho) := L \max\{\mathsf c_\Psi, \bar\rho\, \mathsf u_0\},$$

$$c_* := 4\mathsf r + \tfrac43 + \mathfrak p_0, \qquad \mathsf K(\bar\rho) := \tfrac{27\sqrt3}{2}\, \mathsf k_1 L^4 \mathsf c_\ell(\bar\rho)^4 \mathsf c_\varrho, \qquad B_\natural := \mathsf K(\rho_1)\, e^{1/2} \Big(\frac{2c_*}{e}\Big)^{c_*}, \qquad \rho_\natural := LM\, e^{1-2c_*},$$

and $\hat{\mathsf B}(y) := \max\{\mathsf B(y), B_\natural\}$.

All these functions and numbers are built from the radius ϱ and the constants (the number $B_{[g_1]}(R)$ contains ϱ through ρ_*); none depends on a label, a side, a cutoff or a coupling of a datum. $\mathsf A$ does not increase, $\mathsf B$ and $\hat{\mathsf B}$ do not decrease and are bounded on bounded intervals, and $\mathsf A(x) \le 1 + 27 C_{\mathrm S} S(\kappa)[32(C''_\Sigma(\delta_e) + 10\sqrt3 M/(\mathsf b_- x)) + 4C'_\Sigma(\delta_e, 4)(4\sqrt3/(\mathsf b_- x))^3]$. ■

Proposition 18.201 (All the cubes at all labels, with numbers that depend on $\mathsf d/\mathsf b$ and $R/\mathsf b$ alone)**.** Let $\mathsf b > 0$, $m \in \mathbb Z$, $\ell = 2L^m$, $\rho := \ell/\mathsf b$, $n \ge 2$, $\mathsf d, R > 0$, and let $f_1, \dots, f_n$ be real Lipschitz functions on T_ℓ with pairwise disjoint supports, each contained in a closed ball of radius R, two of which lie at the distance $\ge \mathsf d$; $x := \mathsf d/\mathsf b$, $y := R/\mathsf b$. The limit cumulant $S_n^{(\ell,\mathsf b)}$ is that of Corollary YM3_I:119.2.

(a) *The cubes that are not small.* If $\rho \ge \rho_1$, then

$$|S_n^{(\ell,\mathsf b)}(f_1, \dots, f_n)| \le \mathsf b^{-n} \mathsf A(x)\, \mathsf B(y)^n (n!)^{\varkappa_\star} \prod_q \mathrm{norm}_{\mathsf b}(f_q).$$

(b) *The small cubes.* If $\rho < \rho_1$, then $|S_n^{(\ell,\mathsf b)}(f_1, \dots, f_n)| \le \mathsf b^{-n} \mathsf A(x)\, B_\natural^n (n!)^{\varkappa_\star} \prod_q \mathrm{norm}_{\mathsf b}(f_q)$; the radius R does not enter. If $\rho \le \min\{\rho_1, \rho_\natural\}$, then

$$|S_n^{(\ell,\mathsf b)}(f_1, \dots, f_n)| \le \mathsf A(x) \Big[\mathsf K(\rho_1)\Big(1 + \log\frac{LM}{\rho}\Big)^{c_*} \Big(\frac{\rho}{LM}\Big)^{1/2}\Big]^n (n!)^{\varkappa_\star} \prod_q \mathrm{Lip} f_q,$$

and the right member is at most the same expression with $\mathsf b^{-n} \prod_q \mathrm{norm}_{\mathsf b}(f_q)$ in the place of $\prod_q \mathrm{Lip} f_q$; the base tends to 0 as $\rho \to 0$.

(c) *One set of functions for all the cubes.* For every $\mathsf{b}>0$ and every side $\ell=2L^m$, $m\in\mathbb{Z}$,

$$|S_n^{(\ell,\mathsf{b})}(f_1,\dots,f_n)|\le \mathsf{b}^{-n}\,\hat C_n\big(\tfrac{\mathsf{d}}{\mathsf{b}},\tfrac{R}{\mathsf{b}}\big)\prod_q \mathrm{norm}_{\mathsf{b}}(f_q),\qquad \hat C_n(x,y):=\mathsf{A}(x)\,\hat{\mathsf{B}}(y)^n(n!)^{\varkappa_\star}:$$

the bound has the growth form $\mathsf{A}\cdot\hat{\mathsf{B}}^n(n!)^{\varkappa_\star}$, its functions depend on d/b and R/b alone, and it is uniform in ℓ/b, in particular as $\ell/\mathsf{b}\to 0$.

■

Sketch. A zero entry makes the cumulant and the proposed bounds zero, by multilinearity. Assume that the entries are nonzero and number a separated pair as $1,2$. Corollary YM3_I:119.2 gives the full cutoff limit on every side $2L^m$, $m\in\mathbb{Z}$, and the covariance $S_n^{(\ell,\mathsf{b})}(\underline{f})=L^{zn}S_n^{(L^z\ell,L^z\mathsf{b})}(\underline{f}^{[z]})$, where $f^{[z]}=f(L^{-z}\cdot)$. The finite-cutoff identity and the support and norm changes are YM3_I:(2219)–(2220): the radii and separations acquire the factor L^z, the supremum is unchanged, and the Lipschitz constant acquires the factor L^{-z}.

Step 1: the cubes that are not small (a). Let K be so large that $\beta:=L^K\mathsf{b}>X_{g_1}$; let K' be the cutoff with (K',β) a first-passage datum at g_1 (Proposition YM3_I:74.1), $z:=K-K'$, $\lambda:=L^z\mathsf{b}=a_{K'}\beta$ and $\ell':=L^z\ell=\rho\lambda$. By YM3_I:(1535), $\lambda\in[\mathsf{b}_-,\mathsf{b}_+]$; so $\ell'\ge\rho_1\mathsf{b}_-=\ell_{\mathrm{G}}(g_1)$, and $\ell'\in\mathfrak{L}(g_1)$ by YM3_I:(1491): (K',ℓ',β) is a triple at g_1. The functions $f_q^{[z]}$ are supported in balls of radius $\lambda y\le 2\mathsf{b}_+y$, and two supports lie at the distance $\ge\lambda x\ge\frac12\mathsf{b}_-x$. Proposition YM3_I:89.5 at g_1, with the radius $2\mathsf{b}_+y$ and the distance $\frac12\mathsf{b}_-x$, gives $|S^T_{n;K',\ell',\beta}(\underline{f}^{[z]})|\le A(\frac12\mathsf{b}_-x)B_{[g_1]}(2\mathsf{b}_+y)^n(n!)^{\varkappa_\star}\prod_q\|f_q^{[z]}\|_\sharp$, with $A(\mathsf{d}')=1+\mathsf{U}(\frac{1}{10},\mathsf{d}')\le 1+\mathsf{U}(1,\mathsf{d}')$, as U does not decrease in its first argument by YM3_I:(1785). Further $L^z\|f^{[z]}\|_\sharp=\mathsf{b}^{-1}\max\{\lambda\sup|f|,40M\mathsf{b}\,\mathrm{Lip}f\}\le\mathsf{b}^{-1}\max\{\lambda,40M\}\,\mathrm{norm}_{\mathsf{b}}(f)\le\mathsf{b}^{-1}\kappa_1\mathrm{norm}_{\mathsf{b}}(f)$. Multiplying by L^{zn} and letting $K\to\infty$ gives (a).

Step 2: a radius that moves with the rung. Let $k\ge 0$. As $g_1^{-2}>L^2\bar B$, $\bar B<L^{-2}y_k\le\frac12 y_k$; $y_{k+1}-y_k=(L-1)y_k+(L-3)\bar B>0$ and $y_k\ge L^k y_0$; so the intervals $I(g^{(k)})=(y_k+\bar B,Y_k]$ lie end to end and cover $(y_0+\bar B,\infty)$, and for $\lambda\in I(g^{(k)})$

$$y_k<\lambda\le Y_k<2Ly_k.$$

(i) $\varrho_k\in(0,\infty)$, and $(2\varrho_k)^{-1}\le\mathsf{c}_\varrho t_k^{\mathfrak{p}_0}y_k^{-1/2}$: the larger of $[\sigma^{\mathrm{S}}(y_k-\bar B)]^{-1}\le 2(\sigma^{\mathrm{S}}y_k)^{-1}\le(2/\sigma^{\mathrm{S}})y_k^{-1/2}$ and $(\log y_k)^{\mathfrak{p}_0}y_k^{-1/2}/\sigma^{\mathrm{S}}_{\mathrm{L}}$ is at most their sum, and $t_k\ge1$. (ii) Apply Proposition YM3_I:82.2 with source radius $2\varrho_k$ and lower endpoint $x=y_k$. The first bound in YM3_I:(1717) holds for all $x\ge y_k$ because $x-\bar B$ is increasing. The second holds on this interval because $x^{-1/2}(\log x)^{\mathfrak{p}_0}$ decreases for $\log x>2\mathfrak{p}_0$, which holds already at the initial threshold in the proof of Lemma YM3_I:82.5. The other coupling restrictions of that construction are independent of the source radius and remain valid on $[y_k,\infty)\subset[\gamma^{-2},\infty)$. Thus $g^{(k)}$ is an admissible threshold for the radius $2\varrho_k$. The choice may use its own canonical auxiliary data. (iii) The constants C_{S} and κ in Theorem YM3_I:AD precede the choice of the radius and threshold, as its proof on pp. 676–677 shows. Therefore the same is true of U, p, $\varkappa_\star$ and c_Q. The numbers X_g, $I(g)$ and the allowed sides are given by the first-passage formulas on pp. 614–616. (iv) For $\lambda\in I(g^{(k)})$, $K'\ge1$ and $\ell'\in\mathfrak{L}(g^{(k)})$, Corollary YM3_I:74.2 makes $(K',L^{K'}\lambda)$ a first-passage datum. Theorem YM3_I:AD supplies the source energies with radius $2\varrho_k$, local constants (C_{S},κ), upper exponent $E_+=C_{\mathrm{S}}$ and zero-source lower exponent $C_{\mathrm{low}}=C_{\mathrm{S}}(1+\log y_k)=C_{\mathrm{S}}t_k$. The finite Wilson law and its observables are determined by L,K',ℓ',β and are independent of the auxiliary data.

Step 3: growth in n from a board of side $a_i\le1$. Let $K\in\mathbb{N}$, $\beta>0$, $\ell=2L^m$ with $m>m'$, and a system over (K,ℓ,β) with constants $(\varrho_*;C_e,\kappa_e;E_+,C_{\mathrm{low}})$ in the sense of Sections YM3_I:88 and YM3_I:89: the local energies obey YM3_I:(1772), the residual partition function is bounded by $e^{E_+\ell^3}$ on the source ball, and its zero-source value is at least $e^{-C_{\mathrm{low}}\ell^3}$ be given; let $i\ge0$, $n\ge2$ with $a_K\le a_i/(24n)$, and let $f_1,\dots,f_n$ be real Lipschitz functions on T_ℓ, none 0, each supported in a closed sup ball of radius R, $\mathrm{dist}(\mathrm{supp}f_1,\mathrm{supp}f_2)\ge\mathsf{d}$. With U, p and c_Q formed with (C_e,κ_e),

$C_Q^{(i)} := \mathsf{c}_Q \exp[(E_+ + C_{\rm low})L^{-3i}]$ and $B^{(i)}(R) := 27\cdot 417\, M\, L^i(4L^iR+1)^3 e^{5+\mathsf{p}}(2e\,3^{\mathsf{p}}C_Q^{(i)}+1)/\varrho_*$, we claim

$$|S^T_{n;K,\ell,\beta}(f_1,\dots,f_n)| \le \big(1+\mathsf{U}(\tfrac{1}{10},\mathsf{d})\big)\, B^{(i)}(R)^n (n!)^{5+\mathsf{p}} \prod_q \|f_q\|_\sharp .$$

The mesh $\varepsilon := a_i/(5n) \le \frac{1}{10}$ divides ℓ. Use the periodic tensor tents $\chi^\varepsilon_y(x) = \prod_{\mu=1}^3 \max(0, 1-|x_\mu - y_\mu|_\ell/\varepsilon)$ on the grid of that mesh. They sum to one, have Lipschitz constant at most $\sqrt{3}/\varepsilon$, and at most $(2R/\varepsilon+3)^3$ of their supports meet any one ball. By multilinearity, $S^T_n(\underline{f})$ is a sum of at most $(2R/\varepsilon+3)^{3n}$ terms $S^T_n(v_1,\dots,v_n)$, $v_q = \chi^\varepsilon_{y_q} f_q \ne 0$, with supports in sup balls of radius ε inside those of the f_q and $\|v_q\|_\sharp \le (1+40\sqrt{3}M/\varepsilon)\|f_q\|_\sharp$. Lemma YM3_I:89.3 at this i with radius and margin ε (its condition is $\frac{4}{5}a_i + n a_K \le a_i$) places a translate $\underline{g}$ of the tuple on the board of side a_i with no two occupied cells congruent, the distances inside a cell kept, and $S^T_n(\underline{g}) = S^T_n(\underline{v})$. Proposition YM3_I:89.2, with both sides equal to ℓ, $C_{\rm gap} := 0$ and $R = D = \varepsilon$, gives a holomorphic normaliser $\mathcal{E}$ with $\mathcal{E}(0) = 0$ such that $h := e^{-\mathcal{E}}\langle e^{\sum_q z_q \mathcal{O}(g_q)}\rangle_{K,\ell,\beta}$ is at most $Q^{\#B}$ on the slices $z_q = 0$ for $q \notin B$, where $Q = \exp[(E_+ + C_{\rm low})a_i^3 + \Phi_1(\varepsilon,\varepsilon;a_i)]$; here $\min\{a_i, M\} = a_i$ and $5a_i/2\varepsilon = \frac{25n}{2}$, so by the display of Φ_1 in YM3_I:(1786) $\Phi_1(\varepsilon,\varepsilon;a_i) = \log \mathsf{c}_Q + \mathsf{p}\log\frac{5n}{2}$: the side of the board drops out, and $Q \le C_Q^{(i)} 3^{\mathsf{p}} n^{\mathsf{p}}$. With the generating function $\Gamma(z) := \langle e^{\sum_q z_q \mathcal{O}(g_q)}\rangle_{K,\ell,\beta}$, so that $\Gamma(0) = 1$ and $h = e^{-\mathcal{E}}\Gamma$, Lemma YM3_I:87.2, bounds $|\partial_{z_1}\cdots\partial_{z_n}\mathrm{Log}\,\Gamma(0) - \partial_{z_1}\cdots\partial_{z_n}\mathcal{E}(0)|$ by $(n-1)!\,2^n(eQ)^n\varrho_*^{-n}\prod_q\|v_q\|_\sharp$, and YM3_I:(1793), bounds the mixed derivative of $\mathcal{E}$ by $(n/\varrho_*)^n\prod_q\|v_q\|_\sharp\,\mathsf{U}(\varepsilon,\mathsf{d})$, which is $\le (n/\varrho_*)^n\prod_q\|v_q\|_\sharp\,\mathsf{U}(\frac{1}{10},\mathsf{d})$. As $2R/\varepsilon+3 \le 3n(4L^iR+1)$ and $1+40\sqrt{3}M/\varepsilon \le 417MnL^i$, the number of the terms times $\prod_q\|v_q\|_\sharp/\|f_q\|_\sharp$ is at most $\mathsf{c}^n n^{4n}$, $\mathsf{c} := 27(4L^iR+1)^3\cdot 417ML^i$; with $n^{tn} \le e^{tn}(n!)^t$ at $t = 4+\mathsf{p}$ and $t = 5$ the claim follows, each of the two resulting bases being at most $B^{(i)}(R)$.

Step 4: the norm on a cube. If a real Lipschitz f on T_ℓ vanishes at a point, every point is within $\frac{\sqrt{3}}{2}\ell$ of it, so $\sup|f| \le \frac{\sqrt{3}}{2}\ell\,\mathrm{Lip}f$; and if $L^z\ell \ge 2L^2M$, then $L^z\|f^{[z]}\|_\sharp = \max\{L^z\sup|f|, 40M\,\mathrm{Lip}f\} \le \frac{\sqrt{3}}{2}L^z\ell\,\mathrm{Lip}f \le \frac{\sqrt{3}}{2}L^z\ell\,\mathsf{b}^{-1}\mathrm{norm}_{\mathsf{b}}(f)$, because $\frac{\sqrt{3}}{2}L^z\ell \ge \sqrt{3}L^2M > 40M$.

Step 5: the bound at a rung. Let $k \ge 0$, $\lambda \in I(g^{(k)})$, $\ell' \in \mathfrak{L}(g^{(k)})$ (so $\ell' = 2L^{m''}$ with $m'' \ge m_{\mathfrak{L}}(g^{(k)}) \ge m'+2$), K' with $a_{K'} \le a_{i_k}/(24n)$, and f'_q as in Step 3 on $T_{\ell'}$ with the radius R' and the distance d'. Step 3 at the system of Step 2 (iv) and $i = i_k$: as $L^{3i_k} \ge t_k \ge 1$, $(C_{\rm S} + C_{g^{(k)}})L^{-3i_k} \le (C_{\rm S} + C_{\rm S}t_k)/t_k \le 2C_{\rm S}$, so $C_Q^{(i_k)} \le e^{2C_{\rm S}}\mathsf{c}_Q$ and

$$|S^T_{n;K',\ell',L^{K'}\lambda}(\underline{f}')| \le \big(1+\mathsf{U}(\tfrac{1}{10},\mathsf{d}')\big)\mathsf{B}_k(R')^n(n!)^{\varkappa_\star}\prod_q\|f'_q\|_\sharp, \qquad \mathsf{B}_k(R') := \frac{\mathsf{k}_1 L^{i_k}(4L^{i_k}R'+1)^3}{2\varrho_k}.$$

Step 6: every cube. Let z be the least integer with $L^z\mathsf{b} \ge \mathsf{u}_0$ and $L^z\ell \ge \Psi_{\rm s}(L^z\mathsf{b})$; it exists, because $R(u) < L(\log u)^{\mathsf{r}}$ for $u > e$ gives $\Psi_{\rm s}(\lambda)/\lambda \to 0$, so that both conditions hold for all large z, while the first fails for all small z. Put $\lambda := L^z\mathsf{b}$, $\ell' := L^z\ell = \rho\lambda$, and k the index with $\lambda \in I(g^{(k)})$. Then: $\ell' \in \mathfrak{L}(g^{(k)})$, since $\lambda > y_k$ and R does not decrease give $\ell' \ge \Psi_{\rm s}(\lambda) \ge \ell_{\rm G}(g^{(k)})$; $2L^2M \le \Psi_{\rm s}(\lambda) \le \ell' < L\max\{\Psi_{\rm s}(\lambda), \rho\,\mathsf{u}_0\}$, the first because $R(u) \ge L$ for $u > e$ by the definition of R on p. 614, the last because at $z-1$ one of the two conditions fails; and $y_k > \lambda/2L = \ell'/2L\rho \ge LM/\rho$. Each f_q vanishes at a point, its support being disjoint from the non-empty support of another entry. By Step 5 at $R' = \frac{1}{2}\ell'$, where the sup ball is the whole torus, and $\mathsf{d}' = \lambda x$, by Step 4, and letting $K' \to \infty$,

$$|S^{(\ell,\mathsf{b})}_n(\underline{f})| \le \big(1+\mathsf{U}(\tfrac{1}{10},\lambda x)\big)\mathfrak{B}^n(n!)^{\varkappa_\star}\prod_q \mathrm{Lip}f_q, \qquad \mathfrak{B} := \tfrac{\sqrt{3}}{2}\ell'\,\mathsf{B}_k(\tfrac{1}{2}\ell');$$

and $1+\mathsf{U}(\frac{1}{10},\lambda x) \le \mathsf{A}(x)$, because $\lambda \ge \mathsf{u}_0 > \frac{1}{2}\mathsf{b}_-$ and U does not increase in its second and does not decrease in its first argument by YM3_I:(1785). For $\lambda \le Y_k$: $L(\lambda + \bar{B}) < 2L^2y_k$ and $\log(2L^2y_k) \le (1+\log(2L^2))t_k$, so $\Psi_{\rm s}(\lambda) \le \mathsf{c}_\Psi t_k^{\mathsf{r}}$, and for $\rho \le \bar{\rho}$, $\ell' \le \mathsf{c}_\ell(\bar{\rho})t_k^{\mathsf{r}}$. As $L^{i_k}\ell' \ge 1$ and

$L^{i_k} < L t_k^{1/3}$, Step 2 (i) gives

$$\mathfrak{B} \le \tfrac{27\sqrt{3}}{2}\,\mathsf{k}_1 \frac{L^{4i_k}\ell'^4}{2\varrho_k} \le \mathsf{K}(\bar\rho)\,t_k^{c_*} y_k^{-1/2} = \mathsf{K}(\bar\rho)\,t_k^{c_*} e^{-(t_k-1)/2} \le \mathsf{K}(\bar\rho)\,e^{1/2}\Big(\frac{2c_*}{e}\Big)^{c_*}.$$

For $\rho < \rho_1$ take $\bar\rho = \rho_1$: $\mathfrak{B} \le B_\natural$, and $\mathrm{Lip} f \le \mathsf{b}^{-1}\mathrm{norm}_{\mathsf{b}}(f)$ gives the first bound of (b). The function $u \mapsto (1+\log u)^{c_*}u^{-1/2}$ decreases for $u \ge e^{2c_*-1}$; for $\rho \le \rho_\natural$, $y_k > LM/\rho \ge e^{2c_*-1}$, so $t_k^{c_*}y_k^{-1/2} \le (1+\log\frac{LM}{\rho})^{c_*}(\frac{\rho}{LM})^{1/2}$, which is the second bound of (b).

Step 7: one set (c). For $\rho \ge \rho_1$ use (a) and $\mathsf{B} \le \hat{\mathsf{B}}$; for $\rho < \rho_1$ use (b) and $B_\natural \le \hat{\mathsf{B}}$. □

Definition 18.202 (A coupling that varies with the place)**.** Use the constants and source radius 2ϱ of Theorem YM3_I:AD and Lemma YM3_I:82.5. Let $\mathsf{b} \ge \gamma^{-2}$ and $m \ge 1$ satisfy (Tor), namely $MR(\mathsf{b}) \le L^m$. At every $K \ge 1$ put $\ell = 2L^m$, $\beta = L^K\mathsf{b}$ and $x_j = L^{K-j}\mathsf{b}$ for $0 \le j \le K$. This is an admissible prescribed sequence with zero counterterm increments, and the room condition is that of Lemma YM3_I:82.4. Set

$$\|w\|_\flat = \max\{\sup|w|, (40M/\sqrt{3})\mathrm{Lip}_\infty w\},$$

$$\mathcal{E}_K(w) = \sum_{j=1}^{K}\sum_X e_j(X;w), \qquad G_K(w) = e^{-\mathcal{E}_K(w)}Z_K[w]/Z_K[0].$$

where Lip_∞ uses the torus sup metric and the source energies are those of Proposition YM3_I:83.2. Write $C_{\mathrm{low}}(x) = c_{\mathrm{low}} + \frac{9}{2}\log x$ for the constant of Proposition YM3_I:70.2 and use C_5^{S} and $\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}}$ from YM3_I:(1725)–(1726). Set $Q(\ell,x) = \exp[(\mathsf{C}^{\mathrm{S}}_{\mathrm{maj}} + 2 + C_{\mathrm{low}}(x))\ell^3]$, $Q = Q(\ell,\mathsf{b})$ and $r_1 = \varrho/(Q+1)$. For a real source w, $\|w\|_\flat < 2\varrho$, put $\mu_K^w = Z_K[w]^{-1}e^{-\beta\sum_p a_p + \mathcal{O}_K(w)}dU$, and let $S^w_{n;K}(\underline{f})$ denote the cumulant of $(\mathcal{O}_K(f_q))_q$ in that law. The plaquette coupling under μ_K^{-h} is $a_K^{-1}(\mathsf{b}+h(x(p)))$. A tuple consists of $n \ge 2$ nonzero real Lipschitz functions on T_ℓ with empty common support intersection. Its spread is the positive number $d_{\mathrm{sp}} = \min_{x_q\in\mathrm{supp}\,f_q}\max_{i,j}|x_i - x_j|_\infty$. Write $c_\natural = 54S(\kappa_{\mathcal{D}}+2)C'_\Sigma(2,4)$, with the functions from Lemma YM3_I:88.1 and YM3_I:(1777). Put

$$Q_\flat := \exp\Big[(\tfrac{5}{2}C_5^{\mathrm{S}} + \mathsf{C}^{\mathrm{S}}_{\mathrm{maj}} + 2 + \tfrac{3}{2}c_{\mathrm{low}} + \tfrac{27}{4}\log\mathsf{b})\ell^3\Big], \qquad Q_* := Q\,Q_\flat, \qquad \eta_*(r) := \frac{2\varrho - r}{2(Q_*+1)} \quad (0 \le r < 2\varrho),$$

and for a tuple $\underline{f}$

$$\Sigma^*_{\underline{f}}(r) := \Big[\log 2\Big(\frac{2n}{\eta_*(r)}\Big)^n + \Big(\frac{2n}{2\varrho - r}\Big)^n c_\natural M^3 E_0\Big(\frac{\ell}{d_{\mathrm{sp}}}\Big)^3\Big]\prod_q \|f_q\|_\flat.$$

■

Proposition 18.203 (One torus with the coupling $a_K^{-1}(\mathsf{b}+h(x))$: a floor, the limit along all cutoffs, the series in h, the constant labels)**.** Let the data be as in Definition 18.202.

(a) *The floor; two sides free of the cutoff.* Let $K \ge 1$, $u_\bullet = (x_0,\dots,x_K)$ an admissible finite sequence with the last index K, $((\ell',K),u_\bullet)$ an admissible lattice, $\beta = x_0$, $1 \le k \le K$, $N_k := (L^{K-k}\ell')^3$, and w a real source of the class on $T_{\ell'}$. Then $e^{-E^w_{(k)}}Z_{K,\ell',\beta}[w] \ge \exp[-(\frac{5}{2}C_5^{\mathrm{S}} + \frac{3}{2}C_{\mathrm{low}}(x_k))N_k]$, with the vacuum constant $E^w_{(k)}$ of Proposition YM3_I:83.2. Consequently, on the line of b, for every K and every real w with $\|w\|_\flat < 2\varrho$: $Q_\flat^{-1} \le G_K(w) \le Q$, that is, $Q_\flat^{-1}e^{\mathcal{E}_K(w)} \le \langle e^{\mathcal{O}_K(w)}\rangle_{K,\ell,\beta} \le Q\,e^{\mathcal{E}_K(w)}$.

(b) *A tube without zeros.* Let w_0 be real, $\|w_0\|_\flat \le r_0 < 2\varrho$, and $v \in \mathsf{Lp}(T_\ell)$ complex. For $\|v\|_\flat < 2\varrho - r_0$, $|G_K(w_0+v)/G_K(w_0) - 1| \le (Q_*+1)\|v\|_\flat/(2\varrho - r_0)$; $Z_K[w_0+v] \ne 0$ for $\|v\|_\flat < 2\eta_*(r_0)$; and $|\mathrm{Log}(G_K(w_0+v)/G_K(w_0))| \le \log 2$ for $\|v\|_\flat \le \eta_*(r_0)$. All this for every K.

(c) *A bound free of the cutoff.* Let $w = w_0 + v_0$ with w_0 as in (b) and $\|v_0\|_\flat \le \frac{1}{2}\eta_*(r_0)$, and let $\underline{f}$ be a tuple. The quantity $\mathcal{S}_K(w) := \partial_{z_1}\cdots\partial_{z_n}\lambda(0)$ is independent of the choice of the continuous branch λ of $\log Z_K[w + \sum_q z_q f_q]$ near $z = 0$; when w is real, it equals $S^w_{n;K}(\underline{f})$; moreover $\sup_K |\mathcal{S}_K(w)| \le \Sigma^*_{\underline{f}}(r_0)$.

(d) *The limit along all cutoffs.* For every real Lipschitz h on T_ℓ with $\|h\|_\flat < 2\varrho$ and every tuple $\underline{f}$ the limit

$$S^{(\ell,\mathsf{b}+h)}_n(\underline{f}) := \lim_{K\to\infty} S^{-h}_{n;K}(\underline{f})$$

exists as K tends to infinity through the entire sequence of cutoffs, and it satisfies $|S^{(\ell,\mathsf{b}+h)}_n(\underline{f})| \le \Sigma^*_{\underline{f}}(\|h\|_\flat)$. If an n-tuple, $n \ge 2$, of real Lipschitz functions on T_ℓ has 0 among its entries, then $S^{-h}_{n;K}$ vanishes at it for every K by multilinearity; the limit in the display is then 0, and it is taken as the value of $S^{(\ell,\mathsf{b}+h)}_n$ at that n-tuple. On the tuples and these n-tuples together, $S^{(\ell,\mathsf{b}+h)}_n$ is symmetric and separately linear in every entry.

(e) *The series.* If $\|h\|_\flat < r_1$, in particular if $\|h\|_\sharp \le \varrho/(Q+2)$, then

$$S^{(\ell,\mathsf{b}+h)}_n(\underline{f}) = \sum_{k\ge 0} \frac{(-1)^k}{k!}\, S^{(\ell,\mathsf{b})}_{n+k}(\underline{f}, \underbrace{h,\dots,h}_{k}),$$

with absolute convergence. If $0 < g \le \gamma$, $\ell \in \mathfrak{L}(g)$ and $\gamma^{-2} \le \mathsf{b} \le L(g^{-2} + \bar{B})$, then (Tor) holds and the series holds for $\|h\|_\sharp \le \varrho/(Q(\ell, L(g^{-2}+\bar{B})) + 2)$, a radius in which only ϱ, g, ℓ and the constants enter.

(f) *Constant labels.* For a real constant c_0 with $|c_0| < 2\varrho$: $\mathsf{b} + c_0 > \frac{1}{2}\mathsf{b}$, $S^{-c_0}_{n;K}(\underline{f}) = S^T_{n;K,\ell,L^K(\mathsf{b}+c_0)}(\underline{f})$ for every K, and the limit of (d) at $h = c_0$ is the limit cumulant $S^{(\ell,\mathsf{b}+c_0)}_n(\underline{f})$ at the label $\mathsf{b} + c_0$ (YM3_I:(2212)).

(g) *The function $\mathsf{b} + h$ alone.* If $\mathsf{b} + h = \mathsf{b}' + h'$ as functions, both pairs as in (d), the two sequences of (d) are equal at every K.

■

Sketch. Step 1: the floor (a), first sentence. For real w, the bare density is positive. The source-independent history weights are nonnegative, so YM3_I:(1512)–(1513) makes each history measure positive and $Z_{K,\ell',\beta}[w] \ge \tau^w_{h_\emptyset}(\mathcal{V}_k)$. In the empty history all regular regions are the torus. There are no external fields, boundary contributions or retained factors, and the reference measure is the coarse product Haar probability dV_k, as in the proof of Proposition YM3_I:70.2. The admissible evaluation representatives are those of the real construction and thus can be used at both w and 0. In Theorem YM3_I:AJ, the stay factor is one, the cutoff χ is source-independent, and the last bound of YM3_I:(1731) gives $|\mathbf{E}^w_k| \le C^{\mathrm{S}}_5 N_k$ because no cube is created. The deficit vanishes in YM3_I:(1735). Thus the empty-history density, outside the common reference null set, obeys

$$e^{-E^w_{(k)}} D^w(V) = \chi(V)\exp[-A(\beta^w_k, \mathsf{U}) + \mathbf{E}^w_k(\mathsf{U})]$$

on the cutoff support, with U any admissible representative over V, and the density is zero off it. The exponents are real by conjugation. The source admission in Lemma YM3_I:82.5 bounds the relative change of the level-k coupling by $a = \|w\|_\infty/(x_K - \bar{B}) < 1/2$. Every plaquette action of a real configuration is nonnegative, so $A(\beta^w_k, \mathsf{U}) \le (1+a)A(\beta_k, \mathsf{U})$. Comparing the formulas for D^w and D^0 gives

$$e^{-E^w_{(k)}} D^w \ge e^{-(2+a)C^{\mathrm{S}}_5 N_k}(e^{-E_{(k)}} D^0)^{1+a}.$$

Here the cutoff agrees at both sources, with $\chi \ge \chi^{1+a}$. Integrating, Jensen's inequality for dV_k and the zero-source empty-history floor YM3_I:(1488) give the lower exponent $(2+a)C^{\mathrm{S}}_5 + (1+a)C_{\mathrm{low}}(x_k)$, which is at most $\frac{5}{2}C^{\mathrm{S}}_5 + \frac{3}{2}C_{\mathrm{low}}(x_k)$.

Step 2: two sides (a), second sentence. At the last level of the line of b, $x_K = \mathsf{b}$ and $N_K = \ell^3$. The vacuum splitting YM3_I:(1737) identifies $G_K(w) = \widetilde{Z}_K(w)/\widetilde{Z}_K(0)$. The upper bound YM3_I:(1738) and the zero-source floor YM3_I:(1488) give $|G_K(w)| \le Q$ throughout the complex source ball. Dividing the real-source floor of Step 1 by the same upper bound at $w = 0$ gives $G_K(w) \ge Q_\flat^{-1}$. Proposition YM3_I:83.2 gives holomorphy on the ball and $\mathcal{E}_K(0) = 0$.

Step 3: the tube (b). Put $\mathsf{g}_K(v) := G_K(w_0 + v)/G_K(w_0)$ for $\|v\|_\flat < 2\varrho - r_0$. By Step 2, g_K is holomorphic along every family $w_0 + \sum_i z_i f_i$, $\mathsf{g}_K(0) = 1$ and $|\mathsf{g}_K| \le QQ_\flat = Q_*$. For $v \ne 0$ the function $\zeta \mapsto \mathsf{g}_K(\zeta v) - 1$ is holomorphic on $|\zeta| < (2\varrho - r_0)/\|v\|_\flat$, a radius > 1, vanishes at 0 and has modulus $\le Q_* + 1$; Schwarz's lemma at $\zeta = 1$ gives the first assertion. Where $|\mathsf{g}_K(v) - 1| < 1$, $Z_K[w_0 + v] = Z_K e^{\mathcal{E}_K(w_0+v)} G_K(w_0)\mathsf{g}_K(v) \ne 0$; where it is $\le \frac12$, $|\operatorname{Log} \mathsf{g}_K(v)| \le \log 2$.

Step 4: the bound (c). On $\|v\|_\flat < 2\eta_*(r_0)$ the function $Y^{w_0}(v) := \mathcal{E}_K(w_0+v) - \mathcal{E}_K(w_0) + \operatorname{Log} \mathsf{g}_K(v)$ is holomorphic along every family, $Y^{w_0}(0) = 0$, and $e^{Y^{w_0}(v)} = Z_K[w_0 + v]/Z_K[w_0]$; a continuous branch λ of $\log Z_K[w + \sum_q z_q f_q]$ near 0 differs from $z \mapsto Y^{w_0}(v_0 + \sum_q z_q f_q)$ by a constant, so $\mathcal{S}_K(w)$ is the mixed derivative of the latter, whatever pair (w_0, v_0) represents w. At a real w, with $w_0 = w$ and $v_0 = 0$, $e^{Y^w(\sum_q z_q f_q)} = \mu_K^w(e^{\sum_q z_q \mathcal{O}_K(f_q)})$, and the mixed derivative is the joint cumulant. On the polydisc $|z_q| < \eta_*(r_0)/(2n\|f_q\|_\flat)$, $\|v_0 + \sum_q z_q f_q\|_\flat < \eta_*(r_0)$, so $|\operatorname{Log} \mathsf{g}_K| \le \log 2$ by (b), and Cauchy's inequalities bound the mixed derivative of $\operatorname{Log} \mathsf{g}_K(v_0 + \sum_q z_q f_q)$ at 0 by $\log 2\,(2n/\eta_*(r_0))^n \prod_q \|f_q\|_\flat$. For the local energies take the polydisc $|z_q| < (2\varrho - \|w\|_\flat)/(n\|f_q\|_\flat)$. A term of $\mathcal{E}_K(w + \sum_q z_q f_q)$ has zero full mixed derivative unless its enlarged domain $X^{\sim 1}$ meets every support. At depth $s = K - j$ this implies $d_j(X) \ge d_{\mathrm{sp}} L^s/M - 4$ by YM3_I:(1773). Use $\operatorname{supp} f_1$ to anchor the contributing domains. The count YM3_I:(1774)–(1775), the per-term bound $2M^3 E_0 e^{-\kappa d_j(X)}$ in YM3_I:(1493), and the scale sum YM3_I:(1777) give

$$\sum_{j,X:\, X^{\sim 1} \text{ meets every support}} 2M^3 E_0 e^{-\kappa d_j(X)} \le 54 M^3 E_0 S(\kappa) \sum_{s=0}^{K-1} (\ell L^s/M)^3 e^{-(\kappa - \kappa_{\mathcal{D}})[d_{\mathrm{sp}} L^s/M - 4]_+}$$
$$\le c_\natural M^3 E_0 (\ell/d_{\mathrm{sp}})^3.$$

The last inequality follows by using $\kappa \ge \kappa_{\mathcal{D}} + 2$ in the sum and in S. Cauchy's formula on the stated polydisc then gives the second term in $\Sigma^*_{\underline{f}}(r_0)$, since $2\varrho - \|w\|_\flat \ge (2\varrho - r_0)/2$. Adding the logarithmic and local terms proves (c).

Step 5: from a centre to the whole disc. Let ϕ_K, $K \in \mathbb{N}$, be holomorphic on $|\zeta - \zeta_0| < \rho$ with $|\phi_K| \le \varsigma$, and let $\lim_K \phi_K^{(\nu)}(\zeta_0)$ exist for every $\nu \ge 0$. Then $\lim_K \phi_K^{(\mu)}(\zeta_1)$ exists for every ζ_1 of the disc and every $\mu \ge 0$. Indeed, by Cauchy's inequalities the Taylor coefficients $c_{K,\nu}$ at ζ_0 satisfy $|c_{K,\nu}| \le \varsigma \rho^{-\nu}$, and they converge to numbers c_ν with the same bound; $\phi_K^{(\mu)}(\zeta_1) = \sum_\nu (\nu+\mu)\cdots(\nu+1) c_{K,\nu+\mu}(\zeta_1 - \zeta_0)^\nu$, whose terms are bounded by $\varsigma \rho^{-\mu}(\nu+\mu)^\mu t^\nu$, $t = |\zeta_1 - \zeta_0|/\rho < 1$, uniformly in K; dominated convergence gives the limit, which is the derivative of $\sum_\nu c_\nu(\zeta - \zeta_0)^\nu$ at ζ_1.

Step 6: the limit (d). Let $u := -h \ne 0$ (at $h = 0$ this is Corollary YM3_I:119.2), $r_0 := \|u\|_\flat$, $\eta := \eta_*(r_0)/2r_0$. For $t \in [0,1]$ and $|\zeta - t| < \eta$, $\zeta u = tu + (\zeta - t)u$ with tu real, $\|tu\|_\flat \le r_0$ and $\|(\zeta - t)u\|_\flat < \frac12 \eta_*(r_0)$; so $\Psi_K(\zeta) := \mathcal{S}_K(\zeta u)$ is defined within η of $[0,1]$, independent of t by (c), bounded by $\Sigma^*_{\underline{f}}(r_0)$, and holomorphic, as the mixed derivative in z at 0 of the function $(\zeta', z) \mapsto Y^{tu}(\zeta' u + \sum_q z_q f_q)$, holomorphic in all its variables. At $\zeta = 0$ its derivatives are the joint cumulants $\Psi_K^{(\nu)}(0) = S^T_{n+\nu;K,\ell,L^K\mathsf{b}}(u, \dots, u, \underline{f})$, which converge to $S^{(\ell,\mathsf{b})}_{n+\nu}(u, \dots, u, \underline{f})$ by Corollary YM3_I:119.2: the supports of $(u, \dots, u, \underline{f})$ have no common point, those of $\underline{f}$ having none. Put $t_i := i\eta/2$ for the integers $0 \le i \le I := \lceil 2/\eta \rceil - 1$, and $t_{I+1} := 1$; consecutive points are at distance $\le \frac{\eta}{2}$. Step 5 with $\zeta_0 = t_i$, $\rho = \eta$, $\varsigma = \Sigma^*_{\underline{f}}(r_0)$ and $\zeta_1 = t_{i+1}$ carries the convergence of all the derivatives from t_i to t_{i+1};

at $t_{I+1}=1$, $\Psi_K(1)=\mathcal{S}_K(-h)=S^{-h}_{n;K}(\underline{f})$ converges. The bound passes to the limit; symmetry and linearity hold at every K for the cumulants of one law and pass to the limit.

Step 7: the series (e). At the center $w_0=0$ the proof of (b) uses $G_K(0)=1$ and $|G_K|\le Q$, so it gives $|\operatorname{Log} G_K(w)|\le \log 2$ for $\|w\|_\flat\le r_1$. The polydisc argument in Step 4, using radii $(r_1-\|w\|_\flat)/(n\|f_q\|_\flat)$ for the logarithm and the source-ball radii for $\mathcal{E}_K$, therefore bounds $\mathcal{S}_K(w)$ uniformly in K on each smaller ball $\|w\|_\flat\le r<r_1$. If $h\neq 0$ and $\|h\|_\flat<r_1$, choose $R_0>1$ with $R_0\|h\|_\flat<r_1$. The holomorphic functions $\zeta\mapsto\mathcal{S}_K(-\zeta h)$ are uniformly bounded on $|\zeta|\le R_0$. Their Taylor coefficients at zero are $(-1)^\nu S^T_{n+\nu;K,\ell,\beta}(\underline{f},h^{\times\nu})/\nu!$. Cauchy's estimate bounds these coefficients by a constant times $R_0^{-\nu}$. At $\zeta=1$ the series converges absolutely, and Corollary YM3_I:119.2 and dominated convergence give the claimed series for the limit. The case $h=0$ is immediate. The norm inequality $\|h\|_\flat\le\|h\|_\sharp$ follows from $|x-y|\le\sqrt{3}|x-y|_\infty$. Finally, $Q(\ell,x)$ increases with x, and YM3_I:(1491) gives $L^m\ge LMR(L(g^{-2}+\bar{B}))\ge MR(\mathsf{b})$ in the stated range. This proves the uniform choice of radius.

Step 8: constant labels (f) and the function $\mathsf{b}+h$ (g). Source admission YM3_I:(1717) gives $2\varrho/(\mathsf{b}-\bar{B})\le\sigma^{\mathrm{S}}\le\frac12$; so $2\varrho\le\frac12(\mathsf{b}-\bar{B})$ and $\mathsf{b}+c_0>\frac12\mathsf{b}$. As $\mathcal{O}_K(-c_0)=-c_0L^K\sum_p a_p$, $e^{-L^K\mathsf{b}\sum_p a_p+\mathcal{O}_K(-c_0+w')}=e^{-L^K(\mathsf{b}+c_0)\sum_p a_p+\mathcal{O}_K(w')}$; so $\mu_K^{-c_0}$ is the Wilson measure at $\beta'=L^K(\mathsf{b}+c_0)$, whose label is $\mathsf{b}+c_0$, and $S^{-c_0}_{n;K}=S^T_{n;K,\ell,L^K(\mathsf{b}+c_0)}$; its limit is $S_n^{(\ell,\mathsf{b}+c_0)}$ (Corollary YM3_I:119.2). Finally the weight $\exp[-\sum_p L^K(\mathsf{b}+h(x(p)))\,a_p]$ of μ_K^{-h} depends on the function $\mathsf{b}+h$ alone, which gives (g). □

18.22. **Lattice symmetries of the periodic Gibbs states, block fields of one torus and of the threads, the Hilbert space of the threads, and the two lists of axioms.** With the notation of Definition 18.209, this subsection treats the lattice symmetries of the periodic Gibbs states, the laws of the block fields at one cutoff and at infinite cutoff, the Hilbert space which the threads over $\mathbb{R}^3$ carry, and the relation of the axioms of the main text to two lists of axioms written out in full.

Proposition 18.210 works at one spacing $a>0$ and every $\beta\ge0$. Every periodic Gibbs state of the SU(2) Wilson weight is invariant under the whole group $a\mathbb{Z}^3\rtimes W_3$ of the lattice isometries, parity among them, and reflection positive at all the lattice mirrors of $a\mathbb{Z}^3$; so every bounded function which an isometry multiplies by a number $\omega\neq1$ has mean 0 and conditional mean 0 given the invariant events, every bounded function which is invariant, almost everywhere, under a sublattice of finite index or under the translation by a single vector $w\neq0$ of $a\mathbb{Z}^3$ is invariant, almost everywhere, under all lattice isometries, no isometry permutes the pure phases, a pure phase has no order of a sublattice, odd functions have no long-range order, and a periodic field which is switched off after the volume has been taken to infinity leaves no trace, neither in the order parameter nor in the free energy per term. Proposition 18.218 measures the distance between the laws of the threads over a cell, at infinite cutoff, and the thread measure of one torus T_ℓ by the excess $x=\ell^3(p_\ell-p_\infty)$ of the free energy of that torus over its infinite-volume value: the domination of Lemma 18.217(a) holds with $e^{\underline{x}/8}$, $\underline{x}$ the lower limit of the excess along the subsequence which gives the law, in the place of Q_0, the relative entropy is at most $\underline{x}$, and the distance in total variation is at most $\min\{\sqrt{\underline{x}/2},\mathfrak{t}(\underline{x})\}\le\frac12(\sqrt{\epsilon}+\epsilon)$ with $\epsilon=22.3(e^{\bar{x}/7}-1)$, $\bar{x}$ the upper limit; at the data at g and the sides of $\mathfrak{L}(g)$ the excess is at most $\ell^3(2C_{\mathrm{S}}+C_g)=8\log\mathsf{Q}_0$.

Proposition 18.219 is the clustering bound of the main text applied to bounded functions of the block fields of the depths $\ge d$ in a cube $[-R,R]^3$, at every cutoff, every $\beta\ge0$ and in every periodic Gibbs state, with the physical length $R+\frac12 a_d$ and the absolute constant $4\sqrt{3}\,\mathsf{C}_{\mathrm{dc}}$. Proposition 18.221 passes it to the laws $\boldsymbol{\nu}$ of the towers of block fields in infinite volume, along a defining sequence of a volume-first limit: these laws cluster at the rate $\rho'/|x|$, they are reflection positive at the coordinate planes $\{x_\kappa=c\}$ with $2c\in\bigcup_s a_s\mathbb{Z}$, the coordinate lattice mirrors of all depths, on the functions of the block fields whose footprints lie on one side, and the space $\mathcal{H}^{\mathrm{thr}}$ which this positivity

makes of the bounded functions of the block fields in a half space carries a semigroup of self-adjoint contractions, a Hamiltonian on the closed span of the vectors at positive distance from the mirror, horizontal translations with the cone $H^{\mathrm{thr}} \geq |P_\lambda^{\mathrm{thr}}|$, and a space of zero energy which is L^2 of the invariant events; it holds the loops of the block fields; and along a further subsequence the lattice correlations of a function of the block fields, reflected in the plane, with a combination of centred products of the action density converge to a form bounded by the product of the norms in the two Hilbert spaces, and so give an operator J of norm one from the Hilbert space of S, placed at the plane, into $\mathcal{H}^{\mathrm{thr}}$, with $J\Omega = \Omega$, which intertwines the semigroups, the horizontal translations and the group W_2. Lemma 18.222 bounds one step of the block-averaging map at the lowest layer above a plane between sites, with a constant $\mathsf{c}_L < 0.554\sqrt{L}$, and Proposition 18.223 uses it, with the main text's bound on the mass of the configurations whose block fields of depth d are not small (Proposition YM3_I:115.2), to show that the threads are regular, that the block fields whose footprints touch a plane between sites are, almost surely, functions of the block fields at positive distance above it, and hence that the translation by e_3 is injective on $\mathcal{H}^{\mathrm{thr}}$: the Hamiltonian of the threads is set on the whole space. Proposition 18.224 works on one periodic layer with sides $n_1, n_2 \geq 3$: the transfer operator, the plaquette actions in the layer and the transfer operator with one time-like plaquette inserted generate all bounded operators of the flux-free sector, and the sum of all bounded operators of the four flux sectors on the gauge-invariant space.

Definition 18.225 writes out two lists of axioms, List OS for Euclidean Green's functions in three dimensions and List GW for one Hermitian scalar field on $\mathbb{R}^{1+2}$, and the relation (Sch) between a Wightman theory and its Schwinger functions. Proposition 18.226 is a dictionary: the axioms (E0′)–(E4) of the main text imply List OS, with (E0′) equivalent to the growth axiom of the list; for data (Rec) with the properties of Proposition YM3_I:111.2 the larger test spaces of the main text add no vector to the Hilbert space; the Wightman theories of the main text are the quadruples of List GW, the group of the main text being the restricted Lorentz group; a Wightman theory whose forms are boundary values of holomorphic functions is determined, up to unitary equivalence, by the values of these functions at the time-ordered Euclidean points; the theory which the main text reconstructs from data (Rec) has its forms as boundary values in the strong sense, its fields commute also where the supports of the test functions touch the light cone, and the reflections of space are implemented on it; every ergodic component of every per-limit at g satisfies List OS with constants which are the same for all per-limits at g, and reconstructs a theory of List GW whose Schwinger functions are the kernels of the component, the Hilbert space of List OS being the Hilbert space of the component; and the limit itself satisfies all of List OS but the cluster axiom, which it satisfies exactly when it has one ergodic component, that is, when its vacuum is unique.

Propositions 18.210, 18.219 and 18.224, and clauses (a), (b) of Proposition 18.226, are fixed-spacing or axiomatic statements.

Definition 18.204 (Lattice laws)**.** At spacing a, a configuration assigns an element of $G = \mathrm{SU}(2)$ to each positive coordinate bond, with $U(\bar{b}) = U(b)^{-1}$ on the reversed bond. A law is a Borel probability measure on this compact product space. For a bond set B, $\mathcal{F}(B)$ consists of its bounded Borel observables. The plaquette variable $\partial U(p)$ is the boundary product and $a_p = 1 - \frac{1}{2}\operatorname{tr}\partial U(p)$. For a compactly supported weight f, set

$$\mathcal{O}_a(f) = a^{-1}\sum_p f(x(p))a_p, \qquad \mathcal{O}_K = \mathcal{O}_{a_K},$$

where $x(p)$ is the barycenter. The joint cumulant of these observables under ν is denoted by $S_n^T[\nu]$.

The Wilson torus law $\mu_{K,\ell,\beta}$ has density proportional to $e^{-\beta\sum_p a_p}$ with respect to product Haar measure, and $\tilde{\mu}_{K,\ell,\beta}$ is its periodic extension. The finite-bond Gibbs kernel γ_B integrates the bonds of B with Haar measure and Wilson weight from precisely the plaquettes that use a bond of B, then divides by the integral of that weight. A periodic Gibbs state is a law fixed by every γ_B and

invariant under a finite-index subgroup of translations. Write $\mathcal{G}^{\mathrm{per}}_{a,\beta}$ for these states and use the subscript K when $a = a_K$. The class $\mathcal{G}^{\mathrm{tor}}_{K,\beta}$ consists of weak limits of $\tilde{\mu}_{K,2L^m,\beta}$ with $m \to \infty$ and is included in $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ by Proposition YM3_I:103.4. Write $\mathcal{I}$ for the Borel sets invariant under all lattice translations. A pure phase is a periodic Gibbs state that takes only the values zero and one on $\mathcal{I}$. ∎

Definition 18.205 (Gibbs sequences and their limits)**.** Let $\mathfrak{S}_n$ be the set of n-tuples of real compactly supported C^1 functions with pairwise disjoint supports and include the empty tuple. A type $(\mathsf{d}; R)$ means that the supports are separated by at least d and each fits in a ball of radius R. Put $\|f\|_\sharp = \max\{\sup|f|, 40M \operatorname{Lip} f\}$. A Gibbs sequence at g is a sequence of first-passage data (K_j, β_j) with $K_j \to \infty$, together with $\nu_j \in \mathcal{G}^{\mathrm{per}}_{K_j,\beta_j}$. For $X = (f_1, \dots, f_n)$ let

$$X^\nu_K = \prod_{i=1}^{n} [\mathcal{O}_K(f_i) - \nu(\mathcal{O}_K(f_i))], \qquad \varnothing^\nu_K = 1.$$

The sequence converges if $\nu_j(X^{\nu_j}_{K_j})$ converges for every separated tuple X. A per-limit S has connected functions given by the limits of $S^T_n[\nu_j]$, $n \geq 2$, on such tuples. This Gibbs sequence is a defining sequence of S. It is volume-first if each ν_j lies in $\mathcal{G}^{\mathrm{tor}}_{K_j,\beta_j}$. For a growing-torus limit take cumulants on tori of sides $\ell_j \in \mathfrak{L}(g)$ with $\ell_j \to \infty$ and periodize each tuple. The centered functional σ_S is given by summing the products of $S_{|J|}(X_J)$ over partitions with all blocks of size at least two, with $\sigma_S(\varnothing) = 1$. The inverse formula for a functional σ is

$$S^\sigma_n(X) = \sum_{\pi} (-1)^{|\pi|-1} (|\pi| - 1)! \prod_{J \in \pi} \sigma(X_J).$$

These formulas identify convergence of the centered moments with convergence of the cumulants, since in each degree the two formulas are finite polynomials and the centered one-point term is zero. Use the reconstruction and canonical decomposition of Theorems YM3_I:AL and YM3_I:AP for σ_S. ∎

Definition 18.206 (Towers and windows)**.** Use $a_d = L^{-d}$ and write Bd_d for the positive bonds at depth d. Put $\mathsf{Z}_d = G^{\mathsf{Bd}_d}$, $\mathsf{Z} = \prod_{d \geq 0} \mathsf{Z}_d$, and $\mathsf{Z}^{[s]} = \prod_{d \geq s} \mathsf{Z}_d$. For side ℓ, $\mathsf{V}_d[\ell]$ is the configuration space on $a_d\mathbb{Z}^3/\ell\mathbb{Z}^3$. Write pr_ℓ for the quotient, per_ℓ for periodic extension, and Per_ℓ for that extension on every depth. The map $\mathcal{M}_\ell$ from depth $d+1$ to depth d is the double-block average of Section YM3_I:4. Its lattice version $\mathcal{M}$ uses the same rule in each double block, as justified in Lemma 18.211(a). The tower $\Psi_K U$ has depth-d field $\mathcal{M}^{K-d}U$ for $d \leq K$ and the identity field for $d > K$. The thread set is

$$\mathsf{Thr} = \{\mathsf{z} : \mathsf{z}_d = \mathcal{M}\mathsf{z}_{d+1} \text{ for every } d \geq 0\}.$$

For $v \in a_s\mathbb{Z}^3$, T_v translates the fields at depths $d \geq s$ and fills in $\mathcal{M}^{s-d}\tau_v \mathsf{z}_s$ at $d < s$. Let $\mathcal{I}_\infty$ be the Borel sets invariant on Thr under every such translation. On threads the action is independent of the choice of s, by Lemma 18.217(b).

Fix $\ell = 2L^m$ and $\square = [-\ell/4, \ell/4]^3$. Write w_d for the bonds with endpoints in $\square$, r_d for restriction to those bonds, and $Y_d = G^{\mathsf{w}_d}$. Put $Y = \prod_d Y_d$, $Y^{[d_0]} = \prod_{d \geq d_0} Y_d$ and $Y_{\leq D} = \prod_{d \leq D} Y_d$, with projections $\mathrm{pj}^{[d_0]}$ and q_D. If $o \in a_{d_0}\mathbb{Z}^3$, set $\varpi^{[d_0]}_o(\mathsf{z}) = (r_d \tau_{-o} \mathsf{z}_d)_{d \geq d_0}$. The window tower is $\Upsilon_K = \varpi^{[0]}_0 \Psi_K$. Define m^n_d by extending an input at depth $d+n$ by the identity outside $\square$, applying $\mathcal{M}^n$, and restricting at depth d. Then $\mathsf{Thr}_\square$ consists of the $y \in Y$ with $y_d = \mathsf{m}^1_d(y_{d+1})$ for all d. For closed $\mathfrak{c} \subset \square$, $Y(\mathfrak{c})$ and $p_\mathfrak{c}$ are the product space and coordinate projection retaining only bonds inside $\mathfrak{c}$. ∎

Definition 18.207 (Reference laws and product domination)**.** A compact interval $\mathsf{J} = [b_-, b_+]$ is admitted at $\ell = 2L^m$ if $b_- \geq \gamma^{-2}$ and $MR(b_+) \leq L^m$, where $R(x)$ is the least power L^n, $n \geq 0$,

with $L^n \geq (\log x)^r$ for the room exponent of the construction. The torus thread law $\mu_{\ell,\mathsf{b}}$ and its image $\mu[\ell,\mathsf{b}] = (\varpi_0^{[0]}\mathsf{Per}_\ell)_*\mu_{\ell,\mathsf{b}}$ are constructed in Lemma 18.212. Write $\mu^{[d_0]} = \mathrm{pj}_*^{[d_0]}\mu[\ell,\mathsf{b}]$. For domination $\preceq_{\mathsf{Q}}$ use Lemma 18.214. The product bound for a tower law $\boldsymbol{\pi}$ is

$$\left|\boldsymbol{\pi}\left(\prod_i f_i \circ \varpi^{[d_0]}_{o+(\ell/2)\mathbf{k}_i}\right)\right| \leq \prod_i \mathsf{Q}_0\, \mu^{[d_0]}(|f_i|^8)^{1/8}, \qquad \mathsf{Q}_0 = \exp\left[\tfrac{1}{8}\ell^3(2C_{\mathrm{S}} + C_g)\right],$$

for bounded Borel window functions, distinct $\mathbf{k}_i \in \mathbb{Z}^3$, and any $o \in a_{d_0}\mathbb{Z}^3$. When another constant is specified, use it in place of Q_0. ■

Definition 18.208 (The standing hypothesis for tower limits)**.** In (SH), $0 < g \leq \gamma$, $\ell \in \mathfrak{L}(g)$ and (K_j, β_j) are first-passage data at g with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}$. The law ν_j is either periodic Gibbs or the lift of a torus law of side $\ell_j \geq \ell$ in $\mathfrak{L}$. Infinite volume means that for every R all sufficiently late ν_j are periodic Gibbs or lifted from tori of sides at least R. ■

Definition 18.209 (Notation for the lattice and thread arguments)**.** Use the construction constants for SU(2), including the odd blocking factor $L \geq 13$, the cube size M and the reference couplings $0 < g \leq \gamma$. Write $a_d = L^{-d}$, $\mathfrak{L} = \{2L^m : m \geq 1\}$ and $T_\ell = \mathbb{R}^3/\ell\mathbb{Z}^3$. The first-passage data and $I(g)$ are those of Section YM3_I:74 and Corollary YM3_I:74.2, with $\bar{B} = LB_\sharp/(L-1)$ and $X_g = L(g^{-2} + B_\sharp)$. The side set $\mathfrak{L}(g)$ is given by YM3_I:(1528). The interval $\mathsf{J}_g = [g^{-2}, L(g^{-2} + \bar{B})]$ contains $I^{\mathrm{lab}}(g)$ of YM3_I:(1854). The stability and comparison constants $C_{\mathrm{S}}, C_g, C_{\mathrm{gap}}$ are those of Theorems YM3_I:AD and YM3_I:AJ. The two-point normalization $\mathsf{c}_2 = 9/(16\pi^2)$, kernel $\mathcal{K}_{\mathrm{free}}$ and threshold γ_W are those of Theorem YM3_I:AV.

The configuration space $\mathcal{V}(a\mathbb{Z}^3)$ of Definition 18.204 is a countable product of compact metrizable spaces, with the product topology. For $S \subset \mathbb{R}^3$, $\mathsf{Bd}(S)$ consists of the positively oriented bonds whose closed segments lie in S. Let $\mathcal{F}_{\mathrm{loc}}(S)$ be the bounded complex Borel functions of finitely many such bonds, and $\mathcal{C}_{\mathrm{loc}}(S)$ their continuous members. We write $\mathcal{C}_{\mathrm{loc}}$ for $\mathcal{C}_{\mathrm{loc}}(\mathbb{R}^3)$. This algebra separates points and is closed under conjugation, so it is uniformly dense in $C(\mathcal{V}(a\mathbb{Z}^3))$.

For a finite-index subgroup $\Gamma \subset a\mathbb{Z}^3$, set $\mathrm{sys}(\Gamma) = \min_{0 \neq v \in \Gamma} |v|_\infty$. A period lattice has $\mathrm{sys}(\Gamma) \geq 3a$, and $\mathcal{V}_\Gamma$ consists of the configurations fixed by all translations in Γ. Write S_Γ for the sum of the plaquette actions over the plaquette classes modulo Γ. For a real continuous function Φ on $\mathcal{V}_\Gamma$, $Z_\Gamma[\Phi]$ is the product Haar integral of $e^{-\beta S_\Gamma + \Phi}$ on the periodic configuration space, and μ_Γ^Φ is the probability law with the corresponding normalized density. This is the finite-volume law in YM3_I:(1817). Write $\mathcal{G}_{a,\beta}$ for all laws fixed by the finite-bond Gibbs kernels of Definition 18.204. A locally finite source family $\mathfrak{A} = (A_i, B_i)_i$ consists of real continuous functions A_i carried by finite bond sets B_i, each bond belonging to only finitely many B_i. At strength t the kernel on a finite bond set B adds the term $t\sum_{i:B_i \cap B \neq \emptyset} A_i$ to the Wilson exponent. A Gibbs state for $(\beta, t\mathfrak{A})$ satisfies the resulting finite-bond equations.

Set $\mathfrak{N} = \{e_1, e_2, e_3\} \cup \{e_\mu \pm e_\lambda : 1 \leq \mu < \lambda \leq 3\}$. For $n \in \mathfrak{N}$ the lattice mirror $\Sigma(n,c)$ is the plane $n \cdot x = c$, with $c \in (a/2)\mathbb{Z}$ for coordinate n and $c \in a\mathbb{Z}$ for diagonal n. Its closed sides are $\mathbb{H}^\pm(n,c) = \{x : \pm(n \cdot x - c) \geq 0\}$ and its reflection is $\theta_{n,c}x = x - 2|n|^{-2}(n \cdot x - c)n$. The linear part is a signed permutation, and the translation part belongs to $a\mathbb{Z}^3$. Let $\mathcal{F}^+_{n,c} = \mathcal{F}_{\mathrm{loc}}(\mathbb{H}^+(n,c))$. An isometry acts on configurations by $(\mathsf{r}U)(b) = U(\mathsf{r}^{-1}b)$, on functions by $(\mathsf{r}F)(U) = F(\mathsf{r}^{-1}U)$, and on events by their images. For a translation this gives $\tau_v F = F \circ \tau_{-v}$.

The reflection size $\mathcal{N}_r$ and the absolute constants C_{dc} and $\mathsf{k} = (2/\pi)\log(1+\sqrt{2})$ are given by YM3_I:(1959), YM3_I:(1968) and YM3_I:(1954), respectively. For side ℓ write $\Lambda_{d,\ell} = a_d\mathbb{Z}^3/\ell\mathbb{Z}^3$. A coordinate of a law on Z is $\mathsf{z}_d(c)$, with c a bond at depth d. On 2×2 matrices $|\cdot|$ is the operator norm. The Gibbs sequences, towers, reference laws and hypothesis (SH) are specified in Definitions 18.205–18.208. ■

Proposition 18.210 (No periodic Gibbs state breaks a lattice isometry)**.** Let $a > 0$ and $\beta \geq 0$ be real numbers and let $\nu \in \mathcal{G}^{\mathrm{per}}_{a,\beta}$ be any periodic Gibbs state at (a,β), pure or not, of any period.

For a bounded Borel function h and $v \in a\mathbb{Z}^3$ we write $\tau_v\mathsf{h}$ for the action of the translation by v on functions, $(\tau_v\mathsf{h})(U) = \mathsf{h}(\tau_{-v}U)$, and $\mathbb{E}_\nu[\,\cdot\,|\mathcal{I}]$ is conditional expectation with respect to the invariant events.

(a) *Symmetry and positivity.* $\nu(\mathsf{r}F) = \nu(F)$ for every bounded Borel function F and every $\mathsf{r} \in \mathsf{Iso}(a\mathbb{Z}^3) = a\mathbb{Z}^3 \rtimes W_3$, among them the parity $x \mapsto -x$, the 48 signed permutations and the reflections in all the lattice mirrors; and $\nu(\overline{\theta_{n,c}F}\, F) \geq 0$ at every lattice mirror (n, c) of the nine families for every bounded complex Borel function F of finitely many bonds whose closed segments lie in one closed side of the mirror. In particular the mean $\nu(a_p)$ has one value for all the plaquettes p of the three orientations.

(b) *Odd functions have mean zero, in every phase.* For every bounded Borel function F and every $\mathsf{r} \in \mathsf{Iso}(a\mathbb{Z}^3)$, $\mathbb{E}_\nu[\mathsf{r}F|\mathcal{I}] = \mathbb{E}_\nu[F|\mathcal{I}]$ ν-almost surely. If $\mathsf{r}F = \omega F$ with a complex number $\omega \neq 1$, then $\nu(F) = 0$ and $\mathbb{E}_\nu[F|\mathcal{I}] = 0$ ν-almost surely; in particular $\nu(F) = 0$ for every bounded Borel F that is odd under the parity or under the reflection in a lattice mirror. The clause is not empty on gauge-invariant local functions: for the closed path C of the eight steps $ae_3, ae_3, ae_2, ae_1, -ae_3, -ae_1, -ae_3, -ae_2$ from the site 0 and $W_C(U) = \frac{1}{2}\operatorname{tr} U(C)$, the function $W_C - W_{\mathsf{P}C}$, P the parity, is continuous, local, gauge invariant, odd under P and not 0; so $\nu(W_C) = \nu(W_{\mathsf{P}C})$.

(c) *Functions invariant under a sublattice, or under one translation.* Fix a subgroup $\Gamma' \subset a\mathbb{Z}^3$ whose index is finite, and a bounded Borel function h such that, at each $v \in \Gamma'$, the equality $\tau_v\mathsf{h} = \mathsf{h}$ holds ν-almost everywhere. Then the equality $\mathsf{rh} = \mathsf{h}$ also holds ν-almost everywhere, at each $\mathsf{r} \in \mathsf{Iso}(a\mathbb{Z}^3)$; consequently each Borel set E for which $\nu(\tau_v E \triangle E) = 0$ at all $v \in \Gamma'$ satisfies $\nu(\mathsf{r}E \triangle E) = 0$ for all these r, and this applies in particular to each $E \in \mathcal{I}$, for any value of $\nu(E)$. The same conclusion holds if $\tau_w\mathsf{h} = \mathsf{h}$ ν-almost everywhere for one vector $w \in a\mathbb{Z}^3 \setminus \{0\}$ alone; then h coincides ν-almost everywhere with an $\mathcal{I}$-measurable function.

(d) *Pure phases.* For every regular conditional distribution $(\nu^U)_U$ of ν given $\mathcal{I}$, $\nu = \int \nu^U\, \nu(dU)$, and for ν-almost every U the law ν^U is a pure phase, to which (a)–(c) apply. So $\mathsf{r}_*\rho = \rho$ for every pure phase ρ and every $\mathsf{r} \in \mathsf{Iso}(a\mathbb{Z}^3)$: no lattice isometry permutes the pure phases, and every lattice isometry fixes ν^U for ν-almost every U. A pure phase ρ has $\rho(E) \in \{0, 1\}$ for every Borel set E with $\rho(\tau_w E \triangle E) = 0$ for one $w \in a\mathbb{Z}^3 \setminus \{0\}$; in particular a pure phase has no order of a sublattice: $\rho(E) \in \{0, 1\}$ whenever $\rho(\tau_v E \triangle E) = 0$ for all v of a subgroup of finite index.

(e) *No long-range order of an odd function.* Let $r \geq 1$ be an integer, $Q_r = [-ra, ra]^3$, $A, B \in \mathcal{F}(\mathsf{Bd}(Q_r))$, and let C_{dc} be the absolute number YM3_I:(1968). If $\mathsf{r}A = \omega A$ for some $\mathsf{r} \in \mathsf{Iso}(a\mathbb{Z}^3)$ and some $\omega \neq 1$, then

$$|\nu(\bar{A}\,\tau_x B)| \leq 4\,\mathsf{C}_{\mathrm{dc}}\,\nu(|A|^2)^{1/2}\,\nu(|B|^2)^{1/2}\,\frac{ra}{|x|_\infty} \qquad (x \in a\mathbb{Z}^3,\ |x|_\infty \geq 4ra);$$

an $A \neq 0$ meets this hypothesis only if r has finite order. If $n \in \mathfrak{N}$ and $\theta_{n,0}A = -A$, then $\nu(\bar{A}\,\tau_{jan}A) \leq 0$ for every integer $j \geq 2r$; if $\theta_{n,0}A = A$, then $\nu(\bar{A}\,\tau_{jan}A) \geq 0$ for every integer $j \geq 2r$.

(f) *A periodic field switched off behind the limit of the volume leaves no trace.* (1) Let $\mathfrak{A}$ be a family, $\Gamma' \subset a\mathbb{Z}^3$ a subgroup of finite index, $t_k \to 0$ real numbers, and for each k let ν_k be a Gibbs state for $(\beta, t_k\mathfrak{A})$ that is invariant under Γ'. Then every weak limit point of $(\nu_k)_k$ lies in $\mathcal{G}^{\mathrm{per}}_{a,\beta}$, and $\nu_k(\mathsf{r}f) - \nu_k(f) \to 0$ for every continuous function f on $\mathcal{V}(a\mathbb{Z}^3)$ and every $\mathsf{r} \in \mathsf{Iso}(a\mathbb{Z}^3)$. (2) Let $F \in \mathcal{C}_{\mathrm{loc}}$ be real, let $\Gamma_n \subset \Gamma'$ be period lattices with $\mathrm{sys}(\Gamma_n) \to \infty$, set $\mathbb{F}_n = \sum_{[v] \in \Gamma'/\Gamma_n} \tau_v F$ on $\mathcal{V}_{\Gamma_n}$ and $\mu_{n,t} = \mu^{t\mathbb{F}_n}_{\Gamma_n}$ for $t \in \mathbb{R}$. Then

$$\lim_{t \to 0}\ \limsup_{n \to \infty} |\mu_{n,t}(\mathsf{r}f) - \mu_{n,t}(f)| = 0$$

for every continuous f and every $\mathsf{r} \in \mathsf{Iso}(a\mathbb{Z}^3)$, and $\lim_n |\mu_{n,0}(\mathsf{r}f) - \mu_{n,0}(f)| = 0$. (3) If moreover $F = F_0 - \mathsf{r}F_0$ with a real $F_0 \in \mathcal{C}_{\mathrm{loc}}$ and some $\mathsf{r} \in \mathsf{Iso}(a\mathbb{Z}^3)$ (for instance $F_0 = \frac{1}{2}F$ when $\mathsf{r}F = -F$), then, with $p_n(t) = |\mathbb{F}_n|^{-1} \log(Z_{\Gamma_n}[t\mathbb{F}_n]/Z_{\Gamma_n}[0])$,

$$\lim_{t\to 0} \limsup_{n\to\infty} |\mu_{n,t}(F)| = 0, \qquad \lim_{t\to 0} \limsup_{n\to\infty} \frac{|p_n(t)|}{|t|} = 0 :$$

the order parameter $F_0 - \mathsf{r}F_0$ vanishes when the volume is taken first and the field is switched off afterwards, and no limit point of the free energies per term has a kink at $t = 0$. For $\Gamma' = a\mathbb{Z}^3$ the field is uniform and tests the isometries that are not translations; for $\Gamma' = \{v \in a\mathbb{Z}^3 : (v_1 + v_2 + v_3)/a \text{ even}\}$, $\mathsf{r} = \tau_{ae_1}$ and $F_0 = a_p$ it is the staggered field $\sum_{v\in\Gamma'/\Gamma_n}(a_{p+v} - a_{p+v+ae_1})$, which tests the translation by one step.

The argument uses only fixed-spacing results. ■

Proof. Step 1. Proposition YM3_I:103.4 gives lattice invariance and reflection positivity at all the indicated mirrors. For the plaquette mean, translations and coordinate permutations act transitively on the unoriented plaquettes. A relabelling can conjugate or invert a plaquette holonomy, which preserves its trace in SU(2).

Step 2: clause (b). Let $E \in \mathcal{I}$. Since ν is invariant under r, $\nu(1_E\, \mathsf{r}F) = \nu((\mathsf{r}^{-1}1_E)\, F) = \nu(1_{\mathsf{r}^{-1}E}F)$, and $1_{\mathsf{r}^{-1}E} = 1_E$ ν-almost everywhere by clause (c) at $\Gamma' = a\mathbb{Z}^3$, whose proof (Step 3) does not use (b). So $\nu(1_E\, \mathsf{r}F) = \nu(1_E F)$ for all $E \in \mathcal{I}$, and the two conditional expectations, the unique classes with an $\mathcal{I}$-measurable member and these integrals, agree. If $\mathsf{r}F = \omega F$, then $\nu(F) = \nu(\mathsf{r}F) = \omega\nu(F)$ by (a), and $\mathbb{E}_\nu[F|\mathcal{I}] = \mathbb{E}_\nu[\omega F|\mathcal{I}] = \omega\, \mathbb{E}_\nu[F|\mathcal{I}]$; as $\omega \neq 1$ both vanish. For the example: $(\mathsf{r}W_C)(U) = W_C(\mathsf{r}^{-1}U) = W_{\mathsf{r}C}(U)$, because $(\mathsf{r}^{-1}U)(c) = U(\mathsf{r}c)$ for every bond c; so $\mathsf{P}(W_C - W_{\mathsf{P}C}) = W_{\mathsf{P}C} - W_C$. The path C visits the eight different sites $0, (0,0,1), (0,0,2), (0,1,2), (1,1,2), (1,1,1), (0,1,1), (0,1,0)$, times a, and it runs once through the bond $\langle 0, ae_3\rangle$; the path $\mathsf{P}C$ has no site with a positive coordinate and does not use this bond. At the configuration which is $g \neq \mathbf{1}$ on $\langle 0, ae_3\rangle$ and $\mathbf{1}$ on every other bond, $W_C - W_{\mathsf{P}C} = \frac{1}{2}\operatorname{tr} g - 1 < 0$. The function is gauge invariant, since the holonomy of a closed path is changed by a conjugation.

Step 3. By linearity and addition of constants it suffices to take $\mathsf{h} \geq 0$ with $\nu(\mathsf{h}) > 0$. Put $h = \mathsf{h}/\nu(\mathsf{h})$ and fix a finite bond set B. Continuous local functions are dense in $L^1(\nu)$. For any $\epsilon > 0$ choose a continuous local h' with $\nu(|h - h'|) < \epsilon$. Take $v \in \Gamma'$ such that the support of $\tau_v h'$ is disjoint from B. Since h and ν are Γ'-invariant, $\nu(|h - \tau_v h'|) < \epsilon$. For any bounded Borel F, the Gibbs equation gives $\nu((\tau_v h')\gamma_B F) = \nu((\tau_v h')F)$ because γ_B fixes the outside variables. Replacing $\tau_v h'$ by h changes either side by at most $\epsilon\|F\|_\infty$. Thus $h\nu$ is Gibbs and it is periodic because both h and ν are Γ'-invariant. Clause (a) gives $\nu(h\, \mathsf{r}^{-1}F) = \nu(hF)$. Since ν is invariant under r, this says $\nu((\mathsf{r}h - h)F) = 0$ for all bounded Borel F. Consequently $\mathsf{r}h = h$ almost everywhere, also for $h = 1_E/\nu(E)$ when $\nu(E) > 0$. If $\nu(E) = 0$, its image is null by (a).

Step 4: clause (c) for one translation. Let h be real, $|\mathsf{h}| \leq \varsigma$, $\tau_w\mathsf{h} = \mathsf{h}$ almost everywhere; by induction, and as r carries null sets to null sets by (a), $\tau_{kw}\mathsf{h} = \mathsf{h}$ almost everywhere for all $k \in \mathbb{N}$. Write $\langle f, f'\rangle = \nu(\bar{f}f')$ and Π for the orthogonal projection of $L^2(\nu)$ onto the classes with an $\mathcal{I}$-measurable member, which is $\mathbb{E}_\nu[\,\cdot\,|\mathcal{I}]$. For real $A, B \in \mathcal{C}_{\mathrm{loc}}$, both lie in $\mathcal{F}(\mathsf{Bd}(Q_r))$ for a large integer r, and the clustering bound, YM3_I:(1970), with the sizes $\mathcal{N}_r(A) \leq \nu(|A|^2)$ of the bound following YM3_I:(1959), gives $\langle A, \tau_{kw}B\rangle \to \langle \Pi A, \Pi B\rangle = \langle A, \Pi B\rangle$ as $k \to \infty$. Hence

$$\langle A, \mathsf{h}\rangle - \langle A, \Pi\mathsf{h}\rangle = \langle A, \tau_{kw}(\mathsf{h} - B)\rangle + \big[\langle A, \tau_{kw}B\rangle - \langle A, \Pi B\rangle\big] + \langle A, \Pi(B - \mathsf{h})\rangle,$$

whose first and last terms are at most $\|A\|_2\|\mathsf{h} - B\|_2$ in modulus, by the inequality of Schwarz, the invariance of ν under τ_{kw} and $\|\Pi\| \leq 1$. The algebra $\mathcal{C}_{\mathrm{loc}}$ is dense in $C(\mathcal{V}(a\mathbb{Z}^3))$, hence in $L^2(\nu)$, and the real parts of its members are again in it; so $\|\mathsf{h} - B\|_2$ is as small as we please, and $\langle A, \mathsf{h} - \Pi\mathsf{h}\rangle = 0$ for all real $A \in \mathcal{C}_{\mathrm{loc}}$, whence $\mathsf{h} = \Pi\mathsf{h}$ in $L^2(\nu)$. Let g be an $\mathcal{I}$-measurable member of $\Pi\mathsf{h}$; it is invariant under all translations everywhere, so Step 3 at $\Gamma' = a\mathbb{Z}^3$ gives $\mathsf{rg} = \mathsf{g}$ almost everywhere, and $\mathsf{rh} = \mathsf{rg} = \mathsf{g} = \mathsf{h}$ almost everywhere.

Step 5: clause (d). The decomposition and the statement that $\nu^U \in \mathcal{G}^{\mathrm{per}}_{a,\beta}$ is ergodic for ν-almost every U follow from Proposition YM3_I:106.2; the ergodic members of $\mathcal{G}^{\mathrm{per}}_{a,\beta}$ are its pure phases (Proposition YM3_I:106.1); a pure phase is a periodic Gibbs state, so (a) gives $\mathsf{r}_*\rho = \rho$. Let ρ be a pure phase and $\rho(\tau_w E \triangle E) = 0$ for one $w \neq 0$. By Step 4 for ρ and $\mathsf{h} = 1_E$, 1_E coincides almost everywhere with an $\mathcal{I}$-measurable function, so with $\mathbb{E}_\rho[1_E|\mathcal{I}]$, which is the constant $\rho(E)$, ρ being ergodic; a function with the values 0 and 1 which is almost everywhere constant is almost everywhere 0 or almost everywhere 1. Without the clustering bound the case of a subgroup Γ' of finite index also follows from Step 3: if $0 < \rho(E) < 1$, then $\rho(E)^{-1}1_E\rho$ and $\rho(E^c)^{-1}1_{E^c}\rho$ are two different members of $\mathcal{G}^{\mathrm{per}}_{a,\beta}$ of which ρ is a proper convex combination.

Step 6: clause (e). By (b), $\mathbb{E}_\nu[A|\mathcal{I}] = 0$, so the clustering bound YM3_I:(1970) has no subtracted term, and $\mathcal{N}_r(A) \le \nu(|A|^2)$, $\mathcal{N}_r(B) \le \nu(|B|^2)$ by the bound following YM3_I:(1959), whose hypotheses (invariance under $a\mathbb{Z}^3$ and positivity at $\Sigma(e_\mu, 0)$, $\Sigma(e_\mu, \frac{a}{2})$) hold by (a). Finite order: if r has infinite order, then, W_3 being finite, $\mathsf{r}^m = \tau_u$ with some $m \ge 1$ and $u \neq 0$, and $\tau_u A = \omega^m A$. A function $F \in \mathcal{F}(B)$, B finite, with $\tau_u F = \omega' F$ is constant: if $F \neq 0$ then $|\omega'| = 1$ and $F = \omega'^{-k}\tau_{ku}F \in \mathcal{F}(B + ku)$ for all k, while $B \cap (B + ku) = \varnothing$ for large k; for two configurations U, U' the configuration W which is U on B, U' on $B+ku$ and $\mathbf{1}$ elsewhere has $F(U) = F(W) = F(U')$. So A is a constant c with $c = \mathsf{r}A = \omega c$, and $A = 0$. The sign: put $c' = \frac{1}{2}ja|n|^2$, which lies in $\frac{a}{2}\mathbb{Z}$ for a coordinate normal and in $a\mathbb{Z}$ for a diagonal one; by the formula for the reflection, $\theta_{n,c'} = \tau_{jan}\theta_{n,0}$, and $\theta_{n,0}\tau_{jan} = \tau_{-jan}\theta_{n,0}$. On Q_r, $n \cdot x \ge -ra|n|^2$, the entries of n being $0, \pm 1$; so $F = \tau_{jan}A$ is a function of the bonds of $Q_r + jan \subset \{n \cdot x - c' \ge (\frac{j}{2} - r)a|n|^2\}$, which lies in the closed side $\{n \cdot x \ge c'\}$ for $j \ge 2r$, and $\theta_{n,c'}F = \theta_{n,0}A = \epsilon A$ with $\epsilon = \pm 1$. The positivity (a) at the mirror (n, c') gives $0 \le \nu(\overline{\theta_{n,c'}F}\, F) = \epsilon\, \nu(\bar{A}\, \tau_{jan}A)$.

Step 7. The space of laws on the compact metrizable configuration space is weakly compact. Along any convergent subsequence of ν_k, the limit is Gibbs by Proposition YM3_I:91.1. For a finite bond set B the locally finite source has only finitely many terms in its kernel, and their contribution converges uniformly to zero as $t_k \to 0$. Invariance under the fixed subgroup Γ' is weakly closed, as it can be tested on continuous functions. Every such limit therefore belongs to $\mathcal{G}^{\mathrm{per}}_{a,\beta}$ and is r-invariant by (a). Since $\mathsf{r}f - f$ is continuous, compactness implies $\nu_k(\mathsf{r}f - f) \to 0$.

Step 8. The translates $\tau_v F$ for $v \in \Gamma'$, with supports $\tau_v B_F$ for a finite carrier B_F, form a locally finite family. For every $\Gamma_n \subset \Gamma'$, translation acts on these indices by addition and the periodized source is $t\mathbb{F}_n$. Proposition YM3_I:91.2 gives the Gibbs equations at strength t for every weak limit of $\mu_{n,t}$. The array is unchanged by Γ' because each translation permutes its terms. Product Haar measure and the Wilson action are also unchanged, so the finite-volume and limiting laws are Γ'-invariant.

Suppose $\limsup_n |\mu_{n,t_k}(\mathsf{r}f - f)| > \delta$ along some $t_k \to 0$. For each k, take a weak limit ν_k along indices where the modulus exceeds δ. Then ν_k is a Γ'-invariant Gibbs state at strength t_k and $|\nu_k(\mathsf{r}f - f)| \ge \delta$. This contradicts Step 7. The same argument with $t_k = 0$ gives $\mu_{n,0}(\mathsf{r}f - f) \to 0$.

Step 9: clause (f)(3). $F = F_0 - \mathsf{r}F_0$ is a real member of $\mathcal{C}_{\mathrm{loc}}$, and (2) at $f = F_0$ reads $\lim_{t\to 0}\limsup_n |\mu_{n,t}(F)| = 0$ and $\lim_n \mu_{n,0}(F) = 0$. Fix n and write $\Gamma = \Gamma_n$, $\mathbb{F} = \mathbb{F}_n$, $\mu_t = \mu_{n,t}$. From the definition of the tilted law, $Z_\Gamma[\Phi + \Phi'] = Z_\Gamma[\Phi]\, \mu^\Phi_\Gamma(e^{\Phi'})$ for real $\Phi, \Phi' \in C(\mathcal{V}_\Gamma)$; at $(0, t\mathbb{F})$ and at $(t\mathbb{F}, -t\mathbb{F})$, with Jensen's inequality $\mu(e^X) \ge e^{\mu(X)}$,

$$\frac{Z_\Gamma[t\mathbb{F}]}{Z_\Gamma[0]} \ge e^{t\mu_0(\mathbb{F})}, \qquad \frac{Z_\Gamma[0]}{Z_\Gamma[t\mathbb{F}]} \ge e^{-t\mu_t(\mathbb{F})}.$$

On $\mathcal{V}_\Gamma$, which carries μ_t, $\mathbb{F}$ is the sum of the $|\mathbb{F}| = [\Gamma' : \Gamma]$ functions $\tau_v F$, and $\mu_t(\tau_v F) = \mu_t(F)$ by the invariance of Step 8; so $\mu_t(\mathbb{F}) = |\mathbb{F}|\, \mu_t(F)$ and $t\, \mu_{n,0}(F) \le p_n(t) \le t\, \mu_{n,t}(F)$ for all real t. Hence $|p_n(t)|/|t| \le \max\{|\mu_{n,0}(F)|, |\mu_{n,t}(F)|\}$, and the second limit follows from the first. In the uniform case with $\mathsf{r} = \tau_w$ the array is 0; in the staggered case $\tau_v a_p = a_{p+v}$, and the period lattices $2na\mathbb{Z}^3 \subset \Gamma'$, $n \ge 2$, have sys $\to \infty$.

□

Lemma 18.211 (The block map on the lattice and on a window)**.** Write $\tilde{B}^n(y) = \{x \in a_{d+n}\mathbb{Z}^3 : |x-y|_\infty \le (a_d - a_{d+n})/2\}$ for $y \in a_d\mathbb{Z}^3$.

(a) The double block of a bond at depth d projects injectively to every torus with side in $\mathfrak{L}$. The one-step rule on this chart is independent of the side of the torus and commutes with periodic extension.

(b) The block map is Borel and each bond value is continuous on each of three Borel sets. The map is discontinuous on the full configuration space. It commutes with coarse lattice isometries and is covariant under fine lattice gauges, restricted at the output to the coarse sites. The bond value of $\mathcal{M}^n U$ at c depends only on the bonds with both endpoints in $\tilde{B}^n(c_-) \cup \tilde{B}^n(c_+)$.

(c) For the window $\square = [-\ell/4, \ell/4]^3$ at $\ell = 2L^m$, the restriction r_d commutes with each iterate in the form $r_d\mathcal{M}^n = \mathsf{m}_d^n r_{d+n}$, where m_d^n applies the local rule on the window. These maps are Borel and compose in depth. On a periodically extended torus field the same identity holds with the torus iterates.

(d) The tower map Ψ_K and the window tower map Υ_K are Borel. The thread and window thread sets are Borel, and $\Upsilon_K(U)$ is determined by $r_K U$. For $o \in a_{d_0}\mathbb{Z}^3$ and $K \ge d_0$, $\varpi_o^{[d_0]}\Psi_K = \mathrm{pj}^{[d_0]}\Upsilon_K\tau_{-o}$. On a periodically extended torus field Ψ_K is the periodic extension, depth by depth, of the torus tower.

■

Proof. For (a), the double block has sup diameter $2a_d - a_{d+1}$ and even its one-step enlargement has diameter smaller than $2L \le \ell_1$ for every $\ell_1 \in \mathfrak{L}$. This makes the quotient map a chart for the sites and nearest-neighbor bonds of the double block and hence also for its plaquettes and paths. The three formulas in Section YM3_I:4, with locality from Proposition YM3_I:4.5, use only those bonds and give the same result in that chart regardless of the period.

The three Borel continuity pieces and gauge covariance follow from Proposition YM3_I:4.5. Coarse translations and signed coordinate permutations preserve the double blocks and permute their sets of coordinate paths. For a transformation preserving the orientation of the output bond, relabel the path products in the averaging formulas. For reversal, a relative holonomy Y based at the first endpoint is replaced by $U[c]^{-1}Y^{-1}U[c]$, where $U[c]$ is the direct transport. The logarithm therefore changes by negation and conjugation, and the averaged bond is inverted. The contour mean in the small-field branch is independent of the ordering of its paths, and reversal exchanges the two endpoint contour means. Thus the same calculation works there. The test for the exceptional branch is preserved because inversion and conjugation fix $-\mathbf{1}$. The exceptional formula is the direct transport, which also inverts. For iterated locality use $\tilde{B}^{n-1}(x) \subset \tilde{B}^n(y)$ whenever $x \in \tilde{B}^1(y)$, as follows from $(a_d - a_{d+1})/2 + (a_{d+1} - a_{d+n})/2 = (a_d - a_{d+n})/2$. This proves (b) by induction apart from the discontinuity assertion.

To see discontinuity, take a fine bond crossing between the two blocks, in a row parallel to the coarse bond but displaced transversely by one fine step. Put $u_t = \mathrm{diag}(e^{it}, e^{-it})$ on this bond and the identity on the other bonds. The bond belongs to no endpoint contour and is off the direct coarse path. Of the L^3 parallel paths between corresponding fine sites, exactly the L paths in the chosen row meet it. Near $t = \pm\pi$ a plaquette containing the bond has distance $2|\sin(t/2)|$ from $\mathbf{1}$, so the small-field branch fails. For $|t| < \pi$ the relative holonomies are $\mathbf{1}$ and u_t, so the intrinsic-logarithm branch returns u_{t/L^2}. The two limits at the same input $u_\pi = u_{-\pi}$ are distinct.

For (c), $\ell/(2a_d)$ is odd, so the closest depth-d site to a window wall is at distance $a_d/2$. The dependency blocks from (b) are inside the window. Extending by identity outside therefore defines a Borel local rule and gives the stated identities. The tower maps in (d) are coordinatewise Borel by (b) and (c). A thread is specified by the countable family of equalities between each coordinate and its block average from the next depth. Each equality is Borel because the diagonal in the bond

group is closed. The formula for $\varpi_o^{[d_0]}$ uses translation covariance at each depth $d \geq d_0$, and periodic extension uses (a) at each step. □

Lemma 18.212 (Thread laws and moving labels)**.** Let $\ell = 2L^m$ admit a compact interval J under the torus condition of Corollary 2.8. Write $\mu_d^K[\mathsf{b}]$ for the law of $\mathcal{M}_\ell^{K-d}U$ under $\mu_{K,\ell,L^K\mathsf{b}}$.

(a) At every $\mathsf{b} \in \mathsf{J}$ and $d \geq 0$, $\mu_d^K[\mathsf{b}]$ converges in total variation to a gauge invariant law $\mu_d[\ell, \mathsf{b}]$ and $(\mathcal{M}_\ell)_*\mu_{d+1} = \mu_d$. Uniformly on J, for $K \geq K_{\mathrm{bf}}(\mathsf{J})$ and $d \leq \lceil K/1260 \rceil$,

$$\|\mu_d^{K+1}[\mathsf{b}] - \mu_d^K[\mathsf{b}]\|_{\mathrm{TV}} \leq \mathsf{C}_{\mathrm{bf}}\ell^3 K^{\mathsf{p}_0} L^{-K/10}.$$

(b) There is a unique torus law $\mu_{\ell,\mathsf{b}}$ whose first $D+1$ coordinates have the law of $(\mathcal{M}_\ell^D V, \dots, V)$ for $V \sim \mu_D[\ell, \mathsf{b}]$. It is carried by threads. Its image $\mu[\ell, \mathsf{b}]$ in the window is carried by window threads.

(c) For $\ell \in \mathfrak{L}(g)$ the interval $\mathsf{J}_g = [g^{-2}, L(g^{-2} + \bar{B})]$ is admissible. The first-passage labels belong to $(g^{-2}, L(g^{-2} + \bar{B})] \subset \mathsf{J}_g$ and to $I^{\mathrm{lab}}(g)$. If $\mathsf{b} \in I(g)$ then $(K, L^K\mathsf{b})$ is a datum at g for every $K \geq 1$.

(d) The finite torus towers, filled by identity beyond depth K, converge weakly to $\mu_{\ell,\mathsf{b}}$.

(e) If $K_j \to \infty$ and $\mathsf{b}_j = a_{K_j}\beta_j \to \mathsf{b}$ with all labels in J, then $\mu_d^{K_j}[\mathsf{b}_j]$ converges to $\mu_d[\ell, \mathsf{b}]$ in total variation. The map $\mathsf{b} \mapsto \mu_d[\ell, \mathsf{b}]$ is continuous in that norm. The window tower laws converge weakly to $\mu[\ell, \mathsf{b}]$ and in total variation jointly at every finite set of depths.

(f) If the bounds of (a) hold on every compact positive label interval at a given side, then (b) and (e) apply at that side for all positive limiting labels and every sequence of labels converging to one of them.

■

Proof. Corollary 2.8(a) and (c) give the step estimate in (a), including the extension from gauge-invariant test functions to all Borel sets by averaging indicators under the compact group of lattice gauges. Summing it gives total variation convergence. Consistency passes to the limit from the identities between finite-cutoff marginals because pushforward under the Borel block map contracts total variation. The joint laws in (b) are then consistent under truncation in D. The extension theorem for countable products gives the law. Each adjacent thread identity holds with probability one by the joint law at that pair of depths. The countable intersection still has probability one. Lemma 18.211(c) carries this property to the window.

For (c), the first-passage room estimate YM3_I:(1533) gives the torus room condition at the upper endpoint of J_g. The bounds on all the labels and the assertion at a fixed label in $I(g)$ are Proposition YM3_I:74.1 and equation YM3_I:(1854). For (d), push forward the law at depth D under the map $V \mapsto (\mathcal{M}_\ell^D V, \dots, V)$. This gives convergence in total variation at the depths through D. Continuous cylinder functions are uniformly dense on the compact product, which gives weak convergence.

For each fixed K the density of the finite Wilson law depends continuously on the label in the uniform norm, since its action is bounded and its partition function is positive. Its pushforward to depth d is therefore continuous in total variation. The summable estimate in (a) makes the convergence uniform on J, so the limiting law has the same continuity. The triangle inequality with the intermediate law $\mu_d[\ell, \mathsf{b}_j]$ proves the moving-label assertion. By Lemma 18.211(c) the joint window law through depth D is the image of the depth-D torus law under a fixed Borel map. Total variation contracts under that map and continuous cylinder functions again give weak convergence. This proves (e). For (f), choose a compact interval whose interior contains the limiting label and discard the finitely many terms outside the interval. □

Corollary 18.213 (Uniform cutoff tail)**.** For an admitted interval J, use C_{bf}, K_{bf} and $\mathsf{p} = 2\mathfrak{p}_0 + 1/2$ of Definition 2.7(5). Put

$$\tau_{\mathsf{J}}(K) = \mathsf{C}_{\mathrm{bf}} \ell^3 \sum_{K' \ge K} K'^{\mathsf{p}} L^{-K'/10}.$$

For $K \ge K_{\mathrm{bf}}$ and $d \le \lceil K/1260 \rceil$, the distance in total variation between the depth-d laws at cutoff K and at infinite cutoff is at most $\tau_{\mathsf{J}}(K)$, uniformly on J. If $K(d)$ is the least such $K > d$ with $\tau_{\mathsf{J}}(K) \le L^{-d}$, the error at $K(d)$ is at most L^{-d}. ■□

Proof. Sum the bound of Lemma 18.212(a) for consecutive cutoffs. The tail tends to zero, so $K(d)$ exists. □

Lemma 18.214 (Domination and weak limits)**.** For probability measures $\boldsymbol{\sigma}, \boldsymbol{\rho}$ on the same measurable space, write $\boldsymbol{\sigma} \preceq_{\mathsf{Q}} \boldsymbol{\rho}$ if $|\boldsymbol{\sigma}(f)| \le \mathsf{Q}\, \boldsymbol{\rho}(|f|^8)^{1/8}$ for every bounded complex Borel f. If $\boldsymbol{\sigma} \preceq_{\mathsf{Q}} \boldsymbol{\rho}$, then $\mathsf{Q} \ge 1$ and the following hold.

(DM1) $\boldsymbol{\sigma}(A) \le \mathsf{Q}\, \boldsymbol{\rho}(A)^{1/8}$ for every measurable A.

(DM2) The density $h = d\boldsymbol{\sigma}/d\boldsymbol{\rho}$ satisfies $\int h^{8/7}\, d\boldsymbol{\rho} \le \mathsf{Q}^{8/7}$ and $\boldsymbol{\sigma}(h > t) \le \mathsf{Q}^{8/7} t^{-1/7}$ for $t > 0$.

(DM3) $0 \le \int h \log h\, d\boldsymbol{\rho} \le 7 \log \int h^{8/7}\, d\boldsymbol{\rho} \le 8 \log \mathsf{Q}$.

(DM4) If p is measurable, then $p_* \boldsymbol{\sigma} \preceq_{\mathsf{Q}} p_* \boldsymbol{\rho}$.

(DM5) Conversely, a probability density with $\int h^{8/7}\, d\boldsymbol{\rho} \le \mathsf{Q}^{8/7}$ gives $h\boldsymbol{\rho} \preceq_{\mathsf{Q}} \boldsymbol{\rho}$.

(DM6) There are at most Q^8 pairwise mutually singular probability measures dominated by $\boldsymbol{\rho}$ with the same Q.

(DM7) Let Z, Y be compact metrizable spaces, let $p_i : Z \to Y$ be continuous, and suppose $\sigma_j \to \sigma$ and $\rho_j \to \rho$ weakly on their respective spaces. If

$$\left| \sigma_j \left(\prod_{i=1}^{k} f_i \circ p_i \right) \right| \le \prod_{i=1}^{k} \mathsf{Q}\, \rho_j(|f_i|^8)^{1/8}$$

for all continuous complex f_i, then the same estimate holds for σ, ρ and all bounded complex Borel f_i.

■

Proof. Testing with 1 and 1_A gives $\mathsf{Q} \ge 1$ and (DM1), so $\boldsymbol{\sigma}$ has a Radon–Nikodym density h. For $I_n = \int \min(h, n)^{8/7}\, d\boldsymbol{\rho}$ the test $f = \min(h, n)^{1/7}$ gives $I_n \le \mathsf{Q} I_n^{1/8}$. Monotone convergence gives the norm bound. On $\{h > t\}$ one has $h \le t^{-1/7} h^{8/7}$, proving the tail bound. For (DM3), convexity of $x \log x$ gives the lower bound. Applying concavity of log under the probability measure $h\, d\boldsymbol{\rho}$ to $h^{1/7}$ gives the upper bound. Its positive logarithm is integrable by (DM2) and its negative logarithm is integrable since $x|\log x|$ is bounded on $[0, 1]$. Testing with $f \circ p$ gives (DM4) and Hölder gives (DM5). For a finite pairwise singular family, intersect the sets of full measure for each member and zero measure for each of the others, then remove their overlaps. This gives disjoint carriers A_i, each of $\boldsymbol{\rho}$-mass at least Q^{-8} by (DM1), proving (DM6).

In (DM7) weak convergence gives the estimate for continuous f_i. Approximate each Borel factor f_i by continuous functions with the same uniform bound in $L^1(\rho + (p_i)_* \sigma)$. Such approximants exist by regularity, with truncation by projection onto the closed disc of radius $\|f_i\|_\infty$. Uniform boundedness upgrades the $L^1(\rho)$ convergence to $L^8(\rho)$ convergence. A telescoping sum bounds the error on the left by a sum of $L^1((p_i)_* \sigma)$ errors times the uniform bounds of the other factors. Taking limits proves (DM7). □

Lemma 18.215 (Invariant densities and product bounds)**.** Let T be an invertible measure-preserving transformation of a probability space $(\Omega, \mathbb{P})$, and let $0 \le F \le c$ be measurable. Suppose $\mathbb{E} \prod_{r=1}^{k} (F \circ T^{n_r}) \le C q^k$ for all distinct positive integers $n_1, \dots, n_k$ and all $k \ge 1$, where $C \ge 1$ and $q \ge 0$. If D is nonnegative, integrable and T-invariant almost everywhere, then $\mathbb{E}[DF] \le q \mathbb{E} D$. Also, if $\mathbb{E}[1_E F] \le q \mathbb{P}(E)$ for all E in a sub-σ-algebra $\mathcal{J}$, then $\mathbb{E}[F \mid \mathcal{J}] \le q$ almost surely. ■

Proof. For bounded D with $\mathbb{E}D = 1$, put $A_N = N^{-1}\sum_{n=1}^{N} F \circ T^n$. Invariance gives $\mathbb{E}DF = \mathbb{E}DA_N$. Jensen's inequality under $D\,d\mathbb{P}$ and the count of repeated indices in the expansion of A_N^k give

$$(\mathbb{E}DF)^k \le \|D\|_\infty \mathbb{E}A_N^k \le \|D\|_\infty \left(Cq^k + \binom{k}{2}\frac{c^k}{N} \right).$$

First let $N \to \infty$, then take k-th roots and let $k \to \infty$. Scaling and monotone convergence of $D \wedge m$ give the claim for integrable D, including $D = 0$ almost everywhere. For the conditional expectation, take $E = \{\mathbb{E}[F \mid \mathcal{J}] > q\}$. □

Lemma 18.216 (Several cells compared to a reference torus)**.** Let (K, β) be a first-passage datum at $0 < g \le \gamma$ and $\ell \in \mathfrak{L}(g)$. Use the board of side $\mathsf{l} = \ell/2$ at a lattice site o. For finitely many distinct cells and bounded complex Borel functions $F_{\mathbf{k}}$ of their inner bonds,

$$\left| \nu \left(\prod_{\mathbf{k}} F_{\mathbf{k}} \right) \right| \le \prod_{\mathbf{k}} \mathsf{Q}_0\, \tilde{\mu}_{K,\ell,\beta}(|F_{\mathbf{k}}|^8)^{1/8}, \qquad \mathsf{Q}_0 = \exp\bigl[\mathsf{l}^3(2C_{\mathrm{S}} + C_g)\bigr].$$

Here ν is a periodic Gibbs state or the lifted torus law of side $\ell' \ge \ell$ in $\mathfrak{L}$, with the cells distinct modulo ℓ' in the torus case. With the real first-passage construction alone, the same estimate holds with $C_{\mathrm{gap}} + C_{\mathrm{st}} + C_g$ in place of $2C_{\mathrm{S}} + C_g$. ■

Proof. Since l/a_K is odd, the walls are lattice midplanes. For a bounded nonnegative function G of the inner bonds in a cell, let G^{all} be the product of its reflected copies in every cell of the torus of side t and set $\|G\|_t = \langle G^{\mathrm{all}} \rangle_{K,t,\beta}^{(\mathsf{l}/t)^3}$. By Propositions YM3_I:86.3 and YM3_I:86.4 and Corollary YM3_I:86.6, the finite-torus chessboard inequality bounds the product expectation by $\prod_{\mathbf{k}} \||F_{\mathbf{k}}|\|_t$, and for $t \ge \ell$,

$$\|G\|_t \le \|G\|_\ell \exp\bigl[\mathsf{l}^3(p_\ell - p_t)\bigr].$$

Proposition YM3_I:91.9 gives the same bound for a periodic Gibbs state with a lower limit of the products as $t \to \infty$ through admissible sides. On T_ℓ there are eight copies and reflections preserve its Wilson measure. Hölder for these eight factors gives $\|G\|_\ell \le \tilde{\mu}_{K,\ell,\beta}(G^8)^{1/8}$.

At zero source, Theorem YM3_I:AD writes $p_t = t^{-3}E_t + t^{-3}\log \widetilde{Z}_t(0)$ with $-C_g \le t^{-3}\log \widetilde{Z}_t(0) \le C_{\mathrm{S}}$ and $|\ell^{-3}E_\ell - t^{-3}E_t| \le C_{\mathrm{S}}$. Thus $p_\ell - p_t \le 2C_{\mathrm{S}} + C_g$. For the real construction, Proposition YM3_I:74.4 gives the lower and upper bounds $-C_g$ and $E_+ = C_{\mathrm{maj}} + 2 \le C_{\mathrm{st}}$ for the normalized logarithm per unit volume, and Proposition YM3_I:74.5 gives the bound C_{gap} for the vacuum-density difference. The constants and the first-passage normalization are those of [7, Section 2]. This gives the second pressure bound and hence the two asserted domination estimates. □

Lemma 18.217 (Local limits of window laws and towers)**.** Use the window and tower notation of Lemma 18.211. Let $K_j \to \infty$ and let ν_j be laws invariant under the translations of $a_{K_j}\mathbb{Z}^3$. Suppose their one-cell laws obey the bound of Lemma 18.216 with constant Q and reference window tower laws ρ_j. Suppose $\rho_j \to \mu$ weakly and in total variation through each finite depth, and that μ is supported on window threads. For the product assertions below, suppose also the same bound for any fixed finite set of cells of a common board, for all sufficiently large j. Write $\mu^{[d_0]} = \mathrm{pj}_*^{[d_0]}\mu$.

(a) Every subsequential weak limit σ of $(\Upsilon_{K_j}\tau_{-o_j})_*\nu_j$, with arbitrary offsets $o_j \in a_{K_j}\mathbb{Z}^3$, is dominated by μ with constant Q. Its density and entropy obey Lemma 18.214 and it is carried by window threads. Along the same subsequence the means of all bounded Borel functions of finitely many depths converge. These conclusions pass to tails and to restrictions to a closed subset of the window.

(b) For every subsequential weak limit $\boldsymbol{\nu}$ of $(\Psi_{K_j})_*\nu_j$:

(i) $(\varpi_o^{[d_0]})_*\boldsymbol{\nu} \preceq_{\mathsf{Q}} \mu^{[d_0]}$ for every $d_0 \ge 0$ and $o \in a_{d_0}\mathbb{Z}^3$.

(ii) $\boldsymbol{\nu}(\mathsf{Thr}) = 1$.

(iii) On Thr, translation by a vector v in $\mathbb{D} = \bigcup_s a_s\mathbb{Z}^3$ acts by translation at depths $d \geq s$ for $v \in a_s\mathbb{Z}^3$, and fills in the earlier depths by iteration. This gives a measure-preserving Borel action T_v independent of the choice of s.

(iv) Along the same subsequence the means of bounded Borel functions of finitely many depths in a single window converge. If the hypotheses apply at arbitrarily large sides, the same holds for any bounded spatial support.

(c) Under the product hypothesis, $\boldsymbol{\nu}$ obeys the product bound on every fixed board, with constant Q per factor. So does $D\boldsymbol{\nu}$ for any nonnegative probability density D invariant under one T_v with $v \neq 0$. For a measurable mixture of laws invariant under that same T_v, almost every law of the mixture has the product bound. In particular this holds for the translation-ergodic decomposition.

(d) A reference-null set in any window has measure zero under the corresponding image of each dominated law. At most Q^8 window laws dominated by the same reference can be pairwise mutually singular.

(f) Suppose the ν_j are periodic Gibbs states or lifted Wilson torus laws with sides tending to infinity. Then $\boldsymbol{\nu}$ is gauge invariant on the tower and invariant under the action of $\mathbb{D} \rtimes W_3$ obtained by acting on a sufficiently fine tail and filling in the earlier depths.

(h) For first-passage data with converging labels, the one-cell and product hypotheses hold at each admissible reference side for periodic Gibbs states, including all volume-first states. The product hypothesis also holds for lifted torus laws whose sides tend to infinity. The real construction uses the alternative constant of Lemma 18.216.

■

Proof. Compactness gives weak limit points in the compact products. By locality, the bounded Borel function $f \circ \Upsilon_{K_j} \circ \tau_{-o_j}$ is a function of a single cell. Translation invariance of the torus reference gives $|\sigma_j(f)| \leq \mathsf{Q}\rho_j(|f|^8)^{1/8}$ for its image law σ_j. Lemma 18.214(DM7) gives domination in the limit, including for Borel tests. For a Borel test at finitely many depths, choose uniformly bounded continuous approximants in L^8 of the reference marginal. At these depths total variation convergence controls the integrals of the eighth powers of the differences under ρ_j. Domination bounds the limsup of the error under σ_j and its limit by twice Q times the reference L^8 error. This error tends to zero. The tail projections and restrictions are continuous coordinate projections. Every subsequential limit of the projected laws is the projection of a further weak limit of the full window laws. This gives (a).

By Lemma 18.211(d), the window at o of the tower law at depths $\geq d_0$ is the corresponding tail of the window law formed with offset o. Projection of the weak limit therefore gives (b)(i) and, using the Borel convergence just proved, (b)(iv). To prove (b)(ii), put the origin of a window at the initial endpoint o of a bond c at depth d and use $d_0 = d$. On its window the equality between the value at c and its average from depth $d+1$ holds with reference probability one. By local dependence and domination it holds with $\boldsymbol{\nu}$-probability one. Intersect these countably many events. For (b)(iii), translation commutes with the block map at depths $d \geq s$. Its action on that tail is a continuous permutation of coordinates, so the invariance of the finite laws passes to the weak limit there. Earlier depths on a thread are Borel functions of the tail, which gives invariance on the whole tower. This also shows independence of s, the group law by taking a common tail, and the inverse T_{-v}.

For (c), apply the finite-cutoff product inequality to the window tower tests and use Lemma 18.214(DM7). For a product $F = \prod_i |f_i| \circ \varpi_{o_i}^{[d_0]}$ choose a positive integer multiple w of v in $(\ell/2)\mathbb{Z}^3$ so large that the finite sets of board cells used by $F \circ T_{nw}$ are disjoint for different integers n. Such a multiple exists since $v \in \mathbb{D}$ and $\ell/2 = L^m$. The product bound gives $\boldsymbol{\nu}(\prod_{r=1}^k F \circ T_{n_r w}) \leq q^k$ for distinct n_r, with $q = \prod_i \mathsf{Q}\mu^{[d_0]}(|f_i|^8)^{1/8}$. Apply Lemma 18.215 to T_w and the invariant density. For a measurable mixture $\boldsymbol{\nu} = \int \boldsymbol{\nu}_\xi \, d\lambda(\xi)$ of T_v-invariant laws, the normalized restriction of the

mixture to any set of positive λ-measure has a bounded density relative to $\boldsymbol{\nu}$. The density is invariant by uniqueness of Radon–Nikodym derivatives. Applying the preceding bound to the set where $\boldsymbol{\nu}_\xi(F) > q$ shows that this set is null. Take a countable dense family of continuous window tests for each finite cell set and each d_0, and then use uniform approximation and (DM7) to extend to bounded Borel tests. The group $\mathbb{D}$ is countable and acts by Borel bijections on a standard Borel space, so its ergodic decomposition gives such an invariant mixture. The conclusions in (d) are (DM1) and (DM6).

For (f), any finite set of gauge values at endpoints of the coordinates under test can be implemented by a lattice gauge equal to identity at all remaining sites. For a lifted torus law, the same assignment is well defined modulo its period once the side is large enough to separate these sites. On a periodic Gibbs state invariance under a finite gauge follows by changing variables in the DLR kernel on all bonds incident to its support. The plaquette action is invariant and Haar measure is invariant under left and right multiplication. The same change of variables on the torus gives its invariance. The iterated gauge covariance of Lemma 18.211(b) carries this invariance to each cylinder test and passes to the limit for continuous cylinder tests. An arbitrary tower gauge acts continuously on the full product and preserves the thread identities, so the conclusion holds for the full law. For a signed permutation and lattice translation, choose a tail where the isometry acts at every depth. Finite-law invariance there follows from Proposition YM3_I:103.4 for periodic Gibbs states and from the Haar law and Wilson action on each torus. Commutation, invariance in the limit, and the group law follow as in (b)(iii).

For (h), use Lemmas 18.216 and 18.212. The large torus contains any fixed set of distinct cells without identifying them. Proposition YM3_I:103.4 includes the volume-first states in the periodic Gibbs class. □

Proposition 18.218 (The excess free energy of one torus bounds the distance of the laws of the thread over a cell from its thread measure, at infinite cutoff)**.** For $K \in \mathbb{N}$, $\beta > 0$ and $\ell \in \mathfrak{L}$ let $Z_{K,\ell,\beta}$ be the partition function of the Wilson measure $\mu_{K,\ell,\beta}$ of Definition 18.204, formed with the Haar probability measures, $p_\ell = p_\ell(K,\beta) = \ell^{-3}\log Z_{K,\ell,\beta}$, $p_\infty(K,\beta) = \inf_{\ell' \in \mathfrak{L}} p_{\ell'}(K,\beta)$, and

$$x(K,\beta,\ell) = \ell^3\big(p_\ell(K,\beta) - p_\infty(K,\beta)\big),$$

the excess of the side ℓ at (K,β). Put $\mathfrak{t}(x) = \frac{7}{8}(e^x/8)^{1/7}$ for $0 \le x \le \log 8$ and $\mathfrak{t}(x) = 1 - e^{-x}$ for $x \ge \log 8$, a continuous increasing function with values in $[0,1)$.

(0) *The excess.* $p_\ell(K,\beta)$ does not increase along $\mathfrak{L}$, $p_\infty(K,\beta) = \lim_{\ell\to\infty} p_\ell(K,\beta) \ge -6\beta a_K^{-3}$, and $0 \le x(K,\beta,\ell) \le 6\beta a_K^{-3}\ell^3$. If $0 < g \le \gamma$, $\ell \in \mathfrak{L}(g)$ and (K,β) is a datum at g, then $x(K,\beta,\ell) \le \ell^3(2C_{\mathrm{S}} + C_g) = 8\log \mathsf{Q}_0$, Q_0 the number of Definition 18.207; with the real first-passage construction alone, $x(K,\beta,\ell) \le \ell^3(C_{\mathrm{gap}} + C_{\mathrm{st}} + C_g)$.

(1) *At one pair.* Let $K \in \mathbb{N}$, $\beta > 0$, $\ell \in \mathfrak{L}$, $x = x(K,\beta,\ell)$, let $\square' = o + [-\frac{\ell}{4}, \frac{\ell}{4}]^3$ with $o \in a_K\mathbb{Z}^3$, let $\mathfrak{s} \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, or $\mathfrak{s} = \tilde\mu_{K,\ell',\beta}$ with $\ell \le \ell' \in \mathfrak{L}$, and let Φ be a Borel map of the configurations of $\mathbb{L}_K$ into a compact metrisable space which depends on the bonds with both end points in $\square'$ alone. Then $\Phi_*\mathfrak{s} = h\,\Phi_*\tilde\mu_{K,\ell,\beta}$ with a Borel $h \ge 0$, $\int h^{8/7} d\Phi_*\tilde\mu_{K,\ell,\beta} \le e^{x/7}$, $\Phi_*\mathfrak{s} \preceq_{e^{x/8}} \Phi_*\tilde\mu_{K,\ell,\beta}$, $0 \le \int h\log h\, d\Phi_*\tilde\mu_{K,\ell,\beta} \le x$, and

$$\sup_A \big|\Phi_*\mathfrak{s}(A) - \Phi_*\tilde\mu_{K,\ell,\beta}(A)\big| \le \min\{\sqrt{x/2},\ \mathfrak{t}(x)\},$$

the supremum over the Borel sets. No reference coupling, label or constant but L enters.

(2) *At infinite cutoff.* Assume the standing hypothesis (SH) of Definition 18.208 with the side ℓ and the limit b of the labels, and let $\mu = \mu[\ell,\mathsf{b}]$ be the thread measure of T_ℓ seen in the window (Definition 18.207). Put $x_j = x(K_j,\beta_j,\ell)$ and $\bar x = \limsup_j x_j$, so that $\bar x \le \ell^3(2C_{\mathrm{S}} + C_g)$ by (0). Let $o_j \in a_{K_j}\mathbb{Z}^3$, let ν be a weak limit point on Y of the laws $\sigma_j = (\Upsilon_{K_j} \circ \tau_{-o_j})_*\nu_j$, $\sigma_{j_k} \to \nu$, and $\underline{x} = \liminf_k x_{j_k} \le \bar x$. Then $|\nu(f)| \le e^{\underline{x}/8}\mu(|f|^8)^{1/8}$ for every bounded complex

Borel function f on Y; $\nu = h\mu$ with $\int h^{8/7}d\mu \le e^{\underline{x}/7}$ and $0 \le \int h\log h\,d\mu \le \underline{x}$; and, with $\epsilon = 22.3\,(e^{\bar{x}/7}-1)$,

$$\sup_{A\subset Y \text{ Borel}} |\nu(A)-\mu(A)| \le \min\{\sqrt{\underline{x}/2},\ \mathfrak{t}(\underline{x})\} \le \tfrac{1}{2}(\sqrt{\epsilon}+\epsilon),$$

so that ν and μ share the mass $\int \min\{h,1\}\,d\mu \ge 1-\mathfrak{t}(\underline{x}) > 0$. The right members depend on $\underline{x}$, respectively $\bar{x}$, alone, and on neither the states ν_j, nor the offsets o_j, nor the reference coupling. Nothing is asked of $\bar{x}$ beyond (SH).

(3) *Every depth from d_0 on, every closed cube of the cell.* Let $d_0 \ge 0$ and let $\mathfrak{c} \subset \square$ be closed, for instance a closed cube. Every weak limit point of the laws $(\mathrm{pj}^{[d_0]} \circ \Upsilon_{K_j} \circ \tau_{-o_j})_*\nu_j$ on $Y^{[d_0]}$, or of $(p_{\mathfrak{c}} \circ \Upsilon_{K_j} \circ \tau_{-o_j})_*\nu_j$ on $Y(\mathfrak{c})$, satisfies (2) with $\mu^{[d_0]}$, respectively $(p_{\mathfrak{c}})_*\mu$, in the place of μ and with the same numbers $\underline{x}$, $\bar{x}$, formed along the subsequence which gives it.

(4) *Two limits; the count.* For two laws ν, ν' of (2), formed from two sequences under (SH) with one side ℓ and one limit $\mathfrak{b}$, $\sup_A |\nu(A)-\nu'(A)| \le \min\{\sqrt{\underline{x}/2}, \mathfrak{t}(\underline{x})\} + \min\{\sqrt{\underline{x}'/2}, \mathfrak{t}(\underline{x}')\}$. If $\nu^{(1)}, \dots, \nu^{(n)}$ are such laws, pairwise mutually singular, with $\underline{x}^{(r)} \le x^\sharp$ for all r, then $n \le e^{x^\sharp}$. ∎

Proof. Step 1: the excess, (0). Let $\ell' \le \ell''$ in $\mathfrak{L}$ and take the board of $\mathbb{L}_K$ of side $\frac{\ell'}{2}$; the comparison of chessboard seminorms in Corollary YM3_I:86.6 applied to the constant 1 gives $p_{\ell''} \le p_{\ell'}$. The Wilson action of $a_K\mathbb{Z}^3/\ell\mathbb{Z}^3$ has $3(\ell L^K)^3$ terms in $[0,2]$, so $1 \ge Z_{K,\ell,\beta} \ge e^{-6\beta(\ell L^K)^3}$ and $p_\ell \ge -6\beta a_K^{-3}$; a non-increasing function bounded below has its infimum as its limit, and $0 \le x \le \ell^3(0+6\beta a_K^{-3})$. At data at g and sides of $\mathfrak{L}(g)$, the third link of the proof of Lemma 18.216, which uses the volume bounds of Theorem YM3_I:AD, gives $p_\ell - p_{\ell'} \le 2C_{\mathrm{S}} + C_g$ for all $\ell' \in \mathfrak{L}(g)$; letting $\ell' \to \infty$ in the unbounded set $\mathfrak{L}(g)$ gives $x \le \ell^3(2C_{\mathrm{S}}+C_g)$, and $8\log \mathsf{Q}_0 = \ell^3(2C_{\mathrm{S}}+C_g)$. For the real first-passage construction, the comparison in that proof gives $C_{\mathrm{gap}} + C_{\mathrm{st}} + C_g$ (Lemma 18.216).

Step 2: the domination at one pair. Let F be a bounded Borel function of the inner bonds of the cell $\square'$. Use the chessboard seminorm $|||F|||_t$ on the torus of side t from the proof of Lemma 18.216. Its comparison of sides gives

$$|||F|||_t \le |||F|||_\ell \exp\bigl[(\ell/2)^3(p_\ell - p_t)\bigr] \le e^{x/8}|||F|||_\ell \qquad (t \ge \ell).$$

For a periodic Gibbs state, Proposition YM3_I:91.9 bounds $|\mathfrak{s}(F)|$ by $\liminf_{t\to\infty} |||F|||_t$. For a torus state of side $\ell' \ge \ell$ the chessboard inequality bounds it by $|||F|||_{\ell'}$. On the reference torus the seminorm is bounded by $\tilde{\mu}_{K,\ell,\beta}(|F|^8)^{1/8}$ by Hölder on the eight reflected copies, as in Lemma 18.216. Taking $F = f \circ \Phi$ gives $\Phi_*\mathfrak{s} \preceq_{e^{x/8}} \Phi_*\tilde{\mu}_{K,\ell,\beta}$.

Step 3: from the domination to the density, the entropy and the distance. Let $\boldsymbol{\sigma} \preceq_{\mathsf{Q}} \boldsymbol{\rho}$ with $\mathsf{Q} = e^{x/8}$. By Lemma 18.214, (DM2) and (DM3), $\boldsymbol{\sigma} = h\boldsymbol{\rho}$, $\int h^{8/7}d\boldsymbol{\rho} \le \mathsf{Q}^{8/7} = e^{x/7}$ and $0 \le \int h\log h\,d\boldsymbol{\rho} \le 7\log\int h^{8/7}d\boldsymbol{\rho} \le x$. The inequality of Pinsker, $\sup_A |\boldsymbol{\sigma}(A)-\boldsymbol{\rho}(A)| \le (\frac{1}{2}\int h\log h\,d\boldsymbol{\rho})^{1/2}$, gives the bound $\sqrt{x/2}$. For $\mathfrak{t}$: the supremum is $\tau = \boldsymbol{\sigma}(A_*) - \boldsymbol{\rho}(A_*)$ at $A_* = \{h > 1\}$; with $\alpha = \boldsymbol{\rho}(A_*)$, (DM1) gives $\boldsymbol{\sigma}(A_*) \le \min\{1, e^{x/8}\alpha^{1/8}\}$, so $\tau \le \sup_{\alpha\in[0,1]}(\min\{1, e^{x/8}\alpha^{1/8}\} - \alpha)$. The function $\alpha \mapsto e^{x/8}\alpha^{1/8} - \alpha$ has its maximum $\frac{7}{8}(e^x/8)^{1/7}$ at $\alpha_* = e^{x/7}8^{-8/7}$, and $\alpha_* \le e^{-x}$ exactly when $x \le \log 8$; for $\alpha \ge e^{-x}$ the bound is $1-\alpha \le 1-e^{-x}$, and at $\alpha = e^{-x}$ the two branches meet. This gives $\tau \le \mathfrak{t}(x)$ in both ranges. The shared mass is $1-\tau$. Finally $e^{x/7}-1 \ge x/7$ and $22.3/7 > 2$ give $\sqrt{x/2} \le \frac{1}{2}\sqrt{22.3\,(e^{x/7}-1)}$, and $x \mapsto \frac{1}{2}(\sqrt{\epsilon}+\epsilon)$ increases. This proves (1).

Step 4: the passage to infinite cutoff, (2). Put $\rho_j = (\Upsilon_{K_j})_*\tilde{\mu}_{K_j,\ell,\beta_j}$. By Step 2 with $\Phi = \Upsilon_{K_j} \circ \tau_{-o_j}$, which depends on the bonds with both end points in the cell $o_j + \square$ (Lemma 18.211(d)), and the invariance of $\tilde{\mu}_{K_j,\ell,\beta_j}$ under τ_{-o_j}, which permutes the plaquettes and preserves product Haar measure, $|\sigma_j(f)| \le e^{x_j/8}\rho_j(|f|^8)^{1/8}$ for every bounded Borel f; the case of a torus measure ν_j of side $\ell_j \ge \ell$ is the second case of Step 2. Choose a further subsequence of (j_k) along which $x_{j_k} \to \underline{x}$. As $\rho_j \to \mu$ weakly (Lemma 18.212(e), the labels lying in J_g, Lemma 18.212(c)), the inequality passes to ν at

every continuous f with the constant $e^{\underline{x}/8}$, and from continuous to bounded Borel functions by (DM7) of Lemma 18.214, applied to the constant sequences ν and μ. Step 3 gives the rest of (2).

Step 5: (3) and (4). Let ν' be a weak limit point of the images in (3), reached along a subsequence (j_k), and $\underline{x} = \liminf_k x_{j_k}$. Take first a subsequence of (j_k) on which $x_j \to \underline{x}$, and then, Y being compact and metrisable, a further subsequence on which σ_j converges weakly to a law ν; on the last one the excess still tends to $\underline{x}$, so that (2) gives $\nu \preceq_{e^{\underline{x}/8}} \mu$. As $\mathrm{pj}^{[d_0]}$ and $p_{\mathfrak{c}}$ are continuous, on this subsequence the images of the σ_j tend both to ν' and to the image of ν, so ν' is the image of ν; images keep the domination with the same constant (DM4), the image of μ is $\mu^{[d_0]}$, respectively $(p_{\mathfrak{c}})_*\mu$, and Step 3 applies with $\underline{x}$, the bound by $\bar{x}$ following as in Step 3 from $\underline{x} \le \bar{x}$. For (4), the distance is a metric; and by (DM1) pairwise mutually singular laws with disjoint carriers $\mathcal{A}_r$ have $1 = \nu^{(r)}(\mathcal{A}_r) \le e^{x^\sharp/8}\mu(\mathcal{A}_r)^{1/8}$, so $\mu(\mathcal{A}_r) \ge e^{-x^\sharp}$ and $n \le e^{x^\sharp}$ (DM6). □

Proposition 18.219 (Clustering of functions of block fields at one cutoff, at the physical length $R + \frac{a_d}{2}$)**.** Let $K \in \mathbb{N}$, $\beta \ge 0$ and $\nu \in \mathcal{G}^{\mathrm{per}}_{K,\beta}$, with no condition on (K,β); let $0 \le d \le K$, $w = \frac{1}{2}a_d$, $R \in a_d\mathbb{N}$, and let A, B be bounded complex Borel functions on Z which depend on finitely many depths d' with $d \le d' \le K$ and, at each of them, on the bonds of $a_{d'}\mathbb{Z}^3$ with both end points in $[-R,R]^3$; put $A_K = A \circ \Psi_K$ and $B_K = B \circ \Psi_K$, functions of the configurations of $\mathbb{L}_K$ (Definition 18.206). Then for every $x \in a_K\mathbb{Z}^3$ with $|x| \ge 4\sqrt{3}\,(R+w)$

$$\Big|\nu(\overline{A_K}\,\tau_x B_K) - \nu\big(\overline{\mathbb{E}_\nu[A_K|\mathcal{I}]}\,\mathbb{E}_\nu[B_K|\mathcal{I}]\big)\Big| \le 4\sqrt{3}\,\mathsf{C}_{\mathrm{dc}}\,\nu(|A_K|^2)^{1/2}\,\nu(|B_K|^2)^{1/2}\,\frac{R+w}{|x|} \le 4\sqrt{3}\,\mathsf{C}_{\mathrm{dc}}\,\|A\|_\infty\|B\|_\infty\,\frac{R+w}{|x|},$$

with the absolute number C_{dc} of YM3_I:(1968). The bound depends on none of K, β, ν or a reference coupling. At the cutoff K, A_K and B_K are functions of bonds of $\mathbb{L}_K$ inside the cube of half side $R + \frac{1}{2}(a_d - a_K)$, a number below $R+w$; so one cube free of K, $[-(R+w),R+w]^3$, contains these bonds at all cutoffs. If ν is a pure phase, the subtracted term is $\overline{\nu(A_K)}\,\nu(B_K)$. In particular this holds for $A = F(\mathsf{z}_d|_{\mathsf{B}})$, $B = F'(\mathsf{z}_d|_{\mathsf{B}})$ with bounded Borel functions F, F' of the field of the one depth d on a finite set B of bonds in $[-R,R]^3$, among them the loops $W_C(\mathsf{z}_d) = \frac{1}{2}\operatorname{tr}\mathsf{z}_d(C)$ of the block field along closed paths C of such bonds. ■

Proof. Step 1: the bare bonds. By Lemma 18.211(b), $(\mathcal{M}^{K-d'}U)(c)$ depends only on U on the bonds with both end points in $\tilde{B}^{K-d'}(c_-) \cup \tilde{B}^{K-d'}(c_+)$, and by the block formula in Definition 18.206 a point of $\tilde{B}^n(y)$ differs from y by at most $\frac{1}{2}(L^n-1)a_{d'+n} = \frac{1}{2}(a_{d'} - a_{d'+n})$ in each coordinate. At $n = K - d'$ and $d' \ge d$ this is at most $\frac{1}{2}(a_d - a_K)$. So A_K and B_K are bounded Borel functions of the bonds of $\mathbb{L}_K$ in the cube $Q_r = [-ra_K, ra_K]^3$ with $ra_K = R + \frac{1}{2}(a_d - a_K)$; here $r = L^{K-d}R/a_d + \frac{1}{2}(L^{K-d}-1)$ is an integer ≥ 1, as L is odd and $R \ge a_d$, and $ra_K < R + w$.

Step 2: the lattice bound. Proposition YM3_I:99.7 at spacing a_K, using $r/n + 2r^2/n^2 \le 4ra_K/|x|_\infty$ when $|x|_\infty \ge 4ra_K$, for $A_K, B_K \in \mathcal{F}(\mathsf{Bd}(Q_r))$ and $|x|_\infty \ge 4ra_K$, gives the inequality with $4\,\mathsf{C}_{\mathrm{dc}}\mathcal{N}_r(A_K)^{1/2}\mathcal{N}_r(B_K)^{1/2}ra_K/|x|_\infty$ on the right; and $\mathcal{N}_r(A_K) \le \nu(|A_K|^2) \le \|A\|^2_\infty$ by the bound following YM3_I:(1959), whose hypotheses hold by Proposition YM3_I:103.4. If $|x| \ge 4\sqrt{3}(R+w)$, then $|x|_\infty \ge |x|/\sqrt{3} \ge 4(R+w) > 4ra_K$, and $ra_K/|x|_\infty \le \sqrt{3}(R+w)/|x|$. For a pure phase, the invariant events have probability zero or one, so the conditional expectations are constants. □

Lemma 18.220 (Recovery of the label at every reference coupling)**.** Let $0 < g \le \gamma$ and let S be a limit of separated cumulants through periodic Gibbs states at first-passage data at g, with the cutoffs tending to infinity. The labels $b_j = a_{K_j}\beta_j$ converge along every defining sequence to the same $b(S) \in I^{\mathrm{lab}}(g)$. This applies in particular to volume-first limits. ■

Proof. The first-passage bounds put every b_j in the compact positive interval $I^{\mathrm{lab}}(g)$ (Corollary YM3_I:74.2). Let $b > 0$ be the limit along any subsequence. Choose an integer $z \ge 0$ so that $L^z b \ge 2\gamma_W^{-2}$ and put $g' = (L^z b/2)^{-1/2}$. We have $g' \le \gamma_W$ and $2g'^{-2}$ lies in the interior of $I(g') = (g'^{-2} + \bar{B}, X_{g'} - \bar{B}]$: the first inequality uses $\bar{B} < g'^{-2}$ and the second uses

$X_{g'} - \bar{B} = Lg'^{-2} + (L-2)\bar{B}$ with $L \geq 13$. Thus $L^z b_j \in I(g')$ eventually along the subsequence. The common interval property in Corollary YM3_I:74.2 makes $(K_j - z, \beta_j)$ first-passage data at g' with these labels.

The dilation $D : x \mapsto L^z x$ identifies the two lattices, their oriented plaquettes and their Haar variables. The Wilson Gibbs kernels correspond at the same bare coupling β_j, so the images of the periodic Gibbs states are periodic Gibbs states. The same identification takes a volume-first state to a volume-first state since dilation takes T_{2L^m} to $T_{2L^{m+z}}$. For any separated tuple $f_1, \dots, f_n$, the definition of the action density gives

$$S^T_{n;K_j}(f_1, \dots, f_n) = L^{zn} S^T_{n;K_j - z}(f_1 \circ D^{-1}, \dots, f_n \circ D^{-1})$$

in the corresponding states. The dilated subsequence therefore has a limit at g' with label $L^z b$. Choose a fixed nonzero smooth test pair (f, h) at unit scale and write $f_t = f(\cdot/t)$, $h_t = h(\cdot/t)$. Theorem YM3_I:AW applied at g' to the pair at scale $L^z t$ gives

$$\lim_{t \downarrow 0} \frac{S_2(f_t, h_t)}{\mathsf{c}_2 \, \mathcal{K}_{\mathrm{free}}(f, h)} = b^{-2},$$

because $\mathcal{K}_{\mathrm{free}}$ is invariant under a common dilation of the tests. This limit depends only on S. All subsequential label limits, including those from different defining sequences for S, therefore equal the same positive b. Compactness proves convergence along the whole sequence. □

Proposition 18.221 (The thread laws in infinite volume: clustering, the Hilbert space of the threads, its zero modes, the cone, and the space of the action density)**.** Let $0 < g \leq \gamma$, let S be a volume-first limit at g, with a defining sequence (K_j, β_j, ν_j), $\nu_j \in \mathcal{G}^{\mathrm{tor}}_{K_j, \beta_j}$ for every j (Definition 18.205), and with the label $\mathsf{b} = \mathsf{b}(S)$ (Lemma 18.220), and let $\boldsymbol{\nu}$ be a weak limit point on Z of the laws $\boldsymbol{\sigma}_j = (\Psi_{K_j})_* \nu_j$, $\boldsymbol{\sigma}_{j_k} \to \boldsymbol{\nu}$. Then the standing hypothesis (SH) holds at every side $\ell \in \mathfrak{L}(g)$, in infinite volume, and Lemma 18.217 applies to $\boldsymbol{\nu}$. Signs: $\mathbb{D}^1 = \bigcup_s a_s \mathbb{Z}$ and $\mathbb{D}_+ = \mathbb{D}^1 \cap (0, \infty)$; for $v \in \mathbb{D}$ and a function Φ on Z, $\tau_v \Phi = \Phi \circ T_{-v}$; for $c \in \frac{1}{2}\mathbb{D}^1$, θ_c is the reflection in $\{x_3 = c\}$ and $\theta_c \Phi = \Phi \circ T_{\theta_c}$ (Lemma 18.217(f)); for a bond c' of $a_d \mathbb{Z}^3$ its footprint is $\mathrm{fp}(c') = (c'_- + [-\frac{a_d}{2}, \frac{a_d}{2}]^3) \cup (c'_+ + [-\frac{a_d}{2}, \frac{a_d}{2}]^3)$; for $Q \subset \mathbb{R}^3$, $\mathcal{A}(Q)$ is the set of the bounded complex Borel functions on Z of finitely many coordinates $\mathsf{z}_d(c')$ with $\mathrm{fp}(c') \subset Q$; $\mathcal{I}^{\mathbb{Z}}$ is the σ-algebra of the Borel sets $E \subset \mathsf{Z}$ with $T_v^{-1} E = E$ for all $v \in \mathbb{Z}^3$, the maps T_v being formed at $s = 0$; and $\| \cdot \|_2$ is the norm of $L^2(\boldsymbol{\nu})$.

(a) *Clustering at the rate $\rho'/|x|$.* For $\rho' > 0$, $A, B \in \mathcal{A}([-\rho', \rho']^3)$ and $x \in \mathbb{D} \setminus \{0\}$,

$$\left| \boldsymbol{\nu}(\bar{A} \, \tau_x B) - \boldsymbol{\nu}(\overline{\mathbb{E}[A|\mathcal{I}^{\mathbb{Z}}]} \, \mathbb{E}[B|\mathcal{I}^{\mathbb{Z}}]) \right| \leq 4 \, \mathsf{C}_{\mathrm{dc}} \, \|A\|_2 \|B\|_2 \, \frac{\rho'}{|x|_\infty} \leq 4\sqrt{3} \, \mathsf{C}_{\mathrm{dc}} \, \|A\|_\infty \|B\|_\infty \, \frac{\rho'}{|x|},$$

the conditional expectations being taken under $\boldsymbol{\nu}$. Functions of the block fields on the bonds with both end points in $[-\rho, \rho]^3$ lie in $\mathcal{A}([-\rho', \rho']^3)$ with $\rho' = \rho + \frac{1}{2}$, and with $\rho' = \rho + \frac{1}{2} a_{d_0}$ if they read the depths $\geq d_0$ alone.

(b) *Positivity at the coordinate planes $\{x_\kappa = c\}$, $c \in \frac{1}{2}\mathbb{D}^1$.* For $\kappa \in \{1, 2, 3\}$, $c \in \frac{1}{2}\mathbb{D}^1$, the reflection θ in $\{x_\kappa = c\}$ and every $\Phi \in \mathcal{A}(Q)$ with Q a bounded part of $\{x_\kappa \geq c\}$, $\boldsymbol{\nu}(\overline{\Phi \circ T_\theta} \, \Phi) \geq 0$; at the planes through the sites of a lattice $a_s \mathbb{Z}^3$ as well as at those between them.

(c) *The Hilbert space of the threads; its semigroup.* Fix $c_0 \in \mathbb{Z} + \frac{1}{2}$, so that $c_0 \in a_d(\mathbb{Z} + \frac{1}{2})$ for every $d \geq 0$, put $\theta = \theta_{c_0}$, $H^+_c = \{x_3 \geq c\}$ and $\mathcal{A}^+ = \bigcup_Q \mathcal{A}(Q)$ over the bounded $Q \subset H^+_{c_0}$; a coordinate $\mathsf{z}_d(c')$ has its footprint in $H^+_{c_0}$ exactly when both end points of c' lie in $\{x_3 > c_0\}$. The form $\langle \Phi, \Psi \rangle = \boldsymbol{\nu}(\overline{\theta\Phi} \, \Psi)$ on $\mathcal{A}^+$ is positive semi-definite and $\|[\Phi]\| \leq \|\Phi\|_2$; $\mathcal{H}^{\mathrm{thr}}$ is the completion of $\mathcal{A}^+$ modulo its null vectors, with the classes $[\Phi]$ and $\Omega = [1]$, and $[\Phi]$ extends by continuity to the bounded functions measurable for the σ-algebra of the coordinates with footprints in $H^+_{c_0}$. The classes of the gauge-invariant members of $\mathcal{A}^+$ fill the classes of $\mathcal{A}^+$: $[\Phi] = [\Phi^{\mathrm{inv}}]$, Φ^{inv} the Haar mean of Φ over the gauge transformations at the finitely many

sites which it reads. For $t \in \mathbb{D}_+$ there is one bounded operator T_t with $\mathsf{T}_t[\Phi] = [\tau_{te_3}\Phi]$; it is self-adjoint, $0 \le \mathsf{T}_t \le 1$, $\mathsf{T}_t\mathsf{T}_{t'} = \mathsf{T}_{t+t'}$, and with $\mathsf{A} = \mathsf{T}_1$, $\mathsf{T}_t = \mathsf{A}^t$. For $v \in \mathbb{D}$ with $v_3 = 0$ and $\mathsf{r} \in W_2$, acting on the first two coordinates, $U(v)[\Phi] = [\tau_v\Phi]$ and $U(\mathsf{r})[\Phi] = [\Phi \circ T_{\mathsf{r}^{-1}}]$ are unitary, fix Ω and commute with the T_t. Let $\mathcal{H}^>$ be the closed span of the classes of the $\Phi \in \mathcal{A}^+$ which read coordinates with footprints in $H^+_{c_0+\delta}$ alone, for some $\delta > 0$. Then $\mathcal{H}^{\rm thr} = \ker \mathsf{A} \oplus \mathcal{H}^>$, $\mathcal{H}^> = \overline{\operatorname{Ran} \mathsf{T}_t}$ for every $t \in \mathbb{D}_+$, and on $\mathcal{H}^>$ the Hamiltonian of the threads $H^{\rm thr} = -\log(\mathsf{A}|_{\mathcal{H}^>})$ is self-adjoint and ≥ 0, $e^{-tH^{\rm thr}} = \mathsf{T}_t|_{\mathcal{H}^>}$ for $t \in \mathbb{D}_+$, and $\mathsf{T}_t \to 1$ strongly on $\mathcal{H}^>$ as $t \to 0$ in $\mathbb{D}_+$.

(d) *Zero energy is the invariant events.* Let P_1 be the projection of $\mathcal{H}^{\rm thr}$ onto $\ker(1-\mathsf{A}) = \ker H^{\rm thr}$. Then $\langle [\Phi], P_1[\Psi]\rangle = \boldsymbol{\nu}(\overline{\mathbb{E}[\Phi|\mathcal{I}^{\mathbb{Z}}]}\,\mathbb{E}[\Psi|\mathcal{I}^{\mathbb{Z}}])$ for $\Phi, \Psi \in \mathcal{A}^+$, and $P_1[\Phi] \mapsto \mathbb{E}[\Phi|\mathcal{I}^{\mathbb{Z}}]$ extends to a unitary map of $\ker H^{\rm thr}$ onto $L^2(\mathsf{Z}, \mathcal{I}^{\mathbb{Z}}, \boldsymbol{\nu})$ which carries Ω to 1. The reflection θ acts as the identity on $L^2(\mathsf{Z}, \mathcal{I}^{\mathbb{Z}}, \boldsymbol{\nu})$.

(e) *The horizontal translations; the cone.* For $\lambda \in \{1, 2\}$ and $t \in \mathbb{D}_+$, $(1-\mathsf{A}^t)^2 \ge \mathsf{A}^t(2 - U(te_\lambda) - U(te_\lambda)^*)$ on $\mathcal{H}^{\rm thr}$. On $\mathcal{H}^>$ the representation $v \mapsto U(v)$ extends to one strongly continuous unitary representation of $\mathbb{R}^2$, whose generators $P_1^{\rm thr}, P_2^{\rm thr}$ commute with $H^{\rm thr}$, and the joint spectral measure of $(H^{\rm thr}, P_\lambda^{\rm thr})$ is carried by $\{(E, q) : E \ge |q|\}$: $H^{\rm thr} \ge |P_\lambda^{\rm thr}|$. So, for every depth d, on every closed subspace of $\mathcal{H}^>$ which T_{a_d} and $U(\pm a_d e_\lambda)$ map into itself, among them the closed span of the classes of the functions of the block fields of the depths $\ge d$ which read footprints in some $H^+_{c_0+\delta}$, $\delta > 0$, the joint spectral measure of $(\mathsf{T}_{a_d}, U(a_d e_\lambda))$ is carried by $\{(t, \zeta) : t \le e^{-|\arg\zeta|}\} \subset \{t \le e^{-\mathsf{k}|\arg\zeta|}\}$, k the chord constant YM3_I:(1954): the form of the lattice cone at the spacing a_d, with the constant one.

(f) *Loops.* For a closed path C of bonds c' of $a_d\mathbb{Z}^3$ with both end points of every bond in $\{x_3 > c_0\}$, the loop $W_C(\mathsf{z}_d) = \frac{1}{2}\operatorname{tr}\mathsf{z}_d(C)$ is a continuous member of $\mathcal{A}^+$; so $\mathcal{H}^{\rm thr}$ holds the classes of all such loops of block fields, and $\mathcal{H}^>$ those whose bonds have their end points in some $\{x_3 \ge c_0 + \delta + \frac{1}{2}a_d\}$.

(g) *The space of the action density; the map J.* Let $\mathbb{E}_+ = \{x_3 > c_0\}$, $\mathcal{D}$ the space of the complex combinations $F = \sum_k \zeta_k X_k$ of separated tuples $X_k \in \mathfrak{S}$ over $\mathbb{E}_+$, $F_j = \sum_k \zeta_k (X_k)^{\nu_j}_{K_j}$ with the centred products of Definition 18.205, and $\mathcal{H}_{c_0}(S)$ the Hilbert space of the form $\sigma_S(\theta\bar{F}\cdot F')$ on $\mathcal{D}$, which the translation by $-c_0e_3$ carries unitarily onto $\mathcal{H}(S)$, with its vacuum, its semigroup e^{-tH}, its translations $\mathcal{U}(v)$, $v \in \mathbb{R}^2$, its representation $\mathcal{U}(\mathsf{r})$ of W_2 and its projection P_0 onto $\ker H$. There is a subsequence (j'_i) of (j_k) along which $\mathfrak{q}(\Phi, F) = \lim_i \nu_{j'_i}(\overline{\theta(\Phi \circ \Psi_{K_{j'_i}})}\, F_{j'_i})$ exists for all $\Phi \in \mathcal{A}^+$ and $F \in \mathcal{D}$. Along it $|\mathfrak{q}(\Phi, F)| \le \|[\Phi]\|\,\|[F]\|_S$, where $\|[F]\|_S$ is the norm of the class of F in $\mathcal{H}_{c_0}(S)$, and there is exactly one bounded operator $J\colon \mathcal{H}_{c_0}(S) \to \mathcal{H}^{\rm thr}$ with $\langle [\Phi], J[F]\rangle = \mathfrak{q}(\Phi, F)$ for all $\Phi \in \mathcal{A}^+$ and $F \in \mathcal{D}$; $\|J\| = 1$, $J\Omega = \Omega$, $\operatorname{Ran} J \subset \mathcal{H}^>$, $J\,e^{-tH} = e^{-tH^{\rm thr}}J$ for every real $t \ge 0$, $J\mathcal{U}(v) = U(v)J$ for $v \in \mathbb{R}^2$, $J\mathcal{U}(\mathsf{r}) = U(\mathsf{r})J$ for $\mathsf{r} \in W_2$, and $JP_0 = P_1J$; the positive contraction J^*J commutes with e^{-tH}, $\mathcal{U}(v)$, $\mathcal{U}(\mathsf{r})$ and fixes Ω.

■

Proof. Step 0: the setting. The data at g have labels in J_g and $\ell \in \mathfrak{L}(g)$ admits J_g (Lemma 18.212(c)); the labels converge (Lemma 18.220); all ν_j lie in $\mathcal{G}^{\rm tor}_{K_j,\beta_j} \subset \mathcal{G}^{\rm per}_{K_j,\beta_j}$ (Proposition YM3_I:103.4); so (SH) holds at every side of $\mathfrak{L}(g)$, in infinite volume (Lemma 18.217(h)), and Lemma 18.217(b)(ii)–(iv), (f)(i), (ii) give: $\boldsymbol{\nu}(\mathsf{Thr}) = 1$, the invariance under the maps T_v, $v \in \mathbb{D}$, under T_{r}, $\mathsf{r} \in \mathbb{D} \rtimes W_3$, and under the gauge transformations, and $\boldsymbol{\sigma}_{j_k}(H) \to \boldsymbol{\nu}(H)$ for every bounded Borel H of finitely many depths and bonds in a bounded set. For $v \in a_s\mathbb{Z}^3$ and $K \ge s$, $\Psi_K \circ \tau_v = T_v \circ \Psi_K$, as $\mathcal{M}$ commutes with τ_v at the depths $\ge s$ (Lemma 18.211(b)); so $(\tau_v\Phi) \circ \Psi_K$ is the lattice translate of $\Phi \circ \Psi_K$, and likewise for the isometries of $a_s\mathbb{Z}^3$. By Lemma 18.211(b) and Step 1 of the proof of

Proposition 18.219, $\Phi\circ\Psi_K$ is, for $\Phi\in\mathcal{A}(Q)$ and K at least every depth read, a bounded Borel function of the bonds of $\mathbb{L}_K$ in Q.

Step 1: clause (a). Let $|x|_\infty,|x'|_\infty>4\rho'$ with $x,x'\in\mathbb{D}$, and $K=K_{j_k}$ large, $r=\lceil\rho'/a_K\rceil$, so that $\rho'\le ra_K<\rho'+a_K$, $x,x'\in\mathbb{L}_K$ and $4ra_K\le\min\{|x|_\infty,|x'|_\infty\}$. The lattice bound YM3_I:(1970), with $r/n+2r^2/n^2\le 4ra/|x|_\infty$ at $|x|_\infty\ge 4ra$, at x and at x', whose subtracted terms coincide, the sizes $\mathcal{N}_r\le\nu_j(|\cdot|^2)$ (the bound following YM3_I:(1959)) and the triangle inequality give $|\nu_j(\bar A_K\tau_x B_K)-\nu_j(\bar A_K\tau_{x'}B_K)|\le 4\mathsf{C}_{\rm dc}\nu_j(|A_K|^2)^{1/2}\nu_j(|B_K|^2)^{1/2}ra_K(|x|_\infty^{-1}+|x'|_\infty^{-1})$, with $A_K=A\circ\Psi_K$; the four functions $\bar A\tau_xB$, $\bar A\tau_{x'}B$, $|A|^2$, $|B|^2$ are bounded Borel and local, and Step 0 carries the inequality to $\boldsymbol{\nu}$ with ρ' in the place of ra_K. Now let $e=(1,1,1)$ and $S_nB=n^{-3}\sum_{y\in\{0,\dots,n-1\}^3}\tau_yB$; the maps T_y, $y\in\mathbb{Z}^3$, are homeomorphisms of Z which keep $\boldsymbol{\nu}$, so the mean ergodic theorem gives $S_nB\to\mathbb{E}[B|\mathcal{I}^{\mathbb{Z}}]$ and $\tau_{ne}S_nB\to\mathbb{E}[B|\mathcal{I}^{\mathbb{Z}}]$ in $L^2(\boldsymbol{\nu})$. The points $x'=ne+y$ have $|x'|_\infty\ge n$; the mean of the inequality over them, $n\to\infty$, and $\boldsymbol{\nu}(\bar A\,\mathbb{E}[B|\mathcal{I}^{\mathbb{Z}}])=\boldsymbol{\nu}(\overline{\mathbb{E}[A|\mathcal{I}^{\mathbb{Z}}]}\,\mathbb{E}[B|\mathcal{I}^{\mathbb{Z}}])$ give (a) for $|x|_\infty>4\rho'$. For $0<|x|_\infty\le 4\rho'$ the left side is at most $2\|A\|_2\|B\|_2$ and the right side at least $\mathsf{C}_{\rm dc}\|A\|_2\|B\|_2$, while $\mathsf{C}_{\rm dc}=16(1+\sqrt{2})\mathsf{k}^{-2}\mathsf{C}_{\rm dn}>100$, as $\mathsf{k}<1$ and $\mathsf{C}_{\rm dn}>3$ in the constants of YM3_I:(1968). Finally $|x|_\infty\ge|x|/\sqrt{3}$ and $\|A\|_2\le\|A\|_\infty$. The footprints of the bonds with both end points in $[-\rho,\rho]^3$ lie in $[-\rho-\frac12 a_d,\rho+\frac12 a_d]^3$.

Step 2: clause (b). Let $c\in\frac12 a_s\mathbb{Z}$; then $\theta\in\mathsf{Iso}(a_s\mathbb{Z}^3)$, and for $K\ge s$ the plane $\{x_\kappa=c\}$ is a lattice mirror of $\mathbb{L}_K$ (a site mirror if $c\in a_K\mathbb{Z}$, a bond mirror otherwise), while $\theta(\Phi\circ\Psi_K)=(\Phi\circ T_\theta)\circ\Psi_K$ by the covariance of the block map (Lemma 18.211(b)). For $\Phi\in\mathcal{A}(Q)$, $\Phi\circ\Psi_K$ is a bounded Borel function of finitely many bonds of $\mathbb{L}_K$ whose closed segments lie in $Q\subset\{x_\kappa\ge c\}$, and the positivity of the nine families, Proposition YM3_I:103.4, gives $\nu_j(\overline{\theta(\Phi\circ\Psi_{K_j})}\,\Phi\circ\Psi_{K_j})\ge 0$; Step 0 passes it to $\boldsymbol{\nu}$.

Step 3: clause (c). Positivity is (b) at c_0; $\langle\Phi,\Phi\rangle\le\|\theta\Phi\|_2\|\Phi\|_2=\|\Phi\|_2^2$ by the invariance of $\boldsymbol{\nu}$ under T_θ; so classes extend by L^2-continuity, local functions being dense in L^2 of the σ-algebra which they generate. Gauge means: $\theta\Psi$ reads coordinates with end points in $\{x_3<c_0\}$, which a gauge transformation u at sites of $\{x_3>c_0\}$ does not touch, so by the gauge invariance (Lemma 18.217(f)) and Fubini $\langle\Psi,\Phi\rangle=\int\boldsymbol{\nu}(\overline{\theta\Psi}\,\Phi(\cdot^u))\,du=\langle\Psi,\Phi^{\rm inv}\rangle$. The semigroup: τ_{te_3} maps $\mathcal{A}(Q)$ to $\mathcal{A}(Q+te_3)$; $\theta\tau_{te_3}=\tau_{-te_3}\theta$ and the invariance give $\langle\tau_{te_3}\Phi,\Psi\rangle=\langle\Phi,\tau_{te_3}\Psi\rangle$; then $\|[\tau_{te_3}\Phi]\|^2\le\|[\Phi]\|\,\|[\tau_{2te_3}\Phi]\|$, and by induction $\|[\tau_{te_3}\Phi]\|\le\|[\Phi]\|^{1-2^{-n}}\|\Phi\|_\infty^{2^{-n}}$, so T_t is a well defined symmetric contraction. $\mathsf{T}_t\ge 0$: with $c'=c_0+\frac{t}{2}\in\frac12\mathbb{D}^1$, $\theta=\theta_{c'}\tau_{te_3}$ since $2c'-(x_3+t)=2c_0-x_3$, so $\langle\Phi,\tau_{te_3}\Phi\rangle=\boldsymbol{\nu}(\overline{\theta_{c'}\tau_{te_3}\Phi}\,\tau_{te_3}\Phi)\ge 0$ by (b), $\tau_{te_3}\Phi$ depending on coordinates with footprints in $H^+_{c_0+t}\subset H^+_{c'}$. $\mathsf{T}_{a_s}\ge 0$ and $\mathsf{T}_{a_s}^{Ls}=\mathsf{T}_1$ give $\mathsf{T}_{a_s}=\mathsf{A}^{a_s}$ by the uniqueness of positive roots, hence $\mathsf{T}_t=\mathsf{A}^t$. The horizontal translations and W_2 commute with θ and with τ_{te_3} and keep $\boldsymbol{\nu}$ and $\mathcal{A}^+$. The splitting: $\ker\mathsf{A}^t=\ker\mathsf{A}$ and $\overline{\operatorname{Ran}\mathsf{A}^t}=(\ker\mathsf{A})^\perp$ by the spectral theorem; a Φ with footprints in $H^+_{c_0+\delta}$, $a_s\le\delta$, is $\tau_{a_se_3}\Phi'$ with $\Phi'=\tau_{-a_se_3}\Phi\in\mathcal{A}^+$, so $[\Phi]\in\operatorname{Ran}\mathsf{T}_{a_s}$; conversely T_{a_s} maps the dense set of classes into $\mathcal{H}^>$. On $\mathcal{H}^>=(\ker\mathsf{A})^\perp$, A is injective, $0\le\mathsf{A}\le 1$, and the spectral theorem gives $H^{\rm thr}$, $e^{-tH^{\rm thr}}=\mathsf{A}^t$ and, by dominated convergence, $\mathsf{A}^t\to 1$ strongly.

Step 4: clause (d). The map T_θ carries $\mathcal{I}^{\mathbb{Z}}$ onto itself, as $\theta\tau_y\theta=\tau_{\varrho y}$ with $\varrho=\operatorname{diag}(1,1,-1)$, and keeps $\boldsymbol{\nu}$; so it induces a unitary involution R of $L^2(\mathcal{I}^{\mathbb{Z}})=L^2(\mathsf{Z},\mathcal{I}^{\mathbb{Z}},\boldsymbol{\nu})$. For $\Psi\in\mathcal{A}^+$, $S_n\Psi\in\mathcal{A}^+$ (the shifts have $y_3\ge 0$), $S_n\Psi\to h=\mathbb{E}[\Psi|\mathcal{I}^{\mathbb{Z}}]$, and $0\le\boldsymbol{\nu}(\overline{\theta S_n\Psi}\,S_n\Psi)\to\langle Rh,h\rangle$; as $\mathbb{E}[\tau_y\Psi|\mathcal{I}^{\mathbb{Z}}]=\mathbb{E}[\Psi|\mathcal{I}^{\mathbb{Z}}]$ for $y\in\mathbb{Z}^3$ and every local function is moved into $\mathcal{A}^+$ by some τ_{ne_3}, these h are dense in $L^2(\mathcal{I}^{\mathbb{Z}})$; so $R\ge 0$, and $R^2=1$ gives $R=1$. Now $\mathsf{A}^n\to P_1$ strongly, and by (a), for $\Phi,\Psi\in\mathcal{A}^+$, $\langle[\Phi],\mathsf{A}^n[\Psi]\rangle=\boldsymbol{\nu}(\overline{\theta\Phi}\,\tau_{ne_3}\Psi)\to\boldsymbol{\nu}(\overline{\mathbb{E}[\theta\Phi|\mathcal{I}^{\mathbb{Z}}]}\,\mathbb{E}[\Psi|\mathcal{I}^{\mathbb{Z}}])$, and $\mathbb{E}[\theta\Phi|\mathcal{I}^{\mathbb{Z}}]=R\,\mathbb{E}[\Phi|\mathcal{I}^{\mathbb{Z}}]=\mathbb{E}[\Phi|\mathcal{I}^{\mathbb{Z}}]$. Hence $\|P_1[\Phi]\|=\|\mathbb{E}[\Phi|\mathcal{I}^{\mathbb{Z}}]\|_2$: the map is well defined and isometric on the dense subspace $\{P_1[\Phi]\}$ of $\ker(1-\mathsf{A})$, its range holds the dense set of the h above, and an isometry has a closed range; $\mathbb{E}[1|\mathcal{I}^{\mathbb{Z}}]=1$.

Step 5: clause (e). Let $\Phi\in\mathcal{A}^+$, $t\in\mathbb{D}_+$, and $K=K_{j_k}$ so large that $t\in a_K\mathbb{N}$. In the coordinate picture at (e_3,c_0), Proposition YM3_I:99.3 at spacing a_K puts the joint spectrum of

the one-step time operator and the horizontal step in the set $(1-s)^2 \geq s|1-z|^2$, with $s \in [0,1]$ and $|z| = 1$. For $m = t/a_K \in \mathbb{N}$ this implies $(1-s^m)^2 \geq s^m|1-z^m|^2$. Indeed, for $s > 0$ use $|1-z^m| \leq m|1-z|$ and $s^{-m/2} - s^{m/2} \geq m(s^{-1/2} - s^{1/2})$, the latter by $\sinh(mx) \geq m \sinh x$ for $x \geq 0$. At $s = 0$ the inequality is immediate. Applied to $F = \Phi \circ \Psi_K$ in the positive half-space, the spectral inequality gives $u_j(0) - 4u_j(te_3) + u_j(2te_3) + u_j(te_3 + te_\lambda) + u_j(te_3 - te_\lambda) \geq 0$ with $u_j(w) = \nu_j(\overline{\theta F}\, \tau_w F)$; by Step 0, $u_j(w) \to \langle [\Phi], \mathsf{T}_{w_3} U(w_1 e_1 + w_2 e_2)[\Phi]\rangle$ along (j_k). The limit reads $\langle \psi, [(1-\mathsf{A}^t)^2 - \mathsf{A}^t(2 - U - U^*)]\psi\rangle \geq 0$, $U = U(te_\lambda)$, $\psi = [\Phi]$, and the operators are bounded. On $\mathcal{H}^>$, with ψ there, $\|(1-U)\mathsf{A}^{t/2}\psi\|^2 \leq \|(1-\mathsf{A}^t)\psi\|^2$, so $\|(1-U(te_\lambda))\psi\| \leq \|(1-\mathsf{A}^t)\psi\| + 2\|(1-\mathsf{A}^{t/2})\psi\| \to 0$ as $t \to 0$ (the real powers of A being continuous on $\mathcal{H}^>$); $v \mapsto U(v)\psi$ is uniformly continuous on the dense subgroup $\mathbb{D}^1 e_1 + \mathbb{D}^1 e_2$ of $\mathbb{R}^2$ and extends to a strongly continuous unitary representation; Stone's theorem gives P^{thr}_λ. The inequality says $\int g_t \, d\langle \psi, \mathfrak{E}\psi\rangle \geq 0$ for the joint spectral measure $\mathfrak{E}$ of $(H^{\mathrm{thr}}, P^{\mathrm{thr}}_\lambda)$ and $g_t(E,q) = 2e^{-tE}(\cosh tE + \cos tq - 2)$, hence $\mathfrak{E}(\{g_t < 0\}) = 0$ for every $t \in \mathbb{D}_+$, a countable set; dividing $\cosh tE - 1 \geq 1 - \cos tq$ by t^2 and letting $t \to 0$ gives $E^2 \geq q^2$. On a reducing subspace the joint spectral measure of $(\mathsf{T}_{a_d}, U(a_d e_\lambda)) = (e^{-a_d H^{\mathrm{thr}}}, e^{i a_d P^{\mathrm{thr}}_\lambda})$ is the image of $\mathfrak{E}$ under $(E,q) \mapsto (e^{-a_d E}, e^{i a_d q})$, and $|\arg e^{i a_d q}| \leq a_d|q| \leq a_d E$; $\mathsf{k} < 1$.

Step 6: clause (f). The trace of a product of finitely many coordinates is continuous, and the footprint of a bond with both end points in $\{x_3 > c_0\}$ lies in $H^+_{c_0}$.

Step 7: clause (g). The lattice form. For $F \in \mathcal{D}$, the supports of the entries keep a distance $\delta > 0$ from the plane; for $a_{K_j} < \delta$ each centred product $(X_k)^{\nu_j}_{K_j}$ is a real function, the product over the entries f of X_k of the functions $\mathcal{O}_{K_j}(f) - \nu_j(\mathcal{O}_{K_j}(f))$, and F_j is the combination of these products with the complex coefficients ζ_k; the factors read the bonds of plaquettes within $\frac{1}{2}a_{K_j}$ of the supports, hence bonds in $\{x_3 > c_0\}$; for a tuple X write $X_j = X^{\nu_j}_{K_j}$ for its centred product of Definition 18.205 and $\sigma_{\nu_j}(X) = \nu_j(X_j)$ for the mean of this product in ν_j; by the invariance of ν_j under θ, $\theta(X_j) = (\theta X)_j$, and $\nu_j(\overline{\theta F_j} F'_j) = \sum \bar\zeta_k \zeta'_l \, \sigma_{\nu_j}(\theta X_k \cdot X'_l) \to \sigma_S(\theta \bar F \cdot F')$, because σ_{ν_j} is the sum over the partitions of products of the cumulants $S^T[\nu_j]$ by the moment–cumulant formula, since the first cumulants of the centred variables vanish. The cumulants of order at least two are unchanged by centering and converge to those of S. With $\Phi_j = \Phi \circ \Psi_{K_j}$, the form $G \mapsto \nu_j(\overline{\theta G}\, G)$ is positive on $\mathcal{F}_{\mathrm{loc}}(\mathbb{H}^+(e_3, c_0))$ (Proposition YM3_I:103.4), so $|\nu_j(\overline{\theta\Phi_j} F_j)|^2 \leq \nu_j(\overline{\theta\Phi_j}\Phi_j)\, \nu_j(\overline{F_j} F_j) \leq \|\Phi\|^2_\infty \, \nu_j(\overline{\theta F_j} F_j)$. *The extraction.* By the same partition formula and the uniform bounds of Proposition YM3_I:91.13, $|\sigma_{\nu_j}(Y)| \leq C'_n(\mathsf{d}; R) \prod_i \|f_i\|_\sharp$ for tuples Y of type $(\mathsf{d}; R)$, uniformly in j, with $C'_n = \sum_{\mathfrak{p}} \prod_{\mathfrak{b} \in \mathfrak{p}} C^{\mathrm{per}}_{|\mathfrak{b}|}$ over the partitions into blocks of at least two elements; by multilinearity, $\sup_j \nu_j(\overline{\theta(X_j - X'_j)}(X_j - X'_j))^{1/2}$ is small when the entries of X' are near those of X in $\|\cdot\|_\sharp$, with supports in fixed open sets. Countable sets dense in these senses (tuples over finite unions of rational balls, a countable sup-norm dense set of continuous members of $\mathcal{A}^+$) and a diagonal subsequence give the limits at the continuous Φ. For a bounded Borel $\Phi \in \mathcal{A}^+$ and a continuous Φ' of the same coordinates, $|\nu_j(\overline{\theta(\Phi_j - \Phi'_j)}\, F_j)| \leq \nu_j(|\Phi_j - \Phi'_j|^2)^{1/2} \sup_{j'} \nu_{j'}(\overline{\theta F_{j'}} F_{j'})^{1/2}$, and $\nu_j(|\Phi_j - \Phi'_j|^2) \to \|\Phi - \Phi'\|^2_2$ along (j_k) by Step 0, which is as small as we please; so the limits exist at every $\Phi \in \mathcal{A}^+$. *The bound and the map.* Along (j'_i), $\nu_j(\overline{\theta\Phi_j}\Phi_j) \to \boldsymbol{\nu}(\overline{\theta\Phi}\,\Phi) = \|[\Phi]\|^2$ by Step 0, and $\nu_j(\overline{\theta F_j} F_j) \to \sigma_S(\theta \bar F \cdot F) = \|[F]\|^2_S$; so the first inequality of the lattice form passes to the limit as $|\mathfrak{q}(\Phi, F)| \leq \|[\Phi]\|\, \|[F]\|_S$. Hence $\mathfrak{q}(\Phi, F)$ depends on Φ through $[\Phi]$ and on F through $[F]$ alone, antilinearly in the first and linearly in the second; as the classes $[\Phi]$, $\Phi \in \mathcal{A}^+$, are dense in $\mathcal{H}^{\mathrm{thr}}$, Riesz's lemma gives for every F exactly one vector $J[F]$ with $\langle [\Phi], J[F]\rangle = \mathfrak{q}(\Phi, F)$, and $\|J[F]\| \leq \|[F]\|_S$; so J extends by continuity to $\mathcal{H}_{c_0}(S)$, with $\|J\| \leq 1$, and no other bounded operator has this property. As the empty tuple gives the function 1 at every j, $\mathfrak{q}(\Phi, \varnothing) = \lim \nu_j(\overline{\theta\Phi_j}) = \boldsymbol{\nu}(\overline{\theta\Phi}) = \langle [\Phi], \Omega\rangle$, so $J\Omega = \Omega$ and $\|J\| = 1$. At $t \in \mathbb{D}_+$ the identity $\nu_j(\overline{\theta\Phi_j}\, \tau_{te_3} F_j) = \nu_j(\overline{\theta(\tau_{te_3}\Phi)_j}\, F_j)$ of the lattice gives $J e^{-tH} = \mathsf{T}_t J$; the horizontal translations of $\mathbb{D}^1 e_1 + \mathbb{D}^1 e_2$ and W_2 keep ν_j and commute with θ. A tuple X with supports in $H^+_{c_0+\delta}$, $a_s < \delta$, is $\tau_{a_s e_3} X'$ with X' over $\mathbb{E}_+$, so $J[X] = \mathsf{T}_{a_s} J[X'] \in \mathcal{H}^>$;

then $t \mapsto Je^{-tH}\psi$ and $t \mapsto e^{-tH^{\mathrm{thr}}}J\psi$ are continuous on $[0,\infty)$ (Proposition YM3_I:94.1 and clause (c) above) and agree on the dense set $\mathbb{D}_+$, and the same for $v \in \mathbb{R}^2$ with (e). $P_0 = \lim e^{-nH}$ and $P_1 = \lim \mathsf{A}^n$ strongly give $JP_0 = P_1 J$; taking adjoints, J^*J commutes with e^{-tH}, $\mathcal{U}(v)$, $\mathcal{U}(\mathsf{r})$, and $\langle \Omega, J^*J\Omega\rangle = 1$ with $J^*J \le 1$ gives $J^*J\Omega = \Omega$. □

Lemma 18.222 (One step of the block map at a lowest layer)**.** Let $k \ge 0$ and $z \in a_k(\mathbb{Z} + \frac{1}{2})$. Given $m \in \{k, k+1\}$, write L_m for the set of those bonds of $a_m\mathbb{Z}^3$ whose two end points lie in $\{x_3 > z\}$, one or both of them at the height $z + \frac{1}{2}a_m$, and U_m for the set of those bonds of $a_m\mathbb{Z}^3$ whose two end points lie at heights $\ge z + \frac{3}{2}a_m$. Take a bond c of $a_k\mathbb{Z}^3$ whose two end points lie in $\{x_3 > z\}$, write P_c for the set of those bonds of $a_{k+1}\mathbb{Z}^3$ whose two end points lie in $\tilde{B}^1(c_-) \cup \tilde{B}^1(c_+)$, the double block, and take G-valued configurations U, U' on P_c, each of which fulfils the small-field condition $|\partial U(p) - \mathbf{1}| < \omega_M = \frac{1}{200L^2}$ at all plaquettes p whose corners lie in the double block (YM3_I:(30)), such that $U' = U$ on $\mathsf{P}_c \cap \mathsf{U}_{k+1}$ and $|U'(b) - U(b)| \le \delta$ on $\mathsf{P}_c \cap \mathsf{L}_{k+1}$; here δ is subject to $L\delta \le \frac{1}{100}$, and $|\cdot|$ denotes the operator norm. Then: if $c \in \mathsf{U}_k$, $\mathsf{P}_c \subset \mathsf{U}_{k+1}$ and $(\mathcal{M}U')(c) = (\mathcal{M}U)(c)$; if $c \in \mathsf{L}_k$,

$$|(\mathcal{M}U')(c) - (\mathcal{M}U)(c)| \le \mathsf{c}_L\,\delta, \qquad \mathsf{c}_L = \tfrac{14}{13}\Big[1 + 2.62\Big(\frac{1}{L} + \frac{1}{4}(1 - L^{-2})\Big)\Big].$$

The number c_L decreases in L; $\mathsf{c}_{13} < 1.996$, so $\mathsf{c}_L < 0.554\sqrt{L}$ for every $L \ge 13$. ■

Proof. Step 0: the chart. By Lemma 18.211(a), $(\mathcal{M}U)(c)$ is the average of YM3_I:(37) on a torus, lifted through the covering map. The paths $\Gamma_\sigma(y,x)$ go from y to x along successive coordinate segments, in each ordering σ of the nonzero displacements. The covering map identifies these paths and the straight transports on the double block with their counterparts on the torus. Both configurations satisfy the small-field condition at the radius ω_M, so by Lemma YM3_I:4.4 the contour families have diameter at most $\frac{1}{160}$, their means $U(y,x)$ exist, and the elements $W_x = U(c_-,x)\,U([x,x'])\,U(x',c_+)\,U[c]^{-1}$ satisfy $|W_x - \mathbf{1}| < \frac{1}{14}$; so the small-field formula applies to both and $(\mathcal{M}U)(c) = \exp(L^{-3}\sum_{x\in B(c_-)}\log W_x)\,U[c]$. Write $a' = a_{k+1}$, $a = La'$, $\mathsf{h} = \frac{1}{2}(L-1)$. If $c \in \mathsf{U}_k$, the sites of its double block have heights $\ge z + \frac{3}{2}a - \mathsf{h}a' = z + a + \frac{1}{2}a'$, so $\mathsf{P}_c \subset \mathsf{U}_{k+1}$ and nothing changes. Let $c \in \mathsf{L}_k$ be positively oriented, with an end point y in the lowest layer of $a_k\mathbb{Z}^3$, at the height $z + \frac{1}{2}a$; heights are measured from y in units of a', so that the lowest layer of $a_{k+1}\mathbb{Z}^3$ above z is the height $-\mathsf{h}$. Negatively oriented bonds follow by inversion.

Step 1: rules for unitary matrices. (r1) $|X_1\cdots X_n - Y_1\cdots Y_n| \le \sum_i |X_i - Y_i|$ for unitary factors, and $|X^{-1} - Y^{-1}| = |X - Y|$. (r2) If $|X - \mathbf{1}|, |Y - \mathbf{1}| \le r < 1$, then $|\log X - \log Y| \le |X - Y|/(1-r)$, from the series, as $|A^n - B^n| \le nr^{n-1}|A - B|$ for $|A|, |B| \le r$. (r3) $|e^{\alpha'} - e^{\alpha}| \le |\alpha' - \alpha|$ for anti-hermitian α, α', from $e^{\alpha'} - e^{\alpha} = \int_0^1 e^{t\alpha'}(\alpha' - \alpha)e^{(1-t)\alpha}dt$. (r4) For a C^1 curve X_t of unitary matrices with $|X_t - \mathbf{1}| \le \Delta_0 < 1$, $|\frac{d}{dt}\log X_t - \dot{X}_t| \le |\dot{X}_t|\frac{\Delta_0}{1-\Delta_0}$, from the derivatives of the terms of the series.

Step 2: the means are Lipschitz. Let $\mathbf{V} = (V_i)_{i\le n}$ and $\mathbf{V}' = (V_i')_{i\le n}$ be families in G of diameter at most $\frac{1}{160}$ with $|V_i' - V_i| \le \frac{1}{100}$, and m, m' their means (Proposition YM3_I:4.3 and YM3_I:(28)), which satisfy $|V_i m^{-1} - \mathbf{1}|, |V_i' m'^{-1} - \mathbf{1}| \le \frac{1}{40}$ and $\sum_i \log(V_i m^{-1}) = 0 = \sum_i \log(V_i' m'^{-1})$. Then $|m' - m| \le 1.31 \cdot \frac{1}{n}\sum_i |V_i' - V_i|$. Indeed, put $p_i = V_i m^{-1}$, $p_i' = V_i' m^{-1}$, so $|p_i' - \mathbf{1}| \le 0.035 =: r$, and $X = m'm^{-1}$, $|X - \mathbf{1}| \le 0.06$ by (r1), $Y = \log X$, $|Y| \le 0.0619$. For $t \in [0,1]$ let $\varphi_i(t) = \log(p_i' e^{-tY}) + tY$; then $|p_i' e^{-tY} - \mathbf{1}| \le r + |Y| \le 0.0969 =: \Delta_0$, and by (r4) $|\dot{\varphi}_i| \le |Y|(\frac{\Delta_0}{1-\Delta_0} + \Delta_0) \le 0.2042\,|Y|$. As $\sum_i \varphi_i(1) = nY$ and $\sum_i \varphi_i(0) = \sum_i(\log p_i' - \log p_i)$, (r2) gives $n|Y| \le 0.2042\,n|Y| + \sum_i |V_i' - V_i|/(1-r)$, and $|m' - m| = |e^Y - \mathbf{1}| \le |Y| \le \frac{1}{0.7958\cdot 0.965}\cdot\frac{1}{n}\sum_i |V_i' - V_i|$, with $\frac{1}{0.7958\cdot 0.965} < 1.31$.

Step 3: the touched bonds of a contour. Let $x = y + a'\sum_\nu n_\nu e_\nu \in B(y)$. The path $\Gamma_\sigma(y,x)$ runs between the heights 0 and n_3; if $n_3 > -\mathsf{h}$ none of its bonds lies in L_{k+1}. If $n_3 = -\mathsf{h}$, the bonds of $\Gamma_\sigma(y,x)$ in L_{k+1} are the last vertical one and the horizontal ones which follow the vertical steps; their number $N_\sigma(x)$ is $1 + |n_1| + |n_2|$, $1 + |n_2|$ or $1 + |n_1|$, or 1, as the vertical direction stands first, second (behind 1, behind 2) or last in σ. Over the $|S|!$ members of $\mathcal{G}(y,x)$ the mean of $N_\sigma(x)$ is

$\bar N(x) = 1 + \frac12(|n_1| + |n_2|)$, in each of the cases $n_1 n_2 \neq 0$, exactly one of n_1, n_2 zero, $n_1 = n_2 = 0$; and $N_\sigma(x) \le 1 + 2\mathsf h = L$. By (r1), $|U'(\Gamma_\sigma) - U(\Gamma_\sigma)| \le N_\sigma(x)\delta \le L\delta \le \frac{1}{100}$, and Step 2 gives $|U'(y,x) - U(y,x)| \le 1.31\,\bar N(x)\,\delta$ if $n_3 = -\mathsf h$, and $U'(y,x) = U(y,x)$ otherwise. The straight path $[c_-, c_+]$ runs at heights ≥ 0, so $U'[c] = U[c]$. Moreover $\sum_{|n_1|,|n_2|\le \mathsf h} \bar N(x) = L^2 + \frac14 L(L^2-1)$, as $\sum_{|n|\le \mathsf h} |n| = \mathsf h(\mathsf h+1) = \frac14(L^2-1)$.

Step 4: the two kinds of bonds of $\mathsf L_k$. If c is horizontal, both its end points have the height 0, the contours at c_+ are the translates of those at c_-, and $[x,x']$ has L bonds at the height n_3; for $n_3 = -\mathsf h$, (r1) gives $|W'_x - W_x| \le (2\cdot 1.31\,\bar N(x) + L)\delta$, and $W'_x = W_x$ otherwise. So $\sum_x |W'_x - W_x| \le [2.62(L^2 + \frac14 L(L^2-1)) + L^3]\delta$. If c is vertical, c_+ has the height L and the sites of $B(c_+)$ the heights $\ge L - \mathsf h > -\mathsf h$; only the first bond of $[x,x']$, and only for $n_3 = -\mathsf h$, is touched, and the sum is at most $[1.31(L^2 + \frac14 L(L^2-1)) + L^2]\delta$, which is smaller.

Step 5: the average. With $\alpha = L^{-3}\sum_x \log W_x$ and α' the same for U', both anti-hermitian, (r2) at $r = \frac{1}{14}$ gives $|\alpha' - \alpha| \le L^{-3}\frac{14}{13}\sum_x |W'_x - W_x| \le \mathsf c_L\delta$, and (r3) gives $|(\mathcal M U')(c) - (\mathcal M U)(c)| = |(e^{\alpha'} - e^{\alpha})U[c]| \le \mathsf c_L\delta$. The derivative of $\frac{1}{L} - \frac{1}{4L^2}$ is $-L^{-2} + \frac12 L^{-3} < 0$, and $\mathsf c_{13} = \frac{14}{13}(1 + 2.62\cdot 0.32544\ldots) < 1.996 < 0.554\sqrt{13}$. □

Proposition 18.223 (Regular threads; the block fields at a plane are functions of those above it; the translation by e_3 is injective, and the Hamiltonian of the threads is set on the whole space)**.** Assume the hypotheses and signs of Proposition 18.221, with its law $\boldsymbol\nu$, its plane $c_0 \in \mathbb Z + \frac12$, its space $\mathcal H^{\rm thr}$ and $\mathsf A = \mathsf T_1$. Let $A_0 > 0$ and $\mathfrak p_0 \in \mathbb N$ be the constants of the threshold function $\varepsilon(\mathsf t) = A_0 \mathsf t^{-1/2}(\log \mathsf t)^{\mathfrak p_0}$, $\mathsf t > 1$. Let $\underline{\mathsf b}_g = g^{-2} + B_\sharp - L^{-1}\bar B$ and $\bar{\mathsf b}_g = L(g^{-2} + \bar B)$ be the end points of the outer interval $I^{\rm lab}(g)$ of labels, and put $\eta_d = 4A_0(L^d \underline{\mathsf b}_g)^{-1/2}(\log L^d \bar{\mathsf b}_g)^{\mathfrak p_0}$ for $d \ge 0$. For $Q \subset \mathbb R^3$ let $\mathfrak F(Q)$ be the σ-algebra on $\mathsf Z$ generated by the coordinates $\mathsf z_d(c')$ with $\mathrm{fp}(c') \subset Q$.

(a) *Regularity.* $\boldsymbol\nu$-almost surely, for every bounded set $Q \subset \mathbb R^3$ there is D such that $|\partial \mathsf z_d(p) - \mathbf 1| < \eta_d$ for all $d \ge D$ and all plaquettes p of $a_d\mathbb Z^3$ with their corners in Q. Moreover $\mathsf c_L^d \eta_d \to 0$ as $d \to \infty$, $\mathsf c_L$ the number of Lemma 18.222.

(b) *The germ.* Let $z \in \mathbb Z + \frac12$. Every coordinate $\mathsf z_d(c')$ with $\mathrm{fp}(c') \subset H^+_z$ coincides $\boldsymbol\nu$-almost surely with a function measurable for $\bigvee_{\delta>0} \mathfrak F(H^+_{z+\delta})$.

(c) *Injectivity.* $\mathsf A$ is injective on $\mathcal H^{\rm thr}$, so $\mathcal H^{>} = \mathcal H^{\rm thr}$. Hence $H^{\rm thr} = -\log \mathsf A$ is a densely defined nonnegative self-adjoint operator in $\mathcal H^{\rm thr}$ with $e^{-tH^{\rm thr}} = \mathsf T_t$ for $t \in \mathbb D_+$, $\mathsf T_t \to 1$ strongly as $t \to 0$, the horizontal translations form a strongly continuous unitary representation of $\mathbb R^2$ on $\mathcal H^{\rm thr}$ whose generators satisfy $H^{\rm thr} \ge |P^{\rm thr}_\lambda|$ there, and clauses (d), (e), (g) of Proposition 18.221 hold with $\mathcal H^{\rm thr}$ in the place of $\mathcal H^{>}$.

■

Proof. Step 1: the tail on one torus. Fix $\ell = 2L^m$ in $\mathfrak L(g)$ and write $\mathsf b = \mathsf b(S)$. By Lemma 18.212(c), this side admits $\mathsf b$, so $\mathsf b \ge \gamma^{-2}$ and $MR(\mathsf b) \le L^m$. For sufficiently large d and every $K > d$, take the top level $t = t_* = K - d$ in the calibrated setting of Section YM3_I:115. Its coupling is $x_t = L^d\mathsf b$ and exceeds the fixed calibration threshold for all such d. At zero source the weight $\mathfrak w^{\rm sf}_t$ in that section vanishes unless $\varpi(\mathcal M^t_\ell U) < 2\varepsilon(x_t)$, where ϖ is the largest plaquette distance from the identity. The upper domination in YM3_I:(2189) and the discarded mass estimate YM3_I:(2190), with the indicator of this event as the gauge-invariant test, give

$$\mu_{K,\ell,L^K\mathsf b}\big(\varpi(\mathcal M_\ell^{K-d}U) \ge 2\varepsilon(L^d\mathsf b)\big) \le R(d).$$

Here YM3_I:(2187) gives

$$R(d) = 2M^{-3}(\ell L^d)^3 \exp\Big[-c' A_0^2 (\log L^d\mathsf b)^{2\mathfrak p_0} + (C^{\Sigma}_{\rm maj} + 2 + C_{\rm low}(\mathsf b))\ell^3\Big]$$

with $c' > 0$. The sum of $R(d)$ over large d is finite because $2\mathfrak p_0 \ge 2$. Total-variation convergence in Lemma 18.212(a) gives this same tail bound for the depth-d marginal of the thread measure.

Step 2: the thread measure and the laws $\boldsymbol{\nu}$; (a). The depth-d marginal of $\mu_{\ell,\mathsf{b}}$ is $\mu_d[\ell,\mathsf{b}]$ (Definition 18.207); by the lemma of Borel and Cantelli, $\mu_{\ell,\mathsf{b}}$-almost surely $\varpi(V_d) < 2\varepsilon(L^d\mathsf{b})$ for all large d. Here $2\varepsilon(L^d\mathsf{b}) \le \frac12\eta_d < \eta_d$ for every $d \ge 0$: the label lies in $I^{\mathrm{lab}}(g)$ (Lemma 18.220), so $\underline{\mathsf{b}}_g \le \mathsf{b} \le \bar{\mathsf{b}}_g$, and $L^d\mathsf{b} \ge \mathsf{b} \ge \gamma^{-2} > 1$, so $(L^d\mathsf{b})^{-1/2} \le (L^d\underline{\mathsf{b}}_g)^{-1/2}$ and $0 < \log L^d\mathsf{b} \le \log L^d\bar{\mathsf{b}}_g$. So $\mu_{\ell,\mathsf{b}}$-almost surely $\varpi(V_d) < \eta_d$ for all large d. The covering map is injective on the window $\square$, so the Borel set $\mathcal{E} \subset Y$ of the y with $|\partial y_d(p) - \mathbf{1}| < \eta_d$ for all large d and all plaquettes p with corners in $\square$ has full $\mu[\ell,\mathsf{b}]$-measure. By Lemma 18.217(d), $(\varpi_o^{[0]})^{-1}\mathcal{E}$ has full $\boldsymbol{\nu}$-measure for every $o \in \mathbb{Z}^3$; a plaquette of side $a_d \le 1$ with corners in a bounded Q lies in one of finitely many cells $o + \square$, $o \in \mathbb{Z}^3$, as $\frac{\ell}{4} \ge \frac{L}{2} > 1$. Finally $\mathsf{c}_L^d\eta_d = 4A_0\underline{\mathsf{b}}_g^{-1/2}(\mathsf{c}_L/\sqrt{L})^d(\log L^d\bar{\mathsf{b}}_g)^{\mathfrak{p}_0} \to 0$, as $\mathsf{c}_L/\sqrt{L} < 0.554$ by Lemma 18.222 and the last factor is a polynomial in d.

Step 3: the substitute and the gauge, for (b). Let c' be a bond of $a_d\mathbb{Z}^3$ with $\mathrm{fp}(c') \subset H_z^+$; if both its end points have heights $\ge z + \frac32 a_d$, its footprint lies in $H^+_{z+a_d}$ and there is nothing to show; otherwise $c' \in \mathsf{L}_d$. For $m \ge d$ let $\mathsf{B}^{(m)}$ be the set of the bonds of $a_m\mathbb{Z}^3$ with both end points in $\tilde{B}^{m-d}(c'_-) \cup \tilde{B}^{m-d}(c'_+)$; on Thr, $\mathsf{z}_d(c') = (\mathcal{M}^{m-d}\mathsf{z}_m)(c')$ reads z_m on $\mathsf{B}^{(m)}$ (Lemma 18.211(b)), and $\mathsf{P}_b \subset \mathsf{B}^{(m+1)}$ for $b \in \mathsf{B}^{(m)}$. Let $\mathsf{L}_m, \mathsf{U}_m$ be the sets of Lemma 18.222 at the plane z, which lies in $a_m(\mathbb{Z} + \frac12)$ for all m. For $s > d$ let $\tilde{V}_s$ on $\mathsf{B}^{(s)}$ be z_s on U_s, $\mathbf{1}$ on the vertical bonds of L_s, and $\mathsf{z}_s(b + a_se_3)$ on a horizontal $b \in \mathsf{L}_s$ (the bond $b + a_se_3$ lies in $\mathsf{B}^{(s)} \cap \mathsf{U}_s$, the blocks having $L^{s-d} \ge 3$ layers), and $g_{s,k} = \mathcal{M}^{s-k}\tilde{V}_s$ on $\mathsf{B}^{(k)}$, $d \le k \le s$: a Borel function of z_s on U_s, so $\mathfrak{F}(H^+_{z+a_s})$-measurable. Let u be the gauge transformation of $a_s\mathbb{Z}^3$ with $u(x) = \mathsf{z}_s(\langle x, x + a_se_3\rangle)^{-1}$ at the sites x of $\mathsf{B}^{(s)}$ at the height $z + \frac12 a_s$ and $u = \mathbf{1}$ elsewhere. Then $\mathsf{z}_s^u = \mathbf{1}$ on the vertical bonds of L_s, $\mathsf{z}_s^u = \mathsf{z}_s$ on U_s, and on a horizontal $b = \langle x, x'\rangle \in \mathsf{L}_s$, $\mathsf{z}_s^u(b) = \mathsf{h}_b\,\mathsf{z}_s(b + a_se_3)$ with the holonomy h_b around the vertical plaquette p over b, a conjugate of $\partial\mathsf{z}_s(p)^{\pm1}$; so $|\mathsf{z}_s^u(b) - \tilde{V}_s(b)| = |\partial\mathsf{z}_s(p) - \mathbf{1}|$. No site at the height $z + \frac12 a_s$ lies in $a_k\mathbb{Z}^3$, $k < s$: with $z = a_k(n + \frac12)$ this height is a_sN with $2N = L^{s-k}(2n+1) + 1 \equiv 1$ modulo L^{s-k}. By the gauge covariance (Lemma 18.211(b)), $\mathcal{M}^{s-k}(\mathsf{z}_s^u) = \mathcal{M}^{s-k}\mathsf{z}_s$ on $\mathsf{B}^{(k)}$ for $k < s$. The plaquettes of $\tilde{V}_s$ are those of z_s at four bonds of U_s, equal to $\mathbf{1}$ (up to conjugation) at the vertical plaquettes of the lowest layer, and those of z_s moved up by a_se_3 at the horizontal plaquettes of the lowest layer.

Step 4: the descent. Let $k_0 > d$ with $\eta_k \le \frac12\omega_M$ for $k \ge k_0$, and let E_{k_0} be the event that $\mathsf{z}_k = \mathcal{M}\mathsf{z}_{k+1}$ on $\mathsf{B}^{(k)}$ for all $k \ge d$ and $|\partial\mathsf{z}_k(p) - \mathbf{1}| < \eta_k$ for all $k \ge k_0$ and all plaquettes p with corners in $\mathrm{fp}(c')$; by $\boldsymbol{\nu}(\mathsf{Thr}) = 1$ and (a), $\boldsymbol{\nu}(E_{k_0}) \to 1$. Let s_0 be such that $\mathsf{c}_L^{s-k_0}\eta_s \le \frac18\omega_M$ for $s \ge s_0$; as $\mathsf{c}_L \ge 1$, then $\delta_k := \mathsf{c}_L^{s-k}\eta_s \le \frac18\omega_M$ for $k_0 \le k \le s$. On E_{k_0}, for $s \ge s_0$, put $W_s = \mathsf{z}_s^u$, $W_k = \mathsf{z}_k$ for $k < s$ and $W'_k = g_{s,k}$. We show for $k = s, s-1, \dots, k_0$: $W'_k = W_k$ on $\mathsf{B}^{(k)} \cap \mathsf{U}_k$ and $|W'_k - W_k| \le \delta_k$ on $\mathsf{B}^{(k)} \cap \mathsf{L}_k$. At $k = s$ this is Step 3. From $k+1$ to k: for $b \in \mathsf{B}^{(k)}$, W_{k+1} satisfies the small-field condition on the double block of b ($\eta_{k+1} \le \frac12\omega_M$, plaquettes being conjugated by the gauge transformation); so does W'_{k+1}, by Step 3 at $k+1 = s$ and by $|\partial W'_{k+1}(p) - \mathbf{1}| < \frac12\omega_M + 4\delta_{k+1} \le \omega_M$ (r1) otherwise; $L\delta_{k+1} \le \frac{L\omega_M}{8} \le \frac{1}{100}$; $\mathcal{M}W_{k+1} = W_k$ on $\mathsf{B}^{(k)}$ by the event and Step 3, and $\mathcal{M}W'_{k+1} = W'_k$ by definition. Lemma 18.222 gives the assertion at k. At $k = k_0$: $|g_{s,k_0} - \mathsf{z}_{k_0}| \le \mathsf{c}_L^{s-k_0}\eta_s \to 0$ as $s \to \infty$, on $\mathsf{B}^{(k_0)}$.

Step 5: measurability; (b). The set C_{k_0} on which $(g_{s,k_0})_s$ converges is measurable for $\mathfrak{G}_{0+} = \bigvee_s \mathfrak{F}(H^+_{z+a_s})$; let Z_{k_0} be the limit there and $\mathbf{1}$ elsewhere, and $Y_{k_0} = (\mathcal{M}^{k_0-d}Z_{k_0})(c')$, a $\mathfrak{G}_{0+}$-measurable function, $\mathcal{M}$ being Borel. On E_{k_0}, $Z_{k_0} = \mathsf{z}_{k_0}$ on $\mathsf{B}^{(k_0)}$ and $Y_{k_0} = \mathsf{z}_d(c')$; as the E_{k_0} increase to a set of full measure, $Y_{k_0} \to \mathsf{z}_d(c')$ almost surely. No continuity of $\mathcal{M}$ off the small fields is used.

Step 6: (c). Let $\Phi \in \mathcal{A}^+$ and $\mathfrak{G}_s = \mathfrak{F}(H^+_{c_0+a_s})$, an increasing family with $\bigvee_s \mathfrak{G}_s = \bigvee_{\delta>0}\mathfrak{F}(H^+_{c_0+\delta})$. By (b) at $z = c_0$, Φ coincides almost surely with a $\bigvee_s \mathfrak{G}_s$-measurable function, and Lévy's upward theorem gives $\Phi_s = \mathbb{E}[\Phi|\mathfrak{G}_s] \to \Phi$ in $L^2(\boldsymbol{\nu})$. Each Φ_s has a bounded $\mathfrak{G}_s$-measurable representative,

whose class lies in $\mathcal{H}^{>}$, being an L^2-limit of local functions with footprints in $H^+_{c_0+a_s}$ (Proposition 18.221(c)); and $\|[\Phi_s]-[\Phi]\| \le \|\Phi_s-\Phi\|_2$. So $\mathcal{H}^{>}=\mathcal{H}^{\mathrm{thr}}$, and $\ker \mathsf{A}=\{0\}$ by the splitting of Proposition 18.221(c); the rest is that Proposition on $\mathcal{H}^{>}=\mathcal{H}^{\mathrm{thr}}$. □

Proposition 18.224 (On one lattice: the transfer operator and the plaquette actions act irreducibly on the flux-free sector)**.** Let $a>0$, $\beta>0$ and $n_1,n_2\ge 3$. The periodic layer has site set $\mathsf{X}_0=\mathbb{Z}_{n_1}\times\mathbb{Z}_{n_2}$ in lattice units and positive bond set S_0 in the two coordinate directions. Let $G=\mathrm{SU}(2)$ and $\mathcal{H}=L^2(G^{\mathsf{S}_0})$ with product Haar probability measure. The gauges $w\in G^{\mathsf{X}_0}$ act by $(w\cdot u)(b)=w(b_-)u(b)w(b_+)^{-1}$ and $R_w f(u)=f(w^{-1}\cdot u)$. Let $P=\int R_w\,dw$. Put $\mathsf{a}(g)=1-\frac12\operatorname{tr} g$, $a_p(u)=\mathsf{a}(u(\partial p))$, $V=\sum_p a_p$ and $\mathsf{E}=M_{e^{-\beta V}}$, where M_f denotes multiplication by f. The operator K has kernel

$$k_{\mathsf{S}_0}(u,u')=\prod_{b\in\mathsf{S}_0} k_\beta(u(b)u'(b)^{-1}),\qquad k_\beta(g)=e^{-\beta\mathsf{a}(g)}.$$

Let $K^{[b]}$ have kernel $k_{\mathsf{S}_0}(u,u')\mathsf{a}(u(b)u'(b)^{-1})$. The Peter–Weyl space $\mathcal{M}_{\underline{l}}$ is the tensor product of the matrix coefficient spaces of the spin l_b representations, one per bond. The finite sums of vectors in these spaces form the trigonometric polynomials $\mathcal{T}(G^{\mathsf{S}_0})$. Write $P_{\underline{l}}$ for their individual spin projections and $P^{(b)}_l=\sum_{\underline{l}:l_b=l}P_{\underline{l}}$. Let

$$\mathsf{Q}=\mathsf{E}^{1/2}KP\,\mathsf{E}^{1/2},\qquad \mathsf{Q}_b=\mathsf{E}^{1/2}K^{[b]}P\,\mathsf{E}^{1/2},$$

the transfer operator in its symmetric form and the transfer operator with one time-like plaquette over b inserted: with $C=\mathsf{E}^{1/2}PK^{1/2}$, $\mathsf{Q}=CC^*$, while the transfer operator in the opposite factorization is $\mathsf{M}=C^*C$; the kernel of Q is $e^{-\beta V(u)/2}\int k_{\mathsf{S}_0}(u,w\cdot u')\,dw\,e^{-\beta V(u')/2}$, the weight of the plaquettes between two layers integrated over the vertical variables. For $\mu\in\{1,2\}$ let ζ_μ change the sign of u on the bonds $\langle x,x+e_\mu\rangle$ with $x_\mu=n_\mu-1$, $Z_\mu\psi=\psi\circ\zeta_\mu$, and for $e\in\{0,1\}^2$ let $\mathcal{H}^e=\{\psi\in P\mathcal{H}: Z_\mu\psi=(-1)^{e_\mu}\psi,\ \mu=1,2\}$, the flux sectors; $\mathcal{H}^0=\mathcal{H}^{(0,0)}$ is the flux-free sector. For $\mathcal{K}\in\{\mathcal{H}^0,P\mathcal{H}\}$ let $\mathfrak{W}_{\mathcal{K}}$ be the von Neumann algebra on $\mathcal{K}$ generated by the restrictions of Q, of the M_{a_p} and of the Q_b.

(a) $P\mathcal{H}=\bigoplus_e\mathcal{H}^e$, and every generator maps every $\mathcal{H}^e$ into itself. $\mathsf{Q}\ge 0$ is of trace class and injective on $P\mathcal{H}$; $\|\mathsf{Q}\|$ is a simple eigenvalue, with an eigenvector Ω that is continuous and positive everywhere, and $\Omega\in\mathcal{H}^0$.

(b) $P^{(b)}_l|_{\mathcal{K}}\in\mathfrak{W}_{\mathcal{K}}$ for every $b\in\mathsf{S}_0$ and every $l\in\frac12\mathbb{N}_0$.

(c) $\mathfrak{W}_{\mathcal{H}^0}$ contains the multiplication by every bounded Borel function on G^{S_0} that is invariant under the gauge transformations and under ζ_1,ζ_2, and the projection $|1\rangle\langle 1|$; and $\mathfrak{W}_{\mathcal{H}^0}=\mathcal{B}(\mathcal{H}^0)$: the algebra is irreducible. On all the sectors, $\mathfrak{W}_{P\mathcal{H}}=\bigoplus_e\mathcal{B}(\mathcal{H}^e)$, and its commutant is spanned by the four projections onto the $\mathcal{H}^e$.

(d) The vectors $B_1B_2\cdots B_m\Omega$, $m\ge 0$, $B_i\in\{\mathsf{Q}\}\cup\{M_{a_p}\}\cup\{\mathsf{Q}_b\}$, are total in $\mathcal{H}^0$; so are already those in which no M_{a_p} stands twice between two consecutive factors of the kinds Q, Q_b, before the first or behind the last of them.

■

Proof. Step 1: the spectra of K and $K^{[b]}$. K acts on $\mathcal{M}_{\underline{l}}$ by $\lambda_{\underline{l}}=\prod_b\lambda_{l_b}(\beta)$, where $\lambda_l(\beta)=(2l+1)^{-1}\int k_\beta\chi_l$ by Schur orthogonality. By the Weyl integration formula and $\chi_l(\mathrm{diag}(e^{\mathrm{i}\omega},e^{-\mathrm{i}\omega}))=\sin((2l+1)\omega)/\sin\omega$, $\lambda_l(\beta)=e^{-\beta}\frac{2}{\beta}I_{2l+1}(\beta)$ with the modified Bessel functions I_n. Their series shows $\lambda_l(\beta)>0$ and factorial decay in l at fixed $\beta>0$. Hence $\sum_l(2l+1)^2\lambda_l(\beta)<\infty$ and $\lambda_{\underline{l}}\to 0$ as $\max_b l_b\to\infty$. The operator with the kernel $f(gg'^{-1})$, f a continuous class function on G, commutes with the left and right translations and is the number $\frac{1}{2l+1}\int f\chi_l$ on $\mathcal{M}_l$; at $f=k_\beta\mathsf{a}=-\partial_\beta k_\beta$ this number is $\lambda_l r_l$ with $r_l(\beta)=-\partial_\beta\log\lambda_l(\beta)=1+\frac1\beta-\frac{I'_{2l+1}(\beta)}{I_{2l+1}(\beta)}$. So $K^{[b]}$ is the number $\lambda_{\underline{l}}r_{l_b}$ on $\mathcal{M}_{\underline{l}}$. The map $l\mapsto r_l(\beta)$ is strictly decreasing: $\mathsf{u}_n=I'_n/I_n$ satisfies $\mathsf{u}'_n=1+\frac{n^2}{x^2}-\frac{\mathsf{u}_n}{x}-\mathsf{u}_n^2$ (from

$x^2 I_n'' + x I_n' = (x^2+n^2) I_n$) and $\mathsf{u}_n = \frac{n}{x} + O(x)$ at 0; for $m > n$ the difference $\mathsf{w} = \mathsf{u}_m - \mathsf{u}_n$ is positive near 0 and $\mathsf{w}' = \frac{m^2-n^2}{x^2} - \mathsf{w}(\frac{1}{x} + \mathsf{u}_m + \mathsf{u}_n)$, which is positive at a first zero of w, so $\mathsf{w} > 0$ on $(0,\infty)$.

Step 2: clause (a). P commutes with K since single-bond convolution by a class function commutes with left and right multiplication. The kernel of $K^{[b]}$ is the product over $b' \in \mathsf{S}_0$ of the class functions k_β, for $b' \neq b$, and $k_\beta \mathsf{a}$, for $b' = b$, of $u(b')u'(b')^{-1}$; so by Step 1 $K^{[b]}$ commutes with the left and the right translations in each factor of G^{S_0}, hence with every gauge rotation R_w, which acts through such translations, and with their mean P. The flips Z_μ also act by left multiplication by central signs on selected bonds, so they commute with K and $K^{[b]}$. Further, P commutes with E (V is gauge invariant) and with Z_μ, and $V \circ \zeta_\mu = V$, a plaquette containing two or none of the flipped bonds; the M_{a_p} commute with P and Z_μ; so the generators keep each $\mathcal{H}^e$. $K^{1/2}$ is Hilbert–Schmidt by the summability in Step 1 and the finite product over bonds, so C is, and $\mathsf{Q} = CC^* \geq 0$ is of trace class. If $\psi \in P\mathcal{H}$ and $\mathsf{Q}\psi = 0$, then $K^{1/2}\mathsf{E}^{1/2}\psi = 0$, so $\psi = 0$, K being injective and $\mathsf{E}^{1/2} > 0$. The kernel of Q is continuous and positive, so the top eigenvalue $\|\mathsf{Q}\|$ has an eigenvector $|\psi|$ whenever it has ψ ($\langle|\psi|, \mathsf{Q}|\psi|\rangle \geq \langle\psi, \mathsf{Q}\psi\rangle$), which is continuous and positive; equality forces every real eigenvector to have one sign, two orthogonal such vectors cannot exist, and the eigenvalue is simple; $R_w\Omega$ and $Z_\mu\Omega$ are positive normalised eigenvectors, hence Ω.

Step 3: clause (b). $V = \sum_p a_p$, so $e^{\pm\beta V/2}|_{\mathcal{K}}$ are norm limits of polynomials in the M_{a_p}, and $K|_{\mathcal{K}} = e^{\beta V/2}\mathsf{Q}\, e^{\beta V/2}$, $K^{[b]}|_{\mathcal{K}} = e^{\beta V/2}\mathsf{Q}_b e^{\beta V/2}$ lie in $\mathfrak{W}_{\mathcal{K}}$ ($P = 1$ on $\mathcal{K}$). Every eigenvalue $\mathsf{c} > 0$ of K is isolated and its projection $\mathsf{p}_\mathsf{c} = \sum_{\lambda_{\underline{l}}=\mathsf{c}} P_{\underline{l}}$, of finite rank, is a norm limit of polynomials in K; $\mathsf{p}_\mathsf{c} K^{[b]}$ is self-adjoint of finite rank, and the projections $\sum_{\lambda_{\underline{l}}=\mathsf{c},\ r_{l_b}=r} P_{\underline{l}}$, which are the products of p_c with the spectral projections of $\mathsf{p}_\mathsf{c} K^{[b]}$ at the points $\mathsf{c}r$, $r \in \mathbb{R}$, and so polynomial expressions in p_c and $\mathsf{p}_\mathsf{c} K^{[b]}$, lie in $\mathfrak{W}_{\mathcal{K}}$; their strong sum over c at $r = r_l$ is $P_l^{(b)}$, by the injectivity of $l \mapsto r_l$.

Step 4: Casimir and carré du champ; merging. For $b \in \mathsf{S}_0$ let L_b^α, $\alpha = 1,2,3$, be the derivatives in $u(b) \mapsto u(b)e^{tT^\alpha}$, $T^\alpha = \frac{\mathrm{i}}{2}\sigma^\alpha$, $\Delta_b = \sum_\alpha (L_b^\alpha)^2$ and $\Gamma_b(f,g) = \sum_\alpha (L_b^\alpha f)(L_b^\alpha g)$. Then Δ_b is the number $-l_b(l_b+1)$ on $\mathcal{M}_{\underline{l}}$, and $[M_f, [\Delta_b, M_g]] = -2M_{\Gamma_b(f,g)}$ on $\mathcal{T}(G^{\mathsf{S}_0})$. For a closed path γ put $W_\gamma(u) = \operatorname{tr} u(\gamma)$. If c is b or its reverse, from x to y, and A, B are paths from y to x which avoid b, then, by $\sum_\alpha \operatorname{tr}(T^\alpha M)\operatorname{tr}(T^\alpha N) = -\frac{1}{2}\operatorname{tr}(MN) + \frac{1}{4}\operatorname{tr} M \operatorname{tr} N$ and $\operatorname{tr}(xy) + \operatorname{tr}(xy^{-1}) = \operatorname{tr} x \operatorname{tr} y$ in $\mathrm{SL}_2(\mathbb{C})$,

$$W_{cAcB} = \tfrac{1}{2} W_{cA} W_{cB} - 2\Gamma_b(W_{cA}, W_{cB}), \qquad W_{AB^{-1}} = \tfrac{1}{2} W_{cA} W_{cB} + 2\Gamma_b(W_{cA}, W_{cB}).$$

The loop system. Let $\mathcal{L}_{\mathcal{K}}$ be the set of the closed paths γ of the layer with even winding numbers and $M_{W_\gamma}|_{\mathcal{K}} \in \mathfrak{W}_{\mathcal{K}}$. It holds every ∂p ($W_{\partial p} = 2 - 2a_p$); with a path it holds every equivalent one (cyclic rotations, reversal, insertion or deletion of a pair $c\bar{c}$); with $\gamma_1, \dots, \gamma_r$ every γ for which W_γ is a real polynomial in $W_{\gamma_1}, \dots, W_{\gamma_r}$ (functions even under ζ_μ stay even); and with cA, cB also $cAcB$ and AB^{-1} when A, B avoid the bond of c: put $\Delta^{(n)} = -\sum_{l \leq n} l(l+1) P_l^{(b)} \in \mathfrak{W}_{\mathcal{K}}$ (Step 3) and $\mathsf{D}_n = [M_f, [\Delta^{(n)}, M_g]] \in \mathfrak{W}_{\mathcal{K}}$, $f = W_{cA}$, $g = W_{cB}$; on a trigonometric polynomial $\psi \in \mathcal{K}$, $\mathsf{D}_n\psi = -2\Gamma_b(f,g)\psi$ for large n, and $Y \in \mathfrak{W}_{\mathcal{K}}'$ preserves the trigonometric polynomials in $\mathcal{K}$ because it commutes with every $P_l^{(b)}|_{\mathcal{K}}$. Applying the same eventual equality to ψ and $Y\psi$ in $Y\mathsf{D}_n\psi = \mathsf{D}_n Y\psi$ shows that Y commutes with $M_{\Gamma_b(f,g)}$ on a dense set, $M_{\Gamma_b(f,g)} \in \mathfrak{W}_{\mathcal{K}}'' = \mathfrak{W}_{\mathcal{K}}$, and the display gives the two new loops, whose windings are the sum and the difference of those of cA, cB.

Step 5: grids, and loops that wrap. A connected subgraph D is full if all its closed paths lie in $\mathcal{L}_{\mathcal{K}}$. (i) *Ears.* If D is full and 2-connected, $\delta_0 c \in \mathcal{L}_{\mathcal{K}}$ with a simple path δ_0 in D from x to $y \neq x$ and a simple path c from y to x outside D (no bond and no inner site in D), then every closed path of $D \cup c$ which avoids some bond lies in $\mathcal{L}_{\mathcal{K}}$: the merging of Step 4 at the bonds that a path from x to y passes once spreads $\delta c \in \mathcal{L}_{\mathcal{K}}$ to every path δ in D from x to y that avoids some bond of D (if $\delta c \in \mathcal{L}_{\mathcal{K}}$ and δ passes a bond λ once, the merging at λ of δc and of the closed path $\delta(\delta^*)^{-1}$ of D gives $\delta^* c \in \mathcal{L}_{\mathcal{K}}$ for every path δ^* in D from x to y that avoids λ; this is done at the bonds of δ_0, and at a bond λ off δ_0 with a simple path from x to y through λ, which exists because in

a 2-connected graph any two edges lie on a common cycle (add an extra edge from x to y and apply the vertex form of Menger's theorem to the midpoints of that edge and λ) and which, being simple and other than δ_0, avoids a bond of δ_0 and so has been reached), and a closed path that avoids a bond λ of D is, through a fixed path δ_λ in $D \setminus \lambda$ and $t = \delta_\lambda c$, a word in $t^{\pm 1}$ and closed paths of $D \setminus \lambda$, whose trace is a polynomial in W_α and $W_{t\alpha}$. Indeed, replace t^{-1} by $(\operatorname{tr} t)\mathbf{1} - t$. If a cyclic word has at least two occurrences of t, write it as $tAtB$ with A containing none. Then $\operatorname{tr}(tAtB) = \operatorname{tr}(tA)\operatorname{tr}(tB) - \operatorname{tr}(AB^{-1})$ by the two-factor trace identity, which reduces the number of occurrences. The resulting words with at most one t have the stated form. If $D \cup c$ has at least four independent cycles, every closed path is a word in generators y_i of which any three avoid a fourth independent bond, and all traces of words are polynomials in the traces of words of length at most three. For the latter assertion write $U_i = s_i\mathbf{1} + iv_i \cdot \varsigma$ for the fundamental holonomies. The Pauli multiplication rule expresses the trace of a word using contractions by the Kronecker symbol and the alternating three-index symbol. A pair of alternating symbols reduces to a sum of products of Kronecker symbols. Therefore the trace is a polynomial in s_i, $v_i \cdot v_j$ and $\det(v_i, v_j, v_k)$, which are determined by traces of words of length at most three. Inverses replace v_i by $-v_i$. In the graph, choose a spanning tree so that a word in at most three generators avoids a fourth non-tree bond. The available traces then give fullness. (ii) *Grids are full*: adding the plaquettes of a grid row by row adds an ear each time; it remains to initialize the induction at the first three plaquettes. One plaquette has one generator and all its traces are polynomials in its trace. Two plaquettes sharing a side have generators given by their oriented boundaries based at an endpoint of that side. Orient them oppositely on their common side. The merged boundary gives the trace of their product, and together with the individual traces this gives all traces for two generators.

For the third plaquette, choose the initial three as a line or an L, so that the middle plaquette shares distinct sides with the two outer ones. Choose a basepoint on an unused bond of the middle boundary and orient that boundary in the positive direction. Let B be its holonomy and let AB and CB be the holonomies obtained by replacing, respectively, the first and the second shared side by the remaining three sides of the corresponding outer plaquette, in the order in which the middle boundary visits the sides. The two holonomies A and C are the transported outer plaquette holonomies. The three traces and the traces of AB and CB are available by the merging rule. Merging AB and CB with their common unused bond gives $\operatorname{tr}(AB(CB)^{-1}) = \operatorname{tr}(AC^{-1})$, so the two-factor trace identity gives $\operatorname{tr}(AC)$. Both replacements together give the boundary with holonomy ACB and its trace, by merging either enlarged boundary with the remaining plaquette. To see the order, if the middle path is Ps_1Qs_2R, replacement of s_j by s'_j inserts $Ps'_1s_1^{-1}P^{-1}$ and $(Ps_1Q)s'_2s_2^{-1}(Ps_1Q)^{-1}$ in that order before B. These are A and C. Thus the single, pair and triple traces of the three generators are known. The Pauli reduction also covers this rank, and (i) applies at each later ear. So the grid $D^\flat$ of the sites (i,k), $0 \le i \le n_1 - 1$, $0 \le k \le n_2 - 1$, which holds all bonds of the layer but $h_k = \langle (n_1 - 1, k), (0, k) \rangle$ and $v_i = \langle (i, n_2 - 1), (i, 0) \rangle$, is full. (iii) *Wrapping loops*: merging twice, at $r'_k = \langle (0,k), (0,k+1) \rangle$ and at $r_k = \langle (n_1-1,k), (n_1-1,k+1) \rangle$, for $0 \le k < n_2 - 1$, starting from the plaquette with the base point $(n_1 - 1, k)$, gives $h_k\, \alpha\, h_{k+1}^{-1}\, \beta' \in \mathcal{L}_\mathcal{K}$ for all paths α of $D^\flat$ from $(0,k)$ to $(0,k+1)$ avoiding r_k, r'_k and β' from $(n_1-1,k+1)$ to (n_1-1,k) avoiding r_k; the same in the other direction. Let $\mathcal{L}_*$ be the set of these paths and of the closed paths of $D^\flat$.

Step 6: separation of orbits. For two adjacent plaquettes p, p' of $D^\flat$ based at a common corner z, set $\mathsf{h}_{p,p'} = 2 - W_{[\partial_z p, \partial_z p']} \ge 0$ and $\mathsf{h} = \prod_{p,p'} \mathsf{h}_{p,p'}$. The zero set of each factor is Haar null. Conditional on all bonds except one exclusive bond of each plaquette, the two holonomies are independent Haar variables. A noncentral SU(2) matrix has a circle centralizer, which is Haar null, and the two central elements also have Haar measure zero.

Suppose $\mathsf{h}(u) > 0$ and u, u' have the same traces for $\mathcal{L}_*$. Based holonomies in the grid span $M_2(\mathbb{C})$. In fact, for two noncommuting holonomies the traceless vectors in their Pauli coordinates are independent and their cross product provides the third direction through their product. The

equality of traces also gives equality of all Gram matrices $\operatorname{tr}(u(\gamma_i)^* u(\gamma_j))$. Thus $u(\gamma) \mapsto u'(\gamma)$ extends to a well-defined unital $*$-homomorphism of $M_2(\mathbb{C})$, because concatenation and reversal give products and adjoints. It is inner, and after its conjugation and tree gauges the two configurations agree on all grid bonds.

For fixed k, the grid with r_k, r'_k removed is connected. All horizontal edges are intact and an interior column of vertical edges is intact. It also contains a row of adjacent plaquettes at a different height, since $n_1, n_2 \geq 3$. At $\mathsf{h}(u) > 0$, their transported holonomies from any fixed site in that graph span $M_2(\mathbb{C})$ together with the identity and their product. Appending one fixed connecting path shows that the values of the paths α in Step 5(iii) span $M_2(\mathbb{C})$, and likewise for β', whose allowed paths include those in this same graph. Therefore equality of the wrapping-loop traces gives $\operatorname{tr}(XM_1YM_2) = \operatorname{tr}(X'M_1Y'M_2)$ for every $M_1, M_2 \in M_2(\mathbb{C})$, where X, Y are the values of h_k, h_{k+1}^{-1} and the primes correspond to u'. The nondegenerate trace pairing gives $XM_1Y = X'M_1Y'$. Taking $M_1 = \mathbf{1}$ then shows that $X^{-1}X'$ commutes with every M_1, so $X' = sX$ and $Y' = s^{-1}Y$, with $s = \pm 1$ by the determinant. The comparisons of consecutive k give one sign for all the horizontal wrapping bonds. The vertical comparisons give one sign for the vertical wrapping bonds. These signs are precisely the flips ζ_1, ζ_2. On the exceptional set, for example, commuting constant diagonal holonomies can have all contractible traces equal to 2 while differing in their wrapping holonomies.

Step 7: clause (c). By Step 5, $M_f|_{\mathcal{K}} \in \mathfrak{W}_{\mathcal{K}}$ for f in the real algebra $\mathcal{A}$ generated by 1 and the W_γ, $\gamma \in \mathcal{L}_*$, and for f in its uniform closure; $\mathsf{h} \in \mathcal{A}$. On the compact orbit space Ξ of the group generated by the gauge transformations and ζ_1, ζ_2, Stone–Weierstrass makes the closure of $\mathcal{A}$ the set of the continuous functions constant on the classes of points that $\mathcal{A}$ does not part; for continuous invariant F and continuous $\phi \geq 0$ vanishing near 0, $F\phi(\mathsf{h})$ is such a function, by Step 6, and $M_{F\phi_n(\mathsf{h})} \to M_F$ strongly as $\phi_n \uparrow \mathbf{1}_{(0,\infty)}$, $\{\mathsf{h} = 0\}$ being null. So $M_F|_{\mathcal{K}} \in \mathfrak{W}_{\mathcal{K}}$ for continuous, hence for bounded Borel, invariant F. $P_{\underline{0}} = \prod_b P_0^{(b)} = |1\rangle\langle 1| \in \mathfrak{W}_{\mathcal{K}}$ by Step 3. For $Y \in \mathfrak{W}'_{\mathcal{H}^0}$: $Y1 = YP_{\underline{0}}1 = \mathsf{c}1$ and $YF = YM_F1 = \mathsf{c}F$ for the invariant F, which are dense in $\mathcal{H}^0$; so $Y = \mathsf{c}$. On a sector $e \neq 0$ the simple closed path γ_e with the windings e and the spins $\frac{1}{2}$ on its bonds give $P_{\underline{e}} P\mathcal{H} = \mathbb{C}W_{\gamma_e}$ (Schur), a projection in $\mathfrak{W}_{P\mathcal{H}}$, and $W_{\gamma_e} \neq 0$ almost everywhere makes $\mathfrak{W}_{P\mathcal{H}} W_{\gamma_e}$ dense in $\mathcal{H}^e$; the same argument gives $Y = \mathsf{c}_e$ on $\mathcal{H}^e$ for Y in the commutant.

Step 8: clause (d). The polynomials without constant term in the self-adjoint generators form a non-degenerate $*$-algebra (Q has dense range in $\mathcal{H}^0$); the closure of its orbit of Ω together with $\mathbb{C}\Omega$ is invariant, so its projection lies in $\mathfrak{W}'_{\mathcal{H}^0} = \mathbb{C}$ and is 1. For the second form, the closed span $\mathcal{K}_1$ of the named vectors is invariant under Q, the Q_b and the $M_{a_p}\mathsf{Q}$; as $\mathsf{Q}|_{\mathcal{K}_1}$ is self-adjoint and injective, $\mathsf{Q}\mathcal{K}_1$ is dense in $\mathcal{K}_1$, and the bounded M_{a_p} keep $\mathcal{K}_1$; so $\mathcal{K}_1$ reduces $\mathfrak{W}_{\mathcal{H}^0}$ and contains Ω. □

Definition 18.225 (Two lists of axioms and one relation)**.** Let n, m run through $\mathbb{Z}_+ = \{0, 1, 2, \dots\}$. In this definition a point of $\mathbb{R}^3$ is written $x = (\vec{x}, x^0)$, with $\vec{x} = (x_1, x_2)$ and $x^0 = x_3$, the Euclidean time; on Minkowski space write $a \cdot p = a^0 p^0 - \vec{a} \cdot \vec{p}$, $e_0 = (1, 0, 0)$ and $V_+ = \{(t, \vec{x}) : t > |\vec{x}|\}$. The group $\mathrm{O}(1, 2)$ preserves this bilinear form, and $\mathcal{L}$ is its identity component.

(1) *List OS.* (N1) $\mathscr{S}(\mathbb{R}^{3n})$ is the space of the smooth f with $\sup_x |x^\beta D^\alpha f(x)| < \infty$ for all multi-indices, with the norms $|f|_m = \sup\{(1 + |x|^2)^{m/2} |D^\alpha f(x)| : x \in \mathbb{R}^{3n}, |\alpha| \leq m\}$ and the topology they define. (N2) ${}^0\mathscr{S}(\mathbb{R}^{3n})$ is the space of the $f \in \mathscr{S}(\mathbb{R}^{3n})$ which vanish with all their derivatives on every hyperplane $x_i - x_j = 0$, $i < j$, and ${}^0\mathscr{S}'$ its dual. (N3) $\mathscr{S}_+(\mathbb{R}^{3n})$ is the space of the $f \in \mathscr{S}(\mathbb{R}^{3n})$ with $D^\alpha f(x) = 0$ for all α unless $0 < x_1^0 < \cdots < x_n^0$, and $\underline{\mathscr{S}}_+$ the space of the finite sequences $\underline{f} = (f_0, f_1, \dots)$, $f_0 \in \mathbb{C}$, $f_n \in \mathscr{S}_+(\mathbb{R}^{3n})$. (N4) $f^*(x_1, \dots, x_n) = \overline{f(x_n, \dots, x_1)}$, the order reversed; $\vartheta(\vec{x}, x^0) = (\vec{x}, -x^0)$; $(\Theta f)(x_1, \dots, x_n) = f(\vartheta x_1, \dots, \vartheta x_n)$; $(f \times g)(x_1, \dots, x_{n+m}) = f(x_1, \dots, x_n)\, g(x_{n+1}, \dots, x_{n+m})$; $f_{(a,R)}(x_1, \dots, x_n) = f(Rx_1 + a, \dots, Rx_n + a)$; $f^\pi(x_1, \dots, x_n) = f(x_{\pi(1)}, \dots, x_{\pi(n)})$. A sequence $(\mathfrak{S}_n)_{n \geq 0}$ satisfies: (OS-E0) if $\mathfrak{S}_0 = 1$, $\mathfrak{S}_n \in {}^0\mathscr{S}'(\mathbb{R}^{3n})$ and $\overline{\mathfrak{S}_n(f)} = \mathfrak{S}_n(\Theta f^*)$; (OS-E0′) if $\mathfrak{S}_0 = 1$, $\mathfrak{S}_n \in {}^0\mathscr{S}'(\mathbb{R}^{3n})$, and there are $s \in \mathbb{Z}_+$ and numbers $\sigma_n \leq \alpha(n!)^\beta$ with constants α, β such that $|\mathfrak{S}_n(f)| \leq \sigma_n |f|_{ns}$

for all $n \geq 1$; (OS-E1) if $\mathfrak{S}_n(f) = \mathfrak{S}_n(f_{(a,R)})$ for all $R \in \mathrm{SO}(3)$, $a \in \mathbb{R}^3$; (OS-E2) if $\sum_{n,m} \mathfrak{S}_{n+m}(\Theta f_n^* \times f_m) \geq 0$ for all $\underline{f} \in \underline{\mathscr{S}}_+$; (OS-E3) if $\mathfrak{S}_n(f) = \mathfrak{S}_n(f^\pi)$ for all permutations π; (OS-E4) if $\lim_{\lambda\to\infty} \sum_{n,m} [\mathfrak{S}_{n+m}(\Theta f_n^* \times (g_m)_{(\lambda a,1)}) - \mathfrak{S}_n(\Theta f_n^*)\, \mathfrak{S}_m(g_m)] = 0$ for all $\underline{f}, \underline{g} \in \underline{\mathscr{S}}_+$ and $a = (\vec{a}, 0)$, $\vec{a} \neq 0$. List OS consists of these six conditions.

(2) *List GW.* $L_+^\uparrow = \{\Lambda \in \mathrm{O}(1,2) : \det \Lambda = 1,\ \Lambda^0{}_0 \geq 1\}$ and $\mathcal{P}_+^\uparrow = \mathbb{R}^{1+2} \rtimes L_+^\uparrow$ with $(a,\Lambda)(a',\Lambda') = (a + \Lambda a', \Lambda\Lambda')$. A quadruple $(\mathcal{H}, U, \varphi, D)$ satisfies: (GW1) if $\mathcal{H}$ is a separable Hilbert space and U a strongly continuous unitary representation of $\mathcal{P}_+^\uparrow$ on it; (GW2) if the projection-valued measure E with $U(a,1) = \int e^{ia\cdot p} dE(p)$ has its support in $\overline{V_+}$; (GW3) if some unit vector ψ_0 satisfies $U(a,1)\psi_0 = \psi_0$ for all a, and every unit vector with this property is a constant multiple of ψ_0; (GW4) if D is a dense subspace and φ maps $\mathscr{S}(\mathbb{R}^{1+2})$ to operators with $D \subset \operatorname{dom}\varphi(f) \cap \operatorname{dom}\varphi(f)^*$, $\varphi(f)^*|_D = \varphi(\bar{f})|_D$, $\psi_0 \in D$, $\varphi(f)D \subset D$, and $f \mapsto \varphi(f)\psi$ linear for $\psi \in D$; (GW5) if $f \mapsto \langle \psi_1, \varphi(f)\psi_2\rangle$ is a tempered distribution for $\psi_1, \psi_2 \in D$; (GW6) if $U(a,\Lambda)D \subset D$ and $U(a,\Lambda)\varphi(f)U(a,\Lambda)^{-1}\psi = \varphi(f(\Lambda^{-1}(\cdot - a)))\psi$ for $\psi \in D$; (GW7) if $[\varphi(f)\varphi(g) - \varphi(g)\varphi(f)]\psi = 0$ for $\psi \in D$ whenever the closed supports of f and g are spacelike separated; (GW8) if the set D_0 of the vectors $P\psi_0$, P a polynomial in the $\varphi(f)$ with constants, is dense. List GW consists of these eight conditions. The variants are: (GW-i) U a continuous unitary representation of a topological group $\tilde{\mathcal{P}}$ given with a continuous homomorphism onto $\mathcal{P}_+^\uparrow$; (GW-ii) a unit vector Ψ_0 invariant under all $U(a,\Lambda)$, unique up to a phase among the unit vectors invariant under all $U(a,\Lambda)$.

(3) *Scalar Wightman quintuples.* A quintuple $(\mathcal{H}, U, \Omega, D, \Phi)$ has a separable Hilbert space, a strongly continuous unitary representation of $\mathbb{R}^{1+2} \rtimes \mathcal{L}$, a unit vector Ω in a dense subspace D, and a field $f \mapsto \Phi(f)$ linear on Schwartz tests with common domain D. Its conditions are as follows.

- (W1) The translation spectrum is in $\overline{V_+}$ and Ω is invariant under the representation. Every translation-invariant vector belongs to $\mathbb{C}\Omega$.
- (W2) The field operators and the representation preserve D. Matrix elements of the field on D are tempered and satisfy $\langle \psi, \Phi(f)\psi'\rangle = \langle \Phi(\bar{f})\psi, \psi'\rangle$.
- (W3) The field obeys the covariance identity of (GW6).
- (W4) The commutativity of (GW7) holds on D.
- (W5) The span D_0 of Ω and the vectors $\Phi(f_1)\cdots\Phi(f_n)\Omega$ is dense.

A scalar Wightman theory satisfies (W1)–(W5). A quintuple with a possibly nonunique vacuum satisfies the same conditions with only the last sentence of (W1) omitted. The vacuum forms of either are $\mathcal{W}_n(f_1,\dots,f_n) = \langle \Omega, \Phi(f_1)\cdots\Phi(f_n)\Omega\rangle$.

(4) *The relation (Sch).* Take one of these quintuples. For $n \geq 2$ let $\mathfrak{T}_{n-1} = \{(\zeta_1,\dots,\zeta_{n-1}) : \zeta_k \in \mathbb{R}^{1+2} + iV_+\}$. A family $(W_{n-1})_{n\geq 2}$ of holomorphic functions on the $\mathfrak{T}_{n-1}$ has the forms as its boundary values in the weak sense if $\lim_{\epsilon\downarrow 0} \int \prod_k f_k(x_k)\, W_{n-1}(x_2 - x_1 + i\epsilon e_0, \dots, x_n - x_{n-1} + i\epsilon e_0)\, dx = \mathcal{W}_n(f_1,\dots,f_n)$ for all $n \geq 2$ and $f_k \in C_c^\infty(\mathbb{R}^{1+2};\mathbb{C})$; such a family is called a family of the quintuple in the weak sense. The family has the forms as its boundary values in the strong sense when for each $n \geq 2$ one can find a tempered distribution $\mathcal{W}_n^\sim$ on $\mathbb{R}^{3n}$ such that $\mathcal{W}_n^\sim(f_1 \otimes \cdots \otimes f_n) = \mathcal{W}_n(f_1,\dots,f_n)$ for $f_k \in \mathcal{S}$ and such that, for each $F \in \mathcal{S}(\mathbb{R}^{3n})$, the integrals $I_F(\eta) = \int F(x)\, W_{n-1}(x_2 - x_1 + i\eta_1, \dots, x_n - x_{n-1} + i\eta_{n-1})\, dx$, $\eta = (\eta_1,\dots,\eta_{n-1}) \in V_+^{n-1}$, are absolutely convergent with the limit $\mathcal{W}_n^\sim(F)$ as $\eta \to 0$ in V_+^{n-1}. The choice $F = f_1 \otimes \cdots \otimes f_n$, $\eta_k = \epsilon e_0$ shows that the strong sense implies the weak sense. For a quintuple with a family in the weak sense its Schwinger functions in the sense (Sch) are: $\mathfrak{S}_1$, the number with $\mathcal{W}_1(f) = \mathfrak{S}_1 \int f$ for $f \in \mathcal{S}$, which exists because $\mathcal{W}_1$ is a tempered distribution invariant under all translations ((W1)–(W3)); at the time-ordered points $y = (y_1,\dots,y_n)$, $y_1^0 < \cdots < y_n^0$, $\mathfrak{S}_n(y) = W_{n-1}(\zeta_1,\dots,\zeta_{n-1})$ with $\zeta_k = (i(y_{k+1}^0 - y_k^0), \vec{y}_{k+1} - \vec{y}_k)$; and on $(\mathbb{R}^3)^n_{\neq}$ the continuous function which is symmetric in its arguments and has these values, where there is one.

■

Proposition 18.226 (A dictionary between the axioms of the main text and Lists OS and GW)**.** Write $\mathcal{S}_{\neq} = {}^{0}\mathscr{S}$. The larger positive-time space $\mathcal{S}_+$ consists of Schwartz functions flat outside $V_+^{(n)} = \{x_i^0 > 0 \text{ for all } i,\ x_i \neq x_j \text{ for } i \neq j\}$. In degree zero all these spaces are $\mathbb{C}$. The operations Θ, conjugation and permutation are those of List OS, and $\otimes$ is its product on successive groups of variables. We use (E0′)–(E4) in the form of Proposition YM3_I:111.2: the bound with $|\cdot|_{k_{\mathrm{E}}n}$ and constants $\mathsf{c}_{\mathrm{E}}\mathsf{C}_{\mathrm{E}}^n(n!)^{\varkappa_{\mathrm{E}}}$, invariance under all Euclidean isometries, reflection positivity on the larger spaces, permutation symmetry, and clustering under nonzero translations parallel to the reflection plane. Data (Rec) are the scalar reconstruction data of Section YM3_I:108, with point bound YM3_I:(2049). Write $d_\circ(\mathfrak{z}) = \operatorname{Re}\mathfrak{z}_3 - |\operatorname{Im}\vec{\mathfrak{z}}|$, $\mathsf{Tb}_\circ = \{d_\circ > 0\}$, and $\iota(t,\vec{x}) = (\vec{x}, -it)$.

The Euclidean-variable Schwinger relation uses a constant W_1 and holomorphic functions W_n on $\mathsf{Tb}_\circ^{n-1}$ for $n \geq 2$. They have polynomial growth where the spatial coordinates are real and all real time coordinates are bounded below by a fixed $\epsilon > 0$. Their boundary integrals at consecutive differences $\iota(x_{k+1} - x_k) + \epsilon e_3$ converge to the vacuum forms on Schwartz tensors (S1). At real consecutive differences $y_{k+1} - y_k$ they give the separated-tuple functional by integration on smooth tests with time-ordered supports (S2). The degree-one versions are $\mathcal{W}_1(f) = \mathsf{W}_1 \int f$ and $\sigma(f) = \mathsf{W}_1 \int f$. This is the relation used in Theorem YM3_I:AO.

(a) *The Euclidean side.* Let $(\mathsf{S}_n)_{n\geq 0}$ be complex linear functionals $\mathsf{S}_n \colon \mathcal{S}_{\neq}(\mathbb{R}^{3n}) \to \mathbb{C}$ with $\mathsf{S}_0(z) = z$.

(a1) $\mathscr{S}(\mathbb{R}^{3n})$ is the space of the Schwartz functions of the flat-space convention above, with the same norms $|\cdot|_m$; ${}^{0}\mathscr{S}(\mathbb{R}^{3n}) = \mathcal{S}_{\neq}(\mathbb{R}^{3n})$; and $\mathscr{S}_+(\mathbb{R}^{3n}) \subset \mathcal{S}_+(\mathbb{R}^{3n})$, with equality for $n = 1$ and a proper inclusion for every $n \geq 2$.

(a2) (E0′) with the constants $(k_{\mathrm{E}}, \mathsf{c}_{\mathrm{E}}, \mathsf{C}_{\mathrm{E}}, \varkappa_{\mathrm{E}})$ gives (OS-E0′) with $s = k_{\mathrm{E}}$, $\sigma_n = \mathsf{c}_{\mathrm{E}}\mathsf{C}_{\mathrm{E}}^n(n!)^{\varkappa_{\mathrm{E}}}$, $\alpha = \mathsf{c}_{\mathrm{E}}e^{\mathsf{C}_{\mathrm{E}}}$, $\beta = \varkappa_{\mathrm{E}} + 1$; conversely (OS-E0′) with (s, α, β) gives (E0′) with $(\max\{s,1\}, \alpha, 1, \max\{\beta, 0\})$. The two conditions are equivalent.

(a3) (E1) gives (OS-E1); (E1) is asked for the isometries with $\det \mathsf{r}^\circ = -1$ as well.

(a4) (E2) and (E3) give (OS-E2); (E2) is asked on the larger spaces $\mathcal{S}_+$.

(a5) (E3) is (OS-E3).

(a6) (E4) and (E3) give (OS-E4); (E4) is asked on the larger spaces $\mathcal{S}_+$.

(a7) (E0′), (E1), (E2) give $\mathsf{S}_n(\Theta\bar{\varphi}) = \overline{\mathsf{S}_n(\varphi)}$ for all $\varphi \in \mathcal{S}_{\neq}(\mathbb{R}^{3n})$; with (E3) this is the last member of (OS-E0); with (E1) at the reflection θ, $\mathsf{S}_n(\bar{\varphi}) = \overline{\mathsf{S}_n(\varphi)}$.

(a8) A sequence which satisfies (E0′)–(E4) satisfies all of List OS, and one which satisfies (E0′)–(E3) satisfies all of List OS through the symmetry requirement (OS-E3).

(a9) Let $\underline{C}$ be a bound table, $\bar{\mathfrak{c}} \geq 0$, let $\sigma \in \mathsf{Fct}(\underline{C}, \bar{\mathfrak{c}})$ have the growth, invariance, reflection positivity and clustering hypotheses of Proposition YM3_I:111.2, and let σ also be data (Rec). Then the classes of the sequences of $\underline{\mathscr{S}}_+$ are dense in the completion $\mathcal{H}^{\mathcal{S}}$ of finite sequences in the larger spaces modulo the null vectors of the reflection form, which the unitary map V of the reflection-space identification of Proposition YM3_I:111.2 identifies with $\mathcal{H}(\sigma)$: the larger test spaces add no vector.

(b) *The Minkowski side.*

(b1) $\mathcal{L} = L_+^\uparrow$, so $\mathbb{R}^{1+2} \rtimes \mathcal{L} = \mathcal{P}_+^\uparrow$.

(b2) A Wightman theory $(\mathcal{H}, U, \Omega, D, \Phi)$ as defined above satisfies (GW1)–(GW8) with $\varphi = \Phi$ and $\psi_0 = \Omega$. Conversely, if $(\mathcal{H}, U, \varphi, D)$ satisfies (GW1)–(GW8), then $(\mathcal{H}, U, \psi_0, D, \Phi)$ with $\Phi(f) = \varphi(f)|_D$ is a Wightman theory, and $U(a,\Lambda)\psi_0 = \psi_0$ for all $(a,\Lambda) \in \mathcal{P}_+^\uparrow$. A Wightman theory has the variants (GW-i) and (GW-ii).

(b3) *The two forms of the Schwinger relation.* Let a Wightman theory and a functional σ on separated tuples over $\mathbb{R}^3$ be given, let $\mathsf{W}_1 \in \mathbb{C}$, and for $n \geq 2$ let W_n be a function on $\mathsf{Tb}_\circ^{n-1}$ and $W_{n-1} = \mathsf{W}_n \circ (\iota \times \cdots \times \iota)$. The number W_1 and the functions W_n have the Euclidean-variable growth and boundary properties (S1), (S2), so that

the Schwinger functions of the theory are those of σ, if and only if the following hold: $\mathcal{W}_1(f) = \mathsf{W}_1 \int f$ for $f \in \mathcal{S}$, and $\sigma(f) = \mathsf{W}_1 \int f$ for real $f \in C_c^\infty(\mathbb{R}^3)$; each W_{n-1} is holomorphic on $\mathfrak{T}_{n-1}$ and, for each $\epsilon > 0$, bounded by a polynomial in $\sum_k |\zeta_k|$ on the set of the points with $\operatorname{Im} \zeta_k \in [\epsilon, \infty) e_0$ for all k; $\mathcal{W}_n(f_1, \dots, f_n) = \lim_{\epsilon \downarrow 0} \int \prod_k f_k(x_k)\, W_{n-1}(x_2 - x_1 + i\epsilon e_0, \dots, x_n - x_{n-1} + i\epsilon e_0)\, dx$ for all $f_k \in \mathcal{S}$; and σ has, on the smooth separated tuples with supports ordered in the third coordinate, the continuous kernel $y \mapsto W_{n-1}(\zeta(y))$ of (Sch), the third coordinate being the Euclidean time. Then $(W_{n-1})_{n \geq 2}$ is a family of the theory in the weak sense, and $\mathfrak{S}_1 = \mathsf{W}_1$.

(b4) *A holomorphic function is fixed by its boundary value.* Fix $n \geq 2$ and a holomorphic function D on $\mathfrak{T}_{n-1}$ such that $\lim_{\epsilon \downarrow 0} \int \prod_k f_k(x_k)\, \mathsf{D}(x_2 - x_1 + i\epsilon e_0, \dots, x_n - x_{n-1} + i\epsilon e_0)\, dx = 0$ whenever $f_1, \dots, f_n \in C_c^\infty(\mathbb{R}^{1+2})$ are real. Then $\mathsf{D} = 0$; the hypotheses impose no bound on D. Consequently a quintuple as in (Sch) possesses at most one family in the weak sense, hence at most one in the strong sense; any two continuous symmetric functions on $(\mathbb{R}^3)^n_{\neq}$ with the same values at the time-ordered points coincide; and the quintuple's Schwinger functions in the sense (Sch) are well defined.

(b5) *One theory.* Let two Wightman theories be given, each with a family in the weak sense, whose Schwinger functions agree at the time-ordered points: $\mathcal{W}_1 = \mathcal{W}'_1$ and $W_{n-1} = W'_{n-1}$ at all points with $\zeta_k = (is_k, \vec{\xi}_k)$, $s_k > 0$, $\vec{\xi}_k \in \mathbb{R}^2$. Then $W_{n-1} = W'_{n-1}$ on $\mathfrak{T}_{n-1}$, $\mathcal{W}_n = \mathcal{W}'_n$ on $\mathcal{S}^n$, and there is exactly one unitary $\mathsf{V} \colon \mathcal{H} \to \mathcal{H}'$ with $\mathsf{V}\Omega = \Omega'$ and $\mathsf{V}\Phi(f)\psi = \Phi'(f)\mathsf{V}\psi$ for $\psi \in D_0$; it maps D_0 onto D'_0 and $\mathsf{V}U(a, \Lambda) = U'(a, \Lambda)\mathsf{V}$. In particular two Wightman theories whose Schwinger functions are those of one functional σ are unitarily equivalent in this sense.

(b6) *Locality at touching supports.* Let a Wightman theory have the property (T): for every n there is a tempered distribution $\mathcal{W}_n^\sim$ on $\mathbb{R}^{3n}$ with $\mathcal{W}_n^\sim(f_1 \otimes \cdots \otimes f_n) = \mathcal{W}_n(f_1, \dots, f_n)$ for $f_k \in \mathcal{S}$. Then $\Phi(f)\Phi(h)\psi = \Phi(h)\Phi(f)\psi$ for every $\psi \in D_0$, the span of (W5), whenever $f, h \in \mathcal{S}$ and $f(x)h(y) = 0$ for all $x, y \in \mathbb{R}^{1+2}$ with $(x - y) \cdot (x - y) \geq 0$. The quintuple of Theorem YM3_I:AO has (T), with $\mathcal{W}_n^\sim = \mathcal{W}_n^\sigma$, and its domain $\mathcal{D}_0$ is the polynomial span in (W5).

(b7) *The strong sense for data (Rec).* Let σ be data (Rec) with the numbers $C_\wp, \wp, c_0$, and let $(\mathcal{H}(\sigma), U, \Omega, \mathcal{D}_0, \phi)$ be the quintuple of Theorem YM3_I:AO: a Wightman theory if (Rec5) holds, and otherwise a quintuple as in (Sch). For $n \geq 2$ put $N = \lceil \wp n \rceil + 1$, $\bar{k} = N + 4n$ and $c_n = 2^N (N+1)\, C_\wp^n\, (n(n+1))^N \pi^{2n}$. Then the functions $W_{n-1} = \mathbf{W}_n \circ (\iota \times \cdots \times \iota)$ have the forms of the quintuple as their boundary values in the strong sense, with $\mathcal{W}_n^\sim = \mathcal{W}_n^\sigma$, and $|I_F(\eta)| \leq c_n |F|_{\bar{k}}$ for all $F \in \mathcal{S}(\mathbb{R}^{3n})$ and all $\eta \in V_+^{n-1}$. Its Schwinger functions in the sense (Sch) are $\mathfrak{S}_1 = \mathbf{W}_1$ and, on all of $(\mathbb{R}^3)^n_{\neq}$, $\mathfrak{S}_n = \mathsf{s}_n$, the kernel of Proposition YM3_I:108.3: $\sigma(f_1, \dots, f_n) = \int \mathfrak{S}_n(y) \prod_k f_k(y_k)\, dy$ for all separated tuples $(f_1, \dots, f_n)$ over $\mathbb{R}^3$.

(b8) *Reflections of space.* Let σ be data (Rec) with (Rec5), let $\mathsf{R} \in \mathrm{O}(2)$ and $P(t, \vec{x}) = (t, \mathsf{R}\vec{x})$. Then $P\mathcal{L}P^{-1} = \mathcal{L}$, and there is exactly one unitary operator V_R of $\mathcal{H}(\sigma)$ with $\mathsf{V}_\mathsf{R}\Omega = \Omega$ and $\mathsf{V}_\mathsf{R}\, \phi(f)\psi = \phi(f \circ P^{-1})\, \mathsf{V}_\mathsf{R}\psi$ for all $f \in \mathcal{S}$ and $\psi \in \mathcal{D}_0$; it satisfies $\mathsf{V}_\mathsf{R}\, U(a, \Lambda) = U(Pa, P\Lambda P^{-1})\, \mathsf{V}_\mathsf{R}$. So the isometries with $\det \mathsf{r}^\circ = -1$ of (a3) have a counterpart on the Minkowski side, which neither (W1)–(W5) nor List GW asks.

(c) *For the limits of the main theorems.* Let $0 < g \leq \gamma$, let S be a per-limit at g with a canonical decomposition $(\mathsf{X}, \lambda, (\sigma_\xi)_{\xi \in \mathsf{X}})$ (Theorems YM3_I:AP and YM3_I:AL), and let $\xi \in \mathsf{X}$.

(c1) The Schwinger functions of σ_ξ satisfy (E0′)–(E4) and all of List OS. (OS-E0′) holds with $s = 10$, $\sigma_n = (\mathsf{C}_\mathrm{E}^g)^n (n!)^{\varkappa_\star + 9}$, $\alpha = e^{\mathsf{C}_\mathrm{E}^g}$, $\beta = \varkappa_\star + 10$, and also with $s = 8$, $\sigma_n = 2(\mathsf{C}_\mathrm{E}^{\mathrm{pt},g})^n (n!)^8$, $\alpha = 2e^{\mathsf{C}_\mathrm{E}^{\mathrm{pt},g}}$, $\beta = 9$, where $\mathsf{C}_\mathrm{E}^{\mathrm{pt},g}$ is the point-kernel growth constant of Theorem YM3_I:AP, $\mathsf{C}_\mathrm{E}^g = 2\mathsf{C}_\mathrm{E}^{\mathrm{pt},g}$, and $\varkappa_\star \geq 0$ is arbitrary; these numbers are the same for every per-limit at g, every canonical decomposition and every ξ. The limit

of (E4) holds along every $v \in \mathbb{R}^3$ with $v_3 \geq 0$ and $v \neq 0$, the time direction e_3 among them.

(c2) The Schwinger functions of σ_S satisfy (E0′)–(E3), and so all of List OS through the symmetry requirement (OS-E3). σ_S is data (Rec) with the numbers $C^g_\wp, 4, \frac{1}{2}$, and the quintuple $(\mathcal{H}(S), U, \Omega, \mathcal{D}_0, \phi)$ of Theorem YM3_I:AO formed for σ_S satisfies (GW1), (GW2), (GW4)–(GW8) with $\psi_0 = \Omega$, and the existence of the vector in (GW3). The following five conditions are equivalent: (i) X is one point; (ii) the Schwinger functions of σ_S satisfy (E4); (iii) they satisfy (OS-E4); (iv) $\ker H = \mathbb{C}\Omega$ in $\mathcal{H}(S)$; (v) the uniqueness of (GW3) holds for that quintuple.

(c3) The quintuple $(\mathcal{H}(\sigma_\xi), U, \Omega, \mathcal{D}_0, \phi)$ of Theorem YM3_I:AO satisfies (GW1)–(GW8) with $\psi_0 = \Omega$, the variants (GW-i), (GW-ii), and the locality of (b6). Its Wightman forms are the tempered distributions $\mathcal{W}_n^{\sigma_\xi}$ at the tensors, and the functions $\mathbf{W}_n \circ (\iota \times \cdots \times \iota)$ have them as their boundary values in the strong sense, with the bound of (b7). Its Schwinger functions in the sense (Sch) are the kernels of σ_ξ: $\mathfrak{S}_1 = \mathfrak{c}_\xi$, and $\sigma_\xi(f_1, \dots, f_n) = \int \mathfrak{S}_n(y) \prod_k f_k(y_k)\, dy$ for all $n \geq 2$ and all separated tuples $(f_1, \dots, f_n)$ over $\mathbb{R}^3$. Every Wightman theory with a family in the weak sense whose Schwinger functions agree with these at the time-ordered points, and every Wightman theory whose Schwinger functions are those of σ_ξ in the sense in the Euclidean variables, is unitarily equivalent to it in the sense of (b5). The reflections of space are implemented on $\mathcal{H}(\sigma_\xi)$ as in (b8).

(c4) List OS builds a Hilbert space out of the Schwinger functions of σ_ξ, namely the quotient of $\underline{\mathscr{S}}_+$ by the space of null vectors of the form of (OS-E2), completed; there is a unitary map of this Hilbert space onto $\mathcal{H}(\sigma_\xi)$ which sends the class of $(1, 0, 0, \dots)$ to Ω.

■

Proof. Step 1: (a1). The norms of (N1) give the usual Schwartz topology because $|x^\beta| \leq (1+|x|^2)^{k/2}$ for $|\beta| \leq k$, and $(1+|x|^2)^{k/2}$ is at most a sum of monomials of degree $\leq 2k$ with coefficients adding up to $(1+3n)^k$; so the two families of seminorms define one space and one topology. A function flat outside $(\mathbb{R}^3)^n_{\neq}$ is one which vanishes with all its derivatives on the hyperplanes $x_i = x_j$. A Schwartz function flat outside the open set $O_+^{(n)} = \{0 < x_1^0 < \cdots < x_n^0\}$ is the same as one with support in its closure: at a boundary point some inequality is an equality, and points outside the closure, at which all derivatives vanish, approach it. As $O_+^{(n)} \subset V_+^{(n)}$, functions flat outside the first set are flat outside the second; for $n = 1$ the two sets agree. For $n \geq 2$, let $b \geq 0$ be smooth with $b(0) > 0$ and support in the ball of radius $\frac{1}{4}$ about 0; the tensor $\bigotimes_{i \leq n} b(\cdot - (i, 0, 1))$ has a compact support in $V_+^{(n)}$, so it lies in $\mathcal{S}_+(\mathbb{R}^{3n})$, and it does not vanish at the point $((1,0,1), \dots, (n,0,1))$, a boundary point of $O_+^{(n)}$ with $x_1^0 = x_2^0$, at which every member of $\mathscr{S}_+(\mathbb{R}^{3n})$ vanishes.

Step 2: (a2)–(a6). (a2): a functional bounded for one norm $|\cdot|_k$ is continuous; $e^{\mathsf{C}} \geq \mathsf{C}^n/n!$; conversely $\sigma_1 \geq 0$ forces $\alpha \geq 0$, $(n!)^\beta \leq (n!)^{\max\{\beta, 0\}}$, and the norms increase with the index. (a3): the isometry $y \mapsto R^{-1}(y - a)$ has the linear part $R^{-1} \in \mathrm{O}(3)$ and gives $\mathsf{r}\varphi = \varphi_{(a,R)}$. (a4): $(\Theta f_n^*)(x_1, \dots, x_n) = (\Theta \bar{f}_n)(x_n, \dots, x_1)$, so $\Theta f_n^* \times f_m$ is a permutation of $\Theta \bar{f}_n \otimes f_m$, and (E3) and (E2) apply. (a5): the definitions agree. (a6): $(g_m)_{(\lambda a, 1)} = \tau_{sv} g_m$ with $v = -a$, $s = \lambda$, translations parallel to the plane keep $\mathcal{S}_+$, and (a4)'s permutation with (E3) and (E4) send each of the finitely many summands to 0.

Step 3: (a7), (a8). The form $q(\underline{\varphi}, \underline{\varphi}') = \sum \mathsf{S}_{n+n'}(\Theta \bar{\varphi}_n \otimes \varphi'_{n'})$ on finite sequences of $\mathcal{S}_+$ is positive by (E2), hence Hermitian; at $\underline{\varphi} = (1, 0, \dots)$ and φ' in the place n this gives $\mathsf{S}_n(\Theta \bar{\varphi}') = \overline{\mathsf{S}_n(\varphi')}$ on $\mathcal{S}_+$. A sum of tensors Ψ of smooth separated tuples is moved into $\mathcal{S}_+$ by τ_{te_3} for large t, and $\Theta \overline{\tau_{te_3} \Psi} = \tau_{-te_3} \Theta \bar{\Psi}$, so (E1) gives the identity at Ψ; such sums are dense in $\mathcal{S}_{\neq}$ for every norm $|\cdot|_k$ (Lemma YM3_I:93.2), and (E0′) carries the identity to all φ, since $|\Theta \bar{\varphi}|_k = |\varphi|_k$. With $\Theta \varphi^* = (\Theta \bar{\varphi})^\varsigma$,

ς the reversal, (E3) gives (OS-E0); $\Theta\bar\varphi = \theta\bar\varphi$ and (E1) at θ give the last identity. (a8) collects (a2)–(a7); only (a6) uses (E4).

Step 4: (a9). Proposition YM3_I:111.2 shows that the axioms hold, that the form is positive, that the classes are dense in $\mathcal{H}^{\mathcal{S}}$ and that V is unitary; linearity then reduces the claim to approximating the class of a sequence that has a single member $\varphi \in \mathcal{S}_+(\mathbb{R}^{3n})$, $n \geq 2$. (E3) shows $[\varphi^\varsigma] = [\varphi]$ for every permutation. With a smooth u, $0 \leq u \leq 1$, $u = 0$ on $(-\infty, 1]$, $u = 1$ on $[2, \infty)$, put $\varphi_\epsilon = \prod_{i<l} u((x^0_i - x^0_l)^2/\epsilon)\,\varphi \in \mathcal{S}_+$; it vanishes near the points with two equal times, so it is the sum over the orderings π of the pieces $\mathbf{1}_{\{0<x^0_{\pi(1)}<\cdots<x^0_{\pi(n)}\}}\varphi_\epsilon$, each smooth, and each a permuted member of $\mathscr{S}_+$; so $[\varphi_\epsilon]$ is the class of a sequence of $\underline{\mathscr{S}}_+$. By Theorem YM3_I:AO, including its case without vacuum uniqueness, $\mathsf{S}^\sigma_n(\varphi) = \int \mathsf{s}_n\varphi$ with an absolutely convergent integral, so $\|[\varphi] - [\varphi_\epsilon]\|^2 = \iint \mathsf{s}_{2n}(x,y)(1-g_\epsilon(x))(1-g_\epsilon(y))(\Theta\bar\varphi)(x)\varphi(y)\,dx\,dy \to 0$ by dominated convergence, g_ϵ being the product of the cut-offs, which tends to 1 off the null set of equal times.

Step 5: (b1), (b2). For $\Lambda \in \mathrm{O}(1,2)$ with $\det\Lambda = 1$ and $\Lambda^0{}_0 = \cosh s \geq 1$, $\Lambda e_0 = (\cosh s, \sinh s\,\hat n)$, and $\Lambda = (1 \oplus \mathsf{R}_1)B(s)(1 \oplus \mathsf{R}_2)$, obtained by matching Λe_0 with a rotated boost and noting that the residual transformation fixes e_0, with rotations $\mathsf{R}_1, \mathsf{R}_2$ and the boost $B(s)$, all in $\mathcal{L}$, so that $\Lambda \in \mathcal{L}$; conversely the elements of $\mathcal{L}$ have $\det\Lambda = 1$ and $\Lambda^0{}_0 \geq 1$. (b2) is a comparison of the words of (W1)–(W5) with (GW1)–(GW8): a linear functional on $\mathcal{S}$ is tempered exactly when it is bounded for one norm $|\cdot|_N$, the support of a projection-valued measure lies in $\overline{V_+}$ exactly when the open complement has measure 0, and for $\psi \in D$ the Hermiticity of (W2), $\langle\psi, \Phi(f)\psi'\rangle = \langle\Phi(\bar f)\psi, \psi'\rangle$ for all $\psi' \in D$, says that ψ lies in the domain of $\Phi(f)^*$ and $\Phi(f)^*\psi = \Phi(\bar f)\psi$; conversely (GW4) gives this identity for the restrictions to D. The one step which is no comparison is the invariance of ψ_0 under the Lorentz transformations. By (GW1), $U(a,1)U(0,\Lambda)\psi_0 = U(0,\Lambda)U(\Lambda^{-1}a,1)\psi_0 = U(0,\Lambda)\psi_0$, so (GW3) gives $U(0,\Lambda)\psi_0 = c(\Lambda)\psi_0$ with a continuous character c of $\mathcal{L}$, $|c| = 1$. Conjugation by the rotation by π carries the boost $B(s)$ to $B(-s)$, so $c(B(-s)) = c(B(s))$, and $c(B(s))c(B(-s)) = c(1) = 1$; hence $c(B(s)) = \pm 1$, and $c(B(s)) = 1$ by continuity in s; as every boost is conjugate by a rotation to some $B(s)$, $c = 1$ on all boosts. The product $B(s)B_2(s)$ of the boosts of rapidity s in two orthogonal directions is a boost times the rotation by an angle $\omega(s)$ with $\cos\omega(s) = 2\cosh s/(1+\cosh^2 s)$, which runs through $(0, \frac{\pi}{2})$ as s runs through $(0,\infty)$; so $c = 1$ on the rotations by these angles, hence on all rotations, and on $\mathcal{L}$, which the boosts and the rotations generate. (GW-i): compose U with the homomorphism; (GW-ii): Ω is invariant under all $U(a,\Lambda)$ by (W1), and a vector invariant under all $U(a,\Lambda)$ is invariant under the translations, so it lies in $\mathbb{C}\Omega$.

Step 6: (b3). ι is a complex linear bijection of $\mathbb{C}^{1+2}$ onto $\mathbb{C}^3$ with $\iota(\mathbb{R}^{1+2} + iV_+) = \mathsf{Tb}_\circ$, and $|\iota\zeta| = |\zeta|$. It carries the points ζ with $\operatorname{Im}\zeta \in [\epsilon,\infty)e_0$ onto the points $\mathfrak{z}$ with $\operatorname{Im}\vec{\mathfrak{z}} = 0$ and $\operatorname{Re}\mathfrak{z}_3 \geq \epsilon$, the points $x + i\epsilon e_0$, x real, to $\iota(x) + \epsilon e_3$, and, as $\iota^{-1}(\mathfrak{z}) = (i\mathfrak{z}_3, \vec{\mathfrak{z}})$, the points $\zeta_k(y) = (i(y^0_{k+1} - y^0_k), \vec y_{k+1} - \vec y_k)$ to $y_{k+1} - y_k$. So W_{n-1} is holomorphic on $\mathfrak{T}_{n-1}$ exactly when W_n is holomorphic on $\mathsf{Tb}^{n-1}_\circ$; the growth condition in the Euclidean variables is the polynomial bound of the clause; (S1) is the limit at the functions of $\mathcal{S}$, and at $n = 1$ the identity $\mathcal{W}_1(f) = \mathsf{W}_1\int f$; and (S2) says that σ has the kernel $\mathsf{W}_n(y_2 - y_1, \dots, y_n - y_{n-1}) = W_{n-1}(\zeta(y))$ at the time-ordered tuples, and at $n = 1$ that $\sigma(f) = \mathsf{W}_1\int f$. The limit at the functions of $\mathcal{S}$ contains the limit at the functions of C^∞_c, which defines the weak sense.

Step 7: (b4). Put $N = n-1$, fix real $f_k \in C^\infty_c$ and let $h(z) = \int \prod_k f_k(x_k)\mathsf{D}(x_2 - x_1 + z_1e_0, \dots)\,dx$ for $z \in \mathbb{H}^N$, $\mathbb{H}$ the upper half plane: h is holomorphic, and by real translations of the f_k in time, $h(t + i\epsilon\mathbb{1}) \to 0$ as $\epsilon \downarrow 0$ for every $t \in \mathbb{R}^N$. The sets $A_m = \{t : |h(t + i\epsilon\mathbb{1})| \leq m \text{ for all } \epsilon \in (0,1]\}$, $m \in \mathbb{N}$, are closed, and they cover $\mathbb{R}^N$, since $\epsilon \mapsto h(t + i\epsilon\mathbb{1})$ is continuous on $(0,1]$ with a limit at 0; Baire's theorem gives m, t^* and $r > 0$ with $|h(t + i\epsilon\mathbb{1})| \leq m$ for $|t - t^*|_\infty < 2r$ and $0 < \epsilon \leq 1$. Let $|t - t^*|_\infty < r$ and $G(w) = h(t + w\mathbb{1})$, holomorphic on $\mathbb{H}$; on $Q = \{|\operatorname{Re} w| < \frac{r}{2},\ 0 < \operatorname{Im} w < \frac{1}{2}\}$ it is bounded by m, and $G(u + i\epsilon) \to 0$ as $\epsilon \downarrow 0$ for every real u. Cauchy's formula on ∂Q, applied to $G(\cdot + i\delta)$, and the limit $\delta \downarrow 0$, with dominated convergence on the sides, shows that $\hat G(w_0) = \frac{1}{2\pi i}\int_\Gamma G(w)(w - w_0)^{-1}dw$, Γ the three sides of Q off the real axis, is holomorphic on

$Q^\pm = \{|\operatorname{Re} w| < \frac{r}{2},\ |\operatorname{Im} w| < \frac{1}{2}\}$, equals G on Q, and vanishes at the points of $Q^\pm$ below the axis. The function $w \mapsto \hat G(w - \frac{i}{4})$ is holomorphic on the convex open set $Q^\pm + \frac{i}{4}$ and vanishes at its real points, so it vanishes by the one-variable identity theorem; so $G = 0$ on Q, and $h(t + \frac{i}{4}\mathbb{1}\!\!\!\!\perp) = 0$ whenever $|t - t^*|_\infty < r$. The identity theorem on an open real slice, applied successively in each coordinate to the function $z \mapsto h(z + \frac{i}{4}\mathbb{1}\!\!\!\!\perp)$ on the convex open set $\mathbb{H}^N - \frac{i}{4}\mathbb{1}\!\!\!\!\perp$, which holds $\mathbb{R}^N$, gives $h = 0$ on $\mathbb{H}^N$. Then, for every $y \in (0,\infty)^N$, the integrals of the products $\prod_k f_k(x_k)$ against $\xi \mapsto \mathsf{D}(\xi_1 + iy_1e_0, \dots, \xi_N + iy_Ne_0)$ at $\xi_k = x_{k+1} - x_k$ vanish for all real $f_k \in C_c^\infty$; at $f_k = j_\delta(\cdot - x_k^*)$, with a bump $j_\delta \ge 0$ of integral 1 supported in the ball of radius δ and a chain $x_{k+1}^* = x_k^* + \xi_k^*$, continuity gives $\mathsf{D}(\xi_1^* + iy_1e_0, \dots) = 0$ as $\delta \downarrow 0$, for every $\xi^* \in \mathbb{R}^{3N}$. The same identity theorem on the convex open set $\mathfrak{T}_N - i(y_ke_0)_k$, which holds $\mathbb{R}^{3N}$, gives $\mathsf{D} = 0$. Two continuous symmetric functions on $(\mathbb{R}^3)^n_{\neq}$ which agree at the time-ordered points agree at the points with pairwise different times, which are dense.

Step 8: (b5). The difference $(W_{n-1} - W'_{n-1}) \circ (\iota^{-1})^{\times(n-1)}$ is holomorphic on the convex, so connected, open set $\mathsf{Tb}_\circ^{n-1}$ and vanishes on its real points, which form the set $\mathbb{E}_+^{n-1}$, $\mathbb{E}_+ = \{x_3 > 0\}$, the image under ι of the points with $\zeta_k = (is_k, \vec\xi_k)$, $s_k > 0$; it vanishes by successive one-variable identity theorems. The forms then agree at functions of C_c^∞ by the definition of the weak sense, and at Schwartz functions by the temperedness in each argument, which the Hermiticity of (W2) gives, and the cut-offs $\chi(|x|^2/\varrho^2)$. The norms of the vectors $\sum_j c_j \Phi(f_1^j) \cdots \Phi(f_{n_j}^j)\Omega$ are fixed by the forms, so $\psi \mapsto \psi'$ is well defined, isometric, onto D'_0, between dense subspaces (W5); it extends to the unitary V, which intertwines the fields on D_0, the vacua and, by (W3), the representations. For two theories whose Schwinger functions are those of one σ, (S2) at bumps $j_\delta(\cdot - x_k^*)$ shrinking to the points of a time-ordered chain gives $\mathsf{W}_n = \mathsf{W}'_n$ on $\mathbb{E}_+^{n-1}$, and $\mathsf{W}_1 = \mathsf{W}'_1$ from $\sigma(f_1) = \mathsf{W}_1 \int f_1$; by (b3) the two theories have families in the weak sense which agree at the time-ordered points, and $\mathcal{W}_1 = \mathcal{W}'_1$, so the first part applies.

Step 9: (b6). Both sides are linear in $\psi \in D_0$; let $\psi = \Phi(g_1) \cdots \Phi(g_{a'})\Omega$, and test against the vectors $\Phi(\overline{g'_a}) \cdots \Phi(\overline{g'_1})\Omega$, which span the dense space D_0 (W5). By the Hermiticity of (W2), with $n = a + 2 + a'$, $k = a + 1$, $F = g'_1 \otimes \cdots \otimes g'_a \otimes f \otimes h \otimes g_1 \otimes \cdots \otimes g_{a'}$ and the transposition ς of k and $k+1$, the assertion is $T(F) = 0$ for $T(G) = \mathcal{W}_n^\sim(G) - \mathcal{W}_n^\sim(G^\varsigma)$, a linear functional on $\mathcal{S}(\mathbb{R}^{3n})$ with $|T(G)| \le c_T |G|_N$ for some N and c_T, by (T). For $x = (x_1, \dots, x_n) \in (\mathbb{R}^{1+2})^n$, $x_j = (x_j^0, \vec x_j)$, put $q(x) = |\vec x_k - \vec x_{k+1}|^2 - (x_k^0 - x_{k+1}^0)^2 = -(x_k - x_{k+1}) \cdot (x_k - x_{k+1})$ and $p(x) = |\vec x_k - \vec x_{k+1}| - |x_k^0 - x_{k+1}^0|$, so that $q > 0$ exactly where $p > 0$. (1) $T(G) = 0$ at every tensor G of functions of $\mathcal{S}$ whose k-th and $(k+1)$-th factors have spacelike separated supports, by (W4). (2) $T(G) = 0$ for every $G \in \mathcal{S}(\mathbb{R}^{3n})$ with a compact support $\mathcal{K} \subset \{q > 0\}$. Let $p_0 > 0$ be the least value of p on $\mathcal{K}$ and $\epsilon = p_0/30$; a smooth partition of unity $\sum_{z \in \mathbb{Z}^3} \kappa_{\epsilon,z} = 1$ on $\mathbb{R}^3$, with $\kappa_{\epsilon,z} = 0$ outside the cube $\{|y - \epsilon z|_\infty < \epsilon\}$, and smooth bumps $\eta_{\epsilon,z}$ equal to 1 on that cube and to 0 outside $\{|y - \epsilon z|_\infty < 2\epsilon\}$, split G into the finitely many pieces $G_{z,z'}(x) = \kappa_{\epsilon,z}(x_k)\kappa_{\epsilon,z'}(x_{k+1})G(x)$. For a piece which is not 0, any points y, y' of the supports of $\eta_{\epsilon,z}, \eta_{\epsilon,z'}$ lie within 3ϵ, in the maximum norm, of x_k, x_{k+1} for some $x \in \mathcal{K}$, so $|\vec y - \vec y'| - |y^0 - y'^0| \ge p_0 - (6\sqrt{2} + 6)\epsilon > 0$: the two supports are spacelike separated. With $E(x) = \eta_{\epsilon,z}(x_k)\eta_{\epsilon,z'}(x_{k+1})$ we have $EG_{z,z'} = G_{z,z'}$; sums S_j of tensors of functions of C_c^∞ with $|G_{z,z'} - S_j|_N \to 0$ (cut off, convolve with a product mollifier, then use Riemann sums) give $|G_{z,z'} - ES_j|_N \to 0$ by the rule of Leibniz, E having bounded derivatives, and each ES_j is a sum of tensors as in (1). (3) F is flat at every point of $\{q \le 0\}$: it holds the factor $f(x_k)h(x_{k+1})$, which vanishes where $q \le 0$; on the open set $\{q < 0\}$, $F = 0$, and a point with $q = 0$ is a limit of points with $q < 0$, obtained by moving x_k^0 away from x_{k+1}^0. (4) Let u be smooth, $0 \le u \le 1$, $u = 0$ on $(-\infty, 1]$, $u = 1$ on $[2, \infty)$, and $F_\delta = u(q/\delta)F$ for $0 < \delta \le \frac{1}{2}$. As q is a polynomial of degree 2, the derivatives of order $\le N$ of $1 - u(q/\delta)$ are at most $c_N \delta^{-N}(1 + |x|^2)^{N/2}$, and they vanish where $q \ge 2\delta$. At a point x with $0 < q(x) \le 2\delta$ put $\rho = |\vec x_k - \vec x_{k+1}|$ and $\tau = |x_k^0 - x_{k+1}^0|$; then $(\rho - \tau)^2 \le (\rho - \tau)(\rho + \tau) = q(x) \le 1$, and the point x^* obtained by moving x_k^0 by $\rho - \tau$ away from

x^0_{k+1} has $q(x^*)=0$ and $|x-x^*|_1=\rho-\tau\le(2\delta)^{1/2}$. Taylor's formula along the time coordinate about x^* with $2N+2$ derivatives gives the following bound. Along the segment $1+|x|^2\le 3(1+|y|^2)$ since $|x-y|\le 1$, hence $|\partial^\alpha F(x)|\le\frac{(2\delta)^{N+1}}{(2N+2)!}\,3^{(3N+2)/2}\,|F|_{3N+2}\,(1+|x|^2)^{-(3N+2)/2}$ for $|\alpha|\le N$. With the rule of Leibniz, and as $F-F_\delta$ vanishes with all its derivatives where $q\le 0$ and where $q\ge 2\delta$, $|F-F_\delta|_N\le C_N\,\delta\,|F|_{3N+2}$. (5) The functions $(F_\delta)_\varrho=\chi(|x|^2/\varrho^2)F_\delta$ lie in C^∞_c, with supports in $\{q\ge\delta\}$, so $T((F_\delta)_\varrho)=0$ by (2); $\varrho\to\infty$ and Schwartz convergence of the smooth cutoffs give $T(F_\delta)=0$, and $\delta\downarrow 0$ with (4) gives $T(F)=0$.

Step 10: (b7). For $\eta\in V_+^{n-1}$ put $\mathfrak w_k=\iota(i\eta_k)=(i\vec\eta_k,\eta^0_k)$; then $d_\circ(\mathfrak w_k)=\eta^0_k-|\vec\eta_k|>0$, $|\mathfrak w_k|=|\eta_k|$, $I_F(\eta)=\int F(x)\,\mathbf W_n(\iota(x_2-x_1)+\mathfrak w_1,\dots,\iota(x_n-x_{n-1})+\mathfrak w_{n-1})\,dx$, and the points $\iota(x_{k+1}-x_k)+\mathfrak w_k$, x real, have the margin $d_\circ(\mathfrak w_k)$. For $\mathfrak w\in\overline{\mathsf{Tb}_\circ}^{\,n-1}$, Lemma YM3_I:109.4 applies to $\mathbf F(z)=\mathbf W_n(z_2-z_1+\mathfrak w_1,\dots,z_n-z_{n-1}+\mathfrak w_{n-1})$ on the open set $\mathcal O=\{z: z_{k+1}-z_k+\mathfrak w_k\in\mathsf{Tb}_\circ\text{ for all }k\}$, with $\mathsf h_j=2j$, $\eta_0=1$, $b=C^n_\wp$, $p=\wp n$ and $N\ge p+\frac12$, its height η being written t here; so, for $x=(x_1,\dots,x_n)\in(\mathbb R^{1+2})^n$ with $x_j=(x^0_j,\vec x_j)$, the point $z(x;t)$ of the Lemma is $(\iota(x_j)+2jt\,e_3)_{1\le j\le n}$ and its operator $D_{\mathsf h}$ is $\sum_{j=1}^n 2j\,\partial_{x^0_j}$, the derivative $\partial_{x^0_j}$ in the time of x_j standing for its ∂_{t_j}: at $z(x;t)$ the arguments $\iota(x_{k+1}-x_k)+2te_3+\mathfrak w_k$ have margins $\ge 2t$, so the bound of Theorem YM3_I:AO, $|\mathbf W_n|\le(C_\wp t^{-\wp})^n$ where all margins are $\ge 2t$ and $0<t\le 1$, gives the bound YM3_I:(2082). For $g\in C^\infty_c(\mathbb R^{3n};\mathbb C)$ let $J^{\mathfrak w}_g(t)=\int g(x)\,\mathbf F(z(x;t))\,dx$. The Lemma gives: $J^{\mathfrak w}_g$ is continuously differentiable on $(0,1]$, with the derivative $J^{\mathfrak w}_{-iD_{\mathsf h}g}$; $\sup_{0<t\le1}|J^{\mathfrak w}_g(t)|\le\mathsf Q(g)=2^NC^n_\wp\sum_{i\le N}\|D^i_{\mathsf h}g\|_{L^1}$, a number which does not depend on $\mathfrak w$; and $\lim_{t\downarrow0}J^{\mathfrak w}_g(t)$ exists. As $\sum_j\mathsf h_j=n(n+1)$ and $\|\partial^\alpha g\|_{L^1}\le\pi^{2n}|g|_{|\alpha|+4n}$ (integrate the majorant $\prod_{j=1}^n(1+|x_j|^2)^{-2}$), $\mathsf Q(g)\le c_n|g|_{\bar k}$; and $|J^{\mathfrak w}_g(t)-J^{\mathfrak w}_g(t')|\le\mathsf Q(D_{\mathsf h}g)|t-t'|$ for all $\mathfrak w$. If $\mathfrak w\in\mathsf{Tb}_\circ^{n-1}$, the margins stay $\ge\min_k d_\circ(\mathfrak w_k)>0$ at $t=0$, and $J^{\mathfrak w}_g(t)\to I_g(\eta)$ as $t\downarrow0$; put $\mathsf L(g)=\lim_{t\downarrow0}J^0_g(t)$. Then $|I_g(\eta)|\le\mathsf Q(g)$, $|I_g(\eta)-J^{\mathfrak w}_g(t)|\le\mathsf Q(D_{\mathsf h}g)\,t$ and $|\mathsf L(g)-J^0_g(t)|\le\mathsf Q(D_{\mathsf h}g)\,t$; and at a fixed t, $J^{\mathfrak w}_g(t)\to J^0_g(t)$ as $\mathfrak w\to0$, by uniform continuity on a compact set. Hence $\limsup_{\eta\to0}|I_g(\eta)-\mathsf L(g)|\le 2\,\mathsf Q(D_{\mathsf h}g)\,t$ for every $t\in(0,1]$, so $I_g(\eta)\to\mathsf L(g)$ as $\eta\to0$ in V_+^{n-1}. At a tensor $g=f_1\otimes\cdots\otimes f_n$ of functions of C^∞_c, $J^0_g(t)$ is the integral of (S1) at $\epsilon=2t$, as $\iota(x+i\epsilon e_0)=\iota(x)+\epsilon e_3$; so $\mathsf L(g)=\mathcal W_n(f_1,\dots,f_n)=\mathcal W^\sigma_n(g)$ (Theorem YM3_I:AO). Both $\mathsf L$ and $\mathcal W^\sigma_n$ are bounded for one norm, and sums of such tensors are dense (cut off, convolve with a product mollifier, then use Riemann sums); so $\mathsf L=\mathcal W^\sigma_n$ on C^∞_c. For $F\in\mathcal S(\mathbb R^{3n})$ and $\eta\in V_+^{n-1}$ let $t_\eta=\frac12\min\{2,\min_k d_\circ(\mathfrak w_k)\}$; the bound $|\mathbf W_n|\le(C_\wp t_\eta^{-\wp})^n$ at the arguments of $I_F(\eta)$ and $\|F\|_{L^1}\le\pi^{2n}|F|_{4n}$ make the integral absolutely convergent, and the functions F_ϱ give $|I_F(\eta)|=\lim_\varrho|I_{F_\varrho}(\eta)|\le c_n|F|_{\bar k}$. With $|\mathcal W^\sigma_n(F)|\le c'|F|_{k'}$ and $k''=\max\{\bar k,k'\}$, $|I_F(\eta)-\mathcal W^\sigma_n(F)|\le(c_n+c')|F-F_\varrho|_{k''}+|I_{F_\varrho}(\eta)-\mathcal W^\sigma_n(F_\varrho)|$; choose ϱ by Schwartz convergence of the smooth cutoffs, then $|\eta|$ small. This is the strong sense. Finally $\mathfrak S_1=\mathbf W_1$ by (S1) at $n=1$, and the kernel $\mathsf s_n$ is continuous and symmetric, equals $\mathbf W_n(x_2-x_1,\dots,x_n-x_{n-1})=W_{n-1}(\zeta(x))$ at the time-ordered points, and gives σ (Proposition YM3_I:108.3, YM3_I:(2067), YM3_I:(2065)); so it is the function of (Sch).

Step 11: (b8). On $\mathbb R^{1+2}$, P keeps x^0 and $|\vec x|$, so $P\in\mathrm O(1,2)$, $Pe_0=e_0$, $PV_+=V_+$ and $|\det P|=1$. The map $\Lambda\mapsto P\Lambda P^{-1}$ of $\mathrm O(1,2)$ into itself is continuous and fixes 1, so it maps the connected component $\mathcal L$ of 1 into $\mathcal L$, and so does $\Lambda\mapsto P^{-1}\Lambda P$; hence $P\mathcal LP^{-1}=\mathcal L$, and $(a,\Lambda)\mapsto(Pa,P\Lambda P^{-1})$ is a continuous automorphism of $\mathbb R^{1+2}\rtimes\mathcal L$. Put $U'(a,\Lambda)=U(Pa,P\Lambda P^{-1})$ and $\phi'(f)=\phi(f\circ P^{-1})$ on $\mathcal D_0$; $f\circ P^{-1}\in\mathcal S$, with a bound of its norms by those of f. Then $(\mathcal H(\sigma),U',\Omega,\mathcal D_0,\phi')$ is a Wightman theory: the projection-valued measure of $x\mapsto U'(x,1)$ is $\Delta\mapsto\mathsf E(P\Delta)$, as $(Px)\cdot p=x\cdot(P^{-1}p)$, and it is carried by $\overline{V_+}$; the vectors invariant under all $U'(a,1)$ are those invariant under all $U(a,1)$; (W2) holds by the bound just named and $\overline{f\circ P^{-1}}=\bar f\circ P^{-1}$; (W3) holds, as $U'(a,\Lambda)\phi'(f)U'(a,\Lambda)^{-1}=\phi(f(\Lambda^{-1}(P^{-1}\cdot-a)))=\phi'(f(\Lambda^{-1}(\cdot-a)))$ on $\mathcal D_0$; (W4) holds, as P keeps $(x-x')\cdot(x-x')$; and (W5) holds, as $f\mapsto f\circ P^{-1}$ maps $\mathcal S$ onto itself. Its Schwinger functions are those of σ in the sense in the Euclidean variables, with $\mathsf W'_1=\mathbf W_1$ and

$\mathsf{W}'_n = \mathbf{W}_n \circ (\hat{\mathsf{R}} \times \cdots \times \hat{\mathsf{R}})$, $\hat{\mathsf{R}} = \mathsf{R} \oplus 1$: $\hat{\mathsf{R}}$ keeps $\mathsf{Tb}_\circ$, the margin, the modulus and the set of the growth bound; $\iota P = \hat{\mathsf{R}}\iota$; the substitution $x_k = Py_k$ turns the forms of the second theory into (S1) with W'_n; and the substitution $x_k = \hat{\mathsf{R}}^{-1}y_k$, the tuple $\hat{\mathsf{R}}X$ having supports ordered in the third coordinate, and the invariance (Rec1) of σ give (S2). The last sentence of (b5) gives exactly one unitary V_R with $\mathsf{V}_\mathsf{R}\Omega = \Omega$ and $\mathsf{V}_\mathsf{R}\phi(f)\psi = \phi'(f)\mathsf{V}_\mathsf{R}\psi$ on $\mathcal{D}_0$, and $\mathsf{V}_\mathsf{R}U(a,\Lambda) = U'(a,\Lambda)\mathsf{V}_\mathsf{R}$.

Step 12: (c1). By the moment–cumulant formula the self-centred moments of the defining sequence converge to σ_S, with first moment zero and higher cumulants S_n. Theorem YM3_I:AP applies to this sequence. It gives symmetry, Euclidean invariance, reflection positivity, clustering and (E0′)–(E4) for every σ_ξ. It also gives the bound $2(\mathsf{C}_\mathrm{E}^{\mathrm{pt},g})^n(n!)^8|\varphi|_{8n}$ for the Schwinger functions, with a common constant for all components. Since $|\varphi|_{8n} \le |\varphi|_{10n}$, $2 \le 2^n$ for $n \ge 1$, and $8 \le \varkappa_\star + 9$, this also gives the bound $(\mathsf{C}_\mathrm{E}^g)^n(n!)^{\varkappa_\star+9}|\varphi|_{10n}$. Clauses (a8) and (a2) now give the two sets of numbers in (c1). The time direction: let $v_3 > 0$, $\varphi \in \mathcal{S}_+(\mathbb{R}^{3n})$, $\varphi' \in \mathcal{S}_+(\mathbb{R}^{3n'})$, and let $\psi, \psi' \in \mathcal{H}(\sigma_\xi)$ be the images under V^{-1} of the classes of the sequences with these single members. As $\tau_{sv} = \tau_{sv_3e_3}\tau_{(s\vec{v},0)}$, the reflection-space identification of Proposition YM3_I:111.2 gives the following identity. It holds first on positive-time tuple tensors by the definition of the translations on tuple classes, and extends by their density and the continuous reflection form. Thus $\mathsf{S}_{n+n'}(\Theta\bar{\varphi} \otimes \tau_{sv}\varphi') = \langle \psi, \mathcal{T}_{sv_3}\mathcal{U}(s\vec{v})\psi'\rangle$. By the spectral theorem, $\mathcal{T}_t\psi \to P_0\psi = \langle\Omega,\psi\rangle\Omega$ as $t \to \infty$, as $\ker H = \mathbb{C}\Omega$ (Theorem YM3_I:AP); $\mathcal{U}(s\vec{v})$ is unitary and fixes Ω; so the limit is $\langle\psi,\Omega\rangle\langle\Omega,\psi'\rangle = \mathsf{S}_n(\Theta\bar{\varphi})\,\mathsf{S}_{n'}(\varphi')$, as $\mathsf{V}\Omega = [(1,0,0,\dots)]$. For $v_3 = 0$ this is (E4).

Step 13: (c3), (c4). By Theorem YM3_I:AP, σ_ξ is data (Rec) with (Rec5). Theorem YM3_I:AO gives the Wightman theory, with $\mathsf{W}_n = \mathbf{W}_n$ and the tempered forms $\mathcal{W}_n^{\sigma_\xi}$; (b2) gives (GW1)–(GW8) and the variants; (b6) applies, the quintuple having (T); (b7) gives the strong sense with its bound and the Schwinger functions $\mathfrak{S}_1 = \mathbf{W}_1$, $\mathfrak{S}_n = \mathsf{s}_n$, which give σ_ξ by YM3_I:(2065); and $\mathbf{W}_1 = \mathfrak{c}_\xi$ by Proposition YM3_I:108.3 and the one-point statement of Theorem YM3_I:AP. The family of (b7) is a family in the weak sense, and (b5) gives the uniqueness, in its first form for the theories with a family in the weak sense and in its last sentence for the theories whose Schwinger functions are those of σ_ξ; (b8) applies. For (c4), the form of (OS-E2) on $\underline{\mathscr{S}}_+$ is the restriction of the form $\langle\cdot,\cdot\rangle_\mathcal{S}$ on the larger positive-time spaces, by the permutation of Step 2 and (E3). So the space of List OS is, up to a unitary map, the closure in $\mathcal{H}^\mathcal{S}$ of the classes of the members of $\underline{\mathscr{S}}_+$, which is $\mathcal{H}^\mathcal{S}$ by (a9), whose hypotheses Step 12 and (Rec) give; and V^{-1} carries $\mathcal{H}^\mathcal{S}$ onto $\mathcal{H}(\sigma_\xi)$ and $[(1,0,0,\dots)]$ to Ω (the reflection-space identification of Proposition YM3_I:111.2).

Step 14: (c2). Theorem YM3_I:AP also applies to the full limit σ_S. It gives (E0′)–(E3) and (Rec) with the numbers $C_\wp^g, 4, \frac{1}{2}$. Clause (a8) gives the corresponding List OS properties. Theorem YM3_I:AO reconstructs the quintuple for σ_S with the invariant vacuum, and the comparison of Step 5 gives (GW1), (GW2), (GW4)–(GW8) and the existence in (GW3). (i)⇔(iv): by Theorems YM3_I:AP and YM3_I:AL, $\ker H$ is unitarily equivalent to $L^2(\mathsf{X},\lambda)$, and λ charges every non-empty open set (Theorem YM3_I:AL); so $\dim\ker H = 1$ exactly when X is one point. (i)⇒(ii): the plateau identity at $q = 1$ (Theorem YM3_I:AL) gives $\sigma_S = \sigma_\xi$, and Step 12 applies. (ii)⇒(iii): (a6). (iii)⇒(i): let X be a smooth real separated n-tuple over $\{x_3 > 0\}$ whose supports are ordered in the third coordinate; $\bigotimes X$ has a compact support in $O_+^{(n)}$, so it lies in $\mathscr{S}_+(\mathbb{R}^{3n})$. (OS-E4) at the two sequences with the single member $\bigotimes X$, with (E3) and the values at tensors, gives $\sigma_S(\theta X \cdot \tau_{-\lambda a}X) \to \sigma_S(\theta X)\,\sigma_S(X) = \sigma_S(X)^2$ as $\lambda \to \infty$; the plateau identities at $q = 2$ and at $q = 1$ and the invariance of every component under θ (Theorems YM3_I:AP and YM3_I:AL) give $\int(\sigma_\xi(X) - \sigma_S(X))^2\lambda(d\xi) = 0$, and, $\xi \mapsto \sigma_\xi(X)$ being continuous, $\sigma_\xi(X) = \sigma_S(X)$ for every ξ (Theorem YM3_I:AL). Let $\xi, \xi' \in \mathsf{X}$; both components are data (Rec) (Theorem YM3_I:AP), with the kernels $\mathsf{s}_n, \mathsf{s}'_n$ of Proposition YM3_I:108.3, and $\mathsf{d} = \mathsf{s}_n - \mathsf{s}'_n$ is continuous on $(\mathbb{R}^3)^n_{\neq}$. At a point x^* with $0 < x^*_{13} < \cdots < x^*_{n3}$ the tuples $(j_\delta(\cdot - x^*_k))_k$, for small $\delta > 0$, are smooth, over $\{x_3 > 0\}$, with supports ordered in the third coordinate; so $\int \mathsf{d}(x)\prod_k j_\delta(x_k - x^*_k)\,dx = 0$ by YM3_I:(2065), and $\mathsf{d}(x^*) = 0$ by continuity as $\delta \downarrow 0$. The

kernels are invariant under the translations (Proposition YM3_I:108.3), so $\mathsf{d} = 0$ at all the time-ordered points, and, both kernels being continuous and symmetric, on $(\mathbb{R}^3)^n_{\neq}$ (b4). By YM3_I:(2065), $\sigma_\xi = \sigma_{\xi'}$ on every $\mathfrak{S}_n$, and the injectivity of $\xi \mapsto \sigma_\xi$ (Theorem YM3_I:AL) gives $\xi = \xi'$. (iv)⇒(v): Theorem YM3_I:AO. (v)⇒(iv): for $\psi \in \ker H$ the spectral measure m_ψ of $\mathcal{P}$ is carried by $\{E = 0\}$, as $\int E^2 dm_\psi = \|H\psi\|^2 = 0$, and by (Rec3) by the point $(0,0)$; by the translation spectral representation, $\|U(x)\psi - \psi\|^2 = \int |e^{i(tE+\vec{x}\cdot q)} - 1|^2 \, dm_\psi = 0$; so every vector of $\ker H$ is invariant under the translations, and the uniqueness of (GW3) gives $\ker H = \mathbb{C}\Omega$. □

18.23. **Unbroken lattice symmetries and odd densities; thread laws at every label; compact photons; limits on a slab.** This subsection adds five groups of statements to the preceding one. Proposition 18.227 concerns an arbitrary periodic Gibbs state ν of the SU(2) Wilson weight, at every spacing and every $\beta \geq 0$: the conditional expectation given the invariant events of a bounded Borel function does not change when a lattice isometry is applied to the function, every invariant event is carried onto itself by every lattice isometry up to a ν-null set, and almost every member of a regular conditional distribution of ν given the invariant events is a pure phase which is invariant under all lattice isometries and reflection positive at all lattice mirrors; a function which a lattice isometry multiplies by a number $\omega \neq 1$ has the mean 0 in ν, given the invariant events, in every pure phase and in almost every member of the decomposition. Proposition 18.228 concerns a bounded function of the bonds of a box which is odd, or even, under the one mirror through the centre of the box whose normal belongs to one of the nine families: in every periodic Gibbs state and in each of its pure phases, its correlation with its translate by j steps of the lattice along the normal is ≤ 0, respectively ≥ 0, for every integer j at least twice the radius of the box, and an odd function has the mean 0. Propositions 18.235 and 18.236 concern the thread measures of Definition 18.207 at an arbitrary label $\mathsf{b} > 0$, which Lemma 18.230 forms at every label and on every side: the laws of the threads over a window of two tori of sides ℓ_1 and $L^t\ell_1$ are mutually absolutely continuous, with explicit inequalities in both directions and densities in L^r both ways; and every limit law of the block fields of all depths through periodic Gibbs states whose labels tend to b, every invariant density of it, and almost every member of every decomposition of it into laws invariant under one translation, is dominated in every cell by the thread measure of one torus, with a constant formed from the constants, the label and the side. Proposition 18.237 concerns three compact photon fields: the determinant of the three field strengths at a site, smeared with a test function, has vanishing joint moments and joint cumulants with any number of smeared action densities, at every spacing, every coupling and in every law which is invariant under the conjugation of one colour. Proposition 18.247 concerns the slab $\mathbb{R}^2 \times S^1_l$ whose circumference l is a side at the reference coupling: along first-passage data whose labels converge, every limit point of the Wilson measures of the boxes with two growing sides and the third side l yields, along a subsequence, limits of the cumulants of the action density at all separated tuples over the slab; every such limit is symmetric, obeys explicit bounds, is invariant under all translations of the slab, under the signed permutations of the two open directions and under the reflections of the circle, is regular, and is reflection positive at the mirrors $\{x_1 = c\}$, $\{x_2 = c\}$ and $\{x_1 \pm x_2 = c\}$, $c \in \mathbb{R}$, and at every double mirror $\{x_3 = c\} \cup \{x_3 = c + \frac{l}{2}\}$; and below the ceiling γ_W its two-point function at short distance is $\mathsf{c}_2\mathsf{b}^{-2}\mathcal{K}_{\text{free}}$ up to a relative error which tends to 0 with the distance.

We use the setting and notation of Definition 18.209: the constants with $L \geq 13$ odd, $a_d = L^{-d}$, $\mathbb{L}_K = a_K\mathbb{Z}^3$, the sides $\mathfrak{L}$ and $\mathfrak{L}(g)$, the data at g with their labels, the intervals $I(g)$, J_g, $I^{\text{lab}}(g)$, the numbers C_{S}, C_g, C_{gap}, $\bar{B}$, $B_\sharp$, M, γ_W, c_2 and $\mathcal{K}_{\text{free}}$; the configurations, the laws, the action of $\mathsf{Iso}(a\mathbb{Z}^3) = a\mathbb{Z}^3 \rtimes W_3$ on configurations and on their functions, $(uU)(b) = U(u^{-1}b)$ and $(uF)(U) = F(u^{-1}U)$, the sets $\mathcal{F}(B)$, the Gibbs kernels γ_B, the periodic Gibbs states $\mathcal{G}^{\text{per}}_{a,\beta}$, the σ-algebra $\mathcal{I}$ of the invariant events and the pure phases (Definition 18.204); the torus measures $\mu_{K,\ell,\beta}$, $\tilde{\mu}_{K,\ell,\beta}$, the period lattices and their Wilson laws $\mu^0_{\Gamma,\beta} = \mu^{\varnothing}_{\Gamma,\beta}$ (Definitions 18.204 and 18.209); the normals $\mathfrak{N}$, the nine families of mirrors, the lattice mirrors of $a\mathbb{Z}^3$ and the reflections $\theta_{n,c}$ (Definition 18.209);

the block fields, the block maps $\mathcal{M}_\ell$ and $\mathcal{M}$, the towers Ψ_K, the threads Thr, the maps T_v, the window $\square$ of a side, its towers Υ_K, the spaces Y, $Y^{[d_0]}$, $Y_{\le D}$, the maps q_D, $\mathrm{pj}^{[d_0]}$, $\varpi_o^{[d_0]}$, the window maps m_d^n and $\mathsf{Thr}_\square$ (Definition 18.206); the thread measures $\mu_{\ell,\mathsf{b}}$, $\mu[\ell,\mathsf{b}]$, $\mu^{[d_0]}$, the domination $\preceq_{\mathsf{Q}}$, the product bound and Q_0 (Definition 18.207); and the standing hypothesis (SH) (Definition 18.208). In particular every Borel probability measure on the configurations of a lattice is called a law, and $\nu(F)$ is the integral of F under ν.

Use $\mathsf{Bd} = \mathsf{Bd}(\mathbb{R}^3)$ and the local function spaces of Definition 18.209. For $B \subset \mathsf{Bd}$, U_B is the restriction to B, and for finite B, dV_B is product Haar measure. Put $Q_r = [-ra, ra]^3$. The linear part of $\theta_{n,c}$ is $\varrho_n x = x - 2|n|^{-2}(n \cdot x)n$. Write $\mathrm{Adm}(n)$ for its allowed offsets, $(a/2)\mathbb{Z}$ for coordinate and $a\mathbb{Z}$ for diagonal normals. For $u \in \mathsf{Iso}(a\mathbb{Z}^3)$ the event uE is the image of E under u, so $u1_E = 1_{uE}$. An $\mathcal{I}$-representative of F under ν is an $\mathcal{I}$-measurable representative of $\mathbb{E}_\nu[F \mid \mathcal{I}]$, characterized by $\nu(1_E \mathsf{g}) = \nu(1_E F)$ for all $E \in \mathcal{I}$. A regular conditional distribution $(\nu^U)_U$ given $\mathcal{I}$ is a family of laws for which $U \mapsto \nu^U(F)$ is such a representative for each bounded Borel F. Proposition YM3_I:106.2 gives one for every periodic Gibbs state.

Proposition 18.227 (No lattice isometry is broken in a periodic Gibbs state or in its pure phases)**.** Let $a > 0$, $\beta \ge 0$ and $\nu \in \mathcal{G}^{\mathrm{per}}_{a,\beta}$.

(a) For every bounded Borel function F and every $u \in \mathsf{Iso}(a\mathbb{Z}^3)$, every $\mathcal{I}$-representative of F under ν is an $\mathcal{I}$-representative of uF under ν; hence $\mathbb{E}_\nu[uF|\mathcal{I}] = \mathbb{E}_\nu[F|\mathcal{I}]$ ν-almost surely. This holds in particular for the reflection $\theta_{n,c}$ of every lattice mirror of the nine families and for the parity $x \mapsto -x$.

(b) For every $E \in \mathcal{I}$ and every $u \in \mathsf{Iso}(a\mathbb{Z}^3)$, $\nu(uE \triangle E) = 0$.

(c) Let F be a bounded Borel function, $u \in \mathsf{Iso}(a\mathbb{Z}^3)$ and $\omega \in \mathbb{C} \setminus \{1\}$ with $uF = \omega F$. Then $\nu(F) = 0$, $\mathbb{E}_\nu[F|\mathcal{I}] = 0$ ν-almost surely, and $\nu'(F) = 0$ for every pure phase $\nu' \in \mathcal{G}^{\mathrm{per}}_{a,\beta}$.

(d) Let $(\nu^U)_U$ be a regular conditional distribution of ν given $\mathcal{I}$. Then $\nu(F) = \int \nu^U(F)\,\nu(dU)$ for every bounded Borel F, and for ν-almost every U the law ν^U is a pure phase in $\mathcal{G}^{\mathrm{per}}_{a,\beta}$; it is invariant under $\mathsf{Iso}(a\mathbb{Z}^3)$, reflection positive at every lattice mirror of the nine families, and $\nu^U(F) = 0$ for every bounded Borel F with $uF = \omega F$ for some $u \in \mathsf{Iso}(a\mathbb{Z}^3)$ and some $\omega \ne 1$. So no lattice isometry permutes the pure phases into which ν decomposes.

■

Proof. Step 1: conditioned states. Let $E \in \mathcal{I}$ with $\nu(E) > 0$. The function $\mathsf{h} = \nu(E)^{-1}1_E$ is bounded, non-negative and $\mathcal{I}$-measurable with $\nu(\mathsf{h}) = 1$, so $\mathsf{h}\nu \in \mathcal{G}^{\mathrm{per}}_{a,\beta}$ by Proposition YM3_I:106.1; by the theorem on the nine families, Proposition YM3_I:103.4, $\mathsf{h}\nu$ is invariant under $\mathsf{Iso}(a\mathbb{Z}^3)$, and so $\nu(1_E\, uF) = \nu(1_E F)$ for every bounded Borel F and every $u \in \mathsf{Iso}(a\mathbb{Z}^3)$. If $\nu(E) = 0$ both members vanish.

Step 2: (a). Let g be an $\mathcal{I}$-representative of F. For $E \in \mathcal{I}$, Step 1 gives $\nu(1_E\, uF) = \nu(1_E F) = \nu(1_E \mathsf{g})$, so g is an $\mathcal{I}$-representative of uF. As ν is invariant under the translations of $a\mathbb{Z}^3$ (Proposition YM3_I:103.4), the $\mathcal{I}$-representatives are the $\mathcal{I}$-measurable members of the conditional expectations, and the two conditional expectations are one class. The reflections of the lattice mirrors belong to $\mathsf{Iso}(a\mathbb{Z}^3)$, and the parity is the element -1 of W_3.

Step 3: (b). The function 1_E is $\mathcal{I}$-measurable, so it is an $\mathcal{I}$-representative of itself, and by (a) of $u1_E = 1_{uE}$. So $\nu(1_{E'}1_{uE}) = \nu(1_{E'}1_E)$ for all $E' \in \mathcal{I}$; at $E' = E^c$ this gives $\nu(uE \setminus E) = 0$, and at $E' = E$ it gives $\nu(uE \cap E) = \nu(E)$, that is, $\nu(E \setminus uE) = 0$.

Step 4: (c). By Proposition YM3_I:103.4, $\nu(F) = \nu(uF) = \omega\,\nu(F)$, so $\nu(F) = 0$. If g is an $\mathcal{I}$-representative of F, then $\omega\mathsf{g}$ is one of $\omega F = uF$, and by (a) so is g; two of them agree almost everywhere, so $(1-\omega)\mathsf{g} = 0$ almost everywhere. A pure phase belongs to $\mathcal{G}^{\mathrm{per}}_{a,\beta}$, so the first assertion applies to it.

Step 5: (d). The identity $\nu(F) = \int \nu^U(F)\,\nu(dU)$ is YM3_I:(2029), and by Proposition YM3_I:106.2 the law ν^U belongs to $\mathcal{G}^{\mathrm{per}}_{a,\beta}$ and is ergodic for ν-almost every U; by Proposition YM3_I:106.1

the ergodic members of $\mathcal{G}^{\mathrm{per}}_{a,\beta}$ are its pure phases. Proposition YM3_I:103.4 and clause (c) of the present proposition apply to each such ν^U, which gives the remaining assertions; the last sentence is (b) together with this. □

Proposition 18.228 (A density odd, or even, under the mirror through the centre of its box)**.** Let $a > 0$, $\beta \geq 0$, $\nu \in \mathcal{G}^{\mathrm{per}}_{a,\beta}$, let $r \geq 1$ be an integer, let A be a bounded complex Borel function of the bonds lying in $Q_r = [-ra, ra]^3$, and let $n \in \mathfrak{N}$ and $\epsilon \in \{1, -1\}$ with $\theta_{n,0}A = \epsilon A$.

(a) For every integer $j \geq 2r$ the number $\nu(\bar{A}\,\tau_{jan}A)$ is real, and $\epsilon\,\nu(\bar{A}\,\tau_{jan}A) \geq 0$. In particular, if A is real and odd, $\theta_{n,0}A = -A$, then $\nu(A\,\tau_{jan}A) \leq 0$ for all integers $j \geq 2r$; for $n = e_\mu$ these are the translations by te_μ with $t \in a\mathbb{Z}$, $t \geq 2ra$, and for a diagonal $n = e_\mu \pm e_{\mu'}$ the translations by $ja(e_\mu \pm e_{\mu'})$.

(b) If $\epsilon = -1$, then $\nu(A) = 0$, $\mathbb{E}_\nu[A|\mathcal{I}] = 0$ ν-almost surely, $\nu'(A) = 0$ for every pure phase $\nu' \in \mathcal{G}^{\mathrm{per}}_{a,\beta}$, and $\nu^U(A) = 0$ for ν-almost every U, for every regular conditional distribution $(\nu^U)_U$ of ν given $\mathcal{I}$. Hence, for real A and integers $j \geq 2r$, the connected correlation $\nu(A\,\tau_{jan}A) - \nu(A)\,\nu(\tau_{jan}A)$ equals $\nu(A\,\tau_{jan}A)$ and is ≤ 0.

(c) The inequality of (a) holds in every pure phase $\nu' \in \mathcal{G}^{\mathrm{per}}_{a,\beta}$ in the place of ν; and every $\mathcal{I}$-representative g of $\bar{A}\,\tau_{jan}A$ under ν, $j \geq 2r$, is real and satisfies $\epsilon\,\mathsf{g} \geq 0$ ν-almost everywhere. ■

Proof. Step 1: the mirror midway. Let $j \geq 2r$ be an integer and $c' := \frac{1}{2}ja|n|^2$. For $n = e_\mu$, $c' = \frac{1}{2}ja \in \frac{a}{2}\mathbb{Z}$; for a diagonal n, $|n|^2 = 2$ and $c' = ja \in a\mathbb{Z}$; so (n, c') is a lattice mirror of the nine families. As maps of $\mathbb{R}^3$, $\theta_{n,c'}x = \theta_{n,0}x + 2c'|n|^{-2}n$, that is, $\theta_{n,c'} = \tau_{jan}\theta_{n,0}$; the linear map $\theta_{n,0}$ satisfies $\theta_{n,0}\tau_v = \tau_{\theta_{n,0}v}\theta_{n,0}$ for $v \in a\mathbb{Z}^3$, and $\theta_{n,0}v = -v$ for v parallel to n, so that $\theta_{n,0}\tau_v = \tau_{-v}\theta_{n,0}$ for such v. On functions of the configurations, $(\mathsf{rs})F = \mathsf{r}(\mathsf{s}F)$ for $\mathsf{r}, \mathsf{s} \in \mathsf{Iso}(a\mathbb{Z}^3)$.

Step 2: the translate lies on one side. Put $F := \tau_{jan}A$. It depends on the bonds $b + jan$, b a bond lying in Q_r, whose closed segments lie in $Q_r + jan$. For $y \in Q_r + jan$, $|y_\iota - jan_\iota| \leq ra$ for each ι, and $\sum_\iota |n_\iota| = |n|^2$ for $n \in \mathfrak{N}$; so

$$n \cdot y - c' \geq ja|n|^2 - ra|n|^2 - \tfrac{1}{2}ja|n|^2 = (\tfrac{1}{2}j - r)a|n|^2 \geq 0.$$

Hence $F \in \mathcal{F}_{\mathrm{loc}}(\mathbb{H}^+(n, c'))$.

Step 3: (a). By Step 1, $\theta_{n,c'}F = \tau_{jan}\theta_{n,0}\tau_{jan}A = \tau_{jan}\tau_{-jan}\theta_{n,0}A = \epsilon A$. The theorem on the nine families, Proposition YM3_I:103.4, at the mirror (n, c') gives

$$0 \leq \nu\big(\overline{\theta_{n,c'}F}\,F\big) = \epsilon\,\nu(\bar{A}\,\tau_{jan}A),$$

the number in the middle being real and non-negative. For real odd A this is $\nu(A\,\tau_{jan}A) \leq 0$.

Step 4: (b). The reflection $\theta_{n,0}$ belongs to $\mathsf{Iso}(a\mathbb{Z}^3)$, $0 \in \mathrm{Adm}(n)$, and $\theta_{n,0}A = -A$; Proposition 18.227 (c), (d) at $u = \theta_{n,0}$, $\omega = -1$ give the four assertions on the means. For real A, $\nu(\tau_{jan}A) = \nu(A) = 0$ by the invariance under translations (Proposition YM3_I:103.4), and (a) gives the sign.

Step 5: (c). A pure phase is a member of $\mathcal{G}^{\mathrm{per}}_{a,\beta}$, so (a) applies to it. Let $E \in \mathcal{I}$ with $\nu(E) > 0$; then $\nu(\,\cdot\,|E) \in \mathcal{G}^{\mathrm{per}}_{a,\beta}$ (Proposition YM3_I:106.1), and (a) for this state gives that $\epsilon\,\nu(1_E\,\bar{A}\,\tau_{jan}A)$ is real and ≥ 0; if $\nu(E) = 0$ it vanishes. With an $\mathcal{I}$-representative g, $\nu(1_E\,\epsilon\mathsf{g})$ is real and ≥ 0 for every $E \in \mathcal{I}$. At $E = \{\mathrm{Im}\,\mathsf{g} > 0\}$ and at $E = \{\mathrm{Im}\,\mathsf{g} < 0\}$, both in $\mathcal{I}$, the imaginary part of $\nu(1_E\mathsf{g})$ vanishes, so $\mathrm{Im}\,\mathsf{g} = 0$ almost everywhere; at $E = \{\epsilon\,\mathrm{Re}\,\mathsf{g} < 0\} \in \mathcal{I}$ the integrand is negative on E, so $\nu(E) = 0$. □

The one-point vanishing and the two-point sign pass to limits of these expressions whenever the relevant moments converge. The same argument applies in a component obtained as a limit through conditioned periodic Gibbs states, since the finite-spacing statements hold for every such state.

Thread laws at every label. Definition 18.207 forms the thread measure $\mu_{\ell,\mathsf{b}}$ of T_ℓ at labels b of an interval admitted by the side ℓ. We form it at every label by dilation, and we compare the thread laws of two tori in both directions. We use lattice units. A board (i,o) has the cells $o+a_i\mathbf{k}+[-a_i/2,a_i/2]^3$ with $\mathbf{k}\in\mathbb{Z}^3$, $o\in a_K\mathbb{Z}^3$ and $i\le K$. The walls are bond midplanes because a_i/a_K is odd. For a triple $\underline{N}=(N_1,N_2,N_3)$ of integers ≥ 2 let $\Lambda_{\underline{N}}:=\prod_\mu \mathbb{Z}/N_\mu\mathbb{Z}$, with the bonds (x,μ) from x to $x+e_\mu$, the configurations $U\in G^{\{\text{bonds}\}}$ with the product dU of the Haar measures, $a_p(U):=1-\frac12\operatorname{tr}[U(x,\mu)U(x+e_\mu,\nu)U(x+e_\nu,\mu)^{-1}U(x,\nu)^{-1}]$ for the plaquettes $p=(x;\mu,\nu)$, $\mu<\nu$, and $A_{\underline{N}}:=\sum_p a_p$; for $\beta>0$ and a bounded Borel $F\ge 0$ put $Z_{\underline{N}}[F]:=\int Fe^{-\beta A_{\underline{N}}}dU$, $Z_{\underline{N}}:=Z_{\underline{N}}[1]>0$, $\langle F\rangle_{\underline{N}}:=Z_{\underline{N}}[F]/Z_{\underline{N}}$ and $P_{\underline{N}}:=(N_1N_2N_3)^{-1}\log Z_{\underline{N}}$, and write $P_n:=P_{(n,n,n)}$. For an integer $\lambda\ge 2$ the model cell B_λ is the set of the bonds (x,μ) with x and $x+e_\mu$ in $\{0,\dots,\lambda-1\}^3$, read in $\Lambda_{\underline{N}}$ when all $N_\mu\ge\lambda+1$. For $K\in\mathbb{N}$ and a side $\ell=2L^m$, $m\in\mathbb{Z}$, $K+m\ge 1$, the map $x\mapsto x/a_K$ carries $a_K\mathbb{Z}^3/\ell\mathbb{Z}^3$ onto $\Lambda_{(n,n,n)}$, $n=\ell/a_K$, bonds onto bonds and plaquettes onto plaquettes; so $Z_{K,\ell,\beta}=Z_{(n,n,n)}$ at the same β, and $p_\ell:=\ell^{-3}\log Z_{K,\ell,\beta}$ equals $a_K^{-3}P_n$. A cell $\square$ of side $\ell'/2$, $\ell'=2L^{m'}\in\mathfrak{L}$, of a board of $\mathbb{L}_K$ holds λ^3 sites, $\lambda=L^{K+m'}$ odd, and no site lies on a wall; with its lowest corner site x_0 the chart $x\mapsto(x-x_0)/a_K$ carries the bonds lying in $\square$ onto B_λ, and for $F\in\mathcal{A}(\square):=\mathcal{F}(\mathsf{Bd}(\square))$, $F(U)=H(U_{\mathsf{Bd}(\square)})$, and every side $\ell\ge\ell'$, $\tilde\mu_{K,\ell,\beta}(F)=\langle H\rangle_{(\ell/a_K,\ell/a_K,\ell/a_K)}$, by $\tilde\mu_{K,\ell,\beta}(F)=\langle F\circ\mathsf{per}_\ell\rangle_{K,\ell,\beta}$ by periodic extension and the translation invariance of product Haar measure and the Wilson action.

The dilation number. For a real $\mathsf{b}>0$ and $\ell=2L^m\in\mathfrak{L}$ let $s=s(\mathsf{b},\ell)$ be the least integer $s\ge 0$ such that $\lambda_s:=L^s\mathsf{b}>\max\{2\gamma^{-2},2\bar B\}$ and $m+s-1\ge m_{\mathfrak{L}}(g_s^\circ)$, where $g_s^\circ:=(\lambda_s/2)^{-1/2}$; put $g^\circ:=g^\circ_{s(\mathsf{b},\ell)}$, $\lambda^\circ:=L^{s(\mathsf{b},\ell)}\mathsf{b}$,

$$\mathsf{D}^\circ(\mathsf{b},\ell):=\big(L^{s(\mathsf{b},\ell)}\ell\big)^3(2C_{\mathrm S}+C_{g^\circ}),\qquad \mathsf{Q}^\circ(\mathsf{b},\ell):=e^{\mathsf{D}^\circ(\mathsf{b},\ell)/8}.$$

The integer s exists: $g_s^\circ\le\gamma\le 1$, and the side rule YM3_I:(1528) gives $L^{m_{\mathfrak{L}}(g)}=LM\max\{R(L(g^{-2}+\bar B)),L^{\lceil\log_L C_{\mathrm s}\rceil}\}$ with $R(x)\le L\max\{1,(\log x)^r\}$, the least power of L that is $\ge(\log x)^r$; at $g^{-2}=\frac12L^s\mathsf{b}$ the right side grows at most like a power of s, while L^{m+s-1} grows like L^s. Three facts follow from the choice. (i) $g^\circ\le\gamma$, since $g^{\circ-2}=\lambda^\circ/2\ge\gamma^{-2}$. (ii) λ° lies in the interior of $I(g^\circ)=(g^{\circ-2}+\bar B,L(g^{\circ-2}+B_\sharp)-\bar B]$: $\lambda^\circ-\frac12\lambda^\circ-\bar B>0$ as $\lambda^\circ>2\bar B$, and $L(\frac12\lambda^\circ+B_\sharp)-\bar B-\lambda^\circ=(\frac L2-1)\lambda^\circ+LB_\sharp-\bar B>0$ as $L\ge 13$ and $\bar B=\frac{L}{L-1}B_\sharp\le LB_\sharp$. (iii) $L^{s-1}\ell$ and every larger side lie in $\mathfrak{L}(g^\circ)$. The numbers s, g°, D° and Q° are formed from the constants, b and ℓ alone; C_{g° is a function of σ^- and g° by Theorem YM3_I:AD.

Lemma 18.229 (Dilation)**.** Let $s\ge 0$ be an integer and $\delta_s\colon x\mapsto L^sx$.

(a) For $K\in\mathbb{Z}$, δ_s carries $\mathbb{L}_K$ onto $\mathbb{L}_{K-s}$, bonds onto bonds, plaquettes onto plaquettes with $a_{\delta_s p}(\delta_sU)=a_p(U)$, and configurations, bounded Borel functions and laws on $\mathbb{L}_K$ onto those on $\mathbb{L}_{K-s}$; $a_{K-s}\beta=L^sa_K\beta$. For $\beta>0$ it maps $\mathcal{G}^{\mathrm{per}}_{K,\beta}$ onto $\mathcal{G}^{\mathrm{per}}_{K-s,\beta}$ and carries $\tilde\mu_{K,\ell,\beta}$ to $\tilde\mu_{K-s,L^s\ell,\beta}$ for $\ell=2L^m$ with $K+m\ge 1$; if besides $K-s\ge 1$, and so $K\ge 1$ as well, it carries a board (i,o) of $\mathbb{L}_K$ with its cells $\square_{\mathbf k}$ to the board $(i-s,L^so)$ of $\mathbb{L}_{K-s}$ with the cells $L^s\square_{\mathbf k}$, and $\mathcal{A}(\square_{\mathbf k})$ onto $\mathcal{A}(L^s\square_{\mathbf k})$. On the tori, for every $\ell=2L^m$ with $K+m\ge 1$, it carries $a_K\mathbb{Z}^3/\ell\mathbb{Z}^3$ onto $a_{K-s}\mathbb{Z}^3/L^s\ell\mathbb{Z}^3$ and $\mu_{K,\ell,\beta}$ to $\mu_{K-s,L^s\ell,\beta}$; so $Z_{K,\ell,\beta}=Z_{K-s,L^s\ell,\beta}$, and ℓ^3p_ℓ at (K,β) equals $(L^s\ell)^3p_{L^s\ell}$ at $(K-s,\beta)$.

(b) Let $\ell\in\mathfrak{L}$ and $d\ge s$. Then $\delta_s\circ\mathcal{M}_\ell=\mathcal{M}_{L^s\ell}\circ\delta_s$, as maps from the configurations of $a_{d+1}\mathbb{Z}^3/\ell\mathbb{Z}^3$ to those of $a_{d-s}\mathbb{Z}^3/L^s\ell\mathbb{Z}^3$, and $\delta_s\circ\mathcal{M}=\mathcal{M}\circ\delta_s$ from Z_{d+1} to Z_{d-s}. Consequently, for $K\ge d\ge s$ and $\mathsf{b}'>0$, the law $\mu_d^K[\ell,\mathsf{b}']$ of $\mathcal{M}_\ell^{K-d}U$ under $\mu_{K,\ell,L^K\mathsf{b}'}$ satisfies $(\delta_s)_*\mu_d^K[\ell,\mathsf{b}']=\mu_{d-s}^{K-s}[L^s\ell,L^s\mathsf{b}']$. With the homeomorphisms $\Delta_s\colon\mathsf{Z}^{[s]}\to\mathsf{Z}$, $(\mathsf{z}_d)_{d\ge s}\mapsto(\delta_s\mathsf{z}_{d+s})_{d\ge0}$, and $\Delta_s\colon Y^{[s]}\to Y'$, where Y is formed at the side ℓ and Y' at the side $L^s\ell$ (so that δ_s carries w_d onto w'_{d-s}), one has $\Delta_s((\Psi_K(U)_d)_{d\ge s})=\Psi_{K-s}(\delta_sU)$ and $\Delta_s(\mathrm{pj}^{[s]}(\Upsilon_K(U)))=\Upsilon'_{K-s}(\delta_sU)$ for $K\ge s$ and every configuration U of $\mathbb{L}_K$.

■

Proof. (a) The dilation sends the sites, bonds and plaquettes bijectively to their counterparts and preserves each holonomy after relabelling. It also sends a finite-bond Gibbs kernel to the Gibbs kernel of the image set, since both the Wilson factors and the Haar product are carried to those of the image. A finite-index period subgroup is sent to a finite-index period subgroup. The torus maps have the same relabelling property and commute with periodic extension. In lattice units both tori have $n = \ell/a_K = L^s\ell/a_{K-s}$ sites along each axis. The board formula gives the stated scaling of its cells. (b) The three cases of the block map (Section YM3_I:4.3) form $\mathcal{M}_\ell(U)(c)$ at a bond c of the coarse lattice from the restriction of U to the bonds of the double block of c: from the small-field condition at the radius $\omega_M = \frac{1}{200L^2}$ on the plaquettes of the double block, from the averaged contour variables along the contours from the block centres, from the straight paths, from the means of finite families in G and from the logarithm and the exponential of G; all paths are sequences of unit steps of the fine lattice, written by integers relative to the end points of c, and neither the spacing nor the side enters any of these objects or the numerical constants of the Definition. The map δ_s carries the double block of c, with its bonds, plaquettes, contours and straight paths, onto the double block of $\delta_s c$, and keeps every value of the configuration; so the case of the Definition which applies, and the value, are the same. This is the reasoning of Lemma 18.211 (a), where the side is changed; the map $\mathcal{M}$ over $\mathbb{R}^3$ is read through the maps of the tori (Definition 18.206). The statements on the laws follow by induction on $K - d$ with (a); those on Ψ_K and Υ_K from their definitions and $\delta_s \circ \mathcal{M} = \mathcal{M} \circ \delta_s$, the members of the depths $> K$ and $> K - s$ being unit fields on both sides. □

Lemma 18.230 (The block-field laws and the thread measure at every label)**.** Let $\ell = 2L^m \in \mathfrak{L}$ and let $\mathsf{b} > 0$ be real.

(a) For every $d \geq 0$ the laws $\mu_d^K[\ell, \mathsf{b}]$ of $\mathcal{M}_\ell^{K-d}U$ under $\mu_{K,\ell,L^K\mathsf{b}}$ converge in total variation, as $K \to \infty$, to a Borel probability measure $\mu_d[\ell, \mathsf{b}]$ on $\mathsf{V}_d[\ell]$, and $(\mathcal{M}_\ell)_*\mu_{d+1}[\ell, \mathsf{b}] = \mu_d[\ell, \mathsf{b}]$. If b belongs to an interval of labels admitted by ℓ, these are the laws of Lemma 18.212 (a).

(b) There is exactly one Borel probability measure $\mu_{\ell,\mathsf{b}}$ on $\prod_{d\geq 0}\mathsf{V}_d[\ell]$ whose image at the depths $\leq D$ is the law of $(\mathcal{M}_\ell^D V, \dots, \mathcal{M}_\ell V, V)$ under $\mu_D[\ell, \mathsf{b}]$, for every D; it is carried by the threads of T_ℓ, and $\mu[\ell, \mathsf{b}] := (\varpi_0^{[0]} \circ \mathsf{Per}_\ell)_*\mu_{\ell,\mathsf{b}}$ is carried by $\mathsf{Thr}_\square$. This is the thread measure of T_ℓ at the label b, and $\mu^{[d_0]}[\ell, \mathsf{b}] := \mathrm{pj}_*^{[d_0]}\mu[\ell, \mathsf{b}]$.

(c) Let $K_j \to \infty$ and $\beta_j > 0$ with $a_{K_j}\beta_j \to \mathsf{b}$. Then the law of $\mathcal{M}_\ell^{K_j-d}U$ under μ_{K_j,ℓ,β_j} tends to $\mu_d[\ell, \mathsf{b}]$ in total variation, for every d. For every side $\ell' \geq \ell$ in $\mathfrak{L}$, with Υ_K and Y formed at the side ℓ, the laws $(\Upsilon_{K_j})_*\tilde{\mu}_{K_j,\ell',\beta_j}$ converge to $(\varpi_0^{[0]} \circ \mathsf{Per}_{\ell'})_*\mu_{\ell',\mathsf{b}}$ weakly on Y and in total variation at the depths $\leq D$, for every D; at $\ell' = \ell$ the limit is $\mu[\ell, \mathsf{b}]$.

■

Proof. Step 1: an admitted interval for the dilated side. Since $R(x) \leq L\max\{1, (\log x)^r\}$, there is an integer $s \geq 0$ with $\frac{1}{2}L^s\mathsf{b} \geq \gamma^{-2}$ and $M\,R(2L^s\mathsf{b}) \leq L^{m+s}$; then $\mathsf{J}_s := [\frac{1}{2}L^s\mathsf{b}, 2L^s\mathsf{b}]$ is an interval of labels under (Tor) on the side $L^s\ell$ by YM3_I:(2201), admitted by $L^s\ell$ in the sense of Definition 18.207, and Lemma 18.212 (a), (b), (d), (e) hold at the side $L^s\ell$ and the interval J_s.

Step 2: (a) and (c) at the depths $d \geq s$. By Lemma 18.229 (b), $\mu_d^K[\ell, \mathsf{b}']$ is the image under δ_s^{-1} of $\mu_{d-s}^{K-s}[L^s\ell, L^s\mathsf{b}']$ for $K \geq d$ and every $\mathsf{b}' > 0$; a bijection keeps the distance in total variation. Lemma 18.212 (a) at $L^s\mathsf{b} \in \mathsf{J}_s$ gives the convergence of these laws; and as $L^s a_{K_j}\beta_j \to L^s\mathsf{b}$, all but finitely many of these numbers lie in J_s, and Lemma 18.212 (e) at the side $L^s\ell$ gives the convergence along (K_j, β_j), with the same limit. The consistency $(\mathcal{M}_\ell)_*\mu_{d+1} = \mu_d$ for $d \geq s$ is the image of that of Lemma 18.212 (a).

Step 3: the depths $d < s$. Put $\mu_d[\ell, \mathsf{b}] := (\mathcal{M}_\ell^{s-d})_*\mu_s[\ell, \mathsf{b}]$. As $\mu_d^K = (\mathcal{M}_\ell^{s-d})_*\mu_s^K$ for $K \geq s$, and an image under one Borel map (Lemma 18.211 (b)) does not increase the distance in total variation,

Step 2 gives (a) and the first assertion of (c). If b lies in an interval admitted by ℓ, the limits of Lemma 18.212 (a) and the present ones are limits of one sequence in total variation, so they agree.

Step 4: (b) and the windows. The proofs of Lemma 18.212 (b), (d) and of the part of (e) on the windows read of the labels only the convergence in total variation of the laws of the block fields at every depth; with (a) and (c) in its place they give (b), and the convergence of $(\Upsilon_{K_j})_*\tilde{\mu}_{K_j,\ell',\beta_j}$ when the window is that of the side ℓ' (Kolmogorov's extension theorem; Lemma 18.211 (c), (d); images do not increase the distance in total variation; cylinder functions are dense). For the window of the smaller side ℓ, the restriction from the window of the side ℓ' to the window of the side ℓ is continuous, it carries the window towers and the threads over the larger window to those over the smaller one (Lemma 18.211 (d)), and it maps the functions of the depths $\le D$ to functions of the depths $\le D$. □

Lemma 18.231 (Kernels and sequences)**.** Let X be a compact metrisable space with a Borel probability measure dx, and let $\mathcal{K}$ be the set of the bounded Borel functions $X\times X\to[0,\infty)$. For $P,Q\in\mathcal{K}$ put $(P*Q)(x,z):=\int P(x,y)Q(y,z)\,dy$, $[P,Q]:=\iint P(x,y)Q(x,y)\,dx\,dy$, $P^{\mathsf{T}}(x,y):=P(y,x)$ and $\operatorname{tr}P:=\int P(x,x)\,dx$. Let $T\in\mathcal{K}$ be symmetric, $T^1:=T$, $T^{k+1}:=T^k*T$, and $z(k):=\operatorname{tr}T^k$.

(k1) $*$ is associative and monotone in each factor, $T^j*T^k=T^{j+k}$, every T^k is symmetric, $[P,Q]=\operatorname{tr}(P*Q^{\mathsf{T}})$, and $[P,Q]^2\le[P,P]\,[Q,Q]$.

(k2) $z(j+k)^2\le z(2j)\,z(2k)$ for $j,k\ge1$, and $z(4k)\le z(2k)^2$ for $k\ge1$.

(k3) For $P,R\in\mathcal{K}$ put $Y:=P^{\mathsf{T}}*P$, $S:=R*R^{\mathsf{T}}$, $g(0):=[R,R]$ and $g(j):=[Y^j,S]$ for $j\ge1$. Then $g(0)=\operatorname{tr}S$, $g(j)^2\le g(j-1)\,g(j+1)$ for $j\ge1$, $g(k)\le\operatorname{tr}(Y^k)\operatorname{tr}S$, and $g(1)\le\operatorname{tr}S\,(\operatorname{tr}Y^k)^{1/k}$ for every $k\in\mathbb{N}$.

(c1) If $f\colon\{0,\dots,n_2\}\to[0,\infty)$ satisfies $f(n)^2\le f(n-1)f(n+1)$ for $0<n<n_2$, then $f(n)\le f(0)^{1-n/n_2}f(n_2)^{n/n_2}$ for $0\le n\le n_2$, with $0^0:=1$.

(c2) If $w\colon\mathbb{N}\to\mathbb{R}$ satisfies $2w(k)\le w(k-1)+w(k+1)$ for $k\ge2$ and $w(2k)\le2w(k)$ for $k\ge1$, then $w(n)/n\le w(k)/k$ for all $n\ge k\ge1$.

■

Proof. (k1) is Fubini's theorem for non-negative bounded Borel functions, and the inequality is that of Cauchy and Schwarz in $L^2(X\times X)$. (k2) $[T^j,T^k]=\operatorname{tr}(T^j*T^k)=z(j+k)$, and (k1). Next $T^{2k}(x,y)=\int T^k(x,u)T^k(y,u)\,du\le T^{2k}(x,x)^{1/2}T^{2k}(y,y)^{1/2}$, so $z(4k)=\iint T^{2k}(x,y)^2\le(\int T^{2k}(x,x)\,dx)^2$. (k3) The powers Y^j are symmetric; put $Y^0*R:=R$. For $j=2i+1$, integrating the variables of $S=R*R^{\mathsf{T}}$ first, $[Y^i*R,Y^{i+1}*R]=g(2i+1)$, $[Y^i*R,Y^i*R]=g(2i)$ and $[Y^{i+1}*R,Y^{i+1}*R]=g(2i+2)$; for $j=2i$, $i\ge1$, $[P*Y^{i-1}*R,P*Y^i*R]=g(2i)$, $[P*Y^{i-1}*R,P*Y^{i-1}*R]=g(2i-1)$ and $[P*Y^i*R,P*Y^i*R]=g(2i+1)$; in both cases the inequality is (k1). $g(0)=\iint R(x,w)^2=\operatorname{tr}S$. A kernel $W=Q^{\mathsf{T}}*Q$ has $W(x,y)\le W(x,x)^{1/2}W(y,y)^{1/2}$; S is of this form with $Q=R^{\mathsf{T}}$, and Y^k with $Q=Y^{k/2}$ for even k and $Q=P*Y^{(k-1)/2}$ for odd k; so $g(k)\le(\int Y^k(x,x)^{1/2}S(x,x)^{1/2}dx)^2\le\operatorname{tr}Y^k\operatorname{tr}S$. By the log-convexity just shown and (c1) on $\{0,\dots,k\}$, $g(1)\le g(0)^{1-1/k}g(k)^{1/k}\le\operatorname{tr}S\,(\operatorname{tr}Y^k)^{1/k}$. (c1) If $f>0$ throughout, $\log f$ is convex on the integers, and a convex sequence lies below its chord: the difference with the chord satisfies the same inequality, vanishes at both ends, and at its first point of maximum it would violate the inequality if the maximum were positive. If $f(i)=0$ at some i, the inequality forces $f=0$ at all interior points, where the claim is trivial; at the ends it is an equality. (c2) For $k\le n\le2k$, the chord on $\{k,\dots,2k\}$ and $w(2k)\le2w(k)$ give $w(n)\le\frac{2k-n}{k}w(k)+\frac{n-k}{k}w(2k)\le\frac{n}{k}w(k)$; for $2^ik\le n<2^{i+1}k$ iterate: $\frac{w(n)}{n}\le\frac{w(2^ik)}{2^ik}\le\dots\le\frac{w(k)}{k}$. □

Lemma 18.232 (Slices; the pressure decreases in each side)**.** Let $\beta>0$, $N_2,N_3\ge2$, $\Sigma:=\mathbb{Z}/N_2\times\mathbb{Z}/N_3$, $X:=G^{\Sigma\times\{2,3\}}$ and $\Upsilon:=G^{\Sigma}$, with the product Haar measures. For a configuration U on $\Lambda_{(N_1,N_2,N_3)}$ and $\mathsf{t}\in\mathbb{Z}/N_1$ let $x_{\mathsf{t}}:=(U((\mathsf{t},z),\nu))_{z\in\Sigma,\nu=2,3}\in X$ be the bonds in the slice t and $y_{\mathsf{t}}:=(U((\mathsf{t},z),1))_{z\in\Sigma}\in\Upsilon$ the bonds from the slice t to the slice $\mathsf{t}+1$. There is a continuous,

symmetric and strictly positive function T on $X \times X$, depending on β, N_2, N_3 alone, such that, with the signs of Lemma 18.231:

(s1) $Z_{(N_1,N_2,N_3)} = \operatorname{tr} T^{N_1}$ for every $N_1 \geq 2$.

(s2) Let $\lambda \geq 2$, and let $F \geq 0$ be a bounded Borel function of the slab of direction 1 with λ slices, that is, of $(x_0, y_0, x_1, \dots, y_{\lambda-2}, x_{\lambda-1})$. There is $A_F \in \mathcal{K}$, independent of N_1, with $Z_{(N_1,N_2,N_3)}[F] = \operatorname{tr}(A_F * T^{N_1-\lambda+1})$ for every $N_1 \geq \lambda$; $A_1 = T^{\lambda-1}$, and $F \leq F'$ implies $A_F \leq A_{F'}$.

(s3) The mirror image $F^\flat(x_0, y_0, \dots, y_{\lambda-2}, x_{\lambda-1}) := F(x_{\lambda-1}, y_{\lambda-2}^{-1}, \dots, y_0^{-1}, x_0)$, with the inverses taken entry by entry, which is F read through the lattice reflection $x_1 \mapsto \lambda - 1 - x_1$ (a bond of the direction 1 being reversed), has $A_{F^\flat} = A_F^{\mathsf{T}}$.

(s4) For $k \in \mathbb{N}$ let $F^{\langle k \rangle}$ be the product, on the configurations of $\Lambda_{(2\lambda k,N_2,N_3)}$, of the $2k$ images of F under the lattice maps $x_1 \mapsto 2\lambda j \pm x_1$, $0 \leq j < k$. Then $Z_{(2\lambda k,N_2,N_3)}[F^{\langle k \rangle}] = \operatorname{tr}(Y^k)$ with $Y = P^{\mathsf{T}} * P$, $P = A_F * T$; and $0 \leq F^{\langle k \rangle} \leq F$ if $0 \leq F \leq 1$.

(P) If $\underline{N}$ and $\underline{N}'$ are triples of even integers ≥ 2 with $N_\mu \leq N'_\mu$ for $\mu = 1, 2, 3$, then $P_{\underline{N}'} \leq P_{\underline{N}}$.

The same holds with the direction 2 or 3 in the place of the direction 1. ■

Proof. Put $A_{\mathrm{s}}(x) := \sum_{z \in \Sigma}[1 - \frac{1}{2}\operatorname{tr} x(z,2)x(z+e_2,3)x(z+e_3,2)^{-1}x(z,3)^{-1}]$ and $A_{\mathrm{c}}(x,y,x') := \sum_{z\in\Sigma}\sum_{\nu=2,3}[1 - \frac{1}{2}\operatorname{tr} y(z)x'(z,\nu)y(z+e_\nu)^{-1}x(z,\nu)^{-1}]$. The plaquettes in the slice t give $A_{\mathrm{s}}(x_{\mathsf{t}})$, those between the slices t and $\mathsf{t}+1$ give $A_{\mathrm{c}}(x_{\mathsf{t}}, y_{\mathsf{t}}, x_{\mathsf{t}+1})$, and $U \mapsto (x_{\mathsf{t}}, y_{\mathsf{t}})_{\mathsf{t}}$ carries dU to the product measure. Put $\mathsf{k}(x,x') := \int_\Upsilon e^{-\beta A_{\mathrm{c}}(x,y,x')}dy$ and $T(x,x') := e^{-\frac{\beta}{2}A_{\mathrm{s}}(x)}\mathsf{k}(x,x')e^{-\frac{\beta}{2}A_{\mathrm{s}}(x')}$, continuous and positive. The term (z,ν) of $A_{\mathrm{c}}(x', y^{-1}, x)$ is formed with a matrix conjugate to the inverse of the matrix of the term (z,ν) of $A_{\mathrm{c}}(x,y,x')$, and $\operatorname{tr} u^{-1} = \operatorname{tr} u$ on G, whose Haar measure is invariant under inversion; so T is symmetric. (s1): integrate the variables y_{t} first and split each weight $e^{-\beta A_{\mathrm{s}}(x_{\mathsf{t}})}$ into two halves. (s2): $A_F(x,x')$ is the integral of F against the weights of the slices $0, \dots, \lambda-1$, with half weights at the two end slices, over $y_0, \dots, y_{\lambda-2}, x_1, \dots, x_{\lambda-2}$, at $x_0 = x$, $x_{\lambda-1} = x'$; the variables which F does not read give $T^{N_1-\lambda+1}(x_{\lambda-1}, x_0)$. (s3): rename $x_{\mathsf{t}} \to x_{\lambda-1-\mathsf{t}}$, $y_{\mathsf{t}} \to y_{\lambda-2-\mathsf{t}}^{-1}$, and use the symmetry of A_{c}. (s4): the image under $x_1 \mapsto 2\lambda j + x_1$ reads the slices $2\lambda j, \dots, 2\lambda j + \lambda - 1$ as F reads the slices $0, \dots, \lambda - 1$; the image under $x_1 \mapsto 2\lambda j - x_1$ reads the slices $2\lambda j - \lambda + 1, \dots, 2\lambda j$ as $F^\flat$ reads $0, \dots, \lambda - 1$; the two have the slice $2\lambda j$ in common, and two free steps lead from the slice $2\lambda j + \lambda - 1$ to the slice $2\lambda(j+1) - \lambda + 1$. Integrating as in (s2) gives $\operatorname{tr}((A_F^{\mathsf{T}} * A_F * T^2)^k) = \operatorname{tr}((T * A_F^{\mathsf{T}} * A_F * T)^k)$, and $T * A_F^{\mathsf{T}} * A_F * T = P^{\mathsf{T}} * P$. Each of the $2k$ factors lies in $[0,1]$, and the factor at $j = 0$ with the sign $+$ is F. The other directions: a_p does not change when μ and ν are exchanged in its formula, the matrix becoming its inverse; so a permutation of the coordinates carries $A_{\underline{N}}$, dU and $Z_{\underline{N}}[\cdot]$ to those of the permuted triple. (P): it suffices to raise one entry, by the symmetry the first, from $2k$ to $2n$, $n \geq k \geq 1$. With $w(k) := \log z(2k) = \log Z_{(2k,N_2,N_3)}$, finite as $T > 0$, (k2) gives $2w(k) \leq w(k-1) + w(k+1)$ for $k \geq 2$ and $w(2k) \leq 2w(k)$; (c2) gives $w(n)/n \leq w(k)/k$; divide by $2N_2N_3$. □

Proposition 18.233 (One direction: one copy against $2k$ mirrored copies)**.** Let $\beta > 0$, $N_2, N_3 \geq 2$, let $\lambda \geq 3$ be odd, $k \in \mathbb{N}$, and let F be a Borel function of the slab of direction 1 with λ slices with $0 \leq F \leq 1$; put $Z(n) := Z_{(n,N_2,N_3)}$. Then

$$Z(2\lambda)[F]^{2k} \leq \big[Z(\lambda+1)\,Z(\lambda-1)\big]^k\, Z(2\lambda k)\big[F^{\langle k \rangle}\big].$$

The same holds in the directions 2 and 3. ■

Proof. Put $A := A_F$, $n_1 := \frac{\lambda+1}{2}$, $P := A * T$, $Y := P^{\mathsf{T}} * P$, $R := T^{(\lambda-1)/2}$ and $S := R * R^{\mathsf{T}} = T^{\lambda-1}$; λ is odd and ≥ 3. By (s2) at $N_1 = 2\lambda$ and (k1), $Z(2\lambda)[F] = \operatorname{tr}(A * T^{\lambda+1}) = [A * T^{n_1}, T^{n_1}] \leq [A * T^{n_1}, A * T^{n_1}]^{1/2}[T^{n_1}, T^{n_1}]^{1/2}$: one copy of F on the ring of 2λ slices is bounded by F and its mirror image back to back and by an empty ring of $\lambda+1$ slices; $[T^{n_1}, T^{n_1}] = z(\lambda+1) = Z(\lambda+1)$ by (s1). Next $[A*T^{n_1}, A*T^{n_1}] = \operatorname{tr}(A*T*S*T*A^{\mathsf{T}}) = \operatorname{tr}(S*Y) = g(1)$ in the signs of (k3). By (k3),

$g(1) \le \operatorname{tr} S\,(\operatorname{tr} Y^k)^{1/k}$, with $\operatorname{tr} S = z(\lambda-1) = Z(\lambda-1)$ by (s1), $\lambda-1 \ge 2$, and $\operatorname{tr} Y^k = Z(2\lambda k)[F^{\langle k\rangle}]$ by (s4). So $Z(2\lambda)[F]^2 \le Z(\lambda+1)Z(\lambda-1)Z(2\lambda k)[F^{\langle k\rangle}]^{1/k}$; raise to the power k. □

Proposition 18.234 (Two tori at one cutoff: the converse of the domination)**.** Let $K \in \mathbb{N}$, $\beta > 0$, $\ell = 2L^m$ with $m \in \mathbb{N}$, $\lambda := \ell/(2a_K) = L^{K+m}$, $n := 2\lambda$, $n_0 := 2\lambda/L$, $t \in \mathbb{N}$, $k := L^t$, $n' := 2\lambda k$,

$$\mathsf{D} := n^3(P_{n_0} - P_{n'}), \qquad q_0 := 8k^3 = 8L^{3t}.$$

(a) $\mathsf{D} \ge 0$, and for every Borel function H on G^{B_λ} with $0 \le H \le 1$, with $H^\sharp$ the product, on the configurations of $\Lambda_{(n',n',n')}$, of the $8k^3$ images of H under the maps $x \mapsto (2\lambda j_\mu \pm x_\mu)_\mu$, $j \in \{0,\dots,k-1\}^3$: $0 \le H^\sharp \le H$, $\langle H\rangle_{(n,n,n)}^{8k^3} \le e^{8k^3\mathsf{D}}\langle H^\sharp\rangle_{(n',n',n')}$, and so $\langle H\rangle_{(n,n,n)} \le e^{\mathsf{D}}\langle H\rangle_{(n',n',n')}^{1/q_0}$.

(b) For every cell $\square$ of side $\frac{\ell}{2}$ of a board of $\mathbb{L}_K$ and every $F \in \mathcal{A}(\square)$ with $0 \le F \le 1$: $\tilde\mu_{K,\ell,\beta}(F) \le e^{\mathsf{D}}\,\tilde\mu_{K,L^t\ell,\beta}(F)^{1/q_0}$; and $\mathsf{D} = \ell^3(p_{\ell/L} - p_{L^t\ell})$ when $m \ge 2$.

(c) For the same $\square$ and every bounded Borel $F \in \mathcal{A}(\square)$ with $F \ge 0$: $\tilde\mu_{K,L^t\ell,\beta}(F) \le e^{\frac18\ell^3(p_\ell - p_{L^t\ell})}\,\tilde\mu_{K,\ell,\beta}(F^8)^{1/8}$, and $\ell^3(p_\ell - p_{L^t\ell}) \le \mathsf{D}$.

(d) Let $\mathsf{b} > 0$ and $s = s(\mathsf{b},\ell)$. If $K > s$ and $L^s a_K\beta \in I(g^\circ)$, in particular at every pair $(K, L^K\mathsf{b})$ with $K > s$, then $\mathsf{D} \le \mathsf{D}^\circ(\mathsf{b},\ell)$.

■

Proof. (a) Let $G_0 := H$ and let G_i arise from G_{i-1} by the operation of Lemma 18.232 (s4) in the direction i, $i = 1,2,3$; then $H^\sharp = G_3$. Each G_{i-1} is a product of images of H under maps which move only the coordinates x_μ with $\mu < i$, so it is a Borel function of the slab of direction i with λ slices, with values in $[0,1]$. Proposition 18.233 in the direction i, with the other two sides (n,n), (n',n), (n',n') for $i = 1,2,3$, gives $z_{i-1}^{2k} \le c_i^k z_i$ with $z_0 := Z_{(n,n,n)}[G_0]$, $z_1 := Z_{(n',n,n)}[G_1]$, $z_2 := Z_{(n',n',n)}[G_2]$, $z_3 := Z_{(n',n',n')}[G_3]$, $c_1 := Z_{(\lambda+1,n,n)}Z_{(\lambda-1,n,n)}$, $c_2 := Z_{(n',\lambda+1,n)}Z_{(n',\lambda-1,n)}$ and $c_3 := Z_{(n',n',\lambda+1)}Z_{(n',n',\lambda-1)}$. Hence $z_0^{8k^3} \le c_1^{4k^3}c_2^{2k^2}c_3^k z_3$. All the triples which occur have even entries in $[n_0,n']$, since $\lambda \pm 1$ are even and $n_0 \le \lambda - 1$ (as $L \ge 13$); by (P), $P^- := P_{n'} \le P_{\underline N} \le P_{n_0} =: P^+$ for each of them, so $\mathsf{D} = n^3(P^+ - P^-) \ge 0$. With $\log Z_{\underline N} = N_1N_2N_3P_{\underline N}$, and as the two tori of c_1, c_2, c_3 have together n^3, kn^3, k^2n^3 sites, $\log(c_1^{4k^3}c_2^{2k^2}c_3^k) \le 7k^3n^3P^+$, $\log Z_{(n',n',n')} \le k^3n^3P^+$ and $\log Z_{(n,n,n)} \ge n^3P^-$. So

$$\langle H\rangle_{(n,n,n)}^{8k^3} = \frac{z_0^{8k^3}}{Z_{(n,n,n)}^{8k^3}} \le \frac{c_1^{4k^3}c_2^{2k^2}c_3^k\,Z_{(n',n',n')}}{Z_{(n,n,n)}^{8k^3}}\,\langle H^\sharp\rangle_{(n',n',n')} \le e^{8k^3\mathsf{D}}\langle H^\sharp\rangle_{(n',n',n')},$$

and $H^\sharp = G_3 \le G_2 \le G_1 \le H$ by (s4). (b) is (a) read through the chart of the lattice units, at $\ell/a_K = n$ and $L^t\ell/a_K = n'$, with $n^3P_{n_0} = \ell^3 p_{\ell/L}$ and $n^3P_{n'} = \ell^3 p_{L^t\ell}$ when $\ell/L \in \mathfrak{L}$. (c) Use the seminorm $\|F\|_t$ from the proof of Lemma 18.216, with board side $\mathsf{l} = \ell/2$. The finite-torus chessboard inequality and the comparison of sides give

$$\tilde\mu_{K,L^t\ell,\beta}(F) \le \|F\|_{L^t\ell} \le \|F\|_\ell\, e^{\mathsf{l}^3(p_\ell - p_{L^t\ell})}.$$

The eight reflected factors on the torus of side ℓ have the same L^8 norm, so Hölder gives $\|F\|_\ell \le \tilde\mu_{K,\ell,\beta}(F^8)^{1/8}$. Finally $\mathsf{l}^3 = \ell^3/8$ and $\ell^3(p_\ell - p_{L^t\ell}) = n^3(P_n - P_{n'}) \le \mathsf{D}$ by (P). (d) D is a number of the lattice units: it depends on λ, k, L and β alone, and $\lambda = \ell/(2a_K) = L^s\ell/(2a_{K-s})$. The pair $(K-s,\beta) = (K-s, L^{K-s}\cdot L^s a_K\beta)$ is a datum at g° with the label $L^s a_K\beta \in I(g^\circ)$ (Lemma 18.212 (c)); and $L^{s-1}\ell$, $L^{s+t}\ell$ lie in $\mathfrak{L}(g^\circ)$. So $\mathsf{D} = (L^s\ell)^3(p_{L^{s-1}\ell} - p_{L^{s+t}\ell})$ at $(K-s,\beta)$, and the volume bounds at a datum at g° for two sides of $\mathfrak{L}(g^\circ)$ from Theorem YM3_I:AD give $p_{\ell_1} - p_{\ell_2} \le 2C_{\mathrm S} + C_{g^\circ}$ for $\ell_1,\ell_2 \in \mathfrak{L}(g^\circ)$, as in the proof of Lemma 18.216. At $(K, L^K\mathsf{b})$, $L^s a_K\beta = \lambda^\circ \in I(g^\circ)$. □

Proposition 18.235 (Two tori at every label are mutually absolutely continuous)**.** Let $\mathsf{b} > 0$, $m_1, t \in \mathbb{N}$, $\ell_1 := 2L^{m_1}$, $\ell_2 := L^t\ell_1$, and let the window $\square$, the sets w_d and the space Y be those of

Definition 18.206 at the side ℓ_1. For $i = 1, 2$ let $\nu_i := (\varpi_0^{[0]} \circ \mathsf{Per}_{\ell_i})_* \mu_{\ell_i, \mathsf{b}}$ be the law over $\square$ of the thread measure of T_{ℓ_i} at the label b (Lemma 18.230), so that $\nu_1 = \mu[\ell_1, \mathsf{b}]$; put $\mathsf{D}^\circ := \mathsf{D}^\circ(\mathsf{b}, \ell_1)$ and $q_0 := 8L^{3t}$, $q_0' := q_0/(q_0 - 1)$.

(a) For every Borel set $A \subset Y$, $\nu_1(A) \le e^{\mathsf{D}^\circ} \nu_2(A)^{1/q_0}$; and $\nu_2 \preceq_{e^{\mathsf{D}^\circ/8}} \nu_1$, in particular $\nu_2(A) \le e^{\mathsf{D}^\circ/8} \nu_1(A)^{1/8}$.

(b) ν_1 and ν_2 are mutually absolutely continuous; $d\nu_1/d\nu_2 \in L^r(\nu_2)$ with a norm at most $e^{\mathsf{D}^\circ}(q_0'/(q_0' - r))^{1/r}$ for $1 \le r < q_0'$; $h := d\nu_2/d\nu_1 \in L^{8/7}(\nu_1)$ with a norm at most $e^{\mathsf{D}^\circ/8}$, and $0 \le \int h \log h \, d\nu_1 \le \mathsf{D}^\circ$.

(c) (a) and (b) hold for the images of ν_1 and ν_2 under one Borel map, in particular for the laws of the threads over a ball $\mathbb{B}(0, R)$ with $4R \le \ell_1$, that is, of the block fields of all depths on the bonds with both end points in $\mathbb{B}(0, R)$. So, for every $R > 0$, the thread laws over $\mathbb{B}(0, R)$ at the label b of any two tori with sides $\ell_1 < \ell_2$ in $\mathfrak{L}$, $\ell_1 \ge 16(R + 1)$, are mutually absolutely continuous, with densities in L^r for some $r > 1$ in both directions.

(d) The constants are formed from the constants, b and the smaller side ℓ_1; the exponent $1/q_0$ from ℓ_2/ℓ_1 alone.

■

Proof. Step 1: cylinders at one cutoff. Let $D \ge 0$, let $f \ge 0$ be a bounded Borel function on $Y_{\le D}$, and $K \ge \max\{D, 1\}$. By Lemma 18.211 (d), $\Upsilon_K(U)$ depends on the bonds in $\square$ alone, and Ψ_K is Borel; so $F_K := f \circ q_D \circ \Upsilon_K \in \mathcal{A}(\square)$, where $\square$ is the cell $\mathbf{0}$ of the board of side $\frac{\ell_1}{2}$ with the origin 0. At $f = 1_{A_D}$ it is the indicator of a Borel set of the cell.

Step 2: the two inequalities at one cutoff. Let $K > s(\mathsf{b}, \ell_1)$ and $\beta = L^K \mathsf{b}$. Proposition 18.234 (b), (d) at $f = 1_{A_D}$ give $\tilde\mu_{K,\ell_1,\beta}(F_K) \le e^{\mathsf{D}^\circ} \tilde\mu_{K,\ell_2,\beta}(F_K)^{1/q_0}$, and Proposition 18.234 (c), (d) give $\tilde\mu_{K,\ell_2,\beta}(F_K) \le e^{\mathsf{D}^\circ/8} \tilde\mu_{K,\ell_1,\beta}(F_K^8)^{1/8}$ for every bounded Borel $f \ge 0$.

Step 3: the limit of the cutoff. By Lemma 18.230 (c), the laws $(\Upsilon_K)_* \tilde\mu_{K,\ell_i,L^K\mathsf{b}}$ converge to ν_i in total variation at the depths $\le D$; the maps $x \mapsto x^{1/q_0}$, $x^{1/8}$ are continuous on $[0, 1]$. So both inequalities hold for the cylinder sets $C = q_D^{-1} A_D$, and the second for the cylinder functions $f \circ q_D$.

Step 4: all Borel sets and functions. The cylinder sets form an algebra which generates the Borel sets of Y, the product of countably many compact metric spaces; so every Borel set A is approximated by cylinder sets C with $(\nu_1 + \nu_2)(A \triangle C) \le \epsilon$, and $\nu_1(A) \le \nu_1(C) + \epsilon \le e^{\mathsf{D}^\circ}(\nu_2(A) + \epsilon)^{1/q_0} + \epsilon$; let $\epsilon \to 0$, and likewise for the other inequality. A bounded Borel f on Y with $0 \le f \le c$ is a limit in $L^1(\nu_1 + \nu_2)$ of cylinder functions with values in $[0, c]$, and the inequality $\nu_2(f) \le e^{\mathsf{D}^\circ/8} \nu_1(f^8)^{1/8}$ passes to the limit by $|x^8 - y^8| \le 8c^7 |x - y|$ on $[0, c]$; for complex f use $|\nu_2(f)| \le \nu_2(|f|)$. This is (a).

Step 5: densities. By (a) the two laws have the same null sets, and the theorem of Radon and Nikodym gives the densities. Lemma 18.214 (DM2), (DM3) give the assertions on h, with $8 \log e^{\mathsf{D}^\circ/8} = \mathsf{D}^\circ$. For $\mathsf{g} := d\nu_1/d\nu_2$ and $u > 0$, the set $E_u := \{\mathsf{g} > u\}$ has $u\, \nu_2(E_u) \le \nu_1(E_u) \le e^{\mathsf{D}^\circ} \nu_2(E_u)^{1/q_0}$, so $\nu_2(E_u) \le (e^{\mathsf{D}^\circ}/u)^{q_0'}$; and $\int \mathsf{g}^r d\nu_2 = \int_0^\infty r u^{r-1} \nu_2(E_u)\, du \le e^{r\mathsf{D}^\circ} + \int_{e^{\mathsf{D}^\circ}}^\infty r u^{r-1} (e^{\mathsf{D}^\circ}/u)^{q_0'} du = e^{r\mathsf{D}^\circ} q_0'/(q_0' - r)$ for $1 \le r < q_0'$.

Step 6: images; balls; (d). For a Borel map p, $\mathsf{p}_* \nu_i(A') = \nu_i(\mathsf{p}^{-1} A')$, and (DM4); then Step 5. The bonds with both end points in $\mathbb{B}(0, R) \subset \square$ belong to the sets w_d, and the thread over the ball is a coordinate projection of Y. Two sides $\ell_1 < \ell_2$ of $\mathfrak{L}$ satisfy $\ell_2 = L^t \ell_1$ with $t \ge 1$, and $\ell_1 \ge 16(R + 1)$ gives $4R \le \ell_1$. (d) is the formation of $\mathsf{D}^\circ(\mathsf{b}, \ell_1)$ and q_0. □

Proposition 18.236 (Every limit law of the block fields through periodic Gibbs states, at every label, is dominated by one torus)**.** Let $\mathsf{b} > 0$ and $\ell \in \mathfrak{L}$; put $\mathsf{Q}^\circ := \mathsf{Q}^\circ(\mathsf{b}, \ell)$, let $\mu := \mu[\ell, \mathsf{b}]$ and $\mu^{[d_0]} := \mu^{[d_0]}[\ell, \mathsf{b}]$ be the thread measure of T_ℓ at the label b seen in the window of the side ℓ (Lemma 18.230), and let $(K_j, \beta_j, \nu_j)_j$ be integers $K_j \to \infty$, numbers $\beta_j > 0$ with $a_{K_j} \beta_j \to \mathsf{b}$, and states $\nu_j \in \mathcal{G}^{\mathrm{per}}_{K_j, \beta_j}$; no reference coupling is fixed.

(i) For all $o_j \in a_{K_j}\mathbb{Z}^3$, the laws $(\Upsilon_{K_j} \circ \tau_{-o_j})_*\nu_j$ have weak limit points on Y, and every such limit point ν satisfies $\nu \preceq_{\mathsf{Q}^\circ} \mu$: $\nu = h\mu$ with $\|h\|_{L^{8/7}(\mu)} \le \mathsf{Q}^\circ$ and $0 \le \int h \log h \, d\mu \le \mathsf{D}^\circ(\mathsf{b}, \ell)$, $\nu(\mathcal{A}) \le \mathsf{Q}^\circ \mu(\mathcal{A})^{1/8}$ for every Borel set $\mathcal{A} \subset Y$, and $\nu(\mathsf{Thr}_\square) = 1$.

(ii) The laws $(\Psi_{K_j})_*\nu_j$ have weak limit points on Z, and every such limit point $\boldsymbol{\nu}$ satisfies $(\varpi_o^{[d_0]})_*\boldsymbol{\nu} \preceq_{\mathsf{Q}^\circ} \mu^{[d_0]}$ for all $d_0 \ge 0$ and $o \in a_{d_0}\mathbb{Z}^3$, $\boldsymbol{\nu}(\mathsf{Thr}) = 1$, $(T_v)_*\boldsymbol{\nu} = \boldsymbol{\nu}$ for every $v \in \mathbb{D}$, and the product bound of Definition 18.207 with Q° in the place of Q_0.

(iii) The conclusions of (ii), the domination and the product bound, hold for $D\boldsymbol{\nu}$, for every Borel function $D \ge 0$ with $\boldsymbol{\nu}(D) = 1$ and $D \circ T_v = D$ $\boldsymbol{\nu}$-almost everywhere for one $v \in \mathbb{D} \setminus \{0\}$, and for almost every member of every decomposition of $\boldsymbol{\nu}$ into laws carried by Thr and invariant under one T_v, $v \in \mathbb{D} \setminus \{0\}$; in particular for almost every member of every ergodic decomposition of $\boldsymbol{\nu}$ under $\mathbb{D}$ and of every regular conditional distribution of $\boldsymbol{\nu}$ given $\mathcal{I}_\infty$.

(iv) Every Borel subset of Y of full μ-measure has full measure for every law of (i), and its inverse image under $\varpi_o^{[0]}$, $o \in \mathbb{Z}^3$, has full measure for the laws of (ii) and (iii); of the laws of (i), at most $(\mathsf{Q}^\circ)^8$ are pairwise mutually singular.

(v) Q° and μ are formed from the constants, b and ℓ; they depend neither on the K_j, β_j, ν_j nor on the o_j. Each law ν of (i) is, on Y and all depths together, absolutely continuous with respect to μ; for each law $\boldsymbol{\pi}$ of (ii) or (iii), each $d_0 \ge 0$ and each $o \in a_{d_0}\mathbb{Z}^3$, the law $(\varpi_o^{[d_0]})_*\boldsymbol{\pi}$ of the block fields of the depths $\ge d_0$ over the cell $o + \square$ is absolutely continuous with respect to $\mu^{[d_0]}$. For $t \in \mathbb{N}$ put $\nu_2 := (\varpi_0^{[0]} \circ \mathsf{Per}_{L^t\ell})_*\mu_{L^t\ell,\mathsf{b}}$, the image in the window $\square$ of the side ℓ of the measure $\mu_{L^t\ell,\mathsf{b}}$ of Lemma 18.230; then each such ν is absolutely continuous with respect to ν_2, and each such $(\varpi_o^{[d_0]})_*\boldsymbol{\pi}$ with respect to $\mathrm{pj}_*^{[d_0]}\nu_2$.

■

Proof. Step 1: the bound of Lemma 18.216 at every label. Let $s = s(\mathsf{b}, \ell)$. As $\lambda^\circ = L^s\mathsf{b}$ lies in the interior of $I(g^\circ)$ and $L^s a_{K_j}\beta_j \to \lambda^\circ$, there is j_0 such that for $j \ge j_0$, $K_j > s$ and $L^s a_{K_j}\beta_j \in I(g^\circ)$; then $(K_j - s, \beta_j)$ is a datum at g° (Lemma 18.212 (c)), and $L^s\ell \in \mathfrak{L}(g^\circ)$. Lemma 18.216 at g°, at this datum and at the side $L^s\ell$, with the number $\exp[\frac{1}{8}(L^s\ell)^3(2C_{\mathrm{S}} + C_{g^\circ})] = \mathsf{Q}^\circ$, carried back by δ_s^{-1} (Lemma 18.229 (a)), gives for $j \ge j_0$, every $o \in a_{K_j}\mathbb{Z}^3$, every finite set $\mathcal{K}_0 \subset \mathbb{Z}^3$ and all bounded complex Borel functions $F_{\mathbf{k}}$ of the bonds with both end points in $\square_{\mathbf{k}} = o + \frac{\ell}{2}\mathbf{k} + \square$:

$$\Big|\nu_j\Big(\prod_{\mathbf{k}\in\mathcal{K}_0} F_{\mathbf{k}}\Big)\Big| \le \prod_{\mathbf{k}\in\mathcal{K}_0} \mathsf{Q}^\circ \, \tilde{\mu}_{K_j,\ell,\beta_j}(|F_{\mathbf{k}}|^8)^{1/8}.$$

Step 2: the reference laws. By Lemma 18.230 (c), $\rho_j := (\Upsilon_{K_j})_*\tilde{\mu}_{K_j,\ell,\beta_j}$ converges to μ weakly on Y and in total variation at the depths $\le D$, for every D.

Step 3: passage to the limit. The laws ν_j are translation invariant by Proposition YM3_I: 103.4. Steps 1 and 2 supply the one-cell and several-cell bounds and the convergence of the references. Lemma 18.217(a) gives (i) with $\mathsf{Q} = \mathsf{Q}^\circ$, including concentration on window threads by Lemma 18.230(b). Parts (b), (c), and (d) give (ii), (iii), and (iv), respectively. (v): the first sentence is the formation of Q° and μ. A domination $\boldsymbol{\sigma} \preceq_{\mathsf{Q}^\circ} \boldsymbol{\rho}$, tested at $f = 1_{\mathcal{A}}$, gives $\boldsymbol{\sigma}(\mathcal{A}) \le \mathsf{Q}^\circ \boldsymbol{\rho}(\mathcal{A})^{1/8}$, so every $\boldsymbol{\rho}$-null set is $\boldsymbol{\sigma}$-null; this gives the absolute continuity with respect to μ and to $\mu^{[d_0]}$. Proposition 18.235 (a), (c), at $\ell_1 = \ell$ and $\ell_2 = L^t\ell$, gives $\mu(\mathcal{A}) \le e^{\mathsf{D}^\circ(\mathsf{b},\ell)}\nu_2(\mathcal{A})^{1/q_0}$, $q_0 = 8L^{3t}$, for the Borel sets $\mathcal{A} \subset Y$, and the same inequality between the images $\mathrm{pj}_*^{[d_0]}\mu = \mu^{[d_0]}$ and $\mathrm{pj}_*^{[d_0]}\nu_2$; so the null sets of ν_2, respectively of $\mathrm{pj}_*^{[d_0]}\nu_2$, are null for μ, respectively for $\mu^{[d_0]}$, and hence for the laws which these dominate. □

Compact photons. Let $a > 0$. A configuration of three compact photon fields on $a\mathbb{Z}^3$ is a triple $U = (U^1, U^2, U^3)$ of maps from the bonds to $\mathrm{U}(1) = \{\zeta \in \mathbb{C} : |\zeta| = 1\}$ with $U^c(\bar{b}) = \overline{U^c(b)}$; their space $\mathcal{V}^{\mathrm{ph}}(a\mathbb{Z}^3) = (\mathrm{U}(1)^3)^{\mathsf{Bd}}$ is compact and metrisable. For a plaquette $p = P_{\mu\nu}(x)$, $\mu < \nu$, with the bonds $b_1 = \langle x, x + ae_\mu\rangle$, $b_2 = \langle x + ae_\mu, x + ae_\mu + ae_\nu\rangle$, $b_3 = \langle x + ae_\nu, x + ae_\mu + ae_\nu\rangle$, $b_4 = \langle x, x + ae_\nu\rangle$,

put $U^c(\partial p) := U^c(b_1)U^c(b_2)\overline{U^c(b_3)}\,\overline{U^c(b_4)}$, the field strength $F^c_a(p) := a^{-2}\operatorname{Im} U^c(\partial p)$ and the action density

$$\mathcal{O}^{\mathrm{ph}}_a(h) := a^{-1}\sum_p h(x(p))\sum_{c=1}^{3}(1-\operatorname{Re} U^c(\partial p))$$

for bounded real h with compact support. For a site y let $p_1(y) := P_{23}(y)$, $p_2(y) := P_{13}(y)$, $p_3(y) := P_{12}(y)$, let $\mathsf{D}_a(y) := \det(F^c_a(p_k(y)))_{c,k=1,2,3}$, the determinant of the three field strengths at y, rows indexed by the colour, and $\mathsf{D}_a(f) := a^3\sum_{y\in a\mathbb{Z}^3} f(y)\,\mathsf{D}_a(y)$ for bounded real f with compact support. The conjugation of the colour one is the map $\mathsf{C}_1(U^1,U^2,U^3) := (\overline{U^1},U^2,U^3)$. For a period lattice Γ and $\beta\in\mathbb{R}$, $\mu^{\mathrm{ph}}_{\Gamma,\beta}$ is the law of the Γ-periodic configurations with the density proportional to $\exp[-\beta\sum_{[p]}\sum_c(1-\operatorname{Re}U^c(\partial p))]$, the sum running over the classes of plaquettes modulo Γ, with respect to the Haar measure of the periodic configurations, the product of the Haar measures of $\mathrm{U}(1)^3$ over a set of representatives of the bonds modulo Γ: the product of three Wilson measures of the torus $\mathbb{R}^3/\Gamma$, read on the infinite lattice. For bounded Borel functions $G_0,\dots,G_r$ and a law μ, $\langle G_0;\dots;G_r\rangle_\mu$ is their joint cumulant under μ.

Proposition 18.237 (Compact photons: the determinant of the field strengths has no overlap with the action density)**.** Let $a>0$.

(a) C_1 is a homeomorphism of $\mathcal{V}^{\mathrm{ph}}(a\mathbb{Z}^3)$ with $\mathsf{C}_1\circ\mathsf{C}_1=\mathrm{id}$. For every plaquette, $F^1_a(p)\circ\mathsf{C}_1 = -F^1_a(p)$ and $F^c_a(p)\circ\mathsf{C}_1 = F^c_a(p)$ for $c=2,3$; hence $\mathsf{D}_a(y)\circ\mathsf{C}_1=-\mathsf{D}_a(y)$, $\mathsf{D}_a(f)\circ\mathsf{C}_1=-\mathsf{D}_a(f)$ and $\mathcal{O}^{\mathrm{ph}}_a(h)\circ\mathsf{C}_1=\mathcal{O}^{\mathrm{ph}}_a(h)$. These functions are real, bounded and continuous, $|\mathsf{D}_a(y)|\le 6a^{-6}$.

(b) Every $\mu^{\mathrm{ph}}_{\Gamma,\beta}$, for every period lattice Γ and every $\beta\in\mathbb{R}$, and every weak limit of such laws, is invariant under C_1.

(c) Let μ be a law on $\mathcal{V}^{\mathrm{ph}}(a\mathbb{Z}^3)$ with $(\mathsf{C}_1)_*\mu=\mu$, and let $G_1,\dots,G_r$, $r\ge 0$, be bounded Borel functions each of which is odd or even under C_1, $G_i\circ\mathsf{C}_1=\pm G_i$, an odd number of them being odd. Then $\mu(G_1\cdots G_r)=0$ and $\langle G_1;\dots;G_r\rangle_\mu=0$.

(d) In particular, for every such μ, at every spacing and every coupling, and for all bounded real $f,h_1,\dots,h_r$ with compact supports, $r\ge 0$,

$$\mu\Big(\mathsf{D}_a(f)\prod_{i=1}^{r}\mathcal{O}^{\mathrm{ph}}_a(h_i)\Big)=0,\qquad \big\langle \mathsf{D}_a(f);\mathcal{O}^{\mathrm{ph}}_a(h_1);\dots;\mathcal{O}^{\mathrm{ph}}_a(h_r)\big\rangle_\mu=0;$$

so every limit of these numbers along spacings tending to 0, along any couplings and any such laws, is 0.

■

Proof. (a) C_1 acts by complex conjugation on one factor of each coordinate, a homeomorphism of $\mathrm{U}(1)$ of order two. Conjugating U^1 on every bond conjugates $U^1(\partial p)$, which changes the sign of its imaginary part and keeps its real part. So the first row of the matrix $(F^c_a(p_k(y)))$ changes its sign and the other two rows stay, and the determinant changes its sign; $\mathsf{D}_a(f)$ is a finite real combination of the $\mathsf{D}_a(y)$, and $\mathcal{O}^{\mathrm{ph}}_a(h)$ is a finite sum of functions of the real parts. A 3×3 determinant with entries of modulus $\le a^{-2}$ is at most $3!\,a^{-6}$ in modulus. (b) The Haar measure of $\mathrm{U}(1)$ is invariant under $\zeta\mapsto\bar\zeta$, so the Haar measure of the periodic configurations is invariant under C_1, which maps periodic configurations to periodic configurations; the density depends on the real parts alone. A weak limit of C_1-invariant laws is C_1-invariant, as C_1 is continuous: $\mu(f\circ\mathsf{C}_1)=\lim\mu_n(f\circ\mathsf{C}_1)=\lim\mu_n(f)=\mu(f)$ for continuous f. (c) The product $\Pi := G_1\cdots G_r$ satisfies $\Pi\circ\mathsf{C}_1=-\Pi$, as an odd number of factors change their sign; so $\mu(\Pi)=\mu(\Pi\circ\mathsf{C}_1)=-\mu(\Pi)$. The joint cumulant is the sum over the partitions $\mathfrak{p}$ of $\{1,\dots,r\}$ of $(-1)^{|\mathfrak{p}|-1}(|\mathfrak{p}|-1)!\prod_{J\in\mathfrak{p}}\mu(\prod_{i\in J}G_i)$; in every partition some block contains an odd number of odd factors, since the blocks share out an odd number of them, and the moment of this block vanishes by the first assertion. (d) is (c) with $\mathsf{D}_a(f)$ as the one odd factor, by (a); at each spacing the numbers vanish, so their limits do. □

The slab. Let $a > 0$, $\beta \geq 0$ and $l = N_3 a$ with an integer $N_3 \geq 3$. For a period lattice Γ of $a\mathbb{Z}^3$ (Definition 18.209) the periodic objects used below include the set $\mathcal{V}_\Gamma$ of the configurations U with $\tau_v U = U$ for every $v \in \Gamma$; the domains D of Γ, sets of sites which meet every class of sites modulo Γ in one site, and for such D the set Bd_D of the bonds $\langle x, x + ae_\mu\rangle$, $x \in D$, $\mu = 1, 2, 3$; the bond transversals R of Γ, sets of bonds which meet every class of bonds modulo Γ in one bond, and for $V \in G^R$ the configuration $V^{\mathrm{per}} \in \mathcal{V}_\Gamma$ which agrees with V on R; the number $S_\Gamma(U)$, the sum of $a_p(U)$ over one plaquette of each class modulo Γ; for a real continuous Φ on $\mathcal{V}_\Gamma$, the integral $Z_\Gamma[\Phi] = Z_{\Gamma,\beta}[\Phi]$ of $e^{-\beta S_\Gamma + \Phi}$ against the Haar measure dU_Γ of the periodic configurations, the image of dV_R under $V \mapsto V^{\mathrm{per}}$, and the law $\mu^\Phi_\Gamma = \mu^\Phi_{\Gamma,\beta}$, carried by $\mathcal{V}_\Gamma$, whose density against that measure is $Z_\Gamma[\Phi]^{-1} e^{-\beta S_\Gamma + \Phi}$, so that $\mu_{\Gamma,\beta} := \mu^0_{\Gamma,\beta}$ is the Wilson measure $\mu^\varnothing_{\Gamma,\beta}$; for integers $n_1, n_2, n_3 \geq 3$ the coordinate lattice $\Gamma(n_1, n_2, n_3) := a(n_1\mathbb{Z} \times n_2\mathbb{Z} \times n_3\mathbb{Z})$, a period lattice; and the arrays of item (7). The set $\mathcal{V}^{\mathrm{sl}} := \{U \in \mathcal{V}(a\mathbb{Z}^3) : \tau_{le_3} U = U\}$ is closed, hence compact and metrisable; a slab law is a law ν with $\nu(\mathcal{V}^{\mathrm{sl}}) = 1$. Sites, bonds or plaquettes are congruent if they differ by a vector of $\mathbb{Z}le_3$, and $B^{\mathrm{per}} := B + \mathbb{Z}le_3$. A finite set B of bonds is called thin when no two of its members are congruent; because $N_3 \geq 3$, this holds for the four bonds of a plaquette, and likewise for the six bonds having a given site as an end point. For a thin B, $V \in G^B$ and $U \in \mathcal{V}^{\mathrm{sl}}$, $V \vee U \in \mathcal{V}^{\mathrm{sl}}$ takes the value $V(b)$ at the bonds $b + kle_3$, $b \in B$, $k \in \mathbb{Z}$, and the values of U off B^{per}; $\mathsf{Pl}^{\mathrm{sl}}[B]$ is a set of representatives, up to congruence, of the plaquettes which hold a bond of B^{per}, and $H^{\mathrm{sl}}_B := -\beta \sum_{p \in \mathsf{Pl}^{\mathrm{sl}}[B]} a_p$ on $\mathcal{V}^{\mathrm{sl}}$ does not depend on the representatives. For a bounded Borel F and a real continuous W on $\mathcal{V}^{\mathrm{sl}}$,

$$(\gamma^W_B F)(U) := \frac{\int F(V \vee U)\, e^{(H^{\mathrm{sl}}_B + W)(V \vee U)}\, dV}{\int e^{(H^{\mathrm{sl}}_B + W)(V \vee U)}\, dV}, \qquad \gamma_B := \gamma^0_B;$$

since $e^{H^{\mathrm{sl}}_B} \in [e^{-8\beta \# B}, 1]$, (dens) $|\gamma_B F|(U) \leq e^{8\beta \# B} \int |F|(V \vee U)\, dV$. The slab Gibbs states $\mathcal{G}^{\mathrm{sl}} = \mathcal{G}^{\mathrm{sl}}(a, \beta, l)$ are the slab laws ν with $\nu(\gamma_B F) = \nu(F)$ for every thin B and every $F \in \mathcal{C}_{\mathrm{loc}}$; $\mathcal{G}^{\mathrm{sl,per}}$ is the set of those which are invariant under the translations by a subgroup of finite index of $a\mathbb{Z}^2 \times \{0\}$, such a subgroup containing $Pa\mathbb{Z}^2 \times \{0\}$ for some $P \in \mathbb{N}$. For $\Lambda \in a\mathbb{N}$, $\Lambda \geq 3a$, the box lattice $\Gamma_\Lambda := \Lambda\mathbb{Z} \times \Lambda\mathbb{Z} \times l\mathbb{Z}$ is the coordinate lattice $\Gamma(\Lambda/a, \Lambda/a, N_3)$, and $\mu_{\Gamma_\Lambda,\beta} = \mu^\varnothing_{\Gamma_\Lambda,\beta}$ is its Wilson measure; for an unbounded set $\mathfrak{l}_0 \subset a\mathbb{N}$, $\mathcal{G}^{\mathrm{box}}(a, \beta, l; \mathfrak{l}_0)$ is the set of the weak limit points of $\mu_{\Gamma_\Lambda,\beta}$ as $\Lambda \to \infty$ in $\mathfrak{l}_0$. A slab law is positive at the pair $\Sigma(e_3, c)$, $\Sigma(e_3, c + \frac{l}{2})$, $c \in \frac{a}{2}\mathbb{Z}$, if $\nu(\overline{\theta_{e_3,c} F}\, F) \geq 0$ for all $F \in \mathcal{C}_{\mathrm{loc}}(\{c \leq x_3 \leq c + \frac{l}{2}\})$.

The space of the slab is $\mathbb{E} := \mathbb{R}^2 \times S^1_l = \mathbb{R}^3/\mathbb{Z}le_3$, with the projection pr, the quotient distance $|\mathrm{pr}\, x - \mathrm{pr}\, y| = \min_{k \in \mathbb{Z}} |x - y - kle_3|$ and closed balls; sets $A, A' \subset \mathbb{R}^3$ lie at a distance $\geq \mathsf{d}$ modulo le_3 when $|x - x' - kle_3| \geq \mathsf{d}$ for all $x \in A$, $x' \in A'$ and $k \in \mathbb{Z}$, which, by the formula for the quotient distance, says that the images $\mathrm{pr}A$, $\mathrm{pr}A'$ are separated by at least d in $\mathbb{E}$; $C^1_c(\mathbb{E})$ and $\mathrm{Lip}_c(\mathbb{E})$ are the sets of the real functions on $\mathbb{E}$ with compact support which are of class C^1, respectively Lipschitz, and $\|f\|_\sharp := \max\{\|f\|_\infty, 40M \,\mathrm{Lip}\, f\}$ for functions on $\mathbb{E}$ and on $\mathbb{R}^3$ alike; Lip_c stands for $\mathrm{Lip}_c(\mathbb{R}^3)$, the set of the real Lipschitz functions on $\mathbb{R}^3$ with compact support, and for $f_1, \dots, f_n \in \mathrm{Lip}_c$ and $\varrho > 0$ the source disc $\mathbb{D}_\varrho(f_1, \dots, f_n)$ is the set of the $z \in \mathbb{C}^n$ with $\sum_q |z_q|\, \|f_q\|_\sharp < \varrho$; for a closed ball $\mathcal{B} \subset \mathbb{R}^3$, $\mathrm{Lip}_\mathcal{B}$ is the set of the real Lipschitz functions on $\mathbb{R}^3$ which vanish off $\mathcal{B}$; for an open $O \subset \mathbb{E}$, $\mathfrak{S}_n(O)$ is the set of the n-tuples of functions of $C^1_c(\mathbb{E})$ with pairwise disjoint supports in O, $\mathfrak{S}(O) = \bigcup_{n \geq 0} \mathfrak{S}_n(O)$ with the empty tuple, $\mathbb{C}\mathfrak{S}(O)$ the set of the formal complex combinations, $\bar{F}$ the combination with the conjugate coefficients, and $X \cdot Y$ the concatenation, formed when the result is separated; a tuple is of type $(\mathsf{d}; R)$ if its supports lie in balls of radius R and are pairwise at a distance $\geq \mathsf{d}$; $\|X\|_\sharp := \prod_i \|f_i\|_\sharp$. The maps of $\mathbb{E}$ which we use are the translations τ_v, $v \in \mathbb{R}^3$, the reflections $\theta_{u,c} x = x - 2(u \cdot x - c)u$ for unit vectors $u \perp e_3$, the group W_2 of the eight signed permutations of (x_1, x_2), and the reflections $\mathsf{r}_c \colon (x_1, x_2, x_3) \mapsto (x_1, x_2, 2c - x_3)$ of the circle; a map r acts on tuples by $\mathsf{r}X = (f_i \circ \mathsf{r}^{-1})_i$. For a family $S = (S_n)_{n \geq 2}$ of maps $S_n \colon \mathfrak{S}_n(\mathbb{E}) \to \mathbb{R}$, its centred functional is $\sigma_S(X) := \sum_\pi \prod_{I \in \pi} S_{|I|}(X_I)$, the sum over the partitions of the entries into blocks of at least two

entries, $\sigma_S(\varnothing) = 1$, extended linearly to combinations; S is regular if for every n there is a distribution T_n on $\mathbb{E}^n_{\neq} := \{x \in \mathbb{E}^n : x_i \neq x_{i'} \text{ for } i \neq i'\}$ with $T_n(f_1 \otimes \cdots \otimes f_n) = \sigma_S(f_1, \dots, f_n)$ on the smooth separated tuples. For a bounded f on $\mathbb{E}$ with compact support, $\mathcal{O}^{\mathrm{sl}}_a(f)(U) := a^{-1} \sum_p f(\mathrm{pr}\, x(p))\, a_p(U)$ on $\mathcal{V}^{\mathrm{sl}}$, the sum over a set of representatives of the plaquettes up to congruence; for a bounded $\tilde f$ on $\mathbb{R}^3$ with compact support, $\tilde f^{\langle l\rangle}(\mathrm{pr}\, x) := \sum_{k\in\mathbb{Z}} \tilde f(x + kle_3)$, and sorting the plaquettes by classes gives (per) $\mathcal{O}_a(\tilde f) = \mathcal{O}^{\mathrm{sl}}_a(\tilde f^{\langle l\rangle})$ on $\mathcal{V}^{\mathrm{sl}}$. For a slab law ν, $S^T_n[\nu](f_1, \dots, f_n)$ is the joint cumulant of the $\mathcal{O}^{\mathrm{sl}}_a(f_i)$, and $\sigma_\nu(X) := \nu(\prod_i (\mathcal{O}^{\mathrm{sl}}_a(f_i) - \nu(\mathcal{O}^{\mathrm{sl}}_a(f_i))))$. Each $\mathcal{O}^{\mathrm{sl}}_a(f_i)$ is a finite linear combination of functions a_p, so a bounded continuous function on $\mathcal{V}^{\mathrm{sl}}$; for the centred bounded variables $Y_i := \mathcal{O}^{\mathrm{sl}}_a(f_i) - \nu(\mathcal{O}^{\mathrm{sl}}_a(f_i))$ the inverse formula of moments and cumulants writes $\nu(\prod_i Y_i)$ as the sum, over the partitions of the entries, of the products of the joint cumulants of the blocks; a block of one element contributes $\nu(Y_i) = 0$, and a joint cumulant of order ≥ 2 does not change when constants are added to its variables, so $\sigma_\nu = \sigma_S$ for $S = (S^T_n[\nu])_{n\geq 2}$. The standing data [T] of the slab are: $0 < g \leq \gamma$, a side $l \in \mathfrak{L}(g)$, data (K_j, β_j) at g with $K_j \to \infty$ and $a_{K_j}\beta_j \to \mathsf{b}$, and laws $\mu_j \in \mathcal{G}^{\mathrm{box}}(a_{K_j}, \beta_j, l; \mathfrak{L})$; then $l = N_3 a_{K_j}$ with $N_3 = l/a_{K_j} \geq 3$. We write $\ell_g := \min \mathfrak{L}(g) = 2L^{m_{\mathfrak{L}}(g)}$, and, at a pair (K, β), $p_\ell = \ell^{-3} \log Z_{K,\ell,\beta}$ and $p_\infty := \inf_{\ell\in\mathfrak{L}} p_\ell$.

Lemma 18.238 (Slab kernels, boxes and gauge transformations)**.** Let $a > 0$, $\beta \geq 0$ and $l = N_3 a$, $N_3 \geq 3$.

(a) (DLR on a box.) Let $\Gamma = \Gamma^{(2)} \times l\mathbb{Z}$ be a period lattice, $\Gamma^{(2)} \subset a\mathbb{Z}^2$, Φ a real continuous function on $\mathcal{V}_\Gamma$, B thin and $F \in \mathcal{C}_{\mathrm{loc}}$ with a finite set B_F of bonds on which it depends. Suppose (far): the least norm $|\cdot|_\infty$ of the non-zero vectors of $\Gamma^{(2)}$ exceeds by $3a$ the diameter, in the norm $|\cdot|_\infty$, of the projection to the plane $\{x_3 = 0\}$ of the end points of the bonds of $B \cup B_F$. Suppose that $\Phi = \Phi' + \Phi''$, where $\Phi''(U)$ does not change when U is changed on $B + \Gamma$. Then $|\mu^\Phi_\Gamma(\gamma_B F) - \mu^\Phi_\Gamma(F)| \leq (e^{2\|\Phi'\|_\infty} - 1)\|F\|_\infty$; at $\Phi = 0$, $\mu_{\Gamma,\beta}(\gamma_B F) = \mu_{\Gamma,\beta}(F)$.

(b) Every member of $\mathcal{G}^{\mathrm{box}}(a, \beta, l; \mathfrak{l}_0)$ is a slab Gibbs state, and $\mathcal{G}^{\mathrm{box}}(a, \beta, l; \mathfrak{l}_0) \neq \varnothing$. For a thin B and $F \in \mathcal{F}(B)$, every slab Gibbs state ν satisfies $\nu(|F|) \leq e^{8\beta \# B} \int |F|\, dV_B$.

(c) (Gauge.) Every $\nu \in \mathcal{G}^{\mathrm{sl}}$ is invariant under the gauge transformations h_x, $x \in a\mathbb{Z}^3$, $\mathsf{h} \in G$, which multiply the variables of the bonds starting at a site of $x + \mathbb{Z}le_3$ by h on the left, those of the bonds ending there by h^{-1} on the right, and keep the others.

■

Proof. (a) By (far) the bonds of B are pairwise incongruent modulo Γ: a vector of Γ which carries one to another has a vanishing projection to the plane, so it lies in $\mathbb{Z}le_3$. Let $R \supset B$ be a bond transversal of Γ; by the product Haar representation on this transversal, $\mu^\Phi_\Gamma(F) = Z_\Gamma[\Phi]^{-1} \int F\, e^{-\beta S_\Gamma + \Phi}(V^{\mathrm{per}})\, dV_R$. The terms of S_Γ coming from classes of plaquettes that hold no bond of $B + \Gamma$ do not depend on V_B, and Fubini's theorem yields $\mu^\Phi_\Gamma(F) = \mu^\Phi_\Gamma(\hat\gamma F)$. Here $\hat\gamma F(U)$ denotes $\int F\, e^{\hat H + \Phi'}(V \vee_\Gamma U)\, dV_B$ divided by the corresponding integral without the factor F; $V \vee_\Gamma U$ is the configuration obtained from $U \in \mathcal{V}_\Gamma$ by changing it on $B + \Gamma$; and $\hat H = -\beta \sum a_p$, the sum running over those classes modulo Γ of plaquettes which hold a bond of $B + \Gamma$. By (far), a bond of $B + \Gamma$ which lies in B_F, or in a plaquette holding a bond of B^{per}, lies in B^{per}, and two plaquettes holding bonds of B^{per} which are congruent modulo Γ are congruent modulo le_3. So $F(V \vee_\Gamma U) = F(V \vee U)$ and $\hat H(V \vee_\Gamma U) = H^{\mathrm{sl}}_B(V \vee U)$: at $\Phi' = 0$, $\hat\gamma F = \gamma_B F$ on $\mathcal{V}_\Gamma$. For general Φ' the quotient of the densities of $\hat\gamma$ and γ_B lies between $e^{-2\|\Phi'\|_\infty}$ and $e^{2\|\Phi'\|_\infty}$. (b) Let $\mu = \lim_i \mu_{\Gamma_{\Lambda_i},\beta}$ weakly. Each $\mathcal{V}_{\Gamma_\Lambda}$ lies in the closed set $\mathcal{V}^{\mathrm{sl}}$, so μ is a slab law. For thin B and $F \in \mathcal{C}_{\mathrm{loc}}$, (far) holds for large i, so $\mu_{\Gamma_{\Lambda_i},\beta}(\gamma_B F) = \mu_{\Gamma_{\Lambda_i},\beta}(F)$ by (a); $\gamma_B F$ is the restriction to $\mathcal{V}^{\mathrm{sl}}$ of a continuous local function, an integral of a continuous function of finitely many bonds over some of them, so the equation passes to μ. The set of the laws on the compact metrisable space of the configurations is weakly compact, which gives a limit point. For $F \in \mathcal{F}(B)$, $\int |F|(V \vee U)\, dV = \int |F|\, dV_B$, and (dens) with the equation of B gives the bound, first for continuous and then, by monotone classes, for bounded Borel F. (c) Let B_x

be the six bonds with an end point x, a thin set. The map h_x carries $\mathcal{V}^{\mathrm{sl}}$ onto $\mathcal{V}^{\mathrm{sl}}$ and changes only the variables of the bonds of B_x^{per}, so that $\mathsf{h}_x(V\vee U)=(\mathsf{h}_xV)\vee U$, where $V\mapsto \mathsf{h}_xV$ acts factorwise on G^{B_x} by left and right translations, which preserve dV; moreover $a_p\circ\mathsf{h}_x=a_p$, since h_x conjugates the variable of a plaquette. So $\gamma_{B_x}(F\circ\mathsf{h}_x)=\gamma_{B_x}F$, and $\nu(F\circ\mathsf{h}_x)=\nu(\gamma_{B_x}(F\circ\mathsf{h}_x))=\nu(\gamma_{B_x}F)=\nu(F)$ for $F\in\mathcal{C}_{\mathrm{loc}}$, which is dense in the continuous functions. □

Lemma 18.239 (Three sides; the domination of the box limits)**.** Let $K\in\mathbb{N}$, $\beta\ge 0$, and let (i,o) be a board of $\mathbb{L}_K$ of the side $\mathsf{l}=a_i$, with the cells $\square_{\mathbf{k}}$, the sets $\mathcal{A}(\square_{\mathbf{k}})$ and its mirror copies. For F in cell $\mathbf{k}$, its copy $F^{[\mathbf{k}']}$ is obtained by transport across successive walls to cell $\mathbf{k}'$, with complex conjugation when the total number of reflections is odd. In each coordinate the transporting isometry takes the cell center to the new center with linear sign $(-1)^{k'_\mu-k_\mu}$, which makes the copy independent of the order of the wall reflections. For $\underline{\ell}=(\ell_1,\ell_2,\ell_3)\in\mathfrak{L}^3$ with $\ell_\mu\ge 2\mathsf{l}$ let $\Gamma(\underline{\ell}):=\ell_1\mathbb{Z}\times\ell_2\mathbb{Z}\times\ell_3\mathbb{Z}$, $\mathsf{n}_\mu:=\ell_\mu/\mathsf{l}$ (even integers ≥ 2), $\mathsf{N}(\underline{\ell}):=\mathsf{n}_1\mathsf{n}_2\mathsf{n}_3$, $\mathcal{K}_{\underline{\ell}}:=\prod_\mu\{0,\dots,\mathsf{n}_\mu-1\}$, $Z_{\underline{\ell}}:=Z_{\Gamma(\underline{\ell})}[0]$, and for $F\in\mathcal{A}(\square_{\mathbf{k}})$

$$\mathcal{Z}_{\underline{\ell}}[F]:=Z_{\underline{\ell}}\,\mu_{\Gamma(\underline{\ell}),\beta}\Big(\prod_{\mathbf{k}'\in\mathcal{K}_{\underline{\ell}}}F^{[\mathbf{k}']}\Big),\qquad \|F\|_{\mathrm{ch},\underline{\ell}}:=\big(\mathcal{Z}_{\underline{\ell}}[F]/Z_{\underline{\ell}}\big)^{1/\mathsf{N}(\underline{\ell})}.$$

For $\ell\in\mathfrak{L}$ with $\ell\ge 2\mathsf{l}$ we write $\|F\|_{\mathrm{ch},\ell}:=\|F\|_{\mathrm{ch},(\ell,\ell,\ell)}$, the same reflected-product seminorm on a cube as in Lemma 18.216.

(a) $\mathcal{Z}_{\underline{\ell}}[F]\ge 0$; $|\mu_{\Gamma(\underline{\ell}),\beta}(\prod_{\mathbf{k}\in\mathsf{S}}F_{\mathbf{k}})|\le\prod_{\mathbf{k}\in\mathsf{S}}\|F_{\mathbf{k}}\|_{\mathrm{ch},\underline{\ell}}$ for every finite $\mathsf{S}\subset\mathbb{Z}^3$ whose members are pairwise incongruent modulo $\mathsf{n}_1\mathbb{Z}\times\mathsf{n}_2\mathbb{Z}\times\mathsf{n}_3\mathbb{Z}$ and all $F_{\mathbf{k}}\in\mathcal{A}(\square_{\mathbf{k}})$; and $\mathcal{Z}_{\underline{\ell}}[F]\le\mathcal{Z}_{\underline{\ell}'}[F]^{\mathsf{N}(\underline{\ell})/\mathsf{N}(\underline{\ell}')}$ for $\underline{\ell}'\in\mathfrak{L}^3$ with $2\mathsf{l}\le\ell'_\mu\le\ell_\mu$.

(b) For $\ell',l,\Lambda\in\mathfrak{L}$ with $2\mathsf{l}\le\ell'\le l\le\Lambda$: $\|F\|_{\mathrm{ch},(\Lambda,\Lambda,l)}\le e^{\mathsf{l}^3(p_{\ell'}-p_\Lambda)}\|F\|_{\mathrm{ch},\ell'}$.

(c) For $\ell'\le l$ as in (b), $\mu\in\mathcal{G}^{\mathrm{box}}(a_K,\beta,l;\mathfrak{L})$, $\mathsf{q}_{\mathsf{l}}:=e^{\mathsf{l}^3(p_{\ell'}-p_\infty)}$, every finite $\mathsf{S}\subset\mathbb{Z}^3$ whose members are pairwise incongruent modulo $(l/\mathsf{l})\mathbb{Z}e_3$, and all $F_{\mathbf{k}}\in\mathcal{A}(\square_{\mathbf{k}})$: $|\mu(\prod_{\mathbf{k}\in\mathsf{S}}F_{\mathbf{k}})|\le\prod_{\mathbf{k}\in\mathsf{S}}\mathsf{q}_{\mathsf{l}}\|F_{\mathbf{k}}\|_{\mathrm{ch},\ell'}$.

(d) Let $0<g\le\gamma$, (K,β) a datum at g and $\ell'\in\mathfrak{L}(g)$. Then $p_{\ell'}-p_\infty\le 2C_{\mathrm{S}}+C_g$, so $\mathsf{q}_{\mathsf{l}}\le e^{\mathsf{l}^3(2C_{\mathrm{S}}+C_g)}$ in (c). On a board of the side $\mathsf{l}=\frac12\ell_g$, for $l\in\mathfrak{L}(g)$, $\mu\in\mathcal{G}^{\mathrm{box}}(a_K,\beta,l;\mathfrak{L})$ and F a bounded Borel function of the bonds of one cell, $|\mu(F)|\le\mathsf{Q}_0^{(g)}\|F\|_{\mathrm{ch},\ell_g}\le\mathsf{Q}_0^{(g)}\,\tilde\mu_{K,\ell_g,\beta}(|F|^8)^{1/8}$ with $\mathsf{Q}_0^{(g)}:=\exp[\frac18\ell_g^3(2C_{\mathrm{S}}+C_g)]$, a number formed from the constants and g.

■

Proof. The dictionary for three sides. The quotient of the lattice by $\Gamma(\underline{\ell})$ is the rectangular torus with $N_\mu=\ell_\mu/a_K$ sites along the axes. Its positive bonds are a transversal, so the partition functions and Wilson laws in these two descriptions agree. The cells descend with indices modulo $(\mathsf{n}_1,\mathsf{n}_2,\mathsf{n}_3)$. The even cell counts make the signs and conjugation rules periodic. Thus the reflected product in the display is the chessboard fold for the rectangular board.

(a) If $\lambda=\mathsf{l}/a_K\ge 3$, apply Propositions YM3_I:86.3 and YM3_I:86.5 to that board. They allow any even cell counts and use the same model function on both sides of the volume comparison. Unoccupied cells carry the constant 1. If $\lambda=1$, there are no inner bonds and all the cell functions are constants. The seminorm is then their modulus, and the comparison of folded partition functions is the pressure monotonicity of Lemma 18.232(P).

(b) Put $\underline{\ell}=(\Lambda,\Lambda,l)$. By (a) at $\underline{\ell}'=(\ell',\ell',\ell')$, $\mathcal{Z}_{\underline{\ell}}[F]\le\mathcal{Z}_{\ell'}[F]^{\Lambda^2l/\ell'^3}$; by (a) at the function 1 with the sides $(\Lambda,\Lambda,\Lambda)\ge(\Lambda,\Lambda,l)$, $Z_{K,\Lambda,\beta}\le Z_{\underline{\ell}}^{\Lambda/l}$, that is $Z_{\underline{\ell}}\ge e^{p_\Lambda\Lambda^2l}$. With $\mathcal{Z}_{\ell'}[F]=\|F\|_{\mathrm{ch},\ell'}^{(\ell'/\mathsf{l})^3}e^{p_{\ell'}\ell'^3}$,

$$\|F\|_{\mathrm{ch},\underline{\ell}}=\Big(\frac{\mathcal{Z}_{\underline{\ell}}[F]}{Z_{\underline{\ell}}}\Big)^{\mathsf{l}^3/\Lambda^2l}\le\mathcal{Z}_{\ell'}[F]^{\mathsf{l}^3/\ell'^3}e^{-\mathsf{l}^3p_\Lambda}=e^{\mathsf{l}^3(p_{\ell'}-p_\Lambda)}\|F\|_{\mathrm{ch},\ell'}.$$

(c) Let $\mu=\lim_i\mu_{\Gamma_{\Lambda_i},\beta}$ with $\Lambda_i\in\mathfrak{L}$. For large i the members of S are pairwise incongruent modulo the box, and $p_{\Lambda_i}\ge p_\infty$; (a), (b) give the bound for $\mu_{\Gamma_{\Lambda_i},\beta}$, and for continuous $F_{\mathbf{k}}$ it passes to the limit.

For bounded Borel $F_{\mathbf{k}}$: the set B of the bonds lying in the cells of S is thin, since congruent bonds lie in congruent cells and a cell of side $\mathsf{l} \le \frac{l}{2}$ holds no two congruent bonds; by Lemma 18.238 (b), $\mu(|F|) \le e^{8\beta \# B} \int |F|\, dV_B$ for $F \in \mathcal{F}(B)$, and $\tilde{\mu}_{K,\ell',\beta}$ has a bounded density against the Haar measure of its torus. Continuous $F^{(m)}_{\mathbf{k}} \in \mathcal{A}(\square_{\mathbf{k}})$ with $\sup|F^{(m)}_{\mathbf{k}}| \le \sup|F_{\mathbf{k}}|$ and $F^{(m)}_{\mathbf{k}} \to F_{\mathbf{k}}$ almost everywhere for the Haar measure exist, and both members converge by dominated convergence. (d) As in Lemma 18.216, the volume bounds of Theorem YM3_I:AD give $p_{\ell'} - p_\ell \le 2C_{\mathrm{S}} + C_g$ for $\ell, \ell' \in \mathfrak{L}(g)$; as p_ℓ does not increase with ℓ by Lemma 18.232(P) and $\mathfrak{L}(g)$ contains every side larger than one of its members, $p_\infty \ge p_{\ell'} - (2C_{\mathrm{S}} + C_g)$. On the board of the side $\frac{1}{2}\ell_g$, (c) with one cell and $\ell' = \ell_g \le l$ gives the first inequality, as $(\frac{1}{2}\ell_g)^3(2C_{\mathrm{S}} + C_g) = \log \mathsf{Q}^{(g)}_0$; the second follows by Hölder for the eight factors, whose L^8 norms agree by invariance under the lattice isometries of the cube. □

Lemma 18.240 (One bond more; a half space decides)**.** Let $a > 0$, $\beta > 0$ and $l = N_3 a$, $N_3 \ge 3$.

(a) Let $\rho_1, \rho_2 \in \mathcal{G}^{\mathrm{sl}}$, let $D = D^{\mathrm{per}}$ be a set of bonds, $b \in D$, $b_0 \notin D$ a bond, and p_0 a plaquette which holds b and b_0. Suppose that all the bonds of the four plaquettes holding b lie in $D \cup b_0^{\mathrm{per}}$, and that b_0 is the only one of them in b_0^{per}. If $\rho_1(\Psi) = \rho_2(\Psi)$ for every continuous function Ψ of finitely many bonds of D, then the same holds for every continuous function of finitely many bonds of $D \cup b_0^{\mathrm{per}}$.

(b) Let $\mu \in \{1, 2\}$, $c \in \mathbb{R}$ and $\epsilon = \pm 1$. Two slab Gibbs states which agree on $\mathcal{C}_{\mathrm{loc}}(\{\epsilon(x_\mu - c) \ge 0\})$ are equal.

■

Proof. (a) Going along the boundary of p_0 from an end point of b, $a_{p_0} = 1 - \frac{1}{2}\operatorname{tr}(U(b)X_1U(b_0)^{\pm 1}X_2)$, where X_1, X_2 are products of the variables, or of their inverses, of the two other bonds of p_0, which lie in $D' := D \setminus b^{\mathrm{per}}$; and $a_p = 1 - \frac{1}{2}\operatorname{tr}(U(b)Y_p)$ for the three other plaquettes p holding b, with products Y_p of variables of bonds of D'. Put $\mathsf{u} := X_1U(b_0)^{\pm 1}X_2$, $\mathsf{y} := \sum_{p \ne p_0} Y_p$, $(\mathsf{k}\varphi)(u) := \int_G \varphi(v)\, e^{\frac{\beta}{2}\operatorname{tr}(vu)}\, dv$ for $\varphi \in C(G)$, and $\mathsf{Z} := \int e^{\frac{\beta}{2}\operatorname{tr}(v(\mathsf{u}+\mathsf{y}))} dv$, a positive continuous function of finitely many bonds of $D' \cup b_0^{\mathrm{per}}$. For $\varphi \in C(G)$ and a continuous function g of finitely many bonds of D', the function $F := \varphi(U(b))\, e^{-\frac{\beta}{2}\operatorname{tr}(U(b)\mathsf{y})}\, \mathsf{g}$ depends on finitely many bonds of D, and $\gamma_{\{b\}}F = \mathsf{g} \cdot (\mathsf{k}\varphi)(\mathsf{u})/\mathsf{Z}$, since $H^{\mathrm{sl}}_{\{b\}} = -4\beta + \frac{\beta}{2}\operatorname{tr}(U(b)(\mathsf{u} + \mathsf{y}))$. So $\rho_1(\mathsf{g}\,(\mathsf{k}\varphi)(\mathsf{u})/\mathsf{Z}) = \rho_2(\mathsf{g}\,(\mathsf{k}\varphi)(\mathsf{u})/\mathsf{Z})$. By the class-function expansion in the proof of Proposition 18.224, $e^{\frac{\beta}{2}\operatorname{tr}} = e^{\beta}\sum_l (2l+1)\lambda_l(\beta)\chi_l$ uniformly on G, with $\lambda_l(\beta) > 0$ for all $l \in \frac{1}{2}\mathbb{N}_0$; by the orthogonality relations of the matrix coefficients, the function $\varphi(v) = D^l_{mn}(v^{-1})$ has $(\mathsf{k}\varphi)(u) = e^{\beta}\lambda_l(\beta)D^l_{mn}(u)$. So the image of k contains all matrix coefficients, whose span is dense in $C(G)$. For a finite set $E \subset D'$ which holds the bonds of X_1, X_2, the map $(U_E, U(b_0)) \mapsto (U_E, \mathsf{u})$ is a homeomorphism of $G^E \times G$, and the span of the functions $\mathsf{g}\,\psi(\mathsf{u})$, $\mathsf{g} \in C(G^E)$, ψ a matrix coefficient, is a self-conjugate algebra with the constants which separates the points, dense by the theorem of Stone and Weierstrass. Hence $\rho_1(\Psi/\mathsf{Z}) = \rho_2(\Psi/\mathsf{Z})$ for every continuous Ψ of finitely many bonds of $D' \cup b_0^{\mathrm{per}}$, and with $\Psi\mathsf{Z}$ in the place of Ψ, $\rho_1 = \rho_2$ on these functions. Last, for a continuous Ψ' of finitely many bonds of $D \cup b_0^{\mathrm{per}}$, $\gamma_{\{b\}}\Psi'$ is a continuous function of finitely many bonds of $D' \cup b_0^{\mathrm{per}}$, by the hypothesis on the four plaquettes, and $\rho_i(\Psi') = \rho_i(\gamma_{\{b\}}\Psi')$. (b) Let $\mu = 1$, $\epsilon = 1$; the other cases are the same after renaming. Let c_1 be the least member of $a\mathbb{Z}$ which is $\ge c$, D_m the set of the bonds lying in $\{x_1 \ge c_1 - ma\}$, and suppose $\rho_1 = \rho_2$ on the continuous functions of finitely many bonds of D_m; put $c' := c_1 - ma$. *The bonds which stick out.* Let $E := D_m \cup \{\langle y, y + ae_1\rangle : y_1 = c' - a\}$, Ψ a continuous function of finitely many bonds of E, and Y a finite set of pairwise incongruent sites y with $y_1 = c' - a$ such that Ψ reads no other bond which sticks out, up to congruence. Of the bonds of E, the gauge transformation h_y moves the class of $\langle y, y + ae_1\rangle$ alone, by a left translation; by Lemma 18.238 (c), $\rho_i(\Psi) = \rho_i(\bar{\Psi})$ with $\bar{\Psi} := \int \Psi \circ \prod_{y \in Y}(\mathsf{h}_y)_y \prod_y d\mathsf{h}_y$, which by the invariance of the Haar measure depends on bonds of D_m alone. So $\rho_1 = \rho_2$ on these functions of E. *The bonds of the new plane.* Number the classes of

the bonds $\langle y, y+ae_\nu\rangle$, $y_1 = c'-a$, $\nu\in\{2,3\}$, as $b_0^1, b_0^2, \dots$, and put $E_k := E\cup (b_0^1)^{\rm per}\cup\dots\cup(b_0^k)^{\rm per}$. For $b_0 = b_0^{k+1} = \langle y, y+ae_\nu\rangle$ take $b := \langle y+ae_1, y+ae_1+ae_\nu\rangle \in D_m$ and $p_0 := P_{1\nu}(y)$. The four plaquettes at b are p_0, whose other two bonds stick out, $P_{1\nu}(y+ae_1)$, and two plaquettes in the plane $\{x_1 = c'\}$; of their bonds only b_0 has both end points in $\{x_1 = c'-a\}$. (a) with $D = E_k$ gives $\rho_1 = \rho_2$ on the functions of E_{k+1}. Every continuous function of finitely many bonds of D_{m+1} is one of some E_k. By induction $\rho_1 = \rho_2$ on $\mathcal{C}_{\rm loc}$, which is dense in $C(\mathcal{V}^{\rm sl})$. □

Lemma 18.241 (Separation; a comparison state)**.** (a) Let X be a compact metrisable space, $\mathcal{C}_0$ a dense subspace of the real continuous functions on X, $\mathsf{R}\neq\varnothing$ a convex and weakly compact set of Borel probability measures on X, and ν a Borel probability measure on X with $\nu(A)\le \sup_{\rho\in\mathsf{R}}\rho(A)$ for all $A\in\mathcal{C}_0$. Then $\nu\in\mathsf{R}$.

(b) Let $a>0$, $\beta\ge 0$, $l = N_3 a$ with $N_3\ge 3$, $n\in\{e_1, e_2, e_1+e_2, e_1-e_2\}$, $c_0\in{\rm Adm}(n)$, $\nu\in\mathcal{G}^{\rm sl,per}$, and $A\in\mathcal{C}_{\rm loc}(\mathbb{H}^+(n,c_0))$ real. There is $\nu_0\in\mathcal{G}^{\rm sl,per}$ which is reflection positive at $\Sigma(n,c_0)$ and satisfies $\nu(A)\le\nu_0(A)$.

■

Proof. (a) If $\nu\notin\mathsf{R}$, the theorem of Hahn and Banach in the dual of the real continuous functions, with the weak topology, gives a real continuous A and $\varepsilon>0$ with $\nu(A)\ge\sup_{\mathsf{R}}\rho(A)+3\varepsilon$; an $A'\in\mathcal{C}_0$ with $\|A-A'\|_\infty\le\varepsilon$ violates the hypothesis.

(b) *Step 1: lattices.* Let ν be invariant under $Pa\mathbb{Z}^2\times\{0\}$, and let $n^* := e_2, e_1, e_1-e_2, e_1+e_2$ in the four cases, so that $n^*\perp n$ and $|n^*| = |n|$. Take $q\in\mathbb{N}$ so large that, with $h := qPa|n|^2$, the finite set B_A of bonds on which A depends lies in the slab $\mathbb{S}_1 = \{0\le n\cdot x - c_0\le h\}$; then $v_h := h|n|^{-2}n = qPa\,n$. For integers $i\ge 3$ put $\Gamma' := \mathbb{Z}qPa\,n^*\oplus\mathbb{Z}le_3\oplus\mathbb{Z}v_h$ and $\Gamma_i := \mathbb{Z}iqPa\,n^*\oplus\mathbb{Z}le_3\oplus\mathbb{Z}2iv_h$. Both are subgroups of finite index of $a\mathbb{Z}^3$ of the form $\Gamma^{(2)}\times l\mathbb{Z}$, adapted to n by the perpendicular and normal decomposition in YM3_I:(1820) with the height periods h and $2ih$; $\Gamma_i\subset\Gamma'$, $[\Gamma':\Gamma_i] = 2i^2$; a member $\alpha iqPa\,n^*+\delta 2iqPa\,n$ of $\Gamma_i^{(2)}$ with $(\alpha,\delta)\neq 0$ has a coordinate of modulus $\ge iqPa$, so Γ_i is a period lattice whose plane part has a least norm tending to ∞. Let $\mathbb{A}_i$ be the array of A over Γ'/Γ_i and $\mathbb{A}_i^{\rm f}$ its folded array with the data (a,n,c_0,h), $N=i$ in Proposition YM3_I:91.7; $|\mathbb{A}_i| = 2i^2$.

Step 2: a box against the torus. There is C_∂, independent of i and of $t\in(0,1]$, with $2i^2t\,\nu(A)\le \log(Z_{\Gamma_i}[t\mathbb{A}_i]/Z_{\Gamma_i}[0]) + C_\partial\, i\,(1+2t\|A\|_\infty)$. Indeed, $D_i := \{x\in a\mathbb{Z}^3 : 0\le n\cdot x - c_0 < 2ih,\ 0\le n^*\cdot x < iqPa|n|^2,\ 0\le x_3<l\}$ is a domain of Γ_i. Let r exceed by 2 the diameter of B_A in units of a, D_i° the set of the $x\in D_i$ with $x+w\in D_i+\mathbb{Z}le_3$ for all $w\in a\mathbb{Z}^3$, $|w|_\infty\le ra$, and $B_i := \{\langle x, x+ae_\mu\rangle : x\in D_i^\circ\}$, a thin set; $\#(D_i\setminus D_i^\circ)\le C_1 i$, as these points lie within ra of the four sides of a parallelogram of sides at most $2iqPa|n|$, in N_3 layers. Let R_i be the set of the representatives v of Γ'/Γ_i, so chosen, with $\tau_v B_A\subset B_i^{\rm per}$; the others have a bond starting, up to Γ_i, within ra of $D_i\setminus D_i^\circ$, so $2i^2-\#\mathsf{R}_i\le C_2 i$. Put $W_i := \sum_{v\in\mathsf{R}_i}\tau_v A$. As $\Gamma'\subset Pa\mathbb{Z}^2\times\{0\}+\mathbb{Z}le_3$, $\nu(\tau_v A) = \nu(A)$. Jensen's inequality and the equation of B_i give $e^{t\#\mathsf{R}_i\nu(A)}\le\nu(e^{tW_i}) = \nu(\gamma_{B_i}e^{tW_i})$. Let $\mathsf{P}_i^{\rm in}\subset\mathsf{Pl}^{\rm sl}[B_i]$ be the plaquettes with all their bonds in $B_i^{\rm per}$; the others have a corner in $(D_i\setminus D_i^\circ)+\mathbb{Z}le_3$ or next to it, and their number is at most $C_3 i$. With $I_i(t) := \int e^{tW_i-\beta\sum_{\mathsf{P}_i^{\rm in}}a_p}dV_{B_i}$ and $0\le a_p\le 2$, $\gamma_{B_i}e^{tW_i}\le e^{2\beta C_3 i}I_i(t)/I_i(0)$. On the torus take the bond transversal $\mathsf{Bd}_{D_i}\supset B_i$: the classes of plaquettes are those of $\mathsf{P}_i^{\rm in}$ and at most $C_4 i$ others, and $\mathbb{A}_i$ is W_i plus at most $C_2 i$ terms of modulus $\le\|A\|_\infty$; so $Z_{\Gamma_i}[t\mathbb{A}_i]\ge e^{-2\beta C_4 i - tC_2 i\|A\|_\infty}I_i(t)$ and $Z_{\Gamma_i}[0]\le I_i(0)$. Together with $\#\mathsf{R}_i\nu(A)\ge 2i^2\nu(A) - C_2 i\|A\|_\infty$ this is the claim, with $C_\partial = \max\{C_2, 2\beta(C_3+C_4)\}$.

Step 3: the fold. By the main text's chessboard estimate along one normal, YM3_I:(1828), $Z_{\Gamma_i}[t\mathbb{A}_i]\le Z_{\Gamma_i}[t\mathbb{A}_i^{\rm f}]$. The function $s\mapsto\log Z_{\Gamma_i}[s\mathbb{A}_i^{\rm f}]$ is convex and differentiable, with the derivative $\mu_i^s(\mathbb{A}_i^{\rm f}) = 2i^2\mu_i^s(A)$, $\mu_i^s := \mu_{\Gamma_i}^{s\mathbb{A}_i^{\rm f}}$, by YM3_I:(1829); so $\log(Z_{\Gamma_i}[t\mathbb{A}_i^{\rm f}]/Z_{\Gamma_i}[0])\le 2i^2 t\,\mu_i^t(A)$, and Step 2 gives $\nu(A)\le\mu_i^t(A) + C_\partial(2\|A\|_\infty + t^{-1})/(2i)$. Take $t_i := i^{-1/2}$ and a weak limit point ν_0 of $(\mu_i^{t_i})_i$: then $\nu(A)\le\nu_0(A)$.

Step 4: what ν_0 is. Each $\mathcal{V}_{\Gamma_i}$ lies in $\mathcal{V}^{\mathrm{sl}}$, so ν_0 is a slab law. By Proposition YM3_I:91.7, μ_i^t is reflection positive at the pair $\Sigma(n,c_0)$, $\Sigma(n,c_0+ih)$, the height period of Γ_i along n being $2ih$; this means $\mu_i^t(\overline{\theta_{n,c_0}F}\,F)\ge 0$ for the bounded Borel functions F of the bonds lying in $\{c_0\le n\cdot x\le c_0+ih\}$, which hold every member of $\mathcal{C}_{\mathrm{loc}}(\mathbb{H}^+(n,c_0))$ for large i; so $\nu_0(\overline{\theta_{n,c_0}F}F)\ge 0$ on $\mathcal{C}_{\mathrm{loc}}(\mathbb{H}^+(n,c_0))$, and ν_0 is reflection positive at $\Sigma(n,c_0)$ by Lemma 18.242. The same clause makes μ_i^t invariant under $\tau_{qPa\,n^*}$ and under the wall group of the data (a,n,c_0,h), that is, the group generated by the reflections θ_{n,c_0+kh}, $k\in\mathbb{Z}$, a group containing $\theta_{n,c_0+h}\theta_{n,c_0}=\tau_{2v_h}$; ν_0 inherits these invariances, and hence some subgroup of $a\mathbb{Z}^2\times\{0\}$ with finite index leaves ν_0 invariant. *ν_0 is a slab Gibbs state.* Fix a thin B and a function $F\in\mathcal{C}_{\mathrm{loc}}$. The group W generated by the wall group and the translations by Γ' consists of the maps τ_w and $\tau_w\theta_{n,c_0}$, $w\in\Gamma'$; $\mathbb{A}_i^{\mathrm{f}}=\sum_{j=1}^{2i}\sum_v \mathsf{w}_j\tau_v A$ with $N=i$ in Proposition YM3_I:91.7, where v runs over $\{mqPa\,n^*:0\le m<i\}$, a set of representatives of the i classes of $(\Gamma'\cap n^\perp)/(\Gamma_i\cap n^\perp)$, so that here $v\perp n$, unlike the representatives v of Γ'/Γ_i in Step 2, and where w_j, a map and not one of the sets w_d of a window, is the member of the wall group that carries the slab $\mathbb{S}_1$ onto the slab $\mathbb{S}_j:=\{(j-1)h\le n\cdot x-c_0\le jh\}$ (the translation by $(j-1)v_h$ for odd j, and $\theta_{n,c_0+jh/2}$ for even j); so $\mathbb{A}_i^{\mathrm{f}}$ is a sum of $2i\cdot i=2i^2$ functions $\mathsf{g}A$, $\mathsf{g}=\mathsf{w}_j\tau_v$, $1\le j\le 2i$, v as above, which lie in $2i^2$ different cosets of τ_{Γ_i} in W, as $\mathsf{w}_j\tau_v\in\tau_{\Gamma_i}\mathsf{w}_{j'}\tau_{v'}$ forces the slabs $\mathbb{S}_j$, $\mathbb{S}_{j'}$ to agree up to $2ih$ and then $v-v'\in\Gamma_i$. A term $\mathsf{g}A$ reads the bonds of $B+\Gamma_i$ only if $\mathsf{g}b'\in b+\Gamma_i$ for some $b'\in B_A$, $b\in B$. Every isometry that maps a closed segment onto itself leaves the midpoint of the segment fixed. A map τ_w can fix a point only when $w=0$; a map $\tau_w\theta_{n,c_0}$, with $w=w_\perp+kv_h$ and $w_\perp\perp n$, can fix a point only when $w_\perp=0$, and its fixed points are then precisely the points of the plane $\{n\cdot x=c_0+\frac{kh}{2}\}$; and a midpoint lies on one of these planes at most. So the stabiliser in W of a bond has at most two elements, and as τ_{Γ_i} is normal in W because ϱ_n is the identity on the transverse periods and changes the sign of the normal period, for given b, b' at most two cosets occur. Hence $t_i\mathbb{A}_i^{\mathrm{f}}=\Phi'+\Phi''$ as in Lemma 18.238 (a), with $\|\Phi'\|_\infty\le 2t_i\#B\#B_A\|A\|_\infty\to 0$; (far) holds for large i; so $|\mu_i^{t_i}(\gamma_B F)-\mu_i^{t_i}(F)|\to 0$, and, $\gamma_B F$ and F being continuous, $\nu_0(\gamma_B F)=\nu_0(F)$. □

Lemma 18.242 (Reflection of a periodically translated half-space law)**.** For a law ν on the lattice, reflection positivity at a mirror on continuous local functions extends to bounded Borel functions of finitely many bonds in the same closed half-space. If ν is invariant under translation by a nonzero lattice vector parallel to the mirror normal, this positivity also implies invariance under the reflection. ■

Proof. Approximate a bounded local function by bounded continuous functions of the same coordinates in $L^2(\nu+\theta_*\nu)$. The two-factor integral is continuous in this approximation by Cauchy–Schwarz, so it remains nonnegative. On the positive side the positive sesquilinear form is Hermitian. Taking one argument equal to 1 gives $\nu(\theta F)=\nu(F)$ for every continuous local F on that side. For any continuous local function, a sufficiently large integer multiple of the given period moves its support into the positive side. Reflection changes that shift to its negative. Invariance under both shifts reduces the identity on the translated function to the desired identity on the original function. Continuous local functions determine the law. □

Proposition 18.243 (The mirrors of the slab Gibbs states)**.** Let $a>0$, $\beta\ge 0$ and $l=N_3a$, $N_3\ge 3$.

(a) Every $\nu\in\mathcal{G}^{\mathrm{sl,per}}$ is reflection positive at $\Sigma(e_\mu,c)$ for $\mu=1,2$ and $c\in\frac{a}{2}\mathbb{Z}$, and at $\Sigma(e_1\pm e_2,c)$ for $c\in a\mathbb{Z}$.

(b) Every $\nu\in\mathcal{G}^{\mathrm{sl,per}}$ is invariant under these reflections, under the translations by $a\mathbb{Z}^2\times\{0\}$ and under W_2, acting on configurations.

(c) $\mathcal{G}^{\mathrm{sl,per}}$ coincides with the set of those members of $\mathcal{G}^{\mathrm{sl}}$ which $a\mathbb{Z}^2\times\{0\}$ leaves invariant, and it is a convex and weakly compact set.

(d) $\varnothing\ne\mathcal{G}^{\mathrm{box}}(a,\beta,l;\mathfrak{l}_0)\subset\mathcal{G}^{\mathrm{sl,per}}$; its members are besides invariant under all translations of $a\mathbb{Z}^3$ and under $\theta_{e_3,c}$, $c\in\frac{a}{2}\mathbb{Z}$, and positive at every pair $\Sigma(e_3,c)$, $\Sigma(e_3,c+\frac{l}{2})$, $c\in\frac{a}{2}\mathbb{Z}$.

In [T] every μ_j is therefore reflection positive at the lattice mirrors of $\mathbb{L}_{K_j}$ with the normals $\pm e_1, \pm e_2, \pm(e_1 \pm e_2)$, invariant under the translations of $\mathbb{L}_{K_j}$, under W_2 and under the reflections $\theta_{e_3,c}$, $c \in \frac{1}{2}a_{K_j}\mathbb{Z}$, and positive at the pairs $\Sigma(e_3, c)$, $\Sigma(e_3, c + \frac{l}{2})$. ■

Proof. $\mathcal{G}^{\mathrm{sl}}$ *is weakly compact and convex,* since it consists of those laws on the compact metrisable $\mathcal{V}^{\mathrm{sl}}$ that satisfy the linear conditions $\nu(\gamma_B F - F) = 0$; these conditions are closed, as $\gamma_B F - F$ is continuous for $F \in \mathcal{C}_{\mathrm{loc}}$. At $\beta = 0$, $\gamma_B F = \int F(V \vee \cdot)\, dV$ and every continuous local function is, on $\mathcal{V}^{\mathrm{sl}}$, a function of a thin set B; so $\nu(F) = \int F\, dV_B$, and $\mathcal{G}^{\mathrm{sl}}$ has one member.

(d) Non-empty and slab Gibbs states: Lemma 18.238 (b). Each $\mu_{\Gamma_\Lambda,\beta}$ is invariant under the $\mathsf{r} \in \mathsf{Iso}(a\mathbb{Z}^3)$ with $\mathsf{r}^\circ\Gamma_\Lambda = \Gamma_\Lambda$ by the relabelling of bonds and plaquettes: the translations of $a\mathbb{Z}^3$, W_2, the first two sides being equal, and the reflections $\theta_{e_3,c}$; and it is reflection positive at the pair $\Sigma(e_3, c)$, $\Sigma(e_3, c + \frac{l}{2})$ by Proposition YM3_I:91.4, since the box period lattice is adapted to e_3 with height period l. These properties, read at continuous local functions, pass to weak limits.

(a) for $n = e_\mu$, $\mu \in \{1, 2\}$. Let $\nu \in \mathcal{G}^{\mathrm{sl,per}}$ and $c_0 \in \frac{a}{2}\mathbb{Z}$. Let X be the image of $\mathcal{V}^{\mathrm{sl}}$ under the restriction to the bonds lying in $\mathbb{H}^+(n, c_0)$, ρ^+ the image of a slab law ρ, $\mathcal{C}_0$ the set of the real members of $\mathcal{C}_{\mathrm{loc}}(\mathbb{H}^+(n, c_0))$, dense in the real continuous functions on X by the theorem of Stone and Weierstrass, and $\mathsf{R} := \{\rho^+ : \rho \in \mathcal{G}^{\mathrm{sl}},\ \rho(\overline{\theta_{n,c_0}F}F) \geq 0 \text{ for } F \in \mathcal{C}_{\mathrm{loc}}(\mathbb{H}^+(n, c_0))\}$, the continuous linear image of a convex weakly compact set. By Lemma 18.241 (b), $\mathsf{R} \neq \varnothing$ and $\nu^+(A) \leq \sup_{\mathsf{R}} \rho^+(A)$ on $\mathcal{C}_0$; by Lemma 18.241 (a), $\nu^+ = \rho^+$ for some such ρ. By Lemma 18.240 (b) if $\beta > 0$, and because $\mathcal{G}^{\mathrm{sl}}$ has one member if $\beta = 0$, $\nu = \rho$. By Lemma 18.242, ν is reflection positive at $\Sigma(e_\mu, c_0)$.

(b), first half, and (c). ν is invariant under τ_{Pae_μ}, a translation parallel to e_μ; by Lemma 18.242 it is invariant under $\theta_{e_\mu,c}$ for $c \in \frac{a}{2}\mathbb{Z}$; and $\theta_{e_\mu,a/2}\theta_{e_\mu,0} = \tau_{ae_\mu}$. So every member of $\mathcal{G}^{\mathrm{sl,per}}$ is invariant under $a\mathbb{Z}^2 \times \{0\}$, which is (c), the set being cut out of $\mathcal{G}^{\mathrm{sl}}$ by closed linear conditions.

(a) for $n = e_1 \pm e_2$. Let $c_0 \in a\mathbb{Z}$, X and $\mathcal{C}_0$ as before, and $\mathsf{R} := \{\rho^+ : \rho \in \mathcal{G}^{\mathrm{sl,per}},\ \rho$ positive at $\Sigma(n, c_0)$ on $\mathcal{C}_{\mathrm{loc}}(\mathbb{H}^+(n, c_0))\}$, convex and weakly compact by (c). Lemma 18.241 gives $\nu^+ = \rho^+$. Let $A \in \mathcal{C}_{\mathrm{loc}}$; then $A \in \mathcal{C}_{\mathrm{loc}}(S)$ for a bounded set S, and $\tau_v A \in \mathcal{C}_{\mathrm{loc}}(S + v)$ for $v \in a\mathbb{Z}^3$. For a large $k \in \mathbb{N}$ the vector $v := ka\, n = (ka, \pm ka, 0)$ of $a\mathbb{Z}^2 \times \{0\}$ has $n \cdot v = 2ka$, so $S + v \subset \mathbb{H}^+(n, c_0)$ and $\tau_v A \in \mathcal{C}_{\mathrm{loc}}(\mathbb{H}^+(n, c_0))$; by (c), τ_v leaves ν and ρ invariant, so that $\nu(A) = \nu(\tau_v A) = \rho(\tau_v A) = \rho(A)$. So $\nu = \rho$, and Lemma 18.242 applies.

(b), second half. ν is invariant under τ_{an}, parallel to n, so under $\theta_{n,c}$ by Lemma 18.242. The linear parts of $\theta_{e_1,0}$, $\theta_{e_2,0}$ and $\theta_{e_1-e_2,0}$ generate W_2. Reflection positivity at $\Sigma(-n, -c)$ is the same property of the plane because invariance under the reflection exchanges the two half-spaces. The last sentence is (a), (b), (d) at $a = a_{K_j}$. □

For a tuple $\underline{f} = (f_q)$ placed on a board, each support lies in the interior of one cell. For z in the source disc, write $w_{\mathbf{k}} = \sum_{q \text{ in cell } \mathbf{k}} z_q f_q$ and $B(z) = \{q : z_q \neq 0\}$. The number $\Pi_{\ell'}(z) = \prod_{\mathbf{k}} \|e^{\mathcal{O}_K(w_{\mathbf{k}})}\|_{\mathrm{ch},\ell'}$ uses the occupied cells. A normaliser on a set of sides $\mathfrak{l}$ is a holomorphic $\mathcal{E}$ on the disc with $\mathcal{E}(0) = 0$ and $\Pi_{\ell'}(z) \leq |e^{\mathcal{E}(z)}|Q$ on those sides. In the graded case the bound is $|e^{\mathcal{E}(z)}|Q^{\#B(z)}$.

Proposition 18.244 (Transfer and growth on the slab)**.** (a) (Lift.) Let $f \in \mathrm{Lip}_c(\mathbb{E})$ have its support in a ball of radius R of $\mathbb{E}$, and let $l \geq 1$. There is $\tilde{f} \in \mathrm{Lip}_c(\mathbb{R}^3)$ with $\tilde{f}^{\langle l \rangle} = f$, $\mathrm{pr}(\mathrm{supp}\, \tilde{f}) = \mathrm{supp}\, f$, $\mathrm{supp}\, \tilde{f}$ in a ball of radius $2R + 1$ and $\|\tilde{f}\|_\sharp \leq (1 + 40M)\|f\|_\sharp$; if $R < \frac{l}{2}$, there is one with its support in a ball of radius R and $\|\tilde{f}\|_\sharp \leq \|f\|_\sharp$, of class C^1 if f is.

(b) Let $K \in \mathbb{N}$, $\beta > 0$, $\ell' \leq l$ in $\mathfrak{L}$ and $\mu \in \mathcal{G}^{\mathrm{box}}(a_K, \beta, l; \mathfrak{L})$. Let $\underline{f}$ be placed on a board of the side $\mathsf{l} \leq \frac{1}{2}\ell'$, its occupied cells pairwise incongruent modulo $(l/\mathsf{l})\mathbb{Z}e_3$, and let $\mathcal{E}$ be a normaliser of $\underline{f}$ of the radius ϱ on a set $\mathfrak{l} \ni \ell'$ with the bound Q, respectively a graded normaliser with the base Q. Then, with $w = \sum_q z_q f_q$, $|e^{-\mathcal{E}(z)}\mu(e^{\mathcal{O}_K(w)})| \leq \mathsf{q}_{\mathsf{l}}^{\#\mathrm{occ}(\underline{f})}Q$, respectively $\leq (\mathsf{q}_{\mathsf{l}}Q)^{\#B(z)}$, on $\mathbb{D}_\varrho(\underline{f})$.

(c) In [T], let (K,β) be a datum at g, $\mu\in\mathcal{G}^{\mathrm{box}}(a_K,\beta,l;\mathfrak{L})$ and $\mathsf{q}_g:=e^{2C_{\mathrm{S}}+C_g}$. For $n\ge 2$, $R,\mathsf{d}>0$ and $f_q\in\mathrm{Lip}_c(\mathbb{R}^3)$ with supports in balls of radius R which are pairwise at a distance $\ge\mathsf{d}$ modulo $l e_3$,

$$|S_n^T[\mu](f_1,\dots,f_n)|\le A^{\mathrm{per}}(\mathsf{d})\,B^{\mathrm{sl}}(R)^n\,(n!)^{5+\mathsf{p}}\prod_q\|f_q\|_\sharp,\qquad B^{\mathrm{sl}}(R):=C_B^{\mathrm{sl}}(R+1)^3,$$

where p,C_Q are the constants for the side-one normalizer in Proposition YM3_I:91.12, $A^{\mathrm{per}}(\mathsf{d})=1+\mathsf{U}(1,\mathsf{d})$, and C_B^{sl} is the number in YM3_I:(1848) with q_gC_Q in place of C_Q.

(d) In [T], for $n\ge 2$ and Lipschitz f_i on $\mathbb{E}$ forming a tuple X of type $(\mathsf{d};R)$, whose supports may wind around the circle,

$$\begin{aligned}&|S_n^T[\mu](X)|\le C_n^{\mathrm{sl}}(\mathsf{d};R)\|X\|_\sharp,\\ &C_n^{\mathrm{sl}}(\mathsf{d};R):=A^{\mathrm{per}}(\mathsf{d})\big[(1+40M)B^{\mathrm{sl}}(2R+1)\big]^n(n!)^{5+\mathsf{p}};\\ &|\sigma_\mu(X)|\le C_n^{\sigma}(\mathsf{d};R)\|X\|_\sharp,\\ &C_n^{\sigma}:=\sum_{\pi}\prod_{I\in\pi}C_{|I|}^{\mathrm{sl}},\end{aligned}$$

the sum over the partitions of $\{1,\dots,n\}$ into blocks of at least two elements. These numbers are formed from $\mathfrak{D}$, g and the arguments shown; they read none of K, β, l, the state or a position, and they do not increase in d.

■

Proof. (a) If $R<\frac{l}{2}$, let $\mathbb{B}(\tilde x,R)\subset\mathbb{R}^3$ be a ball over the given ball; two of its points are at a distance $\le 2R<l$, hence never differ by a non-zero multiple of le_3, and pr is injective on this ball; besides, $|\mathrm{pr}\,y-\mathrm{pr}\,y'|\le|y-y'|$ for all $y,y'\in\mathbb{R}^3$. Let $\tilde f$ equal $f\circ\mathrm{pr}$ on $\mathbb{B}(\tilde x,R)$ and vanish off it. The closed set $\mathrm{pr}^{-1}(\mathrm{supp}\,f)$ is the disjoint union of the translates of $\mathrm{supp}\,\tilde f$, pairwise at a distance $\ge l-2R>0$; a segment from a point of $\mathrm{supp}\,\tilde f$ to a point outside it meets a point where $f\circ\mathrm{pr}$ vanishes, so $\mathrm{Lip}\,\tilde f\le\mathrm{Lip}\,f$. If $R\ge\frac{l}{2}$, let $\psi(s)=s$ on $[0,1]$, 1 on $[1,l]$, $l+1-s$ on $[l,l+1]$ and 0 elsewhere; then $\sum_k\psi(s+kl)=1$ and $\mathrm{Lip}\,\psi=1$; put $\tilde f(y):=\psi(y_3)f(\mathrm{pr}\,y)$, whose support lies in a disc of radius R times $[0,l+1]$, so in a ball of radius $2R+1$, and $\mathrm{Lip}\,\tilde f\le\mathrm{Lip}\,f+\|f\|_\infty$. (b) $\mu(e^{\mathcal{O}_K(w)})=\mu(\prod_{\mathbf{k}\in\mathrm{occ}}e^{\mathcal{O}_K(w_{\mathbf{k}})})$ with $e^{\mathcal{O}_K(w_{\mathbf{k}})}\in\mathcal{A}(\square_{\mathbf{k}})$ because any plaquette with center inside a cell of an odd board has all its bonds in that cell; Lemma 18.239 (c) bounds its modulus by $\mathsf{q}_{\mathsf{l}}^{\#\mathrm{occ}}\Pi_{\ell'}(z)$, and the normaliser bounds $\Pi_{\ell'}(z)$ by $|e^{\mathcal{E}(z)}|Q$; in the graded case the cells with $w_{\mathbf{k}}=0$ carry the factor 1, there are at most $\#B(z)$ others, and $\mathsf{q}_{\mathsf{l}}\ge 1$. (c) Suppose first that the entries v_q are nonzero, lie in balls of radius $\eta\le 1/4$ and have separation at least d modulo le_3, with $4a_K\le\eta$ and $4n\eta+na_K\le 1$. An offset in $a_K\mathbb{Z}^3$ places each center at distance at least 2η from all walls of a side-one board. In each coordinate the forbidden intervals have length at most $4n\eta$ modulo one, and rounding to the lattice costs at most na_K. An offset remains by the placement estimate in the proof of Proposition YM3_I:91.13. Choose one occupied cell from each congruence class modulo the period. Translate every entry by a multiple of le_3 into the representative of its cell. These translations preserve the observables on $\mathcal{V}^{\mathrm{sl}}$, the norms and the separation modulo le_3. In particular the ordinary separation is at least d. The third normalizer of Proposition YM3_I:91.12 then has radius ϱ and graded base $Q(\eta)=C_Q(2\eta)^{-\mathsf{p}}$. Its mixed derivative has bound YM3_I:(1845). By (b), with $\ell'=\ell_g$ and $\mathsf{l}=1$, the bound transfers to the slab with base $\mathsf{q}_gQ(\eta)$. The arbitrary-law estimate YM3_I:(1842) and the derivative bound give

$$|S_n^T[\mu](\underline v)|\le\varrho^{-n}\left[(n-1)!(2^n-1)(e\,\mathsf{q}_gQ(\eta))^n+n^n\mathsf{U}(\eta,\mathsf{d})\right]\prod_q\|v_q\|_\sharp.$$

For general f_q, if $a_K>1/(32n)$ the plaquette count gives $\|\mathcal{O}_K(f_q)\|_\infty\le 192\cdot 64^3n^4(R+1)^3\|f_q\|_\sharp$. The bounded-variable cumulant estimate used in the proof of Proposition YM3_I:91.13 then gives its coarse-mesh term. This argument only uses the finite set of plaquette centers in each lifted

support, so applies to the slab law as well. If $a_K \le 1/(32n)$, set $\eta = 1/(8n)$ and split the entries by tensor-product tents of mesh $\eta/\sqrt{3}$. The pieces remain in the original supports, hence preserve the separation modulo le_3. The number of tuples of pieces is at most $[28n(R+1)]^{3n}$, and their sharp norms are at most $961Mn$ times the original norms, as in the proof of Proposition YM3_I:91.13. The small-ball estimate applies to every nonzero tuple of pieces, with $Q(\eta) \le C_Q(8n)^{\mathsf{p}}$ and $\mathsf{U}(\eta, \mathsf{d}) \le \mathsf{U}(1, \mathsf{d})$. Using $n^n \le e^n n!$, the counts and norms contribute four factorial powers. The bracket in the small-ball estimate contributes at most $1 + \mathsf{p}$ more, with the prefactor $1 + \mathsf{U}(1, \mathsf{d})$. Thus the summation gives the constant in YM3_I:(1848) with C_Q replaced by $\mathsf{q}_g C_Q$.

(d) Take lifts by (a): supports in balls of radius $2R+1$, pairwise at a distance $\ge \mathsf{d}$ modulo le_3, $\|\tilde{f}_i\|_\sharp \le (1 + 40M)\|f_i\|_\sharp$; then (per) and (c). The bound on σ_μ is the formula of moments and cumulants, each block X_I being of type $(\mathsf{d}; R)$; $A^{\mathrm{per}} = 1 + \mathsf{U}(1, \cdot)$ does not increase, and their other dependencies are explicit in the bounds above and in Lemma 18.239(d). □

Proposition 18.245 (Short distance on the slab)**.** In [T], let $\vartheta' \in (0,1)$, let (K, β) be a datum at g and $\mu \in \mathcal{G}^{\mathrm{box}}(a_K, \beta, l; \mathfrak{L})$; put $\mathsf{Q}^{\mathrm{sl}} := e^{L^3(2C_{\mathrm{S}} + C_g)}\mathsf{Q}_1(L)$, with $\mathsf{Q}_1(L)$ the first bound of Proposition YM3_I:91.12. Write

$$c_n^{\mathrm{tr}}[Q] = \log 2\,(2Q{+}2)^n (n/\varrho)^n, \qquad \mathsf{A}_n^{\mathrm{sl}}(r) = (r/0.3)^3 c_n^{\mathrm{tr}}[\mathsf{Q}^{\mathrm{sl}}], \qquad C_n^{\mathrm{sl,tr}} = 2(50/3)^3 c_n^{\mathrm{tr}}[\mathsf{Q}^{\mathrm{sl}}](40M/\vartheta')^n.$$

A state at g for (K, β) means a periodic Gibbs state at this datum or a periodically extended cubic torus law on a side in $\mathfrak{L}(g)$, as in Section YM3_I:127.

(a) For every state $\mathfrak{s}'$ at g at (K, β), every $n \ge 1$, every r with $a_K \le r \le \frac{1}{20}$ and all $f_i \in \mathrm{Lip}_c$ which vanish off one ball $\mathbb{B}(x_0, r)$: $|S_n^T[\mu](\underline{f}) - S_n^T[\mathfrak{s}'](\underline{f})| \le 2\mathsf{A}_n^{\mathrm{sl}}(r) \prod_i \|f_i\|_\sharp$.

(b) If $a_K \le 5\mathsf{d} \le \frac{1}{20}$, $r = 5\mathsf{d}$ and $\mathrm{Lip}\, f_i \le \|f_i\|_\infty/(\vartheta'\mathsf{d})$, the difference in (a) is at most $C_n^{\mathrm{sl,tr}} \mathsf{d}^{3-n} \prod_i \|f_i\|_\infty$.

(c) Let $g \le \gamma_W$, $\mathsf{d} \in (0, \mathsf{d}_0(g, \vartheta')]$ with $s(\mathsf{d}) < K$ for the witness depth of Theorem YM3_I: AV, and $(f, h) \in \mathfrak{T}_{\mathbb{R}^3}(\mathsf{d}; \vartheta')$, a test pair on $\mathbb{R}^3$ of YM3_I:(2247). Then $S_2^T[\mu](f, h) = \mathsf{c}_2(a_K\beta)^{-2}\mathcal{K}_{\mathrm{free}}(f, h)(1 + \eta)$ with

$$|\eta| \le \bar{\varepsilon}^{\mathrm{sl}}_{g,\vartheta'}(\mathsf{d}) := \bar{\varepsilon}_{g,\vartheta'}(\mathsf{d}) + \mathsf{C}^{\mathrm{sl}}_{\mathrm{law}}\,\mathsf{d}, \qquad \mathsf{C}^{\mathrm{sl}}_{\mathrm{law}} := 10^6\, C_2^{\mathrm{sl,tr}}\, \bar{x}_0^2/(\mathsf{c}_2\vartheta'^2), \quad \bar{x}_0 := L(g^{-2} + \bar{B}).$$

The function $\bar{\varepsilon}^{\mathrm{sl}}_{g,\vartheta'}$ does not decrease, tends to 0 with d, and reads none of K, β, l, the state or the pair.

■

Proof. (a) At the unit scale, put $\mathcal{B} = \mathbb{B}(0, 1)$ in the central cell of the board of side L. For any $F_1, \dots, F_n$ supported in $\mathcal{B}$, the first normalizer of Proposition YM3_I:91.12 has bound $\mathsf{Q}_1(L)$. Its wall margin requirement holds since $L/2 \ge 6.5$. The bound transfers to $\mathfrak{s}'$ by Proposition YM3_I: 91.11, and to the slab by Proposition 18.244(b) with $\ell' = \ell_g$, where the bound is Q^{sl}. Applying YM3_I:(1841) to both laws cancels the common normalizer derivative. Thus the multilinear difference $\mathsf{D} = S_n^T[\mu] - S_n^T[\mathfrak{s}']$ satisfies

$$|\mathsf{D}(\underline{F})| \le 2c_n^{\mathrm{tr}}[\mathsf{Q}^{\mathrm{sl}}] \prod_i \|F_i\|_\sharp.$$

Pack translates $\mathbb{B}(x_0 + v, r)$ in $\mathcal{B}$ with v in $\delta\mathbb{Z}^3$, $\delta = a_K\lceil 2r/a_K\rceil \in [2r, 3r)$. Require each coordinate of $x_0 + v$ to have modulus at most $0.575 - r$. The balls have disjoint interiors and lie in the unit ball. Each coordinate interval contains at least $0.3/r$ choices, so the set P of translates has cardinality at least $(0.3/r)^3$, by the same packing in Proposition YM3_I:127.1. For $i < n$ use independent signs $\epsilon_{i,v}$ indexed by i, v and set

$$F_i = \sum_{v \in P} \epsilon_{i,v} \tau_v f_i \quad (i < n), \qquad F_n = \sum_{v \in P} \left(\prod_{i<n} \epsilon_{i,v} \right) \tau_v f_n.$$

For $n = 1$ the product is one. The sharp norms of the sums are bounded by those of the original entries. In different balls, each endpoint value is bounded by the Lipschitz constant times the distance to the corresponding exit or entry point along the segment joining them. The sum of these distances is at most the length of the segment. Within one ball the bound is the original Lipschitz bound. Taking the expectation in the multilinear form keeps exactly the terms with all n indices equal. Lattice translation invariance of both laws gives $\mathbb{E}\mathsf{D}(\underline{F}) = |P|\mathsf{D}(\underline{f})$. The unit-scale estimate and the lower bound on $|P|$ prove (a).

(b) $\|f_i\|_\sharp \le \frac{40M}{\vartheta'\mathsf{d}}\|f_i\|_\infty$, as $40M \ge \vartheta'\mathsf{d}$, and $(5\mathsf{d}/0.3)^3 = (\frac{50}{3})^3\mathsf{d}^3$; the product is $C_n^{\mathrm{sl,tr}}$ times d^{3-n}. (c) As in the proof of Theorem YM3_I:AV, $s(\mathsf{d}) < K$ gives $a_K \le \mathsf{d}$, and $\mathsf{d} \le \mathsf{d}_0(g,\vartheta') \le \frac{1}{200}$ (YM3_I:(2350)); so $a_K \le 5\mathsf{d} \le \frac{1}{20}$. The members of a test pair vanish off one ball of radius $5\mathsf{d}$ by the support geometry preceding YM3_I:(2247) and have Lip $\le \|\cdot\|_\infty/(\vartheta'\mathsf{d})$. Take $\mathfrak{s}' = \tilde{\mu}_{K,\ell_g,\beta}$, a state at g of the first kind. By (b) at $n = 2$ and YM3_I:(2247), $|S_2^T[\mu] - S_2^T[\mathfrak{s}']|(f,h) \le C_2^{\mathrm{sl,tr}}\mathsf{d}\|f\|_\infty\|h\|_\infty \le C_2^{\mathrm{sl,tr}}\mathsf{d}\,10^6\vartheta'^{-2}\mathcal{K}_{\mathrm{free}}(f,h)$, which is $[10^6C_2^{\mathrm{sl,tr}}(a_K\beta)^2\mathsf{d}/(\mathsf{c}_2\vartheta'^2)]\,\mathsf{c}_2(a_K\beta)^{-2}\mathcal{K}_{\mathrm{free}}(f,h)$, and $a_K\beta \le \bar{x}_0$ by YM3_I:(1854). By the main text's law of two points, Theorem YM3_I:AV, $\mathfrak{s}'$ obeys the law with the tolerance $\bar{\varepsilon}_{g,\vartheta'}(\mathsf{d})$; add. The properties of $\bar{\varepsilon}^{\mathrm{sl}}$ follow from YM3_I:(2349). □

Lemma 18.246 (Distributions from bounds)**.** Let $y_i \in \mathbb{E}$, $0 < r < \frac{l}{8}$, $\mathsf{Q}_i := y_i + (-r,r)^3$ and $\mathsf{Q}_i' := y_i + (-2r,2r)^3$, $i = 1,\dots,n$, with pairwise disjoint closures of the Q_i', and let $\mathsf{T}\colon \prod_i C_c^\infty(\mathsf{Q}_i') \to \mathbb{R}$ be multilinear with $|\mathsf{T}(\underline{f})| \le C\prod_i\|f_i\|_\sharp$. There is exactly one distribution D on $\prod_i\mathsf{Q}_i$ with $\mathsf{D}(\otimes_i f_i) = \mathsf{T}(\underline{f})$ for $f_i \in C_c^\infty(\mathsf{Q}_i)$, and $|\mathsf{D}(F)| \le C'\max_{|\alpha|\le 6n}\sup|\partial^\alpha F|$. ■

Proof. Take $\chi_i \in C_c^\infty(\mathsf{Q}_i')$ equal to 1 on Q_i, and $\mathsf{e}_k(x) := e^{\mathrm{i}\pi k\cdot x/2r}$, $k \in \mathbb{Z}^3$. A function $F \in C_c^\infty(\prod_i\mathsf{Q}_i)$, continued with the period $4r$ in its $3n$ variables, has the Fourier series $\sum_{\underline{k}}\hat{F}(\underline{k})\prod_i\mathsf{e}_{k_i}(x_i - y_i)$ with $|\hat{F}(\underline{k})|\prod_i(1+\frac{\pi^2}{4r^2}|k_i|^2)^3 \le \sup|\prod_i(1-\Delta_i)^3F|$. Continued complex-multilinearly, $|\mathsf{T}(\chi_1\mathsf{e}_{k_1},\dots)| \le C''\prod_i(1+|k_i|)$, and $\sum_k(1+|k|)(1+c|k|^2)^{-3} < \infty$; so $\mathsf{D}(F) := \sum_{\underline{k}}\hat{F}(\underline{k})\,\mathsf{T}(\chi_1\mathsf{e}_{k_1}(\cdot - y_1),\dots)$ is linear with the bound. For $F = \otimes f_i$ the series $f_i = \sum_k\hat{f}_i(k)\chi_i\mathsf{e}_k$ converges in C^1, so in $\|\cdot\|_\sharp$, and multilinearity with the bound give $\mathsf{T}(\underline{f}) = \mathsf{D}(F)$. A distribution is determined by its values at the tensors, the expansion of F with cut-offs equal to 1 on the projections of its support converging in every C^k with supports in one compact set. □

Proposition 18.247 (Continuum limits on the slab $\mathbb{R}^2\times S_l^1$)**.** Let the data [T] be given: $0 < g \le \gamma$, $l \in \mathfrak{L}(g)$, data (K_j,β_j) at g with $K_j\to\infty$ and $a_{K_j}\beta_j \to \mathsf{b}$, and $\mu_j \in \mathcal{G}^{\mathrm{box}}(a_{K_j},\beta_j,l;\mathfrak{L})$, a limit point, as the two other sides grow along $\mathfrak{L}$, of the Wilson measures of the boxes with the sides (Λ,Λ,l).

(a) (Existence.) There is a subsequence along which $S_n^T[\mu_j](X)$ converges for all $n \ge 2$ and all $X \in \mathfrak{S}_n(\mathbb{E})$.

(b) (Symmetries, bounds, regularity.) Every limit $S = (S_n)_{n\ge2}$, $S_n(X) = \lim S_n^T[\mu_j](X)$ along a subsequence along which all these numbers converge, is real, multilinear and symmetric; it obeys $|S_n(X)| \le C_n^{\mathrm{sl}}(\mathsf{d};R)\|X\|_\sharp$ and $|\sigma_S(X)| \le C_n^\sigma(\mathsf{d};R)\|X\|_\sharp$ at every $X \in \mathfrak{S}_n(\mathbb{E})$ of type $(\mathsf{d};R)$, with the numbers of Proposition 18.244 (d); it is invariant under all the translations of $\mathbb{E}$, under W_2 and under all the reflections r_c, $c \in \mathbb{R}$; and S_n and σ_S each determine a unique distribution on $\mathbb{E}^n_{\ne}$ by evaluation on smooth separated tensors. Both distributions are of order at most $6n$ on compact sets.

(c) (Continuity.) Let S be a limit as in (b), let $\mathsf{d} > 0$, let $X^{(j)} = (f_1^{(j)},\dots,f_n^{(j)}) \in \mathfrak{S}_n(\mathbb{E})$ for every j, and let $X = (f_1,\dots,f_n)$ be an n-tuple of real functions on $\mathbb{E}$ with $\|f_i^{(j)} - f_i\|_\sharp \to 0$ for $i = 1,\dots,n$. Suppose that the supports of all the $f_i^{(j)}$ lie in one compact set and that, for each j, the supports of $f_1^{(j)},\dots,f_n^{(j)}$ are pairwise at a distance $\ge \mathsf{d}$. Then $X \in \mathfrak{S}_n(\mathbb{E})$, the supports of $f_1,\dots,f_n$ are pairwise at a distance $\ge \mathsf{d}$, and $\sigma_{\mu_j}(X^{(j)}) \to \sigma_S(X)$ along the subsequence which defines S.

(d) (Mirrors.) For every limit S, every real c and every $F \in \mathbb{C}\mathfrak{S}(H_+)$, $\sigma_S(\theta\bar{F}\cdot F) \geq 0$ for each of the following pairs (θ, H_+): $(\theta_{e_\mu,c}, \{x_\mu > c\})$, $\mu = 1, 2$; $(\theta_{u,c}, \{u\cdot x > c\})$ with $u = \frac{1}{\sqrt{2}}(e_1 \pm e_2)$; and $(\mathsf{r}_c, \{c < x_3 < c + \frac{l}{2}\})$, the double mirror $\{x_3 = c\} \cup \{x_3 = c + \frac{l}{2}\}$.

(e) (The law of two points.) Let $g \leq \gamma_W$ and $\vartheta' \in (0, 1)$. For every limit S, every $\mathsf{d} \in (0, \mathsf{d}_0(g, \vartheta')]$ and every pair $(f, h) \in \mathfrak{T}^1(\mathsf{d}; \vartheta')$ of C^1 test functions in the class of (c) of Proposition 18.245,

$$S_2(f^{\langle l\rangle}, h^{\langle l\rangle}) = \mathsf{c}_2\, \mathsf{b}^{-2}\, \mathcal{K}_{\mathrm{free}}(f, h)\,(1 + \eta), \qquad |\eta| \leq \bar{\varepsilon}^{\mathrm{sl}}_{g,\vartheta'}(\mathsf{d}),$$

with the function of Proposition 18.245 (c), which tends to 0 with d; the label is determined by S_2: $\mathsf{b}^{-2} = \lim_{t\to 0} S_2(f_t^{\langle l\rangle}, h_t^{\langle l\rangle})/(\mathsf{c}_2\mathcal{K}_{\mathrm{free}}(f, h))$, $f_t = f(\cdot/t)$; and $S_2(f^{\langle l\rangle}, h^{\langle l\rangle}) > 0$ as soon as $\bar{\varepsilon}^{\mathrm{sl}}_{g,\vartheta'}(\mathsf{d}) < 1$.

■

Proof. Step 1: extraction, (a). $C^1_c(\mathbb{E})$ holds a countable set $\mathcal{Q}$ such that for every $f \in C^1_c(\mathbb{E})$ and $\varepsilon > 0$ some $f' \in \mathcal{Q}$ has $\|f - f'\|_\sharp < \varepsilon$ and its support in the ε-neighbourhood of that of f. To obtain this set, take a countable dense set in each subspace of C^1 functions supported in a finite union of closed rational coordinate cubes in the slab, using the function and its first derivatives on that compact set. Any compact support is contained in such a union inside any prescribed neighbourhood of it. By Proposition 18.244 (d), which holds at every j, and a diagonal choice, there is a subsequence along which $S^T_n[\mu_j](X')$ converges at all separated tuples X' with entries in $\mathcal{Q}$. Let X be of type $(\mathsf{d}; R)$, let ε satisfy $\varepsilon \leq 1$ and $\varepsilon < \frac{\mathsf{d}}{4}$, and let X' have entries in $\mathcal{Q}$ with $\|f_i - f'_i\|_\sharp < \varepsilon$ and supports as above. The supports of the entries of all the tuples of the telescope of the multilinear forms lie in balls of radius $R + \varepsilon \leq R + 1$ and are pairwise at a distance $\geq \mathsf{d} - 2\varepsilon > \frac{\mathsf{d}}{2}$, so these tuples are of type $(\frac{\mathsf{d}}{2}; R + 1)$, and their entries other than the differences have norms at most $\|f_i\|_\sharp + \varepsilon \leq \|f_i\|_\sharp + 1$; so $|S^T_n[\mu_j](X) - S^T_n[\mu_j](X')| \leq n\varepsilon\, C^{\mathrm{sl}}_n(\frac{\mathsf{d}}{2}; R + 1) \prod_i(\|f_i\|_\sharp + 1)$ for all j; hence $(S^T_n[\mu_j](X))_j$ is a Cauchy sequence.

Step 2: (c). Let k be the compact set and R' the radius of a ball which holds it. Each f_i is a uniform limit of functions which vanish off k, so $\operatorname{supp} f_i \subset \mathsf{k}$. For a function of class C^1 on $\mathbb{E}$, Lip is the supremum of the modulus of its gradient; so the gradients of the $f_i^{(j)}$ converge uniformly. Integrating along coordinate segments shows that their limit is the gradient of f_i, which is therefore of class C^1. For $k \neq m$, $\liminf_j \operatorname{dist}(\operatorname{supp} f_k^{(j)}, \operatorname{supp} f_m) \geq \mathsf{d}$: otherwise there are $\eta > 0$ and, along a subsequence, $y_j \in \operatorname{supp} f_k^{(j)}$, $x_j \in \operatorname{supp} f_m$ with $|y_j - x_j| \leq \mathsf{d} - \eta$ and $x_j \to x$; a point x' with $f_m(x') \neq 0$ and $|x' - x| < \frac{\eta}{4}$ has $f_m^{(j)}(x') \neq 0$ for large j, by uniform convergence, so $|y_j - x'| \geq \mathsf{d}$, while $|y_j - x'| < \mathsf{d}$. A point z with $f_k(z) \neq 0$ lies in $\operatorname{supp} f_k^{(j)}$ for all large j, so $\operatorname{dist}(z, \operatorname{supp} f_m) \geq \mathsf{d}$ by the bound just shown; these points are dense in $\operatorname{supp} f_k$, hence $\operatorname{dist}(\operatorname{supp} f_k, \operatorname{supp} f_m) \geq \mathsf{d}$, and $X \in \mathfrak{S}_n(\mathbb{E})$. So for large j the tuples of the telescope between $X^{(j)}$ and X are of type $(\frac{\mathsf{d}}{2}; R')$, and Proposition 18.244 (d) gives $|S^T_n[\mu_j](X^{(j)}) - S^T_n[\mu_j](X)| \leq n \max_i \|f_i^{(j)} - f_i\|_\sharp\, C^{\mathrm{sl}}_n(\frac{\mathsf{d}}{2}; R') \prod_i(\|f_i\|_\sharp + 1) \to 0$, while $S^T_n[\mu_j](X) \to S_n(X)$ along the subsequence which defines S; the same holds for the blocks of $\sigma_{\mu_j} = \sigma_{(S^T_n[\mu_j])}$, and (c) follows.

Step 3: (b). Reality, multilinearity, symmetry and the bounds hold at every j by the moment–cumulant formula and Proposition 18.244 (d), and pass to the limit. For a translation τ_v, $v \in \mathbb{R}^3$, or a reflection r_c, take $v_j \in a_{K_j}\mathbb{Z}^3$ with $v_j \to v$, respectively $c_j \in \frac{1}{2}a_{K_j}\mathbb{Z}$ with $c_j \to c$. By Proposition 18.243 (d), μ_j is invariant under τ_{v_j} and θ_{e_3,c_j}, which descend to the quotient. Relabelling the plaquettes gives the corresponding covariance of each observable, hence $S^T_n[\mu_j](\mathsf{r}^{(j)}X) = S^T_n[\mu_j](X)$ for $\mathsf{r}^{(j)} = \tau_{v_j}, \mathsf{r}_{c_j}$. For $f \in C^1_c$, $\|\tau_{v_j} f - \tau_v f\|_\infty \leq \operatorname{Lip} f\, |v_j - v|$ and $\operatorname{Lip}(\tau_{v_j} f - \tau_v f) \leq \sup_x |\nabla f(x - v_j) - \nabla f(x - v)| \to 0$, ∇f being uniformly continuous; so $\mathsf{r}^{(j)}X \to \mathsf{r}X$ as in (c), and the invariance passes to S. The invariance under W_2 holds exactly at every j (Proposition 18.243 (b), (d)). *Regularity.* Each point of $\mathbb{E}^n_{\neq}$ belongs to some product $\prod_i \mathsf{Q}_i$ of the kind in Lemma 18.246, and on such

a product $\mathsf{T} = \sigma_S$, or S_n, satisfies the bounds just established. Where two such products meet, their intersection is once more a product of open boxes, and there the two distributions take equal values at the tensors, hence are equal. With a partition of unity, distributions that are equal on the overlaps are glued into one distribution T_n on $\mathbb{E}^n_{\neq}$, and the bound on its order follows since a given compact set meets just finitely many members of a locally finite cover. Splitting each entry of a smooth separated tuple by a partition of unity and using the multilinearity, one writes the tuple as a sum of tuples lying each in one product, so $T_n(\otimes_i f_i) = \sigma_S(\underline{f})$.

Step 4: (d). Let $F = \sum_k c_k X_k$ with $X_k \in \mathfrak{S}(H_+)$; their supports lie in a compact part of H_+, at a positive distance from its boundary. Let n be the normal, e_μ, $e_1 \pm e_2$ or e_3, and $c_j \in \mathrm{Adm}(n)$ at the spacing a_{K_j} with $|n|^{-1}c_j \to c$; $\theta^{(j)} := \theta_{n,c_j}$. Put $F_j := \sum_k c_k (X_k)^{\mu_j}$, the combination of the centred products $\prod_i (\mathcal{O}^{\mathrm{sl}}_{a_{K_j}}(f_i) - \mu_j(\mathcal{O}^{\mathrm{sl}}_{a_{K_j}}(f_i)))$, read through lifts. The corners of a plaquette lie within a_{K_j} of its barycentre; so for large j, $F_j \in \mathcal{C}_{\mathrm{loc}}(\mathbb{H}^+(n, c_j))$, and in the third case, with lifts in the slab $\{c_j \le x_3 \le c_j + \frac{l}{2}\}$, $F_j \in \mathcal{C}_{\mathrm{loc}}(\{c_j \le x_3 \le c_j + \frac{l}{2}\})$. μ_j is invariant under $\theta^{(j)}$ (Proposition 18.243 (b), (d)), so $\theta^{(j)}(X^{\mu_j}) = (\theta^{(j)}X)^{\mu_j}$ by the same relabelling of the plaquettes, and by Proposition 18.243 (a), (d), $0 \le \mu_j(\overline{\theta^{(j)}F_j}F_j) = \sum_{k,k'} \bar{c}_k c_{k'} \sigma_{\mu_j}(\theta^{(j)}X_k \cdot X_{k'})$. As $\theta^{(j)} = \tau_{v_j}\theta$ with $v_j \to 0$, $\theta^{(j)}X_k \to \theta X_k$ as in (c), and the right member tends to $\sigma_S(\theta\bar{F} \cdot F)$.

Step 5: (e). Both supports lie in one ball of radius $5\mathsf{d}$ by the support geometry preceding YM3_I:(2247). As $\mathsf{d} \le \mathsf{d}_0(g, \vartheta') \le \frac{1}{200}$ (YM3_I:(2350)) and $l \ge 2L$, we have $20\mathsf{d} < l$; for two points x, y of this ball, $|x - y| \le 10\mathsf{d}$ and $|x - y - kle_3| \ge l - 10\mathsf{d} > 10\mathsf{d}$ for every integer $k \neq 0$, so the restriction of pr to the ball is injective and keeps all distances; $(f^{\langle l\rangle}, h^{\langle l\rangle}) \in \mathfrak{S}_2(\mathbb{E})$, and by (per) $S_2^T[\mu_j](f^{\langle l\rangle}, h^{\langle l\rangle}) = S_2^T[\mu_j](f, h)$. For large j, $s(\mathsf{d}) < K_j$, and Proposition 18.245 (c) gives the law at (K_j, β_j) with $\mathsf{b}_j = a_{K_j}\beta_j \to \mathsf{b}$, where $\mathsf{b} \in I^{\mathrm{lab}}(g) \subset (0, \infty)$ (Lemma 18.212 (c)); pass to the limit. With the dilates, $(f_t, h_t) \in \mathfrak{T}^1(t\mathsf{d}; \vartheta')$ and $\mathcal{K}_{\mathrm{free}}(f_t, h_t) = \mathcal{K}_{\mathrm{free}}(f, h)$ by homogeneity and the change of variables $x = tx'$, $y = ty'$, and $\bar{\varepsilon}^{\mathrm{sl}}_{g,\vartheta'}(t\mathsf{d}) \to 0$; this gives the formula for b^{-2}, and $\mathcal{K}_{\mathrm{free}}(f, h) > 0$ (YM3_I:(2247)) gives the sign. □

Symbol	Meaning	Defined in
$a_K, \mathsf{b}, L, T_\ell$	Lattice spacing, physical label, blocking factor and torus	§2
$V, O_K^T, \bar{O}_K^T$	Tensor labels, lattice insertion and cell-mean insertion	§2
$\mathcal{S}_{n;K}$	Truncated tensor correlations at cutoff K	§2
$\mathrm{Sym}\,\mathcal{E}$	Quadratic symbol of a class insertion	§2
$\mathcal{T}, \mathcal{O}$	Tensor and scalar continuum insertions	§3
$\sigma, \mathcal{H}, \Omega, H$	Clustering correlations, Hilbert space, vacuum and energy generator	§3
$\mathcal{K}_q, L_b^+, c_1, c_2$	Homogeneous kernels, two-term approximation and coefficients	§6
κ^{lat}	Coefficient of the scalar kernel of degree -5	§7
$\Psi_r, \mathcal{N}_t$	Dilated test pair and three-scale combination	§8
$G, \mathfrak{g}, C_A, C_\rho$	Compact group, Lie algebra and Casimir normalizations	§9
W_C, κ	Wilson trace and perimeter exponent	§10
$Z_{e,m}, P_e$	Electric-sector partition function and projection	§11
P, J	Pressure and its derivative jump	§12
s, ρ	Radial two-point kernel and positive spectral measure	§13
$\mathcal{A}, \mathcal{A}^d$	Action-density net and Haag-dual completion	§14
$\mathcal{L}_K, \mathcal{E}_K$	Langevin generator and Dirichlet form	§15
Φ_σ	Deterministic lattice gradient flow	§16
$\mathsf{e}, \ell_0, m_*, \sigma_*$	Box defect, physical scale, gap and area constants	§17

Derivatives of continuum tests act on $\mathbb{R}^3$; bond derivatives and covariant lattice differences act on the cutoff lattice. Stochastic time, gradient-flow time and real time in the reconstructed quantum field are distinct. Constants have the dependencies stated in each sketch. A bound uniform in the fine cutoff need not be uniform in the physical volume.
